PROBLEM 1.1

KNOWN: Heat rate, \( q \), through one-dimensional wall of area \( A \), thickness \( L \), thermal conductivity \( k \) and inner temperature, \( T_1 \).

FIND: The outer temperature of the wall, \( T_2 \).

SCHEMATIC:

![Problem Schematic](image)

ASSUMPTIONS: (1) One-dimensional conduction in the x-direction, (2) Steady-state conditions, (3) Constant properties.

ANALYSIS: The rate equation for conduction through the wall is given by Fourier’s law,

\[
q_{\text{cond}} = q_x = q_x A = -k \frac{dT}{dx} A = kA \frac{T_1 - T_2}{L}.
\]

Solving for \( T_2 \) gives

\[
T_2 = T_1 - \frac{q_{\text{cond}} L}{kA}.
\]

Substituting numerical values, find

\[
T_2 = 415^\circ C - \frac{3000 \text{W} \times 0.025 \text{m}}{0.2 \text{W} / \text{m} \cdot \text{K} \times 10 \text{m}^2}
\]

\[
T_2 = 415^\circ C - 37.5^\circ C
\]

\[
T_2 = 378^\circ C.
\]

COMMENTS: Note direction of heat flow and fact that \( T_2 \) must be less than \( T_1 \).
**PROBLEM 1.2**

**KNOWN:** Inner surface temperature and thermal conductivity of a concrete wall.

**FIND:** Heat loss by conduction through the wall as a function of ambient air temperatures ranging from -15 to 38°C.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional conduction in the x-direction, (2) Steady-state conditions, (3) Constant properties, (4) Outside wall temperature is that of the ambient air.

**ANALYSIS:** From Fourier’s law, it is evident that the gradient, \( \frac{dT}{dx} = -\frac{q_x}{k} \), is a constant, and hence the temperature distribution is linear, if \( q_x \) and \( k \) are each constant. The heat flux must be constant under one-dimensional, steady-state conditions; and \( k \) is approximately constant if it depends only weakly on temperature. The heat flux and heat rate when the outside wall temperature is \( T_2 = -15°C \) are

\[
q_x = -k \frac{dT}{dx} = k \frac{T_1 - T_2}{L} = 1 \text{W/m·K} \frac{25°C - (-15°C)}{0.30 \text{m}} = 133.3 \text{W/m}^2. \tag{1}
\]

\[
q_x = q_x^* \times A = 133.3 \text{W/m}^2 \times 20 \text{m}^2 = 2667 \text{W}. \tag{2}
\]

Combining Eqs. (1) and (2), the heat rate \( q_x \) can be determined for the range of ambient temperature, -15 \( \leq T_2 \leq 38°C \), with different wall thermal conductivities, \( k \).

For the concrete wall, \( k = 1 \text{ W/m·K} \), the heat loss varies linearly from +2667 W to -867 W and is zero when the inside and ambient temperatures are the same. The magnitude of the heat rate increases with increasing thermal conductivity.

**COMMENTS:** Without steady-state conditions and constant \( k \), the temperature distribution in a plane wall would not be linear.
PROBLEM 1.3

FIND: Daily cost of heat loss.

SCHEMATIC:

Assumptions: (1) Steady state, (2) One-dimensional conduction, (3) Constant properties.

Analysis: The rate of heat loss by conduction through the slab is

\[
q = k \left( LW \right) \frac{T_1 - T_2}{t} = 1.4 \text{ W/m-K} \left( 11 \text{m} \times 8 \text{m} \right) \frac{7^\circ \text{C}}{0.20 \text{m}} = 4312 \text{ W}
\]

The daily cost of natural gas that must be combusted to compensate for the heat loss is

\[
C_d = \frac{q C_g}{\eta_f} (\Delta t) = \frac{4312 \text{ W} \times 0.01/\text{MJ}}{0.9 \times 10^6 \text{ J/MJ}} (24 \text{ h/d} \times 3600 \text{ s/h}) = $4.14/\text{d}
\]

Comments: The loss could be reduced by installing a floor covering with a layer of insulation between it and the concrete.
**PROBLEM 1.4**

**KNOWN:** Heat flux and surface temperatures associated with a wood slab of prescribed thickness.

**FIND:** Thermal conductivity, \( k \), of the wood.

**SCHEMATIC:**

\[ Q''_x = 40 \text{ W/m}^2 \]
\[ T_1 = 40^\circ \text{C} \]
\[ T_2 = 20^\circ \text{C} \]
\[ L = 0.05 \text{ m} \]

**ASSUMPTIONS:** (1) One-dimensional conduction in the \( x \)-direction, (2) Steady-state conditions, (3) Constant properties.

**ANALYSIS:** Subject to the foregoing assumptions, the thermal conductivity may be determined from Fourier’s law, Eq. 1.2. Rearranging,

\[
 k = q''_x \frac{L}{T_1 - T_2} = 40 \frac{W}{m^2} \frac{0.05 \text{ m}}{(40-20)^\circ \text{C}}
\]

\[ k = 0.10 \text{ W/m \cdot K}. \]

**COMMENTS:** Note that the \( ^\circ \text{C} \) or K temperature units may be used interchangeably when evaluating a temperature difference.
PROBLEM 1.5

KNOWN: Inner and outer surface temperatures of a glass window of prescribed dimensions.

FIND: Heat loss through window.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in the x-direction, (2) Steady-state conditions, (3) Constant properties.

ANALYSIS: Subject to the foregoing conditions the heat flux may be computed from Fourier’s law, Eq. 1.2.

\[ q_x = k \frac{T_1 - T_2}{L} \]

\[ q_x = 1.4 \frac{W}{m \cdot K} \left( \frac{(15-5)^\circ C}{0.005 m} \right) \]

\[ q_x = 2800 \text{ W/m}^2. \]

Since the heat flux is uniform over the surface, the heat loss (rate) is

\[ q = q_x \times A \]

\[ q = 2800 \text{ W/m}^2 \times 3 \text{ m}^2 \]

\[ q = 8400 \text{ W}. \]

COMMENTS: A linear temperature distribution exists in the glass for the prescribed conditions.
PROBLEM 1.6

KNOWN: Width, height, thickness and thermal conductivity of a single pane window and the air space of a double pane window. Representative winter surface temperatures of single pane and air space.

FIND: Heat loss through single and double pane windows.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction through glass or air, (2) Steady-state conditions, (3) Enclosed air of double pane window is stagnant (negligible buoyancy induced motion).

ANALYSIS: From Fourier’s law, the heat losses are

\[
\text{Single Pane: } \quad q_g = k_g A \frac{T_1 - T_2}{L} = 1.4 \text{ W/m·K} \left( \frac{35 \degree C}{0.005\text{m}} \right) = 19,600 \text{ W}
\]

\[
\text{Double Pane: } \quad q_a = k_a A \frac{T_1 - T_2}{L} = 0.024 \left( \frac{25 \degree C}{0.010\text{m}} \right) = 120 \text{ W}
\]

COMMENTS: Losses associated with a single pane are unacceptable and would remain excessive, even if the thickness of the glass were doubled to match that of the air space. The principal advantage of the double pane construction resides with the low thermal conductivity of air (~ 60 times smaller than that of glass). For a fixed ambient outside air temperature, use of the double pane construction would also increase the surface temperature of the glass exposed to the room (inside) air.
PROBLEM 1.7

KNOWN: Dimensions of freezer compartment. Inner and outer surface temperatures.

FIND: Thickness of styrofoam insulation needed to maintain heat load below prescribed value.

SCHEMATIC:

ASSUMPTIONS: (1) Perfectly insulated bottom, (2) One-dimensional conduction through 5 walls of area $A = 4m^2$, (3) Steady-state conditions, (4) Constant properties.

ANALYSIS: Using Fourier's law, Eq. 1.2, the heat rate is

$$ q = q'' \cdot A = k \frac{\Delta T}{L} A_{total} $$

Solving for $L$ and recognizing that $A_{total} = 5 \times W^2$, find

$$ L = \frac{5 k \Delta T W^2}{q} $$

$$ L = \frac{5 \times 0.03 W/m \cdot K \left[ 35 - (-10) \right] ^\circ C \left( 4m^2 \right)}{500 W} $$

$$ L = 0.054m = 54mm. $$

COMMENTS: The corners will cause local departures from one-dimensional conduction and a slightly larger heat loss.
PROBLEM 1.8

KNOWN: Dimensions and thermal conductivity of food/beverage container. Inner and outer surface temperatures.

FIND: Heat flux through container wall and total heat load.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible heat transfer through bottom wall, (3) Uniform surface temperatures and one-dimensional conduction through remaining walls.

ANALYSIS: From Fourier’s law, Eq. 1.2, the heat flux is

\[
q^* = k \frac{T_2 - T_1}{L} = \frac{0.023 \text{ W/m-K} \times (20 - 2) ^\circ \text{C}}{0.025 \text{ m}} = 16.6 \text{ W/m}^2
\]

Since the flux is uniform over each of the five walls through which heat is transferred, the heat load is

\[
q = q^* \times A_{\text{total}} = q^* \left[ H(2W_1 + 2W_2) + W_1 \times W_2 \right]
\]

\[
q = 16.6 \text{ W/m}^2 \left[ 0.6 \text{m} \times (1.6 \text{m} + 1.2 \text{m}) + (0.8 \text{m} \times 0.6 \text{m}) \right] = 35.9 \text{ W}
\]

COMMENTS: The corners and edges of the container create local departures from one-dimensional conduction, which increase the heat load. However, for \( H, W_1, W_2 >> L \), the effect is negligible.
**PROBLEM 1.9**

**KNOWN:** Masonry wall of known thermal conductivity has a heat rate which is 80% of that through a composite wall of prescribed thermal conductivity and thickness.

**FIND:** Thickness of masonry wall.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Both walls subjected to same surface temperatures, (2) One-dimensional conduction, (3) Steady-state conditions, (4) Constant properties.

**ANALYSIS:** For steady-state conditions, the conduction heat flux through a one-dimensional wall follows from Fourier’s law, Eq. 1.2,

\[ q'' = k \frac{\Delta T}{L} \]

where \( \Delta T \) represents the difference in surface temperatures. Since \( \Delta T \) is the same for both walls, it follows that

\[ L_1 = L_2 \frac{k_1}{k_2} \cdot \frac{q_2''}{q_1''}. \]

With the heat fluxes related as

\[ q_1'' = 0.8 q_2'' \]

\[ L_1 = 100\text{mm} \times \frac{0.75 \text{ W/m} \cdot \text{K}}{0.25 \text{ W/m} \cdot \text{K}} \times \frac{1}{0.8} = 375\text{mm}. \]

**COMMENTS:** Not knowing the temperature difference across the walls, we cannot find the value of the heat rate.
PROBLEM 1.10

KNOWN: Thickness, diameter and inner surface temperature of bottom of pan used to boil water. Rate of heat transfer to the pan.

FIND: Outer surface temperature of pan for an aluminum and a copper bottom.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, steady-state conduction through bottom of pan.

ANALYSIS: From Fourier’s law, the rate of heat transfer by conduction through the bottom of the pan is

\[ q = kA \frac{T_1 - T_2}{L} \]

Hence,

\[ T_1 = T_2 + \frac{qL}{kA} \]

where \( A = \pi D^2 / 4 = \pi (0.2 \text{ m})^2 / 4 = 0.0314 \text{ m}^2 \).

Aluminum: \( T_1 = 110 \, ^\circ\text{C} + \frac{600 \, \text{W} (0.005 \, \text{m})}{240 \, \text{W/m} \cdot \text{K} \left(0.0314 \, \text{m}^2\right)} = 110.40 \, ^\circ\text{C} \)

Copper: \( T_1 = 110 \, ^\circ\text{C} + \frac{600 \, \text{W} (0.005 \, \text{m})}{390 \, \text{W/m} \cdot \text{K} \left(0.0314 \, \text{m}^2\right)} = 110.25 \, ^\circ\text{C} \)

COMMENTS: Although the temperature drop across the bottom is slightly larger for aluminum (due to its smaller thermal conductivity), it is sufficiently small to be negligible for both materials. To a good approximation, the bottom may be considered isothermal at \( T \approx 110 \, ^\circ\text{C} \), which is a desirable feature of pots and pans.
PROBLEM 1.11

KNOWN: Dimensions and thermal conductivity of a chip. Power dissipated on one surface.

FIND: Temperature drop across the chip.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Uniform heat dissipation, (4) Negligible heat loss from back and sides, (5) One-dimensional conduction in chip.

ANALYSIS: All of the electrical power dissipated at the back surface of the chip is transferred by conduction through the chip. Hence, from Fourier’s law,

\[ P = q = kA \frac{\Delta T}{t} \]

or

\[ \Delta T = \frac{t \cdot P}{kW^2} = \frac{0.001 \text{ m} \times 4 \text{ W}}{150 \text{ W/m} \cdot \text{K} (0.005 \text{ m})^2} \]

\[ \Delta T = 1.1^\circ \text{C}. \]

COMMENTS: For fixed P, the temperature drop across the chip decreases with increasing k and W, as well as with decreasing t.
PROBLEM 1.12

KNOWN: Heat flux gage with thin-film thermocouples on upper and lower surfaces; output voltage, calibration constant, thickness and thermal conductivity of gage.

FIND: (a) Heat flux, (b) Precaution when sandwiching gage between two materials.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat conduction in gage, (3) Constant properties.

ANALYSIS: (a) Fourier’s law applied to the gage can be written as

\[ q'' = k \ \frac{\Delta T}{\Delta x} \]

and the gradient can be expressed as

\[ \frac{\Delta T}{\Delta x} = \frac{\Delta E / N}{S_{AB} t} \]

where \( N \) is the number of differentially connected thermocouple junctions, \( S_{AB} \) is the Seebeck coefficient for type K thermocouples (A-chromel and B-alumel), and \( \Delta x = t \) is the gage thickness. Hence,

\[ q'' = \frac{k \Delta E}{NS_{AB} t} \]

\[ q'' = \frac{1.4 \text{ W/m·K} \times 350 \times 10^{-6} \text{ V}}{5 \times 40 \times 10^{-6} \text{ V/°C} \times 0.25 \times 10^{-3} \text{ m}} = 9800 \text{ W/m}^2. \]

(b) The major precaution to be taken with this type of gage is to match its thermal conductivity with that of the material on which it is installed. If the gage is bonded between laminates (see sketch above) and its thermal conductivity is significantly different from that of the laminates, one dimensional heat flow will be disturbed and the gage will read incorrectly.

COMMENTS: If the thermal conductivity of the gage is lower than that of the laminates, will it indicate heat fluxes that are systematically high or low?
**PROBLEM 1.13**

**KNOWN:** Hand experiencing convection heat transfer with moving air and water.

**FIND:** Determine which condition feels colder. Contrast these results with a heat loss of 30 W/m² under normal room conditions.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Temperature is uniform over the hand’s surface, (2) Convection coefficient is uniform over the hand, and (3) Negligible radiation exchange between hand and surroundings in the case of air flow.

**ANALYSIS:** The hand will feel colder for the condition which results in the larger heat loss. The heat loss can be determined from Newton’s law of cooling, Eq. 1.3a, written as

\[ q^* = h(T_s - T_\infty) \]

For the air stream:

\[ q_{\text{air}}^* = 40 \text{ W/m}^2 \cdot \text{K} \left[ 30 - (-5) \right] \text{K} = 1,400 \text{ W/m}^2 \]

For the water stream:

\[ q_{\text{water}}^* = 900 \text{ W/m}^2 \cdot \text{K} (30 - 10) \text{K} = 18,000 \text{ W/m}^2 \]

**COMMENTS:** The heat loss for the hand in the water stream is an order of magnitude larger than when in the air stream for the given temperature and convection coefficient conditions. In contrast, the heat loss in a normal room environment is only 30 W/m² which is a factor of 400 times less than the loss in the air stream. In the room environment, the hand would feel comfortable; in the air and water streams, as you probably know from experience, the hand would feel uncomfortably cold since the heat loss is excessively high.
**PROBLEM 1.14**

**KNOWN:** Power required to maintain the surface temperature of a long, 25-mm diameter cylinder with an imbedded electrical heater for different air velocities.

**FIND:** (a) Determine the convection coefficient for each of the air velocity conditions and display the results graphically, and (b) Assuming that the convection coefficient depends upon air velocity as \( h = CV^n \), determine the parameters \( C \) and \( n \).

**SCHEMATIC:**

![Schematic](image)

<table>
<thead>
<tr>
<th>( V ) (m/s)</th>
<th>1</th>
<th>2</th>
<th>4</th>
<th>8</th>
<th>12</th>
</tr>
</thead>
<tbody>
<tr>
<td>( P_e' ) (W/m)</td>
<td>450</td>
<td>658</td>
<td>983</td>
<td>1507</td>
<td>1963</td>
</tr>
<tr>
<td>( h ) (W/m(^2)-K)</td>
<td>22.0</td>
<td>32.2</td>
<td>48.1</td>
<td>73.8</td>
<td>96.1</td>
</tr>
</tbody>
</table>

**ASSUMPTIONS:** (1) Temperature is uniform over the cylinder surface, (2) Negligible radiation exchange between the cylinder surface and the surroundings, (3) Steady-state conditions.

**ANALYSIS:** (a) From an overall energy balance on the cylinder, the power dissipated by the electrical heater is transferred by convection to the air stream. Using Newton’s law of cooling on a per unit length basis,

\[
P_e' = h \left( \pi D \right) (T_s - T_\infty)
\]

where \( P_e' \) is the electrical power dissipated per unit length of the cylinder. For the \( V = 1 \) m/s condition, using the data from the table above, find

\[
h = 450 \text{ W/m} \left/ \pi \times 0.025 \text{ m} \right. (300 - 40) ^\circ C = 22.0 \text{ W/m}^2\text{-K}
\]

Repeating the calculations, find the convection coefficients for the remaining conditions which are tabulated above and plotted below. Note that \( h \) is not linear with respect to the air velocity.

(b) To determine the \((C,n)\) parameters, we plotted \( h \) vs. \( V \) on log-log coordinates. Choosing \( C = 22.12 \text{ W/m}^2\text{-K}(\text{s/m})^n \), assuring a match at \( V = 1 \), we can readily find the exponent \( n \) from the slope of the \( h \) vs. \( V \) curve. From the trials with \( n = 0.8, 0.6 \) and 0.5, we recognize that \( n = 0.6 \) is a reasonable choice. Hence, \( C = 22.12 \) and \( n = 0.6 \).
PROBLEM 1.15

KNOWN: Long, 30mm-diameter cylinder with embedded electrical heater; power required to maintain a specified surface temperature for water and air flows.

FIND: Convection coefficients for the water and air flow convection processes, \( h_w \) and \( h_a \), respectively.

SCHEMATIC:

ASSUMPTIONS: (1) Flow is cross-wise over cylinder which is very long in the direction normal to flow.

ANALYSIS: The convection heat rate from the cylinder per unit length of the cylinder has the form

\[
q' = h (\pi D) (T_s - T_\infty)
\]

and solving for the heat transfer convection coefficient, find

\[
h = \frac{q'}{\pi D (T_s - T_\infty)}.
\]

Substituting numerical values for the water and air situations:

Water
\[
h_w = \frac{28 \times 10^3 \text{ W/m}}{\pi \times 0.030 \text{ m} \times (90-25) \text{ C}} = 4,570 \text{ W/m}^2 \cdot \text{K} <
\]

Air
\[
h_a = \frac{400 \text{ W/m}}{\pi \times 0.030 \text{ m} \times (90-25) \text{ C}} = 65 \text{ W/m}^2 \cdot \text{K.} <
\]

COMMENTS: Note that the air velocity is 10 times that of the water flow, yet

\[h_w \approx 70 \times h_a.\]

These values for the convection coefficient are typical for forced convection heat transfer with liquids and gases. See Table 1.1.
PROBLEM 1.16

FIND: Heater surface temperatures in water and air.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) All of the electrical power is transferred to the fluid by convection, (3) Negligible heat transfer from ends.

ANALYSIS: With $P = q_{\text{conv}}$, Newton’s law of cooling yields

$$P = hA(T_S - T_\infty) = h\pi DL(T_S - T_\infty)$$

$$T_S = T_\infty + \frac{P}{h\pi DL}.$$ 

In water,

$$T_S = 20^\circ C + \frac{2000 \ W}{5000 \ W/m^2\cdot K \times \pi \times 0.02 \ m \times 0.200 \ m}$$

$$T_S = 20^\circ C + 31.8^\circ C = 51.8^\circ C.$$ <

In air,

$$T_S = 20^\circ C + \frac{2000 \ W}{50 \ W/m^2\cdot K \times \pi \times 0.02 \ m \times 0.200 \ m}$$

$$T_S = 20^\circ C + 3183^\circ C = 3203^\circ C.$$ <

COMMENTS: (1) Air is much less effective than water as a heat transfer fluid. Hence, the cartridge temperature is much higher in air, so high, in fact, that the cartridge would melt.

(2) In air, the high cartridge temperature would render radiation significant.
PROBLEM 1.17

KNOWN: Length, diameter and calibration of a hot wire anemometer. Temperature of air stream. Current, voltage drop and surface temperature of wire for a particular application.

FIND: Air velocity

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible heat transfer from the wire by natural convection or radiation.

ANALYSIS: If all of the electric energy is transferred by convection to the air, the following equality must be satisfied

\[ P_{\text{elec}} = EI = hA (T_s - T_\infty) \]

where \( A = \pi DL = \pi (0.0005m \times 0.02m) = 3.14 \times 10^{-5} \text{ m}^2 \).

Hence,

\[ h = \frac{EI}{A(T_s - T_\infty)} = \frac{5V \times 0.1A}{3.14 \times 10^{-5} \text{ m}^2 \times 318 \text{ W/m}^2 \cdot \text{K}} = 318 \text{ W/m}^2 \cdot \text{K} \]

\[ V = 6.25 \times 10^{-5} h^2 = 6.25 \times 10^{-5} \left( 318 \text{ W/m}^2 \cdot \text{K} \right)^2 = 6.3 \text{ m/s} \]

COMMENTS: The convection coefficient is sufficiently large to render buoyancy (natural convection) and radiation effects negligible.
PROBLEM 1.18

KNOWN: Chip width and maximum allowable temperature. Coolant conditions.

FIND: Maximum allowable chip power for air and liquid coolants.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible heat transfer from sides and bottom, (3) Chip is at a uniform temperature (isothermal), (4) Negligible heat transfer by radiation in air.

ANALYSIS: All of the electrical power dissipated in the chip is transferred by convection to the coolant. Hence, 

\[ P = q \]

and from Newton’s law of cooling, 

\[ P = hA(T - T_\infty) = hW^2(T - T_\infty). \]

In air, 

\[ P_{\text{max}} = 200 \text{ W/m}^2 \cdot \text{K}(0.005 \text{ m})^2(85 - 15) \, ^\circ\text{C} = 0.35 \text{ W}. \]

In the dielectric liquid

\[ P_{\text{max}} = 3000 \text{ W/m}^2 \cdot \text{K}(0.005 \text{ m})^2(85-15) \, ^\circ\text{C} = 5.25 \text{ W}. \]

COMMENTS: Relative to liquids, air is a poor heat transfer fluid. Hence, in air the chip can dissipate far less energy than in the dielectric liquid.
PROBLEM 1.19

KNOWN: Length, diameter and maximum allowable surface temperature of a power transistor. Temperature and convection coefficient for air cooling.

FIND: Maximum allowable power dissipation.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible heat transfer through base of transistor, (3) Negligible heat transfer by radiation from surface of transistor.

ANALYSIS: Subject to the foregoing assumptions, the power dissipated by the transistor is equivalent to the rate at which heat is transferred by convection to the air. Hence,

\[ P_{\text{elec}} = q_{\text{conv}} = hA(T_s - T_{\infty}) \]

where

\[ A = \pi \left( DL + D^2 / 4 \right) = \pi \left[ 0.012\text{m} \times 0.01\text{m} + (0.012\text{m})^2 / 4 \right] = 4.90 \times 10^{-4} \text{m}^2. \]

For a maximum allowable surface temperature of 85°C, the power is

\[ P_{\text{elec}} = 100 \text{ W/m}^2 \cdot \text{K} \left( 4.90 \times 10^{-4} \text{m}^2 \right) \left( 85 - 25 \right) \text{°C} = 2.94 \text{ W} \]

COMMENTS: (1) For the prescribed surface temperature and convection coefficient, radiation will be negligible relative to convection. However, conduction through the base could be significant, thereby permitting operation at a larger power.

(2) The local convection coefficient varies over the surface, and hot spots could exist if there are locations at which the local value of \( h \) is substantially smaller than the prescribed average value.
KNOWN: Air jet impingement is an effective means of cooling logic chips.

FIND: Procedure for measuring convection coefficients associated with a 10 mm $\times$ 10 mm chip.

SCHEMATIC:

ASSUMPTIONS: Steady-state conditions.

ANALYSIS: One approach would be to use the actual chip-substrate system, Case (a), to perform the measurements. In this case, the electric power dissipated in the chip would be transferred from the chip by radiation and conduction (to the substrate), as well as by convection to the jet. An energy balance for the chip yields $q_{\text{elec}} = q_{\text{conv}} + q_{\text{cond}} + q_{\text{rad}}$. Hence, with $q_{\text{conv}} = hA(T_s - T_{\infty})$, where $A = 100$ mm$^2$ is the surface area of the chip,

$$h = \frac{q_{\text{elec}} - q_{\text{cond}} - q_{\text{rad}}}{A(T_s - T_{\infty})} \quad (1)$$

While the electric power ($q_{\text{elec}}$) and the jet ($T_{\infty}$) and surface ($T_s$) temperatures may be measured, losses from the chip by conduction and radiation would have to be estimated. Unless the losses are negligible (an unlikely condition), the accuracy of the procedure could be compromised by uncertainties associated with determining the conduction and radiation losses.

A second approach, Case (b), could involve fabrication of a heater assembly for which the conduction and radiation losses are controlled and minimized. A 10 mm $\times$ 10 mm copper block ($k \approx 400$ W/m$\cdot$K) could be inserted in a poorly conducting substrate ($k < 0.1$ W/m$\cdot$K) and a patch heater could be applied to the back of the block and insulated from below. If conduction to both the substrate and insulation could thereby be rendered negligible, heat would be transferred almost exclusively through the block. If radiation were rendered negligible by applying a low emissivity coating ($\varepsilon < 0.1$) to the surface of the copper block, virtually all of the heat would be transferred by convection to the jet. Hence, $q_{\text{cond}}$ and $q_{\text{rad}}$ may be neglected in equation (1), and the expression may be used to accurately determine $h$ from the known ($A$) and measured ($q_{\text{elec}}$, $T_s$, $T_{\infty}$) quantities.

COMMENTS: Since convection coefficients associated with gas flows are generally small, concurrent heat transfer by radiation and/or conduction must often be considered. However, jet impingement is one of the more effective means of transferring heat by convection and convection coefficients well in excess of 100 W/m$^2$K may be achieved.
PROBLEM 1.21

KNOWN: Upper temperature set point, $T_{\text{set}}$, of a bimetallic switch and convection heat transfer coefficient between clothes dryer air and exposed surface of switch.

FIND: Electrical power for heater to maintain $T_{\text{set}}$ when air temperature is $T_{\infty} = 50^\circ\text{C}$.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Electrical heater is perfectly insulated from dryer wall, (3) Heater and switch are isothermal at $T_{\text{set}}$, (4) Negligible heat transfer from sides of heater or switch, (5) Switch surface, $A_s$, loses heat only by convection.

ANALYSIS: Define a control volume around the bimetallic switch which experiences heat input from the heater and convection heat transfer to the dryer air. That is,

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0 \quad q_{\text{elec}} - h_s (T_{\text{set}} - T_{\infty}) = 0.$$  

The electrical power required is,

$$q_{\text{elec}} = h_s (T_{\text{set}} - T_{\infty})$$

$$q_{\text{elec}} = 25 \: \text{W/m}^2 \cdot \text{K} \times 30 \times 10^{-6} \: \text{m}^2 \cdot (70 - 50) \: \text{K} = 15 \: \text{mW}. \quad <$$

COMMENTS: (1) This type of controller can achieve variable operating air temperatures with a single set-point, inexpensive, bimetallic-thermostatic switch by adjusting power levels to the heater.

(2) Will the heater power requirement increase or decrease if the insulation pad is other than perfect?
PROBLEM 1.22

KNOWN: Hot vertical plate suspended in cool, still air. Change in plate temperature with time at the instant when the plate temperature is 225°C.

FIND: Convection heat transfer coefficient for this condition.

SCHEMATIC:

ASSUMPTIONS: (1) Plate is isothermal and of uniform temperature, (2) Negligible radiation exchange with surroundings, (3) Negligible heat lost through suspension wires.

ANALYSIS: As shown in the cooling curve above, the plate temperature decreases with time. The condition of interest is for time \(t_0\). For a control surface about the plate, the conservation of energy requirement is

\[
\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \dot{E}_{\text{st}}
\]

\[
-2hA_s (T_s - T_\infty) = Mc_p \frac{dT}{dt}
\]

where \(A_s\) is the surface area of one side of the plate. Solving for \(h\), find

\[
h = \frac{Mcp}{2A_s (T_s - T_\infty)} \frac{dT}{dt}
\]

\[
h = \frac{3.75 \text{ kg} \times 2770 \text{ J/kg} \cdot \text{K}}{2 \times (0.3 \times 0.3) \text{ m}^2 (225 - 25) \text{K}} = 6.4 \text{ W/m}^2 \cdot \text{K}
\]

COMMENTS: (1) Assuming the plate is very highly polished with emissivity of 0.08, determine whether radiation exchange with the surroundings at 25°C is negligible compared to convection.

(2) We will later consider the criterion for determining whether the isothermal plate assumption is reasonable. If the thermal conductivity of the present plate were high (such as aluminum or copper), the criterion would be satisfied.
**PROBLEM 1.23**

**KNOWN:** Width, input power and efficiency of a transmission. Temperature and convection coefficient associated with air flow over the casing.

**FIND:** Surface temperature of casing.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady state, (2) Uniform convection coefficient and surface temperature, (3) Negligible radiation.

**ANALYSIS:** From Newton’s law of cooling,

\[
q = h A_s \left( T_s - T_\infty \right) = 6 h W^2 \left( T_s - T_\infty \right)
\]

where the output power is \( \eta P_i \) and the heat rate is

\[
q = P_1 - P_o = P_1 (1 - \eta) = 150 \text{ hp} \times 746 \text{ W/hp} \times 0.07 = 7833 \text{ W}
\]

Hence,

\[
T_s = T_\infty + \frac{q}{6 h W^2} = 30^\circ C + \frac{7833 \text{ W}}{6 \times 200 \text{ W/m}^2 \cdot \text{K} \times (0.3 \text{ m})^2} = 102.5^\circ C
\]

**COMMENTS:** There will, in fact, be considerable variability of the local convection coefficient over the transmission case and the prescribed value represents an average over the surface.
**PROBLEM 1.24**

**KNOWN:** Air and wall temperatures of a room. Surface temperature, convection coefficient and emissivity of a person in the room.

**FIND:** Basis for difference in comfort level between summer and winter.

**SCHEMATIC:**

![Schematic diagram](image)

**ASSUMPTIONS:** (1) Person may be approximated as a small object in a large enclosure.

**ANALYSIS:** Thermal comfort is linked to heat loss from the human body, and a chilled feeling is associated with excessive heat loss. Because the temperature of the room air is fixed, the different summer and winter comfort levels can not be attributed to convection heat transfer from the body. In both cases, the heat flux is

\[
q_{\text{conv}}^* = h (T_s - T_{\infty}) = 2 \text{ W/m}^2 \cdot \text{K} \times 12 \degree \text{C} = 24 \text{ W/m}^2
\]

However, the heat flux due to radiation will differ, with values of

**Summer:**

\[
q_{\text{rad}}^* = \varepsilon \sigma \left( T_s^4 - T_{\text{sur}}^4 \right) = 0.9 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left( 305^4 - 300^4 \right) K^4 = 28.3 \text{ W/m}^2
\]

**Winter:**

\[
q_{\text{rad}}^* = \varepsilon \sigma \left( T_s^4 - T_{\text{sur}}^4 \right) = 0.9 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left( 305^4 - 287^4 \right) K^4 = 95.4 \text{ W/m}^2
\]

There is a significant difference between winter and summer radiation fluxes, and the chilled condition is attributable to the effect of the colder walls on radiation.

**COMMENTS:** For a representative surface area of \( A = 1.5 \text{ m}^2 \), the heat losses are \( q_{\text{conv}} = 36 \text{ W} \), \( q_{\text{rad(summer)}} = 42.5 \text{ W} \) and \( q_{\text{rad(winter)}} = 143.1 \text{ W} \). The winter time radiation loss is significant and if maintained over a 24 h period would amount to 2,950 kcal.
**PROBLEM 1.25**

**KNOWN:** Diameter and emissivity of spherical interplanetary probe. Power dissipation within probe.

**FIND:** Probe surface temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible radiation incident on the probe.

**ANALYSIS:** Conservation of energy dictates a balance between energy generation within the probe and radiation emission from the probe surface. Hence, at any instant

\[-\dot{E}_{\text{out}} + \dot{E}_g = 0\]

\[\varepsilon A_s \sigma T_s^4 = \dot{E}_g\]

\[T_s = \left( \frac{\dot{E}_g}{\varepsilon \pi D^2 \sigma} \right)^{1/4}\]

\[T_s = \left\{ \frac{150 \text{W}}{0.8 \pi (0.5 \text{ m})^2 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4} \right\}^{1/4} = 254.7 \text{ K.} <\]

**COMMENTS:** Incident radiation, as, for example, from the sun, would increase the surface temperature.
PROBLEM 1.26

KNOWN: Spherical shaped instrumentation package with prescribed surface emissivity within a large space-simulation chamber having walls at 77 K.

FIND: Acceptable power dissipation for operating the package surface temperature in the range $T_s = 40$ to $85^\circ$C. Show graphically the effect of emissivity variations for 0.2 and 0.3.

SCHEMATIC:

ASSUMPTIONS: (1) Uniform surface temperature, (2) Chamber walls are large compared to the spherical package, and (3) Steady-state conditions.

ANALYSIS: From an overall energy balance on the package, the internal power dissipation $P_e$ will be transferred by radiation exchange between the package and the chamber walls. From Eq. 1.7,

$$q_{\text{rad}} = P_e = \varepsilon A_s \sigma (T_s^4 - T_{\text{sur}}^4)$$

For the condition when $T_s = 40^\circ$C, with $A_s = \pi D^2$ the power dissipation will be

$$P_e = 0.25(\pi \times 0.10 \text{ m}) \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times [(40 + 273)^4 - 77^4] \text{K}^4 = 4.3 \text{ W}$$

Repeating this calculation for the range $40 \leq T_s \leq 85^\circ$C, we can obtain the power dissipation as a function of surface temperature for the $\varepsilon = 0.25$ condition. Similarly, with 0.2 or 0.3, the family of curves shown below has been obtained.

COMMENTS: (1) As expected, the internal power dissipation increases with increasing emissivity and surface temperature. Because the radiation rate equation is non-linear with respect to temperature, the power dissipation will likewise not be linear with surface temperature.

(2) What is the maximum power dissipation that is possible if the surface temperature is not to exceed $85^\circ$C? What kind of a coating should be applied to the instrument package in order to approach this limiting condition?
PROBLEM 1.27

KNOWN: Area, emissivity and temperature of a surface placed in a large, evacuated chamber of prescribed temperature.

FIND: (a) Rate of surface radiation emission, (b) Net rate of radiation exchange between surface and chamber walls.

SCHEMATIC:

ASSUMPTIONS: (1) Area of the enclosed surface is much less than that of chamber walls.

ANALYSIS: (a) From Eq. 1.5, the rate at which radiation is emitted by the surface is

\[ q_{\text{emit}} = E \cdot A = \varepsilon A \sigma T_s^4 \]

\[ q_{\text{emit}} = 0.8 \left(0.5 \text{ m}^2\right) 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left[(150 + 273)\text{K}\right]^4 \]

\[ q_{\text{emit}} = 726 \text{ W}. \]

(b) From Eq. 1.7, the net rate at which radiation is transferred from the surface to the chamber walls is

\[ q = \varepsilon A \sigma \left(T_s^4 - T_{\text{sur}}^4\right) \]

\[ q = 0.8 \left(0.5 \text{ m}^2\right) 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left[(423\text{K})^4 - (298\text{K})^4\right] \]

\[ q = 547 \text{ W}. \]

COMMENTS: The foregoing result gives the net heat loss from the surface which occurs at the instant the surface is placed in the chamber. The surface would, of course, cool due to this heat loss and its temperature, as well as the heat loss, would decrease with increasing time. Steady-state conditions would eventually be achieved when the temperature of the surface reached that of the surroundings.
**PROBLEM 1.28**

**KNOWN:** Length, diameter, surface temperature and emissivity of steam line. Temperature and convection coefficient associated with ambient air. Efficiency and fuel cost for gas fired furnace.

**FIND:** (a) Rate of heat loss, (b) Annual cost of heat loss.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steam line operates continuously throughout year, (2) Net radiation transfer is between small surface (steam line) and large enclosure (plant walls).

**ANALYSIS:** (a) From Eqs. (1.3a) and (1.7), the heat loss is

\[ q = q_{\text{conv}} + q_{\text{rad}} = A \left[ h(T_s - T_\infty) + \varepsilon\sigma \left( T_s^4 - T_{\text{sur}}^4 \right) \right] \]

where \( A = \pi DL = \pi (0.1m \times 25m) = 7.85m^2 \).

Hence,

\[ q = 7.85m^2 \left[ 10 \text{ W/m}^2 \cdot \text{K} \times (150 - 25) \text{ K} + 0.8 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left( 423^4 - 298^4 \right) \text{ K}^4 \right] \]

\[ q = 7.85m^2 \times (1.250 + 1.095) \text{ W/m}^2 = (9813 + 8592) \text{ W} = 18405 \text{ W} \]

(b) The annual energy loss is

\[ E = qt = 18405 \text{ W} \times 3600 \text{ s/h} \times 24 \text{ h/d} \times 365 \text{ d/y} = 5.80 \times 10^{11} \text{ J} \]

With a furnace energy consumption of \( E_f = E/\eta_f = 6.45 \times 10^{11} \text{ J} \), the annual cost of the loss is

\[ C = C_g E_f = 0.01 \$/$\text{MJ} \times 6.45 \times 10^5 \text{ MJ} = 6450 \$ \]

**COMMENTS:** The heat loss and related costs are unacceptable and should be reduced by insulating the steam line.
PROBLEM 1.29

KNOWN: Exact and approximate expressions for the linearized radiation coefficient, \( h_r \) and \( h_{ra} \), respectively.

FIND: (a) Comparison of the coefficients with \( \varepsilon = 0.05 \) and 0.9 and surface temperatures which may exceed that of the surroundings \( (T_{sur} = 25^\circ C) \) by 10 to 100°C; also comparison with a free convection coefficient correlation, (b) Plot of the relative error \( (h_r - h_{ra})/h_r \) as a function of the furnace temperature associated with a workpiece at \( T_s = 25^\circ C \) having \( \varepsilon = 0.05, 0.2 \) or 0.9.

ASSUMPTIONS: (1) Furnace walls are large compared to the workpiece and (2) Steady-state conditions.

ANALYSIS: (a) The linearized radiation coefficient, Eq. 1.9, follows from the radiation exchange rate equation,

\[
h_r = \varepsilon \sigma (T_s + T_{sur}) \left( T_s^2 + T_{sur}^2 \right)
\]

If \( T_s = T_{sur} \), the coefficient may be approximated by the simpler expression

\[
h_{r,a} = 4\varepsilon \sigma \bar{T}^3
\]

\[
\bar{T} = (T_s + T_{sur})/2
\]

For the condition of \( \varepsilon = 0.05, T_s = T_{sur} + 10 = 35^\circ C = 308 \text{ K} \) and \( T_{sur} = 25^\circ C = 298 \text{ K} \), find that

\[
h_r = 0.05 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (308 + 298) \left( 308^2 + 298^2 \right) K^3 = 0.32 \text{ W/m}^2 \cdot \text{K}
\]

\[
h_{r,a} = 4 \times 0.05 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left( (308 + 298)/2 \right)^3 K^3 = 0.32 \text{ W/m}^2 \cdot \text{K}
\]

The free convection coefficient with \( T_s = 35^\circ C \) and \( T_{\infty} = T_{sur} = 25^\circ C \), find that

\[
h = 0.98 \Delta T^{1/3} = 0.98 (T_s - T_{\infty})^{1/3} = 0.98 (308 - 298)^{1/3} = 2.1 \text{ W/m}^2 \cdot \text{K}
\]

For the range \( T_s - T_{sur} = 10 \) to 100°C with \( \varepsilon = 0.05 \) and 0.9, the results for the coefficients are tabulated below. For this range of surface and surroundings temperatures, the radiation and free convection coefficients are of comparable magnitude for moderate values of the emissivity, say \( \varepsilon > 0.2 \). The approximate expression for the linearized radiation coefficient is valid within 2% for these conditions.

(b) The above expressions for the radiation coefficients, \( h_r \) and \( h_{ra} \), are used for the workpiece at \( T_s = 25^\circ C \) placed inside a furnace with walls which may vary from 100 to 1000°C. The relative error, \( (h_r - h_{ra})/h_r \), will be independent of the surface emissivity and is plotted as a function of \( T_{sur} \). For \( T_{sur} > 150^\circ C \), the approximate expression provides estimates which are in error more than 5%. The approximate expression should be used with caution, and only for surface and surrounding temperature differences of 50 to 100°C.

![Graph showing relative error as a function of surroundings temperature](image-url)
PROBLEM 1.30

KNOWN: Chip width, temperature, and heat loss by convection in air. Chip emissivity and temperature of large surroundings.

FIND: Increase in chip power due to radiation.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Radiation exchange between small surface and large enclosure.

ANALYSIS: Heat transfer from the chip due to net radiation exchange with the surroundings is

\[ q_{\text{rad}} = \varepsilon W^2 \sigma \left( T^4 - T_{\text{sur}}^4 \right) \]

\[ q_{\text{rad}} = 0.9 (0.005 \text{ m})^2 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left( 358^4 - 288^4 \right) \approx 0.0122 \text{ W}. \]

The percent increase in chip power is therefore

\[ \frac{\Delta P}{P} \times 100 = \frac{q_{\text{rad}}}{q_{\text{conv}}} \times 100 = \frac{0.0122 \text{ W}}{0.350 \text{ W}} \times 100 = 3.5\%. \]

COMMENTS: For the prescribed conditions, radiation effects are small. Relative to convection, the effect of radiation would increase with increasing chip temperature and decreasing convection coefficient.
PROBLEM 1.31

FIND: (a) Maximum power dissipation for free convection with \( h(W/m^2\cdot K) = 4.2(T - T_{\infty})^{1/4} \), (b) Maximum power dissipation for forced convection with \( h = 250 \, W/m^2\cdot K \).

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Radiation exchange between a small surface and a large enclosure, (3) Negligible heat transfer from sides of chip or from back of chip by conduction through the substrate.

ANALYSIS: Subject to the foregoing assumptions, electric power dissipation by the chip must be balanced by convection and radiation heat transfer from the chip. Hence, from Eq. (1.10),

\[
P_{\text{elec}} = q_{\text{conv}} + q_{\text{rad}} = hA(T_s - T_{\infty}) + \varepsilon\sigma\left(T_s^4 - T_{\text{sur}}^4\right)
\]

where \( A = L^2 = (0.015m)^2 = 2.25\times10^{-4} \, m^2 \).

(a) If heat transfer is by natural convection,

\[
q_{\text{conv}} = C A(T_s - T_{\infty})^{5/4} = 4.2 \, W/m^2\cdot K \times \left(2.25\times10^{-4} \, m^2\right)^{5/4} = 0.158 \, W
\]

\[
q_{\text{rad}} = 0.60 \times 5.67 \times 10^{-8} \, W/m^2\cdot K^4 \times \left(358^4 - 298^4\right)K^4 = 0.065 \, W
\]

\[
P_{\text{elec}} = 0.158 \, W + 0.065 \, W = 0.223 \, W < \]

(b) If heat transfer is by forced convection,

\[
q_{\text{conv}} = hA(T_s - T_{\infty}) = 250 \, W/m^2\cdot K \times \left(2.25\times10^{-4} \, m^2\right)(60K) = 3.375 \, W
\]

\[
P_{\text{elec}} = 3.375 \, W + 0.065 \, W = 3.44 \, W < \]

COMMENTS: Clearly, radiation and natural convection are inefficient mechanisms for transferring heat from the chip. For \( T_s = 85^\circ C \) and \( T_{\infty} = 25^\circ C \), the natural convection coefficient is 11.7 \, W/m^2\cdot K. Even for forced convection with \( h = 250 \, W/m^2\cdot K \), the power dissipation is well below that associated with many of today’s processors. To provide acceptable cooling, it is often necessary to attach the chip to a highly conducting substrate and to thereby provide an additional heat transfer mechanism due to conduction from the back surface.
PROBLEM 1.32

KNOWN: Vacuum enclosure maintained at 77 K by liquid nitrogen shroud while baseplate is maintained at 300 K by an electrical heater.

FIND: (a) Electrical power required to maintain baseplate, (b) Liquid nitrogen consumption rate, (c) Effect on consumption rate if aluminum foil ($\varepsilon_p = 0.09$) is bonded to baseplate surface.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) No heat losses from backside of heater or sides of plate, (3) Vacuum enclosure large compared to baseplate, (4) Enclosure is evacuated with negligible convection, (5) Liquid nitrogen (LN2) is heated only by heat transfer to the shroud, and (6) Foil is intimately bonded to baseplate.

PROPERTIES: Heat of vaporization of liquid nitrogen (given): 125 kJ/kg.

ANALYSIS: (a) From an energy balance on the baseplate,
\[ \dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0 \quad \text{and using Eq. 1.7 for radiative exchange between the baseplate and shroud,} \]
\[ q_{\text{elec}} = \varepsilon_p A_p \sigma \left( T_p^4 - T_{sh}^4 \right). \]
Substituting numerical values, with $A_p = \left( \pi D_p^2 / 4 \right)$, find
\[ q_{\text{elec}} = 0.25 \left( \pi (0.3 \text{ m})^2 / 4 \right) 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left( 300^4 - 77^4 \right) \text{K}^4 = 8.1 \text{ W}. \]

(b) From an energy balance on the enclosure, radiative transfer heats the liquid nitrogen stream causing evaporation,
\[ \dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0 \quad q_{\text{rad}} - \dot{m}_{\text{LN2}} h_{fg} = 0 \]
where $\dot{m}_{\text{LN2}}$ is the liquid nitrogen consumption rate. Hence,
\[ \dot{m}_{\text{LN2}} = q_{\text{rad}} / h_{fg} = 8.1 \text{ W} / 125 \text{ kJ/kg} = 6.48 \times 10^{-5} \text{ kg/s} = 0.23 \text{ kg/h}. \]

(c) If aluminum foil ($\varepsilon_p = 0.09$) were bonded to the upper surface of the baseplate,
\[ q_{\text{rad,foil}} = q_{\text{rad}} \left( \varepsilon_f / \varepsilon_p \right) = 8.1 \text{ W} \left( 0.09/0.25 \right) = 2.9 \text{ W} \]
and the liquid nitrogen consumption rate would be reduced by
\[ (0.25 - 0.09)/0.25 = 64\% \text{ to 0.083 kg/h}. \]

<
**PROBLEM 1.33**

**KNOWN:** Width, input power and efficiency of a transmission. Temperature and convection coefficient for air flow over the casing. Emissivity of casing and temperature of surroundings.

**FIND:** Surface temperature of casing.

**SCHEMATIC:**

![Schematic diagram](image)

**ASSUMPTIONS:** (1) Steady state, (2) Uniform convection coefficient and surface temperature, (3) Radiation exchange with large surroundings.

**ANALYSIS:** Heat transfer from the case must balance heat dissipation in the transmission, which may be expressed as 
\[ q = P_i - P_o = P_i (1 - \eta) = 150 \text{ hp} \times 746 \text{ W/hp} \times 0.07 = 7833 \text{ W}. \] Heat transfer from the case is by convection and radiation, in which case

\[
q = A_s \left[ h(T_s - T_\infty) + \varepsilon\sigma\left(T_s^4 - T_{\text{sur}}^4\right)\right]
\]

where \( A_s = 6 \text{ W}^2 \). Hence,

\[
7833 \text{ W} = 6(0.30 \text{ m})^2 \left[ 200 \text{ W/m}^2 \cdot \text{K} \left(T_s - 303 \text{K}\right) + 0.8 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left(T_s^4 - 303^4\right)\right]
\]

A trial-and-error solution yields

\[ T_s \approx 373 \text{ K} = 100^\circ \text{C} \]

**COMMENTS:** (1) For \( T_s \approx 373 \text{ K}, q_{\text{conv}} \approx 7560 \text{ W} \) and \( q_{\text{rad}} \approx 270 \text{ W} \), in which case heat transfer is dominated by convection, (2) If radiation is neglected, the corresponding surface temperature is \( T_s = 102.5^\circ \text{C} \).
PROBLEM 1.34

KNOWN: Resistor connected to a battery operating at a prescribed temperature in air.

FIND: (a) Considering the resistor as the system, determine corresponding values for $\dot{E}_{\text{in}}$ (W), $\dot{E}_{\text{g}}$ (W), $\dot{E}_{\text{out}}$ (W) and $\dot{E}_{\text{st}}$ (W). If a control surface is placed about the entire system, determine the values for $\dot{E}_{\text{in}}$, $\dot{E}_{\text{g}}$, $\dot{E}_{\text{out}}$, and $\dot{E}_{\text{st}}$. (b) Determine the volumetric heat generation rate within the resistor, $\dot{q}$ (W/m$^3$), (c) Neglecting radiation from the resistor, determine the convection coefficient.

SCHEMATIC:

ASSUMPTIONS: (1) Electrical power is dissipated uniformly within the resistor, (2) Temperature of the resistor is uniform, (3) Negligible electrical power dissipated in the lead wires, (4) Negligible radiation exchange between the resistor and the surroundings, (5) No heat transfer occurs from the battery, (5) Steady-state conditions.

ANALYSIS: (a) Referring to Section 1.3.1, the conservation of energy requirement for a control volume at an instant of time, Eq 1.11a, is

$$\dot{E}_{\text{in}} + \dot{E}_{\text{g}} - \dot{E}_{\text{out}} = \dot{E}_{\text{st}}$$

where $\dot{E}_{\text{in}}$, $\dot{E}_{\text{out}}$ correspond to surface inflow and outflow processes, respectively. The energy generation term $\dot{E}_{\text{g}}$ is associated with conversion of some other energy form (chemical, electrical, electromagnetic or nuclear) to thermal energy. The energy storage term $\dot{E}_{\text{st}}$ is associated with changes in the internal, kinetic and/or potential energies of the matter in the control volume. $\dot{E}_{\text{g}}$, $\dot{E}_{\text{st}}$ are volumetric phenomena. The electrical power delivered by the battery is $P = VI = 24\text{V}\times6\text{A} = 144\text{ W}$.

*Control volume: Resistor.*

\[
\begin{align*}
\dot{E}_{\text{in}} &= 0 & \dot{E}_{\text{out}} &= 144\text{ W} \\
\dot{E}_{\text{g}} &= 144\text{ W} & \dot{E}_{\text{st}} &= 0
\end{align*}
\]

The $\dot{E}_{\text{g}}$ term is due to conversion of electrical energy to thermal energy. The term $\dot{E}_{\text{out}}$ is due to convection from the resistor surface to the air.

Continued...
PROBLEM 1.34 (Cont.)

Control volume: Battery-Resistor System.

\[ \dot{E}_{in} = 0 \quad \dot{E}_{out} = 144 \text{ W} \quad \dot{E}_g = 0 \quad \dot{E}_{st} = -144 \text{ W} \]

The \( \dot{E}_{st} \) term represents the decrease in the chemical energy within the battery. The conversion of chemical energy to electrical energy and its subsequent conversion to thermal energy are processes internal to the system which are not associated with \( \dot{E}_{st} \) or \( \dot{E}_g \). The \( \dot{E}_{out} \) term is due to convection from the resistor surface to the air.

(b) From the energy balance on the resistor with volume, \( V = (\pi D^2/4) L \),

\[ \dot{E}_g = \dot{q} V = 144 \text{ W} = \dot{q} \left( \pi \left(0.06 \text{ m}\right)^2 / 4 \right) \times 0.25 \text{ m} \quad \dot{q} = 2.04 \times 10^5 \text{ W/m}^3 \]

(c) From the energy balance on the resistor and Newton’s law of cooling with \( A_S = \pi D L + 2(\pi D^2/4) \),

\[ \dot{E}_{out} = q_{CV} = h A_S (T_s - T_\infty) \]

\[ 144 \text{ W} = h \left[ \pi \times 0.06 \text{ m} \times 0.25 \text{ m} + 2 \left( \pi \times 0.06^2 \text{ m}^2 / 4 \right) \right] (95 - 25) ^\circ \text{ C} \]

\[ 144 \text{ W} = h \left[ 0.0471 + 0.0057 \right] \text{ m}^2 \text{ (95 - 25) } ^\circ \text{ C} \]

\[ h = 39.0 \text{ W/m}^2 \text{ K} \]

COMMENTS: (1) In using the conservation of energy requirement, Eq. 1.11a, it is important to recognize that \( \dot{E}_{in} \) and \( \dot{E}_{out} \) will always represent surface processes and \( \dot{E}_g \) and \( \dot{E}_{st} \) volumetric processes. The generation term \( \dot{E}_g \) is associated with a conversion process from some form of energy to thermal energy. The storage term \( \dot{E}_{st} \) represents the rate of change of internal energy.

(2) From Table 1.1 and the magnitude of the convection coefficient determined from part (c), we conclude that the resistor is experiencing forced, rather than free, convection.
PROBLEM 1.35

KNOWN: Thickness and initial temperature of an aluminum plate whose thermal environment is changed.

FIND: (a) Initial rate of temperature change, (b) Steady-state temperature of plate, (c) Effect of emissivity and absorptivity on steady-state temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible end effects, (2) Uniform plate temperature at any instant, (3) Constant properties, (4) Adiabatic bottom surface, (5) Negligible radiation from surroundings, (6) No internal heat generation.

ANALYSIS: (a) Applying an energy balance, Eq. 1.11a, at an instant of time to a control volume about the plate, \( \dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \dot{E}_{\text{st}} \), it follows for a unit surface area.

\[
\alpha_s G_S \left(1 m^2\right) - E \left(1 m^2\right) - \eta_{\text{conv}} \left(1 m^2\right) = \left(dT/dt\right)(McT) = \rho \left(1 m^2 \times L\right)c \left(dT/dt\right).
\]

Rearranging and substituting from Eqs. 1.3 and 1.5, we obtain

\[
dT/dt = (1/\rho Lc)\left[\alpha_s G_S - \varepsilon \sigma T^4 + h (T_i - T_{\infty})\right].
\]

\[
dT/dt = \left(2700 \text{ kg/m}^3 \times 0.004 \text{ m} \times 900 \text{ J/kg K}\right)^{-1} \times \left[0.8 \times 900 \text{ W/m}^2 - 0.25 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left(298 \text{ K}\right)^4 - 20 \text{ W/m}^2 \cdot \text{K}\left(25 - 20\right)^{\circ} \text{C}\right]
\]

\[
dT/dt = 0.052 \text{ C/s},
\]

(b) Under steady-state conditions, \( \dot{E}_{\text{st}} = 0 \), and the energy balance reduces to

\[
\alpha_s G_S = \varepsilon \sigma T^4 + h (T - T_{\infty})
\]

\[
0.8 \times 900 \text{ W/m}^2 = 0.25 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times T^4 + 20 \text{ W/m}^2 \cdot \text{K}\left(T - 293 \text{ K}\right)
\]

The solution yields \( T = 321.4 \text{ K} = 48.4^\circ \text{C} \).

(c) Using the IHT First Law Model for an Isothermal Plane Wall, parametric calculations yield the following results.

COMMENTS: The surface radiative properties have a significant effect on the plate temperature, which decreases with increasing \( \varepsilon \) and decreasing \( \alpha_s \). If a low temperature is desired, the plate coating should be characterized by a large value of \( \varepsilon/\alpha_s \). The temperature also decreases with increasing \( h \).
PROBLEM 1.36

KNOWN: Surface area of electronic package and power dissipation by the electronics. Surface emissivity and absorptivity to solar radiation. Solar flux.

FIND: Surface temperature without and with incident solar radiation.

SCHEMATIC:

ASSUMPTIONS: Steady-state conditions.

ANALYSIS: Applying conservation of energy to a control surface about the compartment, at any instant

\[ \dot{E}_{\text{in}} - \dot{E}_{\text{out}} + \dot{E}_g = 0. \]

It follows that, with the solar input,

\[
\alpha_S A_S q_S - A_S E + P = 0
\]

\[
\alpha_S A_S q_S - A_S \varepsilon \sigma T_s^4 + P = 0
\]

\[ T_s = \left( \frac{\alpha_S A_S q_S + P}{A_S \varepsilon \sigma} \right)^{1/4}. \]

In the shade \((q_S = 0)\),

\[
T_s = \left( \frac{1000 \text{ W}}{1 \text{ m}^2 \times 1 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4} \right)^{1/4} = 364 \text{ K.} <
\]

In the sun,

\[
T_s = \left( \frac{0.25 \times 1 \text{ m}^2 \times 750 \text{ W/m}^2 + 1000 \text{ W}}{1 \text{ m}^2 \times 1 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4} \right)^{1/4} = 380 \text{ K.} <
\]

COMMENTS: In orbit, the space station would be continuously cycling between shade and sunshine, and a steady-state condition would not exist.
**Problem 1.37**

**Known:** Daily hot water consumption for a family of four and temperatures associated with ground water and water storage tank. Unit cost of electric power. Heat pump COP.

**Find:** Annual heating requirement and costs associated with using electric resistance heating or a heat pump.

**Schematic:**

**Assumptions:** (1) Process may be modelled as one involving heat addition in a closed system, (2) Properties of water are constant.

**Properties:** Table A-6, Water ($T_{ave} = 308 K$): $\rho = \frac{v_f}{v_f^{-1}} = 993 \text{ kg/m}^3$, $c_{p,f} = 4.178 \text{ kJ/kg} \cdot \text{K}$.

**Analysis:** From Eq. 1.11c, the daily heating requirement is $Q_{\text{daily}} = \Delta U_t = M c \Delta T$

$= \rho V c (T_f - T_i)$. With $V = 100 \text{ gal}/264.17 \text{ gal/m}^3 = 0.379 \text{ m}^3$,

$Q_{\text{daily}} = 993 \text{ kg/m}^3 \left(0.379 \text{ m}^3\right)4.178\text{ kJ/kg} \cdot \text{K} \left(40^\circ \text{C}\right) = 62,900 \text{ kJ}$

The annual heating requirement is then, $Q_{\text{annual}} = 365 \text{ days} (62,900 \text{ kJ/day}) = 2.30 \times 10^7 \text{ kJ}$, or, with $1 \text{ kWh} = 1 \text{ kJ/s} (3600 \text{ s}) = 3600 \text{ kJ}$,

$Q_{\text{annual}} = 6380 \text{ kWh} <$

With electric resistance heating, $Q_{\text{annual}} = Q_{\text{elec}}$ and the associated cost, $C$, is

$C = 6380 \text{ kWh} ($0.08/\text{kWh}) = $510 <$

If a heat pump is used, $Q_{\text{annual}} = COP (W_{\text{elec}})$. Hence,

$W_{\text{elec}} = Q_{\text{annual}}/(COP) = 6380 \text{ kWh}/(3) = 2130 \text{ kWh}$

The corresponding cost is

$C = 2130 \text{ kWh} ($0.08/\text{kWh}) = $170 <$

**Comments:** Although annual operating costs are significantly lower for a heat pump, corresponding capital costs are much higher. The feasibility of this approach depends on other factors such as geography and seasonal variations in COP, as well as the time value of money.
**PROBLEM 1.38**

**KNOWN:** Initial temperature of water and tank volume. Power dissipation, emissivity, length and diameter of submerged heaters. Expressions for convection coefficient associated with natural convection in water and air.

**FIND:** (a) Time to raise temperature of water to prescribed value, (b) Heater temperature shortly after activation and at conclusion of process, (c) Heater temperature if activated in air.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss from tank to surroundings, (2) Water is well-mixed (at a uniform, but time varying temperature) during heating, (3) Negligible changes in thermal energy storage for heaters, (4) Constant properties, (5) Surroundings afforded by tank wall are large relative to heaters.

**ANALYSIS:** (a) Application of conservation of energy to a closed system (the water) at an instant, Eq. (1.11d), yields

$$\frac{dU}{dt} = Mc \frac{dT}{dt} = \rho\gamma c \frac{dT}{dt} = q = 3q_1$$

Hence,

$$t = \int_0^T \left( \frac{1}{3} \right) T_f \left( \frac{T_f}{T_i} \right) dT$$

With water temperatures of $T_i \approx 295$ K and $T_f = 335$ K shortly after the start of heating and at the end of heating, respectively,

$$T_{s,i} = 319 \text{ K} \quad T_{s,f} = 359 \text{ K}$$

Continued ....
PROBLEM 1.38 (Continued)

(c) From Eq. (1.10), the heat rate in air is

\[ q_1 = \pi DL \left[ 0.70 (T_s - T_\infty)^{4/3} + \varepsilon \sigma \left( T_s^4 - T_{\text{sur}}^4 \right) \right] \]

Substituting the prescribed values of \( q_1, D, L, T_\infty = T_{\text{sur}} \) and \( \varepsilon \), an iterative solution yields

\[ T_s = 830 \text{ K} \]

COMMENTS: In part (c) it is presumed that the heater can be operated at \( T_s = 830 \text{ K} \) without experiencing burnout. The much larger value of \( T_s \) for air is due to the smaller convection coefficient. However, with \( q_{\text{conv}} \) and \( q_{\text{rad}} \) equal to 59 W and 441 W, respectively, a significant portion of the heat dissipation is effected by radiation.
PROBLEM 1.39

KNOWN: Power consumption, diameter, and inlet and discharge temperatures of a hair dryer.

FIND: (a) Volumetric flow rate and discharge velocity of heated air, (b) Heat loss from case.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Constant air properties, (3) Negligible potential and kinetic energy changes of air flow, (4) Negligible work done by fan, (5) Negligible heat transfer from casing of dryer to ambient air (Part (a)), (6) Radiation exchange between a small surface and a large enclosure (Part (b)).

ANALYSIS: (a) For a control surface about the air flow passage through the dryer, conservation of energy for an open system reduces to

\[ \dot{m}(u + pv)_i - \dot{m}(u + pv)_o + q = 0 \]

where \( u + pv = i \) and \( q = P_{\text{elec}} \). Hence, with \( \dot{m}(i - i_0) = \dot{m}c_p(T_i - T_o) \),

\[ \dot{m} = \frac{P_{\text{elec}}}{c_p(T_o - T_i)} = \frac{500 \text{ W}}{1007 \text{ J/kg} \cdot \text{K}(25^\circ \text{C})} = 0.0199 \text{ kg/s} \]

\[ \dot{\vartheta} = \frac{\dot{m}}{\rho} = \frac{0.0199 \text{ kg/s}}{1.10 \text{ kg/m}^3} = 0.0181 \text{ m}^3 / \text{s} \]

\[ \dot{V}_o = \frac{\dot{\vartheta}}{A_c} = \frac{4\dot{\vartheta}}{\pi D^2} = \frac{4 \times 0.0181 \text{ m}^3 / \text{s}}{\pi (0.07 \text{ m})^2} = 4.7 \text{ m/s} \]

(b) Heat transfer from the casing is by convection and radiation, and from Eq. (1.10)

\[ q = hA_s(T_s - T_\infty) + \varepsilon A_s\sigma(T_s^4 - T_{s\text{sur}}^4) \]

Continued …..
where \( A_S = \pi DL = \pi (0.07 \text{ m} \times 0.15 \text{ m}) = 0.033 \text{ m}^2 \). Hence,

\[
q = 4 \text{W/m}^2 \cdot \text{K} \left( 0.033 \text{ m}^2 \right) \left( 20^\circ \text{C} \right) + 0.8 \times 0.033 \text{ m}^2 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left( 313^4 - 293^4 \right) \text{K}^4
\]

\[
q = 2.64 \text{ W} + 3.33 \text{ W} = 5.97 \text{ W}
\]

The heat loss is much less than the electrical power, and the assumption of negligible heat loss is justified.

**COMMENTS:** Although the mass flow rate is invariant, the volumetric flow rate increases as the air is heated in its passage through the dryer, causing a reduction in the density. However, for the prescribed temperature rise, the change in \( \rho \), and hence the effect on \( \dot{V} \), is small.
**PROBLEM 1.40**

**KNOWN:** Speed, width, thickness and initial and final temperatures of 304 stainless steel in an annealing process. Dimensions of annealing oven and temperature, emissivity and convection coefficient of surfaces exposed to ambient air and large surroundings of equivalent temperatures. Thickness of pad on which oven rests and pad surface temperatures.

**FIND:** Oven operating power.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) steady-state, (2) Constant properties, (3) Negligible changes in kinetic and potential energy.

**PROPERTIES:** Table A.1, St.St.304 \( \bar{T} = (T_i + T_o)/2 = 775 \text{K} \): \( \rho = 7900 \text{kg/m}^3 \), \( c_p = 578 \text{J/kg} \cdot \text{K} \)

Table A.3, Concrete, \( T = 300 \text{K} \): \( k_c = 1.4 \text{W/m} \cdot \text{K} \).

**ANALYSIS:** The rate of energy addition to the oven must balance the rate of energy transfer to the steel sheet and the rate of heat loss from the oven. With \( E_{in} - E_{out} = 0 \), it follows that

\[
P_{elec} + \dot{m} (u_i - u_o) - q = 0
\]

where heat is transferred from the oven. With \( \dot{m} = \rho V_s \left(W_s t_s\right) \), \( (u_i - u_o) = c_p \left(T_i - T_o\right) \), and

\[
q = (2H_o L_o + 2H_o W_o + W_o L_o) \times \left[h \left(T_s - T_{\infty}\right) + \varepsilon_s \sigma \left(T_s^4 - T_{sur}^4\right)\right] + k_c \left(W_o L_o\right) \left(T_s - T_b\right) t_c
\]

it follows that

\[
P_{elec} = \rho V_s \left(W_s t_s\right) c_p \left(T_o - T_i\right) + (2H_o L_o + 2H_o W_o + W_o L_o) \times \left[h \left(T_s - T_{\infty}\right) + \varepsilon_s \sigma \left(T_s^4 - T_{sur}^4\right)\right] + k_c \left(W_o L_o\right) \left(T_s - T_b\right) t_c
\]

\[
P_{elec} = 7900 \text{kg/m}^3 \times 0.01 \text{m/s} (2 \text{m} \times 0.008 \text{m}) 578 \text{J/kg} \cdot \text{K} (1250 - 300) \text{K} + (2 \times 2 \text{m} \times 25 \text{m} + 2 \times 2 \text{m} \times 2.4 \text{m} + 2.4 \text{m} \times 25 \text{m}) \left[10 \text{W/m}^2 \cdot \text{K} (350 - 300) \text{K} + 0.8 \times 5.67 \times 10^{-8} \text{W/m}^2 \cdot \text{K}^4 \left(350^4 - 300^4\right) \right] + 1.4 \text{W/m} \cdot \text{K} (2.4 \text{m} \times 25 \text{m})(350 - 300) \text{K}/0.5 \text{m}
\]

Continued.....
PROBLEM 1.40 (Cont.)

\[ P_{\text{elec}} = 694,000 \text{W} + 169.6 m^2 (500 + 313) \text{W/m}^2 + 8400 \text{W} \]

\[ = (694,000 + 84,800 + 53,100 + 8400) \text{W} = 840 \text{kW} \]

**COMMENTS:** Of the total energy input, 83\% is transferred to the steel while approximately 10\%, 6\% and 1\% are lost by convection, radiation and conduction from the oven. The convection and radiation losses can both be reduced by adding insulation to the side and top surfaces, which would reduce the corresponding value of \( T_s \).
PROBLEM 1.41

KNOWN: Hot plate-type wafer thermal processing tool based upon heat transfer modes by conduction through gas within the gap and by radiation exchange across gap.

FIND: (a) Radiative and conduction heat fluxes across gap for specified hot plate and wafer temperatures and gap separation; initial time rate of change in wafer temperature for each mode, and (b) heat fluxes and initial temperature-time change for gap separations of 0.2, 0.5 and 1.0 mm for hot plate temperatures $300 < T_h < 1300^\circ C$. Comment on the relative importance of the modes and the influence of the gap distance. Under what conditions could a wafer be heated to $900^\circ C$ in less than 10 seconds?

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions for flux calculations, (2) Diameter of hot plate and wafer much larger than gap spacing, approximating plane, infinite planes, (3) One-dimensional conduction through gas, (4) Hot plate and wafer are blackbodies, (5) Negligible heat losses from wafer backside, and (6) Wafer temperature is uniform at the onset of heating.

PROPERTIES: Wafer: $\rho = 2700 \text{ kg/m}^3, c = 875 \text{ J/kg} \cdot \text{K}$; Gas in gap: $k = 0.0436 \text{ W/m} \cdot \text{K}$.

ANALYSIS: (a) The radiative heat flux between the hot plate and wafer for $T_h = 600^\circ C$ and $T_w = 20^\circ C$ follows from the rate equation,

$$q_{\text{rad}}^* = \sigma \left( T_h^4 - T_w^4 \right) = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left( (600 + 273)^4 - (20 + 273)^4 \right) \text{K}^4 = 32.5 \text{ kW/m}^2 \quad <$$

The conduction heat flux through the gas in the gap with $L = 0.2 \text{ mm}$ follows from Fourier’s law,

$$q_{\text{cond}}^* = k \frac{T_h - T_w}{L} = 0.0436 \text{ W/m} \cdot \text{K} \left( \frac{(600 - 20) \text{K}}{0.0002 \text{ m}} \right) = 126 \text{ kW/m}^2 \quad <$$

The initial time rate of change of the wafer can be determined from an energy balance on the wafer at the instant of time the heating process begins,

$$\dot{E}_{\text{in}}^* - \dot{E}_{\text{out}}^* = \dot{E}_{\text{st}}^* \quad \dot{E}_{\text{st}}^* = \rho c d \left( \frac{dT_w}{dt} \right)_{d}$$

where $\dot{E}_{\text{out}}^* = 0$ and $\dot{E}_{\text{in}}^* = q_{\text{rad}}^*$ or $q_{\text{cond}}^*$. Substituting numerical values, find

$$\frac{dT_w}{dt} \bigg|_{\text{rad}} = \frac{q_{\text{rad}}^*}{\rho c d} = \frac{32.5 \times 10^3 \text{ W/m}^2}{2700 \text{ kg/m}^3 \times 875 \text{ J/kg} \cdot \text{K} \times 0.00078 \text{ m}} = 17.6 \text{ K/s} \quad <$$

$$\frac{dT_w}{dt} \bigg|_{\text{cond}} = \frac{q_{\text{cond}}^*}{\rho c d} = 68.4 \text{ K/s} \quad <$$

Continued …..
(b) Using the foregoing equations, the heat fluxes and initial rate of temperature change for each mode can be calculated for selected gap separations \( L \) and range of hot plate temperatures \( T_h \) with \( T_w = 20^\circ C \).

In the left-hand graph, the conduction heat flux increases linearly with \( T_h \) and inversely with \( L \) as expected. The radiative heat flux is independent of \( L \) and highly non-linear with \( T_h \), but does not approach that for the highest conduction heat rate until \( T_h \) approaches 1200\(^\circ C\).

The general trends for the initial temperature-time change, \( (dT_w/dt)_i \), follow those for the heat fluxes. To reach 900\(^\circ C\) in 10 s requires an average temperature-time change rate of 90 K/s. Recognizing that \( (dT_w/dt) \) will decrease with increasing \( T_w \), this rate could be met only with a very high \( T_h \) and the smallest \( L \).
PROBLEM 1.42

KNOWN: Silicon wafer, radiantly heated by lamps, experiencing an annealing process with known backside temperature.

FIND: Whether temperature difference across the wafer thickness is less than 2°C in order to avoid damaging the wafer.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in wafer, (3) Radiation exchange between upper surface of wafer and surroundings is between a small object and a large enclosure, and (4) Vacuum condition in chamber, no convection.

PROPERTIES: Wafer: \( k = 30 \text{ W/m-K} \), \( \varepsilon = \alpha_r = 0.65 \).

ANALYSIS: Perform a surface energy balance on the upper surface of the wafer to determine \( T_{w,u} \). The processes include the absorbed radiant flux from the lamps, radiation exchange with the chamber walls, and conduction through the wafer.

\[
\hat{E}_{in}^\sigma - \hat{E}_{out}^\sigma = 0
\]

\[
\alpha_r q_s - q_{rad} - q_{cd} = 0
\]

\[
\alpha_r q_s - \varepsilon \sigma \left( T_{w,u}^4 - T_{sur}^4 \right) - k \frac{T_{w,u} - T_{w,l}}{L} = 0
\]

\[
0.65 \times 3.0 \times 10^5 \text{W/m}^2 - 0.65 \times 5.67 \times 10^{-8} \text{W/m}^2 \cdot K^4 \left( T_{w,u}^4 - (27 + 273)^4 \right) K^4
\]

\[
-30 \text{W/m-K} \left[ T_{w,u} - (997 + 273) \right] / 0.00078 \text{m} = 0
\]

\[ T_{w,u} = 1273 \text{K} = 1000^\circ\text{C} \]

COMMENTS: (1) The temperature difference for this steady-state operating condition, \( T_{w,u} - T_{w,l} \), is larger than 2°C. Warping of the wafer and inducing slip planes in the crystal structure could occur.

(2) The radiation exchange rate equation requires that temperature must be expressed in kelvin units. Why is it permissible to use kelvin or Celsius temperature units in the conduction rate equation?

(3) Note how the surface energy balance, Eq. 1.12, is represented schematically. It is essential to show the control surfaces, and then identify the rate processes associated with the surfaces. Make sure the directions (in or out) of the process are consistent with the energy balance equation.
PROBLEM 1.43

KNOWN: Silicon wafer positioned in furnace with top and bottom surfaces exposed to hot and cool zones, respectively.

FIND: (a) Initial rate of change of the wafer temperature corresponding to the wafer temperature \( T_{w,i} = 300 \) K, and (b) Steady-state temperature reached if the wafer remains in this position. How significant is convection for this situation? Sketch how you’d expect the wafer temperature to vary as a function of vertical distance.

SCHEMATIC:

ASSUMPTIONS: (1) Wafer temperature is uniform, (2) Transient conditions when wafer is initially positioned, (3) Hot and cool zones have uniform temperatures, (3) Radiation exchange is between small surface (wafer) and large enclosure (chamber, hot or cold zone), and (4) Negligible heat losses from wafer to mounting pin holder.

ANALYSIS: The energy balance on the wafer illustrated in the schematic above includes convection from the upper (u) and lower (l) surfaces with the ambient gas, radiation exchange with the hot- and cool-zone (chamber) surroundings, and the rate of energy storage term for the transient condition.

\[
\dot{E}_{in}^\omega - \dot{E}_{out}^\omega = \dot{E}_{st}
\]

\[
q_{rad,h} + q_{rad,c} - q_{cv,u} - q_{cv,l} = \rho c d \frac{dT_w}{dt}
\]

\[
\varepsilon \sigma \left(T_{sur,h}^4 - T_w^4\right) + \varepsilon \sigma \left(T_{sur,c}^4 - T_w^4\right) - h_u (T_w - T_\infty) - h_l (T_w - T_\infty) = \rho c d \frac{dT_w}{dt}
\]

(a) For the initial condition, the time rate of temperature change of the wafer is determined using the energy balance above with \( T_w = T_{w,i} = 300 \) K,

\[
0.65 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left(1500^4 - 300^4\right) \text{K}^4 + 0.65 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left(330^4 - 300^4\right) \text{K}^4 - 8 \text{ W/m}^2 \cdot \text{K} (300 - 700) \text{K} - 4 \text{ W/m}^2 \cdot \text{K} (300 - 700) \text{K} =
\]

\[
2700 \text{ kg/m}^3 \times 875 \text{ J/kg} \cdot \text{K} \times 0.00078 \text{ m (d T_w / dt)}
\]

\[
(d T_w / dt)_i = 104 \text{ K/s}
\]

(b) For the steady-state condition, the energy storage term is zero, and the energy balance can be solved for the steady-state wafer temperature, \( T_w = T_{w,ss} \).

Continued ….
PROBLEM 1.43 (Cont.)

\[
0.65\sigma \left(1500^4 - T_{w,ss}^4\right)K^4 + 0.65\sigma \left(330^4 - T_{w,ss}^4\right)K^4
\]

\[
-8 \text{ W/m}^2 \cdot K \left(T_{w,ss} - 700\right)K - 4 \text{ W/m}^2 \cdot K \left(T_{w,ss} - 700\right)K = 0
\]

\[
T_{w,ss} = 1251 \text{ K}
\]

To determine the relative importance of the convection processes, re-solve the energy balance above ignoring those processes to find \(\left(\frac{dT_w}{dt}\right)_i = 101 \text{ K/s} \) and \(T_{w,ss} = 1262 \text{ K}\). We conclude that the radiation exchange processes control the initial time rate of temperature change and the steady-state temperature.

If the wafer were elevated above the present operating position, its temperature would increase, since the lower surface would begin to experience radiant exchange with progressively more of the hot zone chamber. Conversely, by lowering the wafer, the upper surface would experience less radiant exchange with the hot zone chamber, and its temperature would decrease. The temperature-distance trend might appear as shown in the sketch.
**PROBLEM 1.44**

**KNOWN:** Radial distribution of heat dissipation in a cylindrical container of radioactive wastes. Surface convection conditions.

**FIND:** Total energy generation rate and surface temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible temperature drop across thin container wall.

**ANALYSIS:** The rate of energy generation is

\[
\dot{E}_g = \int \dot{q} \mathrm{d}V = \int_0^{r_0} \left[ 1 - \left( \frac{r}{r_0} \right)^2 \right] 2\pi r L \mathrm{d}r
\]

or per unit length,

\[
\dot{E}_g' = \frac{\pi \dot{q}_o r_0^2}{2}
\]

Performing an energy balance for a control surface about the container yields, at an instant,

\[
\dot{E}_g' - \dot{E}_{\text{out}}' = 0
\]

and substituting for the convection heat rate per unit length,

\[
\frac{\pi \dot{q}_o r_0^2}{2} = h \left( 2\pi r_0 \right) \left( T_s - T_\infty \right)
\]

\[
T_s = T_\infty + \frac{\dot{q}_o r_0}{4h}
\]

**COMMENTS:** The temperature within the radioactive wastes increases with decreasing r from \(T_s\) at \(r_0\) to a maximum value at the centerline.
**PROBLEM 1.45**

**KNOWN:** Rod of prescribed diameter experiencing electrical dissipation from passage of electrical current and convection under different air velocity conditions. See Example 1.3.

**FIND:** Rod temperature as a function of the electrical current for $0 \leq I \leq 10$ A with convection coefficients of 50, 100 and 250 W/m$^2$·K. Will variations in the surface emissivity have a significant effect on the rod temperature?

**SCHEMATIC:**

![Schematic diagram](image)

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Uniform rod temperature, (3) Radiation exchange between the outer surface of the rod and the surroundings is between a small surface and large enclosure.

**ANALYSIS:** The energy balance on the rod for steady-state conditions has the form,

$$q_{\text{conv}} + q_{\text{rad}} = \dot{E}_{\text{gen}}$$

$$\pi Dh(T - T_{\infty}) + \pi D\varepsilon\sigma(T^4 - T_{\text{sur}}^4) = I^2R_e'$$

Using this equation in the Workspace of IHT, the rod temperature is calculated and plotted as a function of current for selected convection coefficients.

![Graph](image)

**COMMENTS:** (1) For forced convection over the cylinder, the convection heat transfer coefficient is dependent upon air velocity approximately as $h \sim V^{0.6}$. Hence, to achieve a 5-fold change in the convection coefficient (from 50 to 250 W/m$^2$·K), the air velocity must be changed by a factor of nearly 15.

Continued .....
PROBLEM 1.45 (Cont.)

(2) For the condition of \( I = 4 \) A with \( h = 50 \) W/m\(^2\)-K with \( T = 63.5^\circ\)C, the convection and radiation exchange rates per unit length are, respectively, \( q_{cv} = 5.7 \) W/m and \( q_{\text{rad}} = 0.67 \) W/m. We conclude that convection is the dominate heat transfer mode and that changes in surface emissivity could have only a minor effect. Will this also be the case if \( h = 100 \) or \( 250 \) W/m\(^2\)-K?

(3) What would happen to the rod temperature if there was a “loss of coolant” condition where the air flow would cease?

(4) The Workspace for the IHT program to calculate the heat losses and perform the parametric analysis to generate the graph is shown below. It is good practice to provide commentary with the code making your solution logic clear, and to summarize the results. It is also good practice to show plots in customary units, that is, the units used to prescribe the problem. As such the graph of the rod temperature is shown above with Celsius units, even though the calculations require temperatures in kelvins.

```plaintext
// Energy balance; from Ex. 1.3, Comment 1
-q_{cv} - q_{\text{rad}} + Edot'g = 0
q_{cv} = \pi*D*h*(T - T_{\text{inf}})
q_{\text{rad}} = \pi*D*\text{eps}*\sigma*(T^4 - T_{\text{sur}}^4)
\sigma = 5.67e^{-8}

// The generation term has the form

PROBLEM 1.46

KNOWN: Long bus bar of prescribed diameter and ambient air and surroundings temperatures. Relations for the electrical resistivity and free convection coefficient as a function of temperature.

FIND: (a) Current carrying capacity of the bus bar if its surface temperature is not to exceed 65°C; compare relative importance of convection and radiation exchange heat rates, and (b) Show graphically the operating temperature of the bus bar as a function of current for the range 100 ≤ I ≤ 5000 A for bus-bar diameters of 10, 20 and 40 mm. Plot the ratio of the heat transfer by convection to the total heat transfer for these conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Bus bar and conduit are very long in direction normal to page, (3) Uniform bus-bar temperature, (4) Radiation exchange between the outer surface of the bus bar and the conduit is between a small surface and a large enclosure.

PROPERTIES: Bus-bar material, \( \rho_e = \rho_{e,0} \left[1 + \alpha (T - T_0) \right] \), \( \rho_{e,0} = 0.0171 \mu \Omega \cdot m \), \( T_0 = 25^\circ C \), \( \alpha = 0.00396 K^{-1} \).

ANALYSIS: An energy balance on the bus-bar for a unit length as shown in the schematic above has the form

\[
\dot{E'}_{in} - \dot{E'}_{out} + \dot{E'}_{gen} = 0
\]

\[-q'_\text{rad} - q'_\text{conv} + I^2 R'_c = 0\]

\[-\varepsilon \pi D \sigma \left(T^4 - T_{\text{sur}}^4 \right) - h \pi D (T - T_\infty) + I^2 \rho_e / A_c = 0\]

where \( R'_c = \rho_e / A_c \) and \( A_c = \pi D^2 / 4 \). Using the relations for \( \rho_e (T) \) and \( h (T, D) \), and substituting numerical values with \( T = 65^\circ C \), find

\[
q'_\text{rad} = 0.85 \pi \left(0.020m\right) \times 5.67 \times 10^{-8} W / m^2 \cdot K^4 \left(\left[65 + 273\right]^4 - \left[30 + 273\right]^4\right) K^4 = 223 W / m
\]

\[
q'_\text{conv} = 7.83 W / m^2 \cdot K \pi \left(0.020m\right) (65 - 30) K = 17.2 W / m
\]

where

\[
h = 1.21 W \cdot m^{-1.75} \cdot K^{-1.25} \left(0.020m\right)^{-0.25} (65 - 30)^{0.25} = 7.83 W / m^2 \cdot K
\]

\[
I^2 R'_c = I^2 \left(198.2 \times 10^{-6} \Omega \cdot m\right) / \pi \left(0.020\right)^2 m^2 / 4 = 6.31 \times 10^{-5} I^2 W / m
\]

where \( \rho_e = 0.0171 \times 10^{-6} \Omega \cdot m \left[1 + 0.00396 K^{-1} (65 - 25) K\right] = 198.2 \mu \Omega \cdot m \)

The maximum allowable current capacity and the ratio of the convection to total heat transfer rate are

\[
I = 1950 A \quad q'_{cv} / (q'_{cv} + q'_{rad}) = q'_{cv} / q'_{tot} = 0.072
\]

For this operating condition, convection heat transfer is only 7.2% of the total heat transfer.

(b) Using these equations in the Workspace of IHT, the bus-bar operating temperature is calculated and plotted as a function of the current for the range 100 ≤ I ≤ 5000 A for diameters of 10, 20 and 40 mm. Also shown below is the corresponding graph of the ratio (expressed in percentage units) of the heat transfer by convection to the total heat transfer, \( q'_{cv} / q'_{tot} \). 

Continued …..
PROBLEM 1.46 (Cont.)

COMMENTS:

1. The trade-off between current-carrying capacity, operating temperature and bar diameter is shown in the first graph. If the surface temperature is not to exceed 65°C, the maximum current capacities for the 10, 20 and 40-mm diameter bus bars are 960, 1950, and 4000 A, respectively.

2. From the second graph with \( \frac{q'_{cv}}{q'_{tot}} \) vs. \( T \), note that the convection heat transfer rate is always a small fraction of the total heat transfer. That is, radiation is the dominant mode of heat transfer. Note also that the convection contribution increases with increasing diameter.

3. The Workspace for the IHT program to perform the parametric analysis and generate the graphs is shown below. It is good practice to provide commentary with the code making your solution logic clear, and to summarize the results.

```c
/* Results: base-case conditions, Part (a) */

T sur_C  eps
T 30 0.85 */

// Energy balance, on a per unit length basis; steady-state conditions
// Edot'in - Edot'out + Edot'gen = 0
q'cv - q'rad + Edot'gen = 0
q'cv = hbar * P * (Ts - Tinf)
P = pi * D
q'rad = eps * sigma * (Ts^4 - Tsur^4)
sigma = 5.67e-8
Edot'gen = I^2 * R'
R' = rho / Ac
rho = rhoeo * (1 + alpha * (Ts - To))
To = 25 + 273
Ac = pi * D/4

// Convection coefficient
hbar = 1.21 * (D^-0.25) * (Ts - Tinf)^0.25 // Compact convection coeff. correlation

// Convection vs. total heat rates
cvovertot = q'cv / (q'cv + q'rad) * 100

// Input parameters
D = 0.020
// D = 0.010 // Values of diameter for parameter study
// D = 0.040
// I = 1950 // Base case condition unknown
rhoeo = 0.01711e-6
alpha = 0.00396
Tinf_C = 30
Tinf = Tinf_C + 273
Ts_C = 65 // Base case condition to determine current
Ts = Ts_C + 273
Tsur_C = 30
Tsur = Tsur_C + 273
eps = 0.85
```
PROBLEM 1.47

KNOWN: Elapsed times corresponding to a temperature change from 15 to 14°C for a reference sphere and test sphere of unknown composition suddenly immersed in a stirred water-ice mixture. Mass and specific heat of reference sphere.

FIND: Specific heat of the test sphere of known mass.

SCHEMATIC:

ASSUMPTIONS: (1) Spheres are of equal diameter, (2) Spheres experience temperature change from 15 to 14°C, (3) Spheres experience same convection heat transfer rate when the time rates of surface temperature are observed, (4) At any time, the temperatures of the spheres are uniform, (5) Negligible heat loss through the thermocouple wires.

PROPERTIES: Reference-grade sphere material: \( c_r = 447 \text{ J/kg K} \).

ANALYSIS: Apply the conservation of energy requirement at an instant of time, Eq. 1.11a, after a sphere has been immersed in the ice-water mixture at \( T_{\infty} \).

\[
\dot{E}_{in} - \dot{E}_{out} = \dot{E}_{st}
\]

\[ -q_{conv} = Mc \frac{dT}{dt} \]

where \( q_{conv} = h A_s (T - T_{\infty}) \). Since the temperatures of the spheres are uniform, the change in energy storage term can be represented with the time rate of temperature change, \( dT/dt \). The convection heat rates are equal at this instant of time, and hence the change in energy storage terms for the reference (r) and test (t) spheres must be equal.

\[
M_r c_r \frac{dT}{dt} = M_t c_t \frac{dT}{dt}
\]

Approximating the instantaneous differential change, \( dT/dt \), by the difference change over a short period of time, \( \Delta T/\Delta t \), the specific heat of the test sphere can be calculated.

\[ 0.515 \text{ kg} \times 447 \text{ J/kg K} \times \frac{(15 - 14) \text{ K}}{6.35 \text{ s}} = 1.263 \text{ kg} \times c_t \times \frac{(15 - 14) \text{ K}}{4.59 \text{ s}} \]

\[ c_t = 132 \text{ J/kg K} \]

COMMENTS: Why was it important to perform the experiments with the reference and test spheres over the same temperature range (from 15 to 14°C)? Why does the analysis require that the spheres have uniform temperatures at all times?
PROBLEM 1.48

KNOWN: Inner surface heating and new environmental conditions associated with a spherical shell of prescribed dimensions and material.

FIND: (a) Governing equation for variation of wall temperature with time. Initial rate of temperature change, (b) Steady-state wall temperature, (c) Effect of convection coefficient on canister temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible temperature gradients in wall, (2) Constant properties, (3) Uniform, time-independent heat flux at inner surface.

PROPERTIES: Table A.1, Stainless Steel, AISI 302: $\rho = 8055 \text{ kg/m}^3$, $c_p = 510 \text{ J/kg} \cdot \text{K}$.

ANALYSIS: (a) Performing an energy balance on the shell at an instant of time, $\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \dot{E}_{\text{st}}$.

Identifying relevant processes and solving for $dT/dt$,

$$\frac{dT}{dt} = \frac{3}{\rho c_p \left( r_0^2 - r_1^2 \right)} \left[ q_i \left( 4 \pi r_1^2 \right) - h \left( 4 \pi r_0^2 \right) (T - T_\infty) \right].$$

Substituting numerical values for the initial condition, find

$$\frac{dT}{dt} = \frac{3 \left[ 10^5 \frac{\text{W}}{\text{m}^2} (0.5 \text{m})^2 - 500 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} (0.6 \text{m})^2 (500 - 300) \text{K} \right]}{8055 \frac{\text{kg}}{\text{m}^3} 510 \frac{\text{J}}{\text{kg} \cdot \text{K}} [(0.6)^3 - (0.5)^3] \text{m}^3} = -0.089 \text{ K/s}.$$

(b) Under steady-state conditions with $\dot{E}_{\text{st}} = 0$, it follows that

$$q_i \left( 4 \pi r_1^2 \right) = h \left( 4 \pi r_0^2 \right) (T - T_\infty)$$

Continued …..
PROBLEM 1.48 (Cont.)

\[
T = T_\infty + \frac{q_i^2}{h} \left( \frac{r_i}{r_o} \right)^2 = 300K + \frac{10^5 \text{W/m}^2}{500 \text{W/m}^2 \cdot \text{K}} \left( \frac{0.5m}{0.6m} \right)^2 = 439K
\]

(c) Parametric calculations were performed using the IHT First Law Model for an Isothermal Hollow Sphere. As shown below, there is a sharp increase in temperature with decreasing values of \( h < 1000 \text{W/m}^2\cdot\text{K} \). For \( T > 380 \text{K} \), boiling will occur at the canister surface, and for \( T > 410 \text{K} \) a condition known as film boiling (Chapter 10) will occur. The condition corresponds to a precipitous reduction in \( h \) and increase in \( T \).

![Graph showing temperature vs. convection coefficient](image)

Although the canister remains well below the melting point of stainless steel for \( h = 100 \text{W/m}^2\cdot\text{K} \), boiling should be avoided, in which case the convection coefficient should be maintained at \( h > 1000 \text{W/m}^2\cdot\text{K} \).

**COMMENTS:** The governing equation of part (a) is a first order, nonhomogenous differential equation with constant coefficients. Its solution is

\[
\theta = \left( \frac{S}{R} \right) \left( 1 - e^{-Rt} \right) + \theta_i e^{-Rt}, \text{ where } \theta \equiv T - T_\infty
\]

\[
S \equiv 3q_i r_i^2 / \rho c_p \left( r_o^3 - r_i^3 \right), \quad R = 3hr_o^2 / \rho c_p \left( r_o^3 - r_i^3 \right).
\]

Note results for \( t \to \infty \) and for \( S = 0 \).
PROBLEM 1.49

KNOWN: Boiling point and latent heat of liquid oxygen. Diameter and emissivity of container. Free convection coefficient and temperature of surrounding air and walls.

FIND: Mass evaporation rate.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Temperature of container outer surface equals boiling point of oxygen.

ANALYSIS: (a) Applying an energy balance to a control surface about the container, it follows that, at any instant,
\[
\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0 \quad \text{or} \quad q_{\text{conv}} + q_{\text{rad}} - q_{\text{evap}} = 0.
\]

The evaporative heat loss is equal to the product of the mass rate of vapor production and the heat of vaporization. Hence,
\[
\dot{m}_{\text{evap}} = \frac{h(T_{\infty} - T_s) + \varepsilon\sigma(T_{\text{sur}}^4 - T_s^4)}{h_f g} = \frac{\pi D^2}{h_f g} [10 \text{ W/m}^2 \cdot \text{K}(298 - 263)\text{K} + 0.2 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (298^4 - 263^4)\text{K}^4] \pi (0.5 \text{ m})^2
\]
\[
\dot{m}_{\text{evap}} = \frac{(350 + 35.2) \text{ W/m}^2 (0.785 \text{ m}^2)}{214 \text{ kJ/kg}} = 1.41 \times 10^{-3} \text{ kg/s}.
\]

(b) Using the energy balance, Eq. (1), the mass rate of vapor production can be determined for the range of emissivity 0.2 to 0.94. The effect of increasing emissivity is to increase the heat rate into the container and, hence, increase the vapor production rate.

COMMENTS: To reduce the loss of oxygen due to vapor production, insulation should be applied to the outer surface of the container, in order to reduce \(q_{\text{conv}}\) and \(q_{\text{rad}}\). Note from the calculations in part (a), that heat transfer by convection is greater than by radiation exchange.
**PROBLEM 1.50**

**KNOWN:** Frost formation of 2-mm thickness on a freezer compartment. Surface exposed to convection process with ambient air.

**FIND:** Time required for the frost to melt, \( t_m \).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Frost is isothermal at the fusion temperature, \( T_f \), (2) The water melt falls away from the exposed surface, (3) Negligible radiation exchange at the exposed surface, and (4) Backside surface of frost formation is adiabatic.

**PROPERTIES:** Frost, \( \rho_f = 770 \text{ kg/m}^3, \ h_{sf} = 334 \text{ kJ/kg} \).

**ANALYSIS:** The time \( t_m \) required to melt a 2-mm thick frost layer may be determined by applying an energy balance, Eq 1.11b, over the differential time interval \( dt \) and to a differential control volume extending inward from the surface of the layer \( dx \). From the schematic above, the energy in is the convection heat flux over the time period \( dt \) and the change in energy storage is the latent energy change within the control volume, \( A_s dx \).

\[
E_{in} - E_{out} = E_{st}
\]

\[
q_{conv} A_s dt = dU_{lat}
\]

\[
h A_s (T_\infty - T_f) dt = -\rho_f A_s h_{sf} dx
\]

Integrating both sides of the equation and defining appropriate limits, find

\[
h (T_\infty - T_f) \int_0^{t_m} dt = -\rho_f h_{sf} \int_{x_0}^0 dx
\]

\[
t_m = \frac{\rho_f h_{sf} x_0}{h (T_\infty - T_f)}
\]

\[
t_m = \frac{700 \text{ kg/m}^3 \times 334 \times 10^3 \text{ J/kg} \times 0.002 \text{m}}{2 \text{ W/m}^2 \cdot \text{K} (20 - 0) \text{K}} = 11,690 \text{ s} = 3.2 \text{ hour}
\]

**COMMENTS:** (1) The energy balance could be formulated intuitively by recognizing that the total heat in by convection during the time interval \( t_m (q_{ev} \cdot t_m) \) must be equal to the total latent energy for melting the frost layer \( \rho x_0 h_{sf} \). This equality is directly comparable to the derived expression above for \( t_m \).

(2) Explain why the energy storage term in the analysis has a negative sign, and the limits of integration are as shown. **Hint:** Recall from the formulation of Eq. 1.11b, that the storage term represents the change between the final and initial states.
PROBLEM 1.51

KNOWN: Vertical slab of Woods metal initially at its fusion temperature, $T_f$, joined to a substrate. Exposed surface is irradiated with laser source, $G_\ell \left( \text{W}/\text{m}^2 \right)$.

FIND: Instantaneous rate of melting per unit area, $\dot{m}_m^* \left( \text{kg/s} \cdot \text{m}^2 \right)$, and the material removed in a period of 2 s, (a) Neglecting heat transfer from the irradiated surface by convection and radiation exchange, and (b) Allowing for convection and radiation exchange.

SCHEMATIC:

ASSUMPTIONS: (1) Woods metal slab is isothermal at the fusion temperature, $T_f$, and (2) The melt runs off the irradiated surface.

ANALYSIS: (a) The instantaneous rate of melting per unit area may be determined by applying an energy balance, Eq 1.11a, on the metal slab at an instant of time neglecting convection and radiation exchange from the irradiated surface.

$$\dot{E}_{in}^* - \dot{E}_{out}^* = \dot{E}_{st}$$

$$\dot{m}_m^* = \frac{\alpha_\ell G_\ell}{h_{sf}}$$

where $\dot{m}_m^*$ is the time rate of change of mass in the control volume. Substituting values,

$$\dot{m}_m^* = -6.06 \times 10^{-3} \text{ kg/s} \cdot \text{m}^2$$

The material removed in a 2s period per unit area is

$$M_{2s} = \dot{m}_m^* \cdot \Delta t = 121 \text{ g/m}^2$$

(b) The energy balance considering convection and radiation exchange with the surroundings yields

$$\dot{m}_m^* = \dot{m}_m^* \cdot \Delta t = 121 \text{ g/m}^2$$

COMMENTS: (1) The effects of heat transfer by convection and radiation reduce the estimate for the material removal rate by a factor of two. The heat transfer by convection is nearly 5 times larger than by radiation exchange.

(2) Suppose the work piece were horizontal, rather than vertical, and the melt puddled on the surface rather than ran off. How would this affect the analysis?

(3) Lasers are common heating sources for metals processing, including the present application of melting (heat transfer with phase change), as well as for heating work pieces during milling and turning (laser-assisted machining).
PROBLEM 1.52

KNOWN: Hot formed paper egg carton of prescribed mass, surface area and water content exposed to infrared heater providing known radiant flux.

FIND: Whether water content can be reduced from 75% to 65% by weight during the 18s period carton is on conveyor.

SCHEMATIC: 

ASSUMPTIONS: (1) All the radiant flux from the heater bank is absorbed by the carton, (2) Negligible heat loss from carton by convection and radiation, (3) Negligible mass loss occurs from bottom side.

PROPERTIES: Water (given): $h_{fg} = 2400$ kJ/kg.

ANALYSIS: Define a control surface about the carton, and write the conservation of energy requirement for an interval of time, $\Delta t$,

\[ E_{in} - E_{out} = \Delta E_{st} = 0 \]

where $E_{in}$ is due to the absorbed radiant flux, $q''$, from the heater and $E_{out}$ is the energy leaving due to evaporation of water from the carton. Hence.

\[ q'' \cdot A_s \cdot \Delta t = \Delta M \cdot h_{fg} \cdot \Delta t \]

For the prescribed radiant flux $q''$,

\[ \Delta M = \frac{q'' A_s \Delta t}{h_{fg}} = \frac{5000 \text{ W/m}^2 \times 0.0625 \text{ m}^2 \times 18\text{s}}{2400 \text{ kJ/kg}} = 0.00234 \text{ kg} \]

The chief engineer’s requirement was to remove 10% of the water content, or

\[ \Delta M_{req} = 0.220 \text{ kg} \times 0.10 = 0.022 \text{ kg} \]

which is nearly an order of magnitude larger than the evaporative loss. Considering heat losses by convection and radiation, the actual water removal from the carton will be less than $\Delta M$. Hence, the purchase should not be recommended, since the desired water removal cannot be achieved.
**PROBLEM 1.53**

**KNOWN:** Average heat sink temperature when total dissipation is 20 W with prescribed air and surroundings temperature, sink surface area and emissivity.

**FIND:** Sink temperature when dissipation is 30 W.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) All dissipated power in devices is transferred to the sink, (3) Sink is isothermal, (4) Surroundings and air temperature remain the same for both power levels, (5) Convection coefficient is the same for both power levels, (6) Heat sink is a small surface within a large enclosure, the surroundings.

**ANALYSIS:** Define a control volume around the heat sink. Power dissipated within the devices is transferred into the sink, while the sink loses heat to the ambient air and surroundings by convection and radiation exchange, respectively.

\[
\dot{E}_{in} - \dot{E}_{out} = 0 \\
P_e - h A_s (T_s - T_\infty) - A_s \varepsilon \sigma (T_s^4 - T_{sur}^4) = 0. 
\]

Consider the situation when \( P_e = 20 \) W for which \( T_s = 42^\circ C \); find the value of \( h \).

\[
h = \frac{P_e / A_s - \varepsilon \sigma (T_s^4 - T_{sur}^4)}{(T_s - T_\infty)} \\
h = \left[ \frac{20 \text{ W} / 0.045 \text{ m}^2 - 0.8 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (315^4 - 300^4) \text{ K}^4}{(315 - 300) \text{ K}} \right] \\
h = 24.4 \text{ W/m}^2 \cdot \text{K}. 
\]

For the situation when \( P_e = 30 \) W, using this value for \( h \) with Eq. (1), obtain

\[
30 \text{ W} - 24.4 \text{ W/m}^2 \cdot \text{K} \times 0.045 \text{ m}^2 (T_s - 300) \text{ K} \\
-0.045 \text{ m}^2 \times 0.8 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (T_s^4 - 300^4) \text{ K}^4 = 0 \\
30 = 1.098 (T_s - 300) + 2.041 \times 10^{-9} (T_s^4 - 300^4). 
\]

By trial-and-error, find

\[
T_s = 322 \text{ K} = 49^\circ C. 
\]

**COMMENTS:** (1) It is good practice to express all temperatures in kelvin units when using energy balances involving radiation exchange.

(2) Note that we have assumed \( A_s \) is the same for the convection and radiation processes. Since not all portions of the fins are completely exposed to the surroundings, \( A_{s,\text{rad}} \) is less than \( A_{s,\text{conv}} = A_s \).

(3) Is the assumption that the heat sink is isothermal reasonable?
PROBLEM 1.54

KNOWN: Number and power dissipation of PCBs in a computer console. Convective coefficient associated with heat transfer from individual components in a board. Inlet temperature of cooling air and fan power requirement. Maximum allowable temperature rise of air. Heat flux from component most susceptible to thermal failure.

FIND: (a) Minimum allowable volumetric flow rate of air, (b) Preferred location and corresponding surface temperature of most thermally sensitive component.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Constant air properties, (3) Negligible potential and kinetic energy changes of air flow, (4) Negligible heat transfer from console to ambient air, (5) Uniform convection coefficient for all components.

ANALYSIS: (a) For a control surface about the air space in the console, conservation of energy for an open system, Eq. (1.11e), reduces to

\[ \dot{m}(u + pv) - \dot{m}(u + pv)_{i} + q - \dot{W} = 0 \]

where \( u + pv = 1 \), \( q = 5P_b \), and \( \dot{W} = -P_f \). Hence, with \( \dot{m}(i_{i} - i_{o}) = \dot{mc}_{p}(T_{o} - T_{i}) \),

\[ \dot{m}c_{p}(T_{o} - T_{i}) = 5P_b + P_f \]

For a maximum allowable temperature rise of 15°C, the required mass flow rate is

\[ \dot{m} = \frac{5P_b + P_f}{c_{p}(T_{o} - T_{i})} = \frac{5 \times 20 \text{ W} + 25 \text{ W}}{1007 \text{ J/kg K}(15^\circ \text{C})} = 8.28 \times 10^{-3} \text{ kg/s} \]

The corresponding volumetric flow rate is

\[ \dot{V} = \frac{\dot{m}}{\rho} = \frac{8.28 \times 10^{-3} \text{ kg/s}}{1.161 \text{ kg/m}^3} = 7.13 \times 10^{-3} \text{ m}^3 / \text{s} \]

(b) The component which is most susceptible to thermal failure should be mounted at the bottom of one of the PCBs, where the air is coolest. From the corresponding form of Newton’s law of cooling,

\[ q^* = h(T_s - T_i) \],

the surface temperature is

\[ T_s = T_i + \frac{q^*}{h} = 20^\circ \text{C} + \frac{1 \times 10^4 \text{ W/m}^2}{200 \text{ W/m}^2 \cdot \text{K}} = 70^\circ \text{C} \]

COMMENTS: (1) Although the mass flow rate is invariant, the volumetric flow rate increases as the air is heated in its passage through the console, causing a reduction in the density. However, for the prescribed temperature rise, the change in \( \rho \), and hence the effect on \( \dot{V} \), is small. (2) If the thermally sensitive component were located at the top of a PCB, it would be exposed to warmer air \( (T_o = 35^\circ \text{C}) \) and the surface temperature would be \( T_s = 85^\circ \text{C} \).
**PROBLEM 1.55**

**KNOWN:** Top surface of car roof absorbs solar flux, $q_{S,\text{abs}}^\prime \prime$, and experiences for case (a): convection with air at $T_\infty$ and for case (b): the same convection process and radiation emission from the roof.

**FIND:** Temperature of the plate, $T_s$, for the two cases. Effect of airflow on roof temperature.

**SCHEMATIC:**

![Diagram of car roof with convection and radiation processes.](image)

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible heat transfer to auto interior, (3) Negligible radiation from atmosphere.

**ANALYSIS:** (a) Apply an energy balance to the control surfaces shown on the schematic. For an instant of time, $\dot{E}_{in} - \dot{E}_{out} = 0$. Neglecting radiation emission, the relevant processes are convection between the plate and the air, $q_{\text{conv}}^\prime \prime$, and the absorbed solar flux, $q_{S,\text{abs}}^\prime \prime$. Considering the roof to have an area $A_s$,

$$q_{S,\text{abs}}^\prime \prime A_s - hA_s (T_s - T_\infty) = 0$$

$$T_s = T_\infty + \frac{q_{S,\text{abs}}^\prime \prime}{h}$$

$$T_s = 20^\circ C + \frac{800 \text{ W/m}^2}{12 \text{ W/m}^2 \cdot K} = 20^\circ C + 66.7^\circ C = 86.7^\circ C$$

(b) With radiation emission from the surface, the energy balance has the form

$$q_{S,\text{abs}}^\prime \prime A_s - q_{\text{conv}}^\prime \prime - E \cdot A_s = 0$$

$$q_{S,\text{abs}}^\prime \prime A_s - hA_s (T_s - T_\infty) - \varepsilon A_s \sigma T_s^4 = 0.$$ 

Substituting numerical values, with temperature in absolute units (K),

$$800 \frac{\text{W}}{\text{m}^2} - 12 \frac{\text{W}}{\text{m}^2 \cdot K} (T_s - 293 \text{K}) - 0.8 \times 5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot K^4} T_s^4 = 0$$

$$12T_s + 4.536 \times 10^{-8} T_s^4 = 4316$$

It follows that $T_s = 320 \text{ K} = 47^\circ \text{C}$.

Continued.....
(c) Parametric calculations were performed using the IHT First Law Model for an Isothermal Plane Wall. As shown below, the roof temperature depends strongly on the velocity of the auto relative to the ambient air. For a convection coefficient of $h = 40 \text{ W/m}^2\text{K}$, which would be typical for a velocity of 55 mph, the roof temperature would exceed the ambient temperature by less than $10^\circ\text{C}$.

**COMMENTS:** By considering radiation emission, $T_s$ decreases, as expected. Note the manner in which $q''_{\text{conv}}$ is formulated using Newton’s law of cooling; since $q''_{\text{conv}}$ is shown leaving the control surface, the rate equation must be $h(T_s - T_\infty)$ and not $h(T_\infty - T_s)$. 
**PROBLEM 1.56**

**KNOWN:** Detector and heater attached to cold finger immersed in liquid nitrogen. Detector surface of \( \varepsilon = 0.9 \) is exposed to large vacuum enclosure maintained at 300 K.

**FIND:** (a) Temperature of detector when no power is supplied to heater, (b) Heater power (W) required to maintain detector at 195 K, (c) Effect of finger thermal conductivity on heater power.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional conduction through cold finger, (3) Detector and heater are very thin and isothermal at \( T_s \), (4) Detector surface is small compared to enclosure surface.

**PROPERTIES:** Cold finger (given): \( k = 10 \text{ W/m} \cdot \text{K} \).

**ANALYSIS:** Define a control volume about detector and heater and apply conservation of energy requirement on a rate basis, Eq. 1.11a,

\[
\dot{E}_\text{in} - \dot{E}_\text{out} = 0
\]

where

\[
\dot{E}_\text{in} = q_{\text{rad}} + q_{\text{elec}}; \quad \dot{E}_\text{out} = q_{\text{cond}}
\]

Combining Eqs. (2,3) with (1), and using the appropriate rate equations,

\[
\varepsilon A_s \sigma (T_{\text{sur}}^4 - T_s^4) + q_{\text{elec}} = k A_s (T_s - T_L) L.
\]

(a) Where \( q_{\text{elec}} = 0 \), substituting numerical values

\[
0.9 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left(300^4 - T_s^4\right) \text{K}^4 = 10 \text{ W/m} \cdot \text{K} (T_s - 77) \text{ K} / 0.050 \text{ m}
\]

\[
5.103 \times 10^{-8} \left(300^4 - T_s^4\right) = 200 (T_s - 77)
\]

\[ T_s = 79.1 \text{ K} \]

Continued.....
PROBLEM 1.56 (Cont.)

(b) When $T_S = 195$ K, Eq. (4) yields

\[
0.9 \times [\pi \left( \frac{0.005 \text{ m}}{4} \right)^2] \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left( 300^4 - 195^4 \right) \text{K}^4 + q_{\text{elec}}
\]

\[
= 10 \text{ W/m} \cdot \text{K} \times [\pi \left( \frac{0.005 \text{ m}}{4} \right)^2] \times (195 - 77) \text{ K} / 0.050 \text{ m}
\]

\[
q_{\text{elec}} = 0.457 \text{ W} = 457 \text{ mW}
\]

(c) Calculations were performed using the First Law Model for a Nonisothermal Plane Wall. With net radiative transfer to the detector fixed by the prescribed values of $T_S$ and $T_{\text{sur}}$, Eq. (4) indicates that $q_{\text{elec}}$ increases linearly with increasing $k$.

![Graph showing the relationship between heater power and thermal conductivity](image)

Heat transfer by conduction through the finger material increases with its thermal conductivity. Note that, for $k = 0.1$ W/m·K, $q_{\text{elec}} = -2$ mW, where the minus sign implies the need for a heat sink, rather than a heat source, to maintain the detector at 195 K. In this case $q_{\text{rad}}$ exceeds $q_{\text{cond}}$, and a heat sink would be needed to dispose of the difference. A conductivity of $k = 0.114$ W/m·K yields a precise balance between $q_{\text{rad}}$ and $q_{\text{cond}}$. Hence to circumvent having to use a heat sink, while minimizing the heater power requirement, $k$ should exceed, but remain as close as possible to the value of 0.114 W/m·K. Using a graphite fiber composite, with the fibers oriented normal to the direction of conduction, Table A.2 indicates a value of $k \approx 0.54$ W/m·K at an average finger temperature of $\bar{T} = 136$ K. For this value, $q_{\text{elec}} = 18$ mW

**COMMENTS:** The heater power requirement could be further reduced by decreasing $\varepsilon$. 
PROBLEM 1.57

KNOWN: Conditions at opposite sides of a furnace wall of prescribed thickness, thermal conductivity and surface emissivity.

FIND: Effect of wall thickness and outer convection coefficient on surface temperatures. Recommended values of L and \( h_2 \).

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Negligible radiation exchange at surface 1, (4) Surface 2 is exposed to large surroundings.

ANALYSIS: The unknown temperatures may be obtained by simultaneously solving energy balance equations for the two surface. At surface 1,

\[
q_{\text{conv},1} = q_{\text{cond}}
\]

\[
h_1 (T_{\infty,1} - T_1) = k (T_1 - T_2) / L
\]

At surface 2,

\[
q_{\text{cond}} = q_{\text{conv}} + q_{\text{rad}}
\]

\[
k (T_1 - T_2) / L = h_2 (T_2 - T_{\infty,2}) + \varepsilon \sigma (T_2^4 - T_{\text{sur}}^4)
\]

Using the IHT First Law Model for a Nonisothermal Plane Wall, we obtain

Continued …..
Both $q_{\text{cond}}$ and $T_2$ decrease with increasing wall thickness, and for the prescribed value of $h_2 = 10$ W/m$^2$K, a value of $L \geq 0.275$ m is needed to maintain $T_2 \leq 373$ K = 100 °C. Note that inner surface temperature $T_1$, and hence the temperature difference, $T_1 - T_2$, increases with increasing $L$.

Performing the calculations for the prescribed range of $h_2$, we obtain

For the prescribed value of $L = 0.15$ m, a value of $h_2 \geq 24$ W/m$^2$K is needed to maintain $T_2 \leq 373$ K. The variation has a negligible effect on $T_1$, causing it to decrease slightly with increasing $h_2$, but does have a strong influence on $T_2$.

**COMMENTS:** If one wishes to avoid use of active (forced convection) cooling on side 2, reliance will have to be placed on free convection, for which $h_2 \approx 5$ W/m$^2$K. The minimum wall thickness would then be $L = 0.40$ m.
PROBLEM 1.58

KNOWN: Furnace wall with inner surface temperature \( T_1 = 352^\circ C \) and prescribed thermal conductivity experiencing convection and radiation exchange on outer surface. See Example 1.5.

FIND: (a) Outer surface temperature \( T_2 \) resulting from decreasing the wall thermal conductivity \( k \) or increasing the convection coefficient \( h \) by a factor of two; benefit of applying a low emissivity coating (\( \varepsilon < 0.8 \)); comment on the effectiveness of these strategies to reduce risk of burn injury when \( T_2 \leq 65^\circ C \); and (b) Calculate and plot \( T_2 \) as a function of \( h \) for the range \( 20 \leq h \leq 100 \) W/m\(^2\)-K for three materials with \( k = 0.3, 0.6, \) and 1.2 W/m-K; what conditions will provide for safe outer surface temperatures.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in wall, (3) Radiation exchange is between small surface and large enclosure, (4) Inner surface temperature remains constant for all conditions.

ANALYSIS: (a) The surface \( (x = L) \) energy balance is

\[
\frac{k}{L} \left( T_1 - T_2 \right) = h \left( T_2 - T_\infty \right) + \varepsilon \sigma \left( T_2^4 - T_{\text{surf}}^4 \right)
\]

With \( T_1 = 352^\circ C \), the effects of parameters \( h, k \) and \( \varepsilon \) on the outer surface temperature are calculated and tabulated below.

(b) Using the energy balance relation in the Workspace of IHT, the outer surface temperature can be calculated and plotted as a function of the convection coefficient for selected values of the wall thermal conductivity.

Continued …..
**PROBLEM 1.58 (Cont.)**

![Graph showing outer surface temperature vs. convection coefficient for different thermal conductivities](image)

**COMMENTS:**

1. From the parameter study of part (a), note that decreasing the thermal conductivity is more effective in reducing $T_2$ than is increasing the convection coefficient. Only if both changes are made will $T_2$ be in the safe range.

2. From part (a), note that applying a low emissivity coating is not beneficial. Did you suspect that before you did the analysis? Give a physical explanation for this result.

3. From the parameter study graph we conclude that safe wall conditions ($T_2 \leq 65^\circ C$) can be maintained for these conditions: with $k = 1.2 \text{ W/m} \cdot \text{K}$ when $h > 55 \text{ W/m}^2 \cdot \text{K}$; with $k = 0.6 \text{ W/m} \cdot \text{K}$ when $h > 25 \text{ W/m}^2 \cdot \text{K}$; and with $k = 0.3 \text{ W/m} \cdot \text{K}$ when $h > 20 \text{ W/m} \cdot \text{K}$.
Known: Inner surface temperature, thickness and thermal conductivity of insulation exposed at its outer surface to air of prescribed temperature and convection coefficient.

Find: Outer surface temperature.

Schematic:

Assumptions: (1) Steady-state conditions, (2) One-dimensional conduction in the insulation, (3) Negligible radiation exchange between outer surface and surroundings.

Analysis: From an energy balance at the outer surface at an instant of time,

\[ q''_{\text{cond}} = q''_{\text{conv}}. \]

Using the appropriate rate equations,

\[ k \frac{T_1 - T_2}{L} = h (T_2 - T_\infty). \]

Solving for \( T_2 \), find

\[
T_2 = \frac{k}{L} \frac{T_1 + h T_\infty}{k + \frac{h}{L}} = \frac{0.1 \text{ W/m·K}}{0.025 \text{ m}} \left( \frac{400^\circ C}{\text{m}} \right) + \frac{500 \text{ W/m}^2 \cdot \text{K}}{500 \text{ W/m}^2 \cdot \text{K}} \left( \frac{35^\circ C}{\text{m}} \right)
\]

\[ T_2 = 37.9^\circ C. \]

Comments: If the temperature of the surroundings is approximately that of the air, radiation exchange between the outer surface and the surroundings will be negligible, since \( T_2 \) is small. In this case convection makes the dominant contribution to heat transfer from the outer surface, and assumption (3) is excellent.
PROBLEM 1.60

KNOWN: Thickness and thermal conductivity, $k$, of an oven wall. Temperature and emissivity, $\varepsilon$, of front surface. Temperature and convection coefficient, $h$, of air. Temperature of large surroundings.

FIND: (a) Temperature of back surface, (b) Effect of variations in $k$, $h$ and $\varepsilon$.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) One-dimensional conduction, (3) Radiation exchange with large surroundings.

ANALYSIS: (a) Applying an energy balance, Eq. 1.13, at an instant of time to the front surface and substituting the appropriate rate equations, Eqs. 1.2, 1.3a and 1.7, find

$$k \frac{T_1 - T_2}{L} = h \left( T_2 - T_\infty \right) + \varepsilon \sigma \left( T_2^4 - T_{sur}^4 \right).$$

Substituting numerical values, find

$$T_1 - T_2 = \frac{0.05 \text{ m}}{0.7 \text{ W/m} \cdot \text{ K}} \left[ 20 \frac{\text{ W}}{\text{ m}^2 \cdot \text{ K}} - 100 \text{ K} + 0.8 \times 5.67 \times 10^{-8} \frac{\text{ W}}{\text{ m}^2 \cdot \text{ K}^4} \left( 400 \text{ K}^4 - (300 \text{ K})^4 \right) \right] = 200 \text{ K}.$$

Since $T_2 = 400 \text{ K}$, it follows that $T_1 = 600 \text{ K}$.

(b) Parametric effects may be evaluated by using the IHT First Law Model for a Nonisothermal Plane Wall. Changes in $k$ strongly influence conditions for $k < 20 \text{ W/m} \cdot \text{ K}$, but have a negligible effect for larger values, as $T_2$ approaches $T_1$ and the heat fluxes approach the corresponding limiting values.
PROBLEM 1.60 (Cont.)

The implication is that, for \( k > 20 \text{ W/m}\cdot\text{K} \), heat transfer by conduction in the wall is extremely efficient relative to heat transfer by convection and radiation, which become the \textit{limiting} heat transfer processes. Larger fluxes could be obtained by increasing \( \varepsilon \) and \( h \) and/or by decreasing \( T_\infty \) and \( T_{\text{sur}} \).

With increasing \( h \), the front surface is cooled more effectively (\( T_2 \) decreases), and although \( q^{\text{rad}} \) decreases, the reduction is exceeded by the increase in \( q^{\text{conv}} \). With a reduction in \( T_2 \) and fixed values of \( k \) and \( L \), \( q^{\text{cond}} \) must also increase.

The surface temperature also decreases with increasing \( \varepsilon \), and the increase in \( q^{\text{rad}} \) exceeds the reduction in \( q^{\text{conv}} \), allowing \( q^{\text{cond}} \) to increase with \( \varepsilon \).

**COMMENTS:** Conservation of energy, of course, dictates that, irrespective of the prescribed conditions, \( q^{\text{cond}} = q^{\text{conv}} + q^{\text{rad}} \).
**PROBLEM 1.61**

**KNOWN:** Temperatures at 10 mm and 20 mm from the surface and in the adjoining airflow for a thick steel casting.

**FIND:** Surface convection coefficient, \( h \).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) One-dimensional conduction in the x-direction, (3) Constant properties, (4) Negligible generation.

**ANALYSIS:** From a surface energy balance, it follows that

\[
q^" \text{cond} = q^" \text{conv}
\]

where the convection rate equation has the form

\[
q^" \text{conv} = h \left( T_\infty - T_0 \right),
\]

and \( q^" \text{cond} \) can be evaluated from the temperatures prescribed at surfaces 1 and 2. That is, from Fourier’s law,

\[
q^" \text{cond} = k \frac{T_1 - T_2}{x_2 - x_1}
\]

\[
q^" \text{cond} = 15 \frac{W}{m \cdot K} \frac{(50 - 40)^{°}C}{(20 - 10) \times 10^{-3} m} = 15,000 \text{ W/m}^2.
\]

Since the temperature gradient in the solid must be linear for the prescribed conditions, it follows that

\( T_0 = 60^{°}C. \)

Hence, the convection coefficient is

\[
h = \frac{q^" \text{cond}}{T_\infty - T_0}
\]

\[
h = \frac{15,000 \text{ W/m}^2}{40^{°}C} = 375 \text{ W/m}^2 \cdot K.
\]

**COMMENTS:** The accuracy of this procedure for measuring \( h \) depends strongly on the validity of the assumed conditions.
PROBLEM 1.62

KNOWN: Duct wall of prescribed thickness and thermal conductivity experiences prescribed heat flux \( q_0^* \) at outer surface and convection at inner surface with known heat transfer coefficient.

FIND: (a) Heat flux at outer surface required to maintain inner surface of duct at \( T_i = 85^\circ C \), (b) Temperature of outer surface, \( T_o \), (c) Effect of \( h \) on \( T_o \) and \( q_0^* \).

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in wall, (3) Constant properties, (4) Backside of heater perfectly insulated, (5) Negligible radiation.

ANALYSIS: (a) By performing an energy balance on the wall, recognize that \( q_0^* = q_{\text{cond}}^* \). From an energy balance on the top surface, it follows that \( q_{\text{cond}}^* = q_{\text{conv}}^* = q_0^* \). Hence, using the convection rate equation,

\[
q_0^* = q_{\text{conv}}^* = h (T_i - T_\infty) = 100 \text{ W/m}^2 \cdot \text{K} (85 - 30) ^\circ C = 5500 \text{ W/m}^2.
\]

(b) Considering the duct wall and applying Fourier’s Law,

\[
q_o^* = k \frac{\Delta T}{\Delta X} = k \frac{T_o - T_i}{L}
\]

\[
T_o = T_i + \frac{q_o^* L}{k} = 85^\circ C + \frac{5500 \text{ W/m}^2 \times 0.010 \text{ m}}{20 \text{ W/m} \cdot \text{K}} = (85 + 2.8) ^\circ C = 87.8^\circ C.
\]

(c) For \( T_i = 85^\circ C \), the desired results may be obtained by simultaneously solving the energy balance equations

\[
q_o^* = k \frac{T_o - T_i}{L} \quad \text{and} \quad k \frac{T_o - T_i}{L} = h (T_i - T_\infty)
\]

Using the IHT First Law Model for a Nonisothermal Plane Wall, the following results are obtained.

Since \( q_{\text{conv}}^* \) increases linearly with increasing \( h \), the applied heat flux \( q_0^* \) must be balanced by an increase in \( q_{\text{cond}}^* \), which, with fixed \( k \), \( T_i \) and \( L \), necessitates an increase in \( T_o \).

COMMENTS: The temperature difference across the wall is small, amounting to a maximum value of \( (T_o - T_i) = 5.5^\circ C \) for \( h = 200 \text{ W/m}^2 \cdot \text{K} \). If the wall were thinner (\( L < 10 \text{ mm} \)) or made from a material with higher conductivity (\( k > 20 \text{ W/m} \cdot \text{K} \)), this difference would be reduced.
PROBLEM 1.63

KNOWN: Dimensions, average surface temperature and emissivity of heating duct. Duct air inlet temperature and velocity. Temperature of ambient air and surroundings. Convection coefficient.

FIND: (a) Heat loss from duct, (b) Air outlet temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Constant air properties, (3) Negligible potential and kinetic energy changes of air flow, (4) Radiation exchange between a small surface and a large enclosure.

ANALYSIS: (a) Heat transfer from the surface of the duct to the ambient air and the surroundings is given by Eq. (1.10)

\[ q = hA_s(T_s - T_\infty) + \varepsilon A_s\sigma(T_s^4 - T_{sur}^4) \]

where \( A_s = L(2W + 2H) = 15 \text{ m} (0.7 \text{ m} + 0.5 \text{ m}) = 16.5 \text{ m}^2 \). Hence,

\[ q = 4 \text{ W/m}^2 \cdot \text{K} \times 16.5 \text{ m}^2 \times 45^\circ \text{C} + 0.5 \times 16.5 \text{ m}^2 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left(323^4 - 278^4\right) K^4 \]

\[ q = q_{conv} + q_{rad} = 2970 \text{ W} + 2298 \text{ W} = 5268 \text{ W} \]

(b) With \( i = u + pv \), \( \dot{W} = 0 \) and the third assumption, Eq. (1.11e) yields,

\[ m(i_i - i_o) = mc_p(T_i - T_o) = q \]

where the sign on \( q \) has been reversed to reflect the fact that heat transfer is from the system.

With \( \dot{m} = \rho VA_C = 1.10 \text{ kg/m}^3 \times 4 \text{ m/s} \times (0.35 \text{ m} \times 0.20 \text{ m}) = 0.308 \text{ kg/s} \), the outlet temperature is

\[ T_o = T_i - \frac{q}{mc_p} = 58^\circ \text{C} - \frac{5268 \text{ W}}{0.308 \text{ kg/s} \times 1008 \text{ J/kg} \cdot \text{K}} = 41^\circ \text{C} \]

COMMENTS: The temperature drop of the air is large and unacceptable, unless the intent is to use the duct to heat the basement. If not, the duct should be insulated to insure maximum delivery of thermal energy to the intended space(s).
**PROBLEM 1.64**

**KNOWN:** Uninsulated pipe of prescribed diameter, emissivity, and surface temperature in a room with fixed wall and air temperatures. See Example 1.2.

**FIND:** (a) Which option to reduce heat loss to the room is more effective: reduce by a factor of two the convection coefficient (from 15 to 7.5 W/m²·K) or the emissivity (from 0.8 to 0.4) and (b) Show graphically the heat loss as a function of the convection coefficient for the range $5 \leq h \leq 20$ W/m²·K for emissivities of 0.2, 0.4 and 0.8. Comment on the relative efficacy of reducing heat losses associated with the convection and radiation processes.

**SCHEMATIC:**

![Schematic of heat loss calculation](image)

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Radiation exchange between pipe and the room is between a small surface in a much larger enclosure, (3) The surface emissivity and absorptivity are equal, and (4) Restriction of the air flow does not alter the radiation exchange process between the pipe and the room.

**ANALYSIS:** (a) The heat rate from the pipe to the room per unit length is

$$q' = \frac{q'}{L} = q'_{\text{conv}} + q'_{\text{rad}} = h (\pi D) (T_s - T_{\infty}) + \varepsilon (\pi D) \sigma (T_s^4 - T_{\text{sur}}^4)$$

Substituting numerical values for the two options, the resulting heat rates are calculated and compared with those for the conditions of Example 1.2. We conclude that both options are comparably effective.

(b) Using IHT, the heat loss can be calculated as a function of the convection coefficient for selected values of the surface emissivity.

![Graph of heat loss vs. convection coefficient](image)

Continued …..
COMMENTS: (1) In Example 1.2, Comment 3, we read that the heat rates by convection and radiation exchange were comparable for the base case conditions (577 vs. 421 W/m). It follows that reducing the key transport parameter (h or $\varepsilon$) by a factor of two yields comparable reductions in the heat loss. Coating the pipe to reduce the emissivity might be the more practical option as it may be difficult to control air movement.

(2) For this pipe size and thermal conditions ($T_s$ and $T_\infty$), the minimum possible convection coefficient is approximately 7.5 W/m$^2$K, corresponding to free convection heat transfer to quiescent ambient air. Larger values of h are a consequence of forced air flow conditions.

(3) The Workspace for the IHT program to calculate the heat loss and generate the graph for the heat loss as a function of the convection coefficient for selected emissivities is shown below. It is good practice to provide commentary with the code making your solution logic clear, and to summarize the results.

```plaintext
// Heat loss per unit pipe length; rate equation from Ex. 1.2
q' = q'cv + q'rad
q'cv = pi*D*h*(Ts - Tinf)
q'rad = pi*D*eps*sigma*(Ts^4 - Tsur^4)
sigma = 5.67e-8

// Input parameters
D = 0.07
Ts_C = 200          // Representing temperatures in Celsius units using _C subscripting
Ts = Ts_C +273
Tinf_C = 25
Tinf = Tinf_C + 273
h = 15              // For graph, sweep over range from 5 to 20
Tsur_C = 25
Tsur = Tsur_C + 273
eps = 0.8           // Values of emissivity for parameter study
eps = 0.4
eps = 0.2

/* Base case results

298  473  298  997.9  577.3  420.6  0.07  25  200  25  0.8  15  5.67E-8 */
```
PROBLEM 1.65

KNOWN: Conditions associated with surface cooling of plate glass which is initially at 600°C. Maximum allowable temperature gradient in the glass.

FIND: Lowest allowable air temperature, \( T_\infty \)

SCHEMATIC:

ASSUMPTIONS: (1) Surface of glass exchanges radiation with large surroundings at \( T_{\text{sur}} = T_\infty \), (2) One-dimensional conduction in the \( x \)-direction.

ANALYSIS: The maximum temperature gradient will exist at the surface of the glass and at the instant that cooling is initiated. From the surface energy balance, Eq. 1.12, and the rate equations, Eqs. 1.1, 1.3a and 1.7, it follows that

\[
-k \frac{dT}{dx} - h(T_s - T_\infty) - \varepsilon \sigma (T_s^4 - T_{\text{sur}}^4) = 0
\]

or, with \((dT/dx)_{\text{max}} = -15{\degree}C/mm = -15,000{\degree}C/m\) and \(T_{\text{sur}} = T_\infty\),

\[
-1.4 \frac{W}{m \cdot K} \left[ -15,000 \frac{\degree C}{m} \right] = 5 \frac{W}{m^2 \cdot K} (873 - T_\infty) K
\]

\[
+0.8 \times 5.67 \times 10^{-8} \frac{W}{m^2 \cdot K^4} [873^4 - T_\infty^4] K^4.
\]

\(T_\infty\) may be obtained from a trial-and-error solution, from which it follows that, for \(T_\infty = 618K\),

\[
21,000 \frac{W}{m^2} \approx 1275 \frac{W}{m^2} + 19,730 \frac{W}{m^2}.
\]

Hence the lowest allowable air temperature is

\(T_\infty = 618K = 345{\degree}C\).

COMMENTS: (1) Initially, cooling is determined primarily by radiation effects.

(2) For fixed \(T_\infty\), the surface temperature gradient would decrease with increasing time into the cooling process. Accordingly, \(T_\infty\) could be decreasing with increasing time and still keep within the maximum allowable temperature gradient.
PROBLEM 1.66

KNOWN: Hot-wall oven, in lieu of infrared lamps, with temperature $T_{\text{sur}} = 200\,^\circ\text{C}$ for heating a coated plate to the cure temperature. See Example 1.6.

FIND: (a) The plate temperature $T_s$ for prescribed convection conditions and coating emissivity, and (b) Calculate and plot $T_s$ as a function of $T_{\text{sur}}$ for the range $150 \leq T_{\text{sur}} \leq 250\,^\circ\text{C}$ for ambient air temperatures of 20, 40 and 60$\,^\circ\text{C}$; identify conditions for which acceptable curing temperatures between 100 and 110$\,^\circ\text{C}$ may be maintained.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible heat loss from back surface of plate, (3) Plate is small object in large isothermal surroundings (hot oven walls).

ANALYSIS: (a) The temperature of the plate can be determined from an energy balance on the plate, considering radiation exchange with the hot oven walls and convection with the ambient air.

\[
\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0 \quad \text{or} \quad q_{\text{rad}} - q_{\text{conv}} = 0
\]

\[
\varepsilon \sigma \left( T_{\text{sur}}^4 - T_s^4 \right) - h \left( T_s - T_{\infty} \right) = 0
\]

\[
0.5 \times 5.67 \times 10^{-8} \, \text{W/m}^2 \cdot \text{K}^4 \left( [200 + 273]^4 - T_s^4 \right) K^4 - 15 \, \text{W/m}^2 \cdot \text{K} \left( T_s - [20 + 273] \right) K = 0
\]

\[
T_s = 357 \, \text{K} = 84^\circ\text{C}
\]

(b) Using the energy balance relation in the Workspace of IHT, the plate temperature can be calculated and plotted as a function of oven wall temperature for selected ambient air temperatures.

COMMENTS: From the graph, acceptable cure temperatures between 100 and 110$^\circ\text{C}$ can be maintained for these conditions: with $T_{\infty} = 20^\circ\text{C}$ when $225 \leq T_{\text{sur}} \leq 240^\circ\text{C}$; with $T_{\infty} = 40^\circ\text{C}$ when $205 \leq T_{\text{sur}} \leq 220^\circ\text{C}$; and with $T_{\infty} = 60^\circ\text{C}$ when $175 \leq T_{\text{sur}} \leq 195^\circ\text{C}$.
**PROBLEM 1.67**

**KNOWN:** Operating conditions for an electrical-substitution radiometer having the same receiver temperature, $T_s$, in electrical and optical modes.

**FIND:** Optical power of a laser beam and corresponding receiver temperature when the indicated electrical power is 20.64 mW.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Conduction losses from backside of receiver negligible in optical mode, (3) Chamber walls form large isothermal surroundings; negligible effects due to aperture, (4) Radiation exchange between the receiver surface and the chamber walls is between small surface and large enclosure, (5) Negligible convection effects.

**PROPERTIES:** Receiver surface: $\varepsilon = 0.95$, $\alpha_{\text{opt}} = 0.98$.

**ANALYSIS:** The schematic represents the operating conditions for the electrical mode with the optical beam blocked. The temperature of the receiver surface can be found from an energy balance on the receiver, considering the electrical power input, conduction loss from the backside of the receiver, and the radiation exchange between the receiver and the chamber.

\[
\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0
\]

\[
P_{\text{elec}} - q_{\text{loss}} - q_{\text{rad}} = 0
\]

\[
P_{\text{elec}} - 0.05 P_{\text{elec}} - \varepsilon A_s \sigma \left( T_s^4 - T_{\text{sur}}^4 \right) = 0
\]

\[
20.64 \times 10^{-3} \, W \left( 1 - 0.05 \right) - 0.95 \left( \pi 0.015^2 / 4 \right) m^2 \times 5.67 \times 10^{-8} \, W / m^2 \cdot K^4 \left( T_s^4 - 77^4 \right) K^4 = 0
\]

\[
T_s = 213.9 \, K
\]

For the optical mode of operation, the optical beam is incident on the receiver surface, there is no electrical power input, and the receiver temperature is the same as for the electrical mode. The optical power of the beam can be found from an energy balance on the receiver considering the absorbed beam power and radiation exchange between the receiver and the chamber.

\[
\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0
\]

\[
\alpha_{\text{opt}} P_{\text{opt}} - q_{\text{rad}} = 0.98 P_{\text{opt}} - 19.60 \, mW = 0
\]

\[
P_{\text{opt}} = 19.99 \, mW
\]

where $q_{\text{rad}}$ follows from the previous energy balance using $T_s = 213.9K$.

**COMMENTS:** Recognizing that the receiver temperature, and hence the radiation exchange, is the same for both modes, an energy balance could be directly written in terms of the absorbed optical power and equivalent electrical power, $\alpha_{\text{opt}} P_{\text{opt}} = P_{\text{elec}} - q_{\text{loss}}$. 

PROBLEM 1.68

KNOWN: Surface temperature, diameter and emissivity of a hot plate. Temperature of surroundings and ambient air. Expression for convection coefficient.

FIND: (a) Operating power for prescribed surface temperature, (b) Effect of surface temperature on power requirement and on the relative contributions of radiation and convection to heat transfer from the surface.

SCHEMATIC:

ASSUMPTIONS: (1) Plate is of uniform surface temperature, (2) Walls of room are large relative to plate, (3) Negligible heat loss from bottom or sides of plate.

ANALYSIS: (a) From an energy balance on the hot plate, \( P_{\text{elec}} = q_{\text{conv}} + q_{\text{rad}} = A_p \left( \dot{q}_{\text{conv}} + \dot{q}_{\text{rad}} \right) \).

Substituting for the area of the plate and from Eqs. (1.3a) and (1.7), with \( h = 0.70 \left( T_s - T_\infty \right)^{1/3} \), it follows that

\[
\begin{align*}
P_{\text{elec}} &= \pi \left( \frac{D^2}{4} \right) \left[ 0.70 \left( T_s - T_\infty \right)^{4/3} + \varepsilon \sigma \left( T_s^4 - T_{\text{sur}}^4 \right) \right] \\
P_{\text{elec}} &= \pi \left( 0.3 \right)^2 \left[ 0.70 \left( 175 \right)^{4/3} + 0.8 \times 5.67 \times 10^{-8} \left( 473^4 - 298^4 \right) \right] \text{W/m}^2 \\
P_{\text{elec}} &= 0.0707 \text{m}^2 \left[ 685 \text{W/m}^2 + 1913 \text{W/m}^2 \right] = 48.4 \text{ W} + 135.2 \text{ W} = 190.6 \text{ W}
\end{align*}
\]

(b) As shown graphically, both the radiation and convection heat rates, and hence the requisite electric power, increase with increasing surface temperature.

However, because of its dependence on the fourth power of the surface temperature, the increase in radiation is more pronounced. The significant relative effect of radiation is due to the small convection coefficients characteristic of natural convection, with \( 3.37 \leq h \leq 5.2 \text{ W/m}^2 \cdot \text{K} \) for \( 100 \leq T_s < 300^\circ \text{C} \).

COMMENTS: Radiation losses could be reduced by applying a low emissivity coating to the surface, which would have to maintain its integrity over the range of operating temperatures.
**PROBLEM 1.69**

**KNOWN:** Long bus bar of rectangular cross-section and ambient air and surroundings temperatures. Relation for the electrical resistivity as a function of temperature.

**FIND:** (a) Temperature of the bar with a current of 60,000 A, and (b) Compute and plot the operating temperature of the bus bar as a function of the convection coefficient for the range 10 ≤ h ≤ 100 W/m²·K. Minimum convection coefficient required to maintain a safe operating temperature below 120°C. Will increasing the emissivity significantly affect this result?

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Bus bar is long, (3) Uniform bus-bar temperature, (3) Radiation exchange between the outer surface of the bus bar and its surroundings is between a small surface and a large enclosure.

**PROPERTIES:** Bus-bar material, \( \rho_e = \rho_{e,0} \left[ 1 + \alpha (T - T_0) \right] \), \( \rho_{e,0} = 0.0828 \mu \Omega \cdot \text{m} \), \( T_0 = 25^\circ \text{C} \), \( \alpha = 0.0040 \text{K}^{-1} \).

**ANALYSIS:** (a) An energy balance on the bus-bar for a unit length as shown in the schematic above has the form

\[
\dot{E}_\text{in}' - \dot{E}_\text{out}' + \dot{E}_\text{gen}' = 0 \\
-\varepsilon \sigma (T^4 - T_{\text{sur}}^4) - h (T - T_\infty) + I^2 R_e' = 0
\]

where \( P = 2 (H + W) \), \( R_e' = \rho_e / A_c \) and \( A_c = H \times W \). Substituting numerical values,

\[
-0.8 \times 2 (0.600 + 0.200) \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (T^4 - [30 + 273]^4) \text{ K}^4 \\
-10 \text{ W/m}^2 \cdot \text{K} \times 2 (0.600 + 0.200) \text{ m} (T - [30 + 273]) \text{ K} \\
+(60,000 \text{ A})^2 \left\{ 0.0828 \times 10^{-6} \mu \Omega \cdot \text{m} \left[ 1 + 0.0040 \text{K}^{-1} (T - [25 + 273]) \text{ K} \right] \right\} / (0.600 \times 0.200) \text{ m}^2 = 0
\]

Solving for the bus-bar temperature, find \( T = 426 \text{ K} = 153^\circ \text{C} \). <

(b) Using the energy balance relation in the Workspace of IHT, the bus-bar operating temperature is calculated as a function of the convection coefficient for the range 10 ≤ h ≤ 100 W/m²·K. From this graph we can determine that to maintain a safe operating temperature below 120°C, the minimum convection coefficient required is

\( h_{\text{min}} = 16 \text{ W/m}^2 \cdot \text{K} \). <

Continued ….
Using the same equations, we can calculate and plot the heat transfer rates by convection and radiation as a function of the bus-bar temperature.

Note that convection is the dominant mode for low bus-bar temperatures; that is, for low current flow. As the bus-bar temperature increases toward the safe-operating limit (120°C), convection and radiation exchange heat transfer rates become comparable. Notice that the relative importance of the radiation exchange rate increases with increasing bus-bar temperature.

**COMMENTS:**
1. It follows from the second graph that increasing the surface emissivity will be only significant at higher temperatures, especially beyond the safe-operating limit.
2. The Workspace for the IHT program to perform the parametric analysis and generate the graphs is shown below. It is good practice to provide commentary with the code making your solution logic clear, and to summarize the results.

```plaintext
/* Results for base case conditions: */

```
**PROBLEM 1.70**

**KNOWN:** Solar collector designed to heat water operating under prescribed solar irradiation and loss conditions.

**FIND:** (a) Useful heat collected per unit area of the collector, \( q_u'' \), (b) Temperature rise of the water flow, \( T_o - T_i \), and (c) Collector efficiency.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) No heat losses out sides or back of collector, (3) Collector area is small compared to sky surroundings.

**PROPERTIES:** Table A.6, Water (300K): \( c_p = 4179 \text{ J/kg} \cdot \text{K} \).

**ANALYSIS:** (a) Defining the collector as the control volume and writing the conservation of energy requirement on a per unit area basis, find that

\[
E_{in} - E_{out} + E_{gen} = E_{st}.
\]

Identifying processes as per above right sketch,

\[
q_{solar}'' - q_{rad}'' - q_{conv}'' - q_u'' = 0
\]

where \( q_{solar}'' = 0.9 q_s'' \); that is, 90% of the solar flux is absorbed in the collector (Eq. 1.6). Using the appropriate rate equations, the useful heat rate per unit area is

\[
q_u'' = 0.9 q_s'' - \varepsilon \sigma \left( T_{cp}^4 - T_{sky}^4 \right) - h(T_s - T_\infty)
\]

\[
q_u'' = 0.9 \times 700 \frac{\text{W}}{\text{m}^2} - 0.94 \times 5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} \left( 303^4 - 263^4 \right) \text{K}^4 - 10 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} (30 - 25) \text{C}
\]

\[
q_u'' = 630 \text{ W/m}^2 - 194 \text{ W/m}^2 - 50 \text{ W/m}^2 = 386 \text{ W/m}^2.
\]

(b) The total useful heat collected is \( q_u'' \cdot A \). Defining a control volume about the water tubing, the useful heat causes an enthalpy change of the flowing water. That is,

\[
q_u'' \cdot A = mc_p (T_i - T_o) \quad \text{or}
\]

\[
(T_i - T_o) = 386 \text{ W/m}^2 \times 3 \text{ m}^2 / 0.01 \text{ kg/s} \times 4179 \text{ J/kg} \cdot \text{K} = 27.7 \text{ C}.
\]

(c) The efficiency is

\[
\eta = \frac{q_u''}{q_s''} = \frac{386 \text{ W/m}^2}{700 \text{ W/m}^2} = 0.55 \text{ or } 55\%.
\]

**COMMENTS:** Note how the sky has been treated as large surroundings at a uniform temperature \( T_{sky} \).
PROBLEM 1.71

KNOWN: Surface-mount transistor with prescribed dissipation and convection cooling conditions.

FIND: (a) Case temperature for mounting arrangement with air-gap and conductive paste between case and circuit board, (b) Consider options for increasing $\dot{E}_g$, subject to the constraint that $T_c = 40^\circ$C.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Transistor case is isothermal, (3) Upper surface experiences convection; negligible losses from edges, (4) Leads provide conduction path between case and board, (5) Negligible radiation, (6) Negligible energy generation in leads due to current flow, (7) Negligible convection from surface of leads.

PROPERTIES: (Given): Air, $k_{ga} = 0.0263$ W/m·K; Paste, $k_{gp} = 0.12$ W/m·K; Metal leads, $k_{\ell} = 25$ W/m·K.

ANALYSIS: (a) Define the transistor as the system and identify modes of heat transfer.

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_g = \Delta \dot{E}_{st} = 0$$

$$-q_{conv} - q_{cond, gap} - 3q_{lead} + \dot{E}_g = 0$$

$$-hA_s(T_c - T_\infty) - k_gA_s\frac{T_c - T_b}{t} - 3k_\ell A_c\frac{T_c - T_b}{L} + \dot{E}_g = 0$$

where $A_s = L_1 \times L_2 = 4 \times 8$ mm$^2 = 32 \times 10^{-6}$ m$^2$ and $A_c = t \times w = 0.25 \times 1$ mm$^2 = 25 \times 10^{-8}$ m$^2$.

Rearranging and solving for $T_c$,

$$T_c = \left\{ hA_sT_\infty + \left[ k_gA_s/t + 3\left(k_\ell A_c/L\right)\right]T_b + \dot{E}_g\right\}/\left[hA_s + k_gA_s/t + 3\left(k_\ell A_c/L\right)\right]$$

Substituting numerical values, with the air-gap condition ($k_{ga} = 0.0263$ W/m·K)

$$T_c = \left\{50 \text{W/m}^2\cdot\text{K}\times32\times10^{-6} \text{m}^2\times20^\circ\text{C} + \left[0.0263 \text{W/m}\cdot\text{K}\times32\times10^{-6} \text{m}^2/0.2\times10^{-3} \text{m}\right] + 3\left(25 \text{W/m}\cdot\text{K}\times25\times10^{-8} \text{m}^2/4\times10^{-3} \text{m}\right)\right\}/\left[1.600\times10^{-3} + 4.208\times10^{-3} + 4.688\times10^{-3}\right]\text{W/K}$$

$$T_c = 47.0^\circ\text{C}.$$
PROBLEM 1.71 (Cont.)

With the paste condition \(( k_{\text{p}} = 0.12 \text{ W/m} \cdot \text{K})\), \( T_c = 39.9^\circ \text{C} \). As expected, the effect of the conductive paste is to improve the coupling between the circuit board and the case. Hence, \( T_c \) decreases.

(b) Using the keyboard to enter model equations into the workspace, IHT has been used to perform the desired calculations. For values of \( k_{\ell} = 200 \) and 400 W/m·K and convection coefficients in the range from 50 to 250 W/m²·K, the energy balance equation may be used to compute the power dissipation for a maximum allowable case temperature of 40°C.

As indicated by the energy balance, the power dissipation increases linearly with increasing \( h \), as well as with increasing \( k_{\ell} \). For \( h = 250 \text{ W/m}^2\cdot\text{K} \) (enhanced air cooling) and \( k_{\ell} = 400 \text{ W/m} \cdot \text{K} \) (copper leads), the transistor may dissipate up to 0.63 W.

**COMMENTS:** Additional benefits may be derived by increasing heat transfer across the gap separating the case from the board, perhaps by inserting a highly conductive material in the gap.
PROBLEM 1.72(a)

KNOWN: Solar radiation is incident on an asphalt paving.

FIND: Relevant heat transfer processes.

SCHEMATIC:

The relevant processes shown on the schematic include:

$q_s^{''}$ Incident solar radiation, a large portion of which $q_{S,\text{abs}}^{''}$, is absorbed by the asphalt surface,

$q_{\text{rad}}^{''}$ Radiation emitted by the surface to the air,

$q_{\text{conv}}^{''}$ Convection heat transfer from the surface to the air, and

$q_{\text{cond}}^{''}$ Conduction heat transfer from the surface into the asphalt.

Applying the surface energy balance, Eq. 1.12,

$$q_{S,\text{abs}}^{''} - q_{\text{rad}}^{''} - q_{\text{conv}}^{''} = q_{\text{cond}}^{''}.$$ 

COMMENTS: (1) $q_{\text{cond}}^{''}$ and $q_{\text{conv}}^{''}$ could be evaluated from Eqs. 1.1 and 1.3, respectively.

(2) It has been assumed that the pavement surface temperature is higher than that of the underlying pavement and the air, in which case heat transfer by conduction and convection are from the surface.

(3) For simplicity, radiation incident on the pavement due to atmospheric emission has been ignored (see Section 12.8 for a discussion). Eq. 1.6 may then be used for the absorbed solar irradiation and Eq. 1.5 may be used to obtain the emitted radiation $q_{\text{rad}}^{''}$.

(4) With the rate equations, the energy balance becomes

$$q_{S,\text{abs}}^{''} - \varepsilon \sigma T_s^{4} - h(T_s - T_\infty) = -k \frac{dT}{dx}_{s}. $$
PROBLEM 1.72(b)

KNOWN: Physical mechanism for microwave heating.

FIND: Comparison of (a) cooking in a microwave oven with a conventional radiant or convection oven and (b) a microwave clothes dryer with a conventional dryer.

(a) Microwave cooking occurs as a result of volumetric thermal energy generation throughout the food, without heating of the food container or the oven wall. Conventional cooking relies on radiant heat transfer from the oven walls and/or convection heat transfer from the air space to the surface of the food and subsequent heat transfer by conduction to the core of the food. Microwave cooking is more efficient and is achieved in less time.

(b) In a microwave dryer, the microwave radiation would heat the water, but not the fabric, directly (the fabric would be heated indirectly by energy transfer from the water). By heating the water, energy would go directly into evaporation, unlike a conventional dryer where the walls and air are first heated electrically or by a gas heater, and thermal energy is subsequently transferred to the wet clothes. The microwave dryer would still require a rotating drum and air flow to remove the water vapor, but is able to operate more efficiently and at lower temperatures. For a more detailed description of microwave drying, see Mechanical Engineering, March 1993, page 120.
**PROBLEM 1.72(c)**

**KNOWN:** Surface temperature of exposed arm exceeds that of the room air and walls.

**FIND:** Relevant heat transfer processes.

**SCHEMATIC:**

Neglecting evaporation from the surface of the skin, the only relevant heat transfer processes are:

- \( q_{\text{conv}} \) Convection heat transfer from the skin to the room air, and
- \( q_{\text{rad}} \) Net radiation exchange between the surface of the skin and the surroundings (walls of the room).

You are not imagining things. Even though the room air is maintained at a fixed temperature (\( T_\infty = 15^\circ \text{C} \)), the inner surface temperature of the outside walls, \( T_{\text{sur}} \), will decrease with decreasing outside air temperature. Upon exposure to these walls, body heat loss will be larger due to increased \( q_{\text{rad}} \).

**COMMENTS:** The foregoing reasoning assumes that the thermostat measures the true room air temperature and is shielded from radiation exchange with the outside walls.
PROBLEM 1.72(d)

KNOWN: Tungsten filament is heated to 2900 K in an air-filled glass bulb.

FIND: Relevant heat transfer processes.

SCHEMATIC:

The relevant processes associated with the filament and bulb include:

- $q_{\text{rad},f}$ Radiation emitted by the tungsten filament, a portion of which is transmitted through the glass,

- $q_{\text{conv},f}$ Free convection from filament to air of temperature $T_{a,i} < T_f$,

- $q_{\text{rad},g,i}$ Radiation emitted by inner surface of glass, a small portion of which is intercepted by the filament,

- $q_{\text{conv},g,i}$ Free convection from air to inner glass surface of temperature $T_{g,i} < T_{a,i}$,

- $q_{\text{cond},g}$ Conduction through glass wall,

- $q_{\text{conv},g,o}$ Free convection from outer glass surface to room air of temperature $T_{a,o} < T_{g,o}$, and

- $q_{\text{rad},g-sur}$ Net radiation heat transfer between outer glass surface and surroundings, such as the walls of a room, of temperature $T_{\text{sur}} < T_{g,o}$.

COMMENTS: If the glass bulb is evacuated, no convection is present within the bulb; that is, $q_{\text{conv},f} = q_{\text{conv},g,i} = 0$. 
PROBLEM 1.72(e)

KNOWN: Geometry of a composite insulation consisting of a honeycomb core.

FIND: Relevant heat transfer processes.

SCHEMATIC:

The above schematic represents the cross section of a single honeycomb cell and surface slabs. Assumed direction of gravity field is downward. Assuming that the bottom (inner) surface temperature exceeds the top (outer) surface temperature \((T_{s,i} > T_{s,o})\), heat transfer is in the direction shown.

Heat may be transferred to the inner surface by convection and radiation, whereupon it is transferred through the composite by

- \(q_{\text{cond},i}\): Conduction through the inner solid slab,
- \(q_{\text{conv},hc}\): Free convection through the cellular airspace,
- \(q_{\text{cond},hc}\): Conduction through the honeycomb wall,
- \(q_{\text{rad},hc}\): Radiation between the honeycomb surfaces, and
- \(q_{\text{cond},o}\): Conduction through the outer solid slab.

Heat may then be transferred from the outer surface by convection and radiation. Note that for a single cell under steady state conditions,

\[
q_{\text{rad},i} + q_{\text{conv},i} = q_{\text{cond},i} = q_{\text{conv},hc} + q_{\text{cond},hc} = q_{\text{rad},hc} + q_{\text{cont},o}.
\]

COMMENTS: Performance would be enhanced by using materials of low thermal conductivity, \(k\), and emissivity, \(\varepsilon\). Evacuating the airspace would enhance performance by eliminating heat transfer due to free convection.
PROBLEM 1.72(f)

KNOWN: A thermocouple junction is used, with or without a radiation shield, to measure the temperature of a gas flowing through a channel. The wall of the channel is at a temperature much less than that of the gas.

FIND: (a) Relevant heat transfer processes, (b) Temperature of junction relative to that of gas, (c) Effect of radiation shield.

SCHEMATIC:

ASSUMPTIONS: (1) Junction is small relative to channel walls, (2) Steady-state conditions, (3) Negligible heat transfer by conduction through the thermocouple leads.

ANALYSIS: (a) The relevant heat transfer processes are:

\[ q_{\text{rad}} \] Net radiation transfer from the junction to the walls, and

\[ q_{\text{conv}} \] Convection transfer from the gas to the junction.

(b) From a surface energy balance on the junction,

\[ q_{\text{conv}} = q_{\text{rad}} \]

or from Eqs. 1.3a and 1.7,

\[ h A (T_j - T_g) = \varepsilon A \sigma (T_j^4 - T_s^4). \]

To satisfy this equality, it follows that

\[ T_s < T_j < T_g. \]

That is, the junction assumes a temperature between that of the channel wall and the gas, thereby sensing a temperature which is less than that of the gas.

(c) The measurement error \( (T_g - T_j) \) is reduced by using a radiation shield as shown in the schematic. The junction now exchanges radiation with the shield, whose temperature must exceed that of the channel wall. The radiation loss from the junction is therefore reduced, and its temperature more closely approaches that of the gas.
PROBLEM 1.72(g)

KNOWN: Fireplace cavity is separated from room air by two glass plates, open at both ends.

FIND: Relevant heat transfer processes.

SCHEMATIC:

The relevant heat transfer processes associated with the double-glazed, glass fire screen are:

$q_{\text{rad},1}$ Radiation from flames and cavity wall, portions of which are absorbed and transmitted by the two panes,

$q_{\text{rad},2}$ Emission from inner surface of inner pane to cavity,

$q_{\text{rad},3}$ Net radiation exchange between outer surface of inner pane and inner surface of outer pane,

$q_{\text{rad},4}$ Net radiation exchange between outer surface of outer pane and walls of room,

$q_{\text{conv},1}$ Convection between cavity gases and inner pane,

$q_{\text{conv},2}$ Convection across air space between panes,

$q_{\text{conv},3}$ Convection from outer surface to room air,

$q_{\text{cond},1}$ Conduction across inner pane, and

$q_{\text{cond},2}$ Conduction across outer pane.

COMMENTS: (1) Much of the luminous portion of the flame radiation is transmitted to the room interior.

(2) All convection processes are buoyancy driven (free convection).
PROBLEM 1.73(a)

KNOWN: Room air is separated from ambient air by one or two glass panes.

FIND: Relevant heat transfer processes.

SCHEMATIC:

The relevant processes associated with single (above left schematic) and double (above right schematic) glass panes include.

- $q_{\text{conv},1}$ Convection from room air to inner surface of first pane,
- $q_{\text{rad},1}$ Net radiation exchange between room walls and inner surface of first pane,
- $q_{\text{cond},1}$ Conduction through first pane,
- $q_{\text{conv},s}$ Convection across airspace between panes,
- $q_{\text{rad},s}$ Net radiation exchange between outer surface of first pane and inner surface of second pane (across airspace),
- $q_{\text{cond},2}$ Conduction through a second pane,
- $q_{\text{conv},2}$ Convection from outer surface of single (or second) pane to ambient air,
- $q_{\text{rad},2}$ Net radiation exchange between outer surface of single (or second) pane and surroundings such as the ground, and
- $q_S$ Incident solar radiation during day; fraction transmitted to room is smaller for double pane.

COMMENTS: Heat loss from the room is significantly reduced by the double pane construction.
PROBLEM 1.73(b)

KNOWN: Configuration of a flat plate solar collector.

FIND: Relevant heat transfer processes with and without a cover plate.

SCHEMATIC:

The relevant processes without (above left schematic) and with (above right schematic) include:

- $q_s$: Incident solar radiation, a large portion of which is absorbed by the absorber plate. Reduced with use of cover plate (primarily due to reflection off cover plate).

- $q_{rad,\infty}$: Net radiation exchange between absorber plate or cover plate and surroundings,

- $q_{conv,\infty}$: Convection from absorber plate or cover plate to ambient air,

- $q_{rad,a-c}$: Net radiation exchange between absorber and cover plates,

- $q_{conv,a-c}$: Convection heat transfer across airspace between absorber and cover plates,

- $q_{cond}$: Conduction through insulation, and

- $q_{conv}$: Convection to working fluid.

COMMENTS: The cover plate acts to significantly reduce heat losses by convection and radiation from the absorber plate to the surroundings.
PROBLEM 1.73(c)

KNOWN: Configuration of a solar collector used to heat air for agricultural applications.

FIND: Relevant heat transfer processes.

SCHEMATIC:

Assume the temperature of the absorber plates exceeds the ambient air temperature. At the cover plates, the relevant processes are:

- $q_{\text{conv,a-i}}$: Convection from inside air to inner surface,
- $q_{\text{rad,p-i}}$: Net radiation transfer from absorber plates to inner surface,
- $q_{\text{conv,i-o}}$: Convection across airspace between covers,
- $q_{\text{rad,i-o}}$: Net radiation transfer from inner to outer cover,
- $q_{\text{conv,o-\infty}}$: Convection from outer cover to ambient air,
- $q_{\text{rad,o}}$: Net radiation transfer from outer cover to surroundings, and
- $q_S$: Incident solar radiation.

Additional processes relevant to the absorber plates and airspace are:

- $q_{S,t}$: Solar radiation transmitted by cover plates,
- $q_{\text{conv,p-a}}$: Convection from absorber plates to inside air, and
- $q_{\text{cond}}$: Conduction through insulation.
PROBLEM 1.73(d)

KNOWN: Features of an evacuated tube solar collector.

FIND: Relevant heat transfer processes for one of the tubes.

SCHEMATIC:

The relevant heat transfer processes for one of the evacuated tube solar collectors includes:

- $q_S$: Incident solar radiation including contribution due to reflection off panel (most is transmitted),
- $q_{conv,o}$: Convection heat transfer from outer surface to ambient air,
- $q_{rad,o-sur}$: Net rate of radiation heat exchange between outer surface of outer tube and the surroundings, including the panel,
- $q_{S,t}$: Solar radiation transmitted through outer tube and incident on inner tube (most is absorbed),
- $q_{rad,i-o}$: Net rate of radiation heat exchange between outer surface of inner tube and inner surface of outer tube, and
- $q_{conv,i}$: Convection heat transfer to working fluid.

There is also conduction heat transfer through the inner and outer tube walls. If the walls are thin, the temperature drop across the walls will be small.
PROBLEM 2.1

KNOWN: Steady-state, one-dimensional heat conduction through an axisymmetric shape.

FIND: Sketch temperature distribution and explain shape of curve.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, one-dimensional conduction, (2) Constant properties, (3) No internal heat generation.

ANALYSIS: Performing an energy balance on the object according to Eq. 1.11, \( \dot{E}_{in} - \dot{E}_{out} = 0 \), it follows that

\[
\dot{E}_{in} - \dot{E}_{out} = q_x
\]

and that \( q_x \neq q_x(x) \). That is, the heat rate within the object is everywhere constant. From Fourier’s law,

\[
q_x = -kA_x \frac{dT}{dx},
\]

and since \( q_x \) and \( k \) are both constants, it follows that

\[
A_x \frac{dT}{dx} = \text{Constant}.
\]

That is, the product of the cross-sectional area normal to the heat rate and temperature gradient remains a constant and independent of distance \( x \). It follows that since \( A_x \) increases with \( x \), then \( dT/dx \) must decrease with increasing \( x \). Hence, the temperature distribution appears as shown above.

COMMENTS: (1) Be sure to recognize that \( dT/dx \) is the slope of the temperature distribution. (2) What would the distribution be when \( T_2 > T_1 \)? (3) How does the heat flux, \( q''_x \), vary with distance?
PROBLEM 2.2

KNOWN: Hot water pipe covered with thick layer of insulation.

FIND: Sketch temperature distribution and give brief explanation to justify shape.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional (radial) conduction, (3) No internal heat generation, (4) Insulation has uniform properties independent of temperature and position.

ANALYSIS: Fourier’s law, Eq. 2.1, for this one-dimensional (cylindrical) radial system has the form

\[ q_r = -kA_r \frac{dT}{dr} = -k(2\pi r) \frac{dT}{dr} \]

where \( A_r = 2\pi \ell \) and \( \ell \) is the axial length of the pipe-insulation system. Recognize that for steady-state conditions with no internal heat generation, an energy balance on the system requires \( E_{in} = E_{out} \) since \( E_g = E_{st} = 0 \). Hence

\[ q_r = \text{Constant}. \]

That is, \( q_r \) is independent of radius \( r \). Since the thermal conductivity is also constant, it follows that

\[ r \left[ \frac{dT}{dr} \right] = \text{Constant}. \]

This relation requires that the product of the radial temperature gradient, \( dT/dr \), and the radius, \( r \), remains constant throughout the insulation. For our situation, the temperature distribution must appear as shown in the sketch.

COMMENTS: (1) Note that, while \( q_r \) is a constant and independent of \( r \), \( q''_r \) is not a constant. How does \( q''_r(r) \) vary with \( r \)? (2) Recognize that the radial temperature gradient, \( dT/dr \), decreases with increasing radius.
PROBLEM 2.3

KNOWN: A spherical shell with prescribed geometry and surface temperatures.

FIND: Sketch temperature distribution and explain shape of the curve.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in radial (spherical coordinates) direction, (3) No internal generation, (4) Constant properties.

ANALYSIS: Fourier’s law, Eq. 2.1, for this one-dimensional, radial (spherical coordinate) system has the form

\[ q_r = -k \frac{dT}{dr} = -k \left( 4\pi r^2 \right) \frac{dT}{dr} \]

where \( A_r \) is the surface area of a sphere. For steady-state conditions, an energy balance on the system yields \( E_{in} = E_{out} \), since \( E_g = E_{st} = 0 \). Hence,

\[ q_{in} = q_{out} = q_r \neq q_r(r) \]

That is, \( q_r \) is a constant, independent of the radial coordinate. Since the thermal conductivity is constant, it follows that

\[ r^2 \left[ \frac{dT}{dr} \right] = \text{Constant}. \]

This relation requires that the product of the radial temperature gradient, \( dT/dr \), and the radius squared, \( r^2 \), remains constant throughout the shell. Hence, the temperature distribution appears as shown in the sketch.

COMMENTS: Note that, for the above conditions, \( q_r \neq q_r(r) \); that is, \( q_r \) is everywhere constant. How does \( q_r'' \) vary as a function of radius?
PROBLEM 2.4

KNOWN: Symmetric shape with prescribed variation in cross-sectional area, temperature distribution and heat rate.

FIND: Expression for the thermal conductivity, k.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in x-direction, (3) No internal heat generation.

ANALYSIS: Applying the energy balance, Eq. 1.11a, to the system, it follows that, since \( \dot{E}_{in} = \dot{E}_{out} \),

\[ q_x = \text{Constant} \neq f(x). \]

Using Fourier’s law, Eq. 2.1, with appropriate expressions for \( A_x \) and \( T \), yields

\[ q_x = -k A_x \frac{dT}{dx} = \frac{6000 \text{W}}{k \cdot (1-x) m^2} \cdot \frac{d}{dx} \left[ 300 \left( 1 - 2x - x^3 \right) \right] \frac{K}{m}. \]

Solving for \( k \) and recognizing its units are W/m·K,

\[ k = \frac{-6000}{(1-x) \left[ 300 \left( -2 - 3x^2 \right) \right]} = \frac{20}{(1-x) \left( 2 + 3x^2 \right)}. \]

COMMENTS: (1) At \( x = 0 \), \( k = 10 \text{W/m-K} \) and \( k \to \infty \) as \( x \to 1 \). (2) Recognize that the 1-D assumption is an approximation which becomes more inappropriate as the area change with \( x \), and hence two-dimensional effects, become more pronounced.
PROBLEM 2.5

KNOWN: End-face temperatures and temperature dependence of k for a truncated cone.

FIND: Variation with axial distance along the cone of $q_x$, $q''_x$, $k$, and $dT/dx$.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in x (negligible temperature gradients along y), (2) Steady-state conditions, (3) Adiabatic sides, (4) No internal heat generation.

ANALYSIS: For the prescribed conditions, it follows from conservation of energy, Eq. 1.11a, that for a differential control volume, $\dot{E}_{in} = \dot{E}_{out}$ or $q_x = q_{x+dx}$. Hence

$q_x$ is independent of x.

Since $A(x)$ increases with increasing x, it follows that $q''_x = q_x / A(x)$ decreases with increasing x.

Since $T$ decreases with increasing x, $k$ increases with increasing x. Hence, from Fourier’s law, Eq. 2.2,

$$q''_x = -k \frac{dT}{dx},$$

it follows that $|dT/dx|$ decreases with increasing x.
**PROBLEM 2.6**

**KNOWN:** Temperature dependence of the thermal conductivity, \( k(T) \), for heat transfer through a plane wall.

**FIND:** Effect of \( k(T) \) on temperature distribution, \( T(x) \).

**ASSUMPTIONS:** (1) One-dimensional conduction, (2) Steady-state conditions, (3) No internal heat generation.

**ANALYSIS:** From Fourier’s law and the form of \( k(T) \),

\[
q_x'' = -k \frac{dT}{dx} = -(k_o + aT) \frac{dT}{dx}.
\]

(1)

The shape of the temperature distribution may be inferred from knowledge of \( \frac{d^2T}{dx^2} = \frac{dT}{dx} \frac{dT}{dx} \). Since \( q_x'' \) is independent of \( x \) for the prescribed conditions,

\[
\frac{dq_x''}{dx} = \frac{d}{dx} \left[ (k_o + aT) \frac{dT}{dx} \right] = 0
\]

\[-(k_o + aT) \frac{d^2T}{dx^2} - a \left[ \frac{dT}{dx} \right]^2 = 0.
\]

Hence,

\[
\frac{d^2T}{dx^2} = \frac{-a}{k_o + aT} \left[ \frac{dT}{dx} \right]^2 \quad \text{where} \quad \left[ \frac{dT}{dx} \right]^2 > 0
\]

from which it follows that for

\[
\begin{align*}
    a > 0: & \quad \frac{d^2T}{dx^2} < 0 \\
    a = 0: & \quad \frac{d^2T}{dx^2} = 0 \\
    a < 0: & \quad \frac{d^2T}{dx^2} > 0.
\end{align*}
\]

**COMMENTS:** The shape of the distribution could also be inferred from Eq. (1). Since \( T \) decreases with increasing \( x \),

\[
\begin{align*}
    a > 0: & \quad k \text{ decreases with increasing } x = > |dT/dx| \text{ increases with increasing } x \\
    a = 0: & \quad k = k_o \quad > |dT/dx| \text{ is constant} \\
    a < 0: & \quad k \text{ increases with increasing } x = > |dT/dx| \text{ decreases with increasing } x.
\end{align*}
\]
PROBLEM 2.7

KNOWN: Thermal conductivity and thickness of a one-dimensional system with no internal heat generation and steady-state conditions.

FIND: Unknown surface temperatures, temperature gradient or heat flux.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional heat flow, (2) No internal heat generation, (3) Steady-state conditions, (4) Constant properties.

ANALYSIS: The rate equation and temperature gradient for this system are

\[ q_x^* = -k \frac{dT}{dx} \quad \text{and} \quad \frac{dT}{dx} = \frac{T_1 - T_2}{L} \quad (1,2) \]

Using Eqs. (1) and (2), the unknown quantities can be determined.

(a) \( \frac{dT}{dx} = \frac{(400 - 300) K}{0.5 m} = 200 K/m \)

\[ q_x^* = -25 \frac{W}{m \cdot K} \times 200 \frac{K}{m} = -5000 \text{ W/m}^2 \]

(b) \[ q_x^* = -25 \frac{W}{m \cdot K} \times \left[ -250 \frac{K}{m} \right] = 6250 \text{ W/m}^2 \]

\[ T_2 = T_1 - L \left[ \frac{dT}{dx} \right] = 1000^\circ C \cdot 0.5m \left[ -250 \frac{K}{m} \right] \]

\[ T_2 = 225^\circ C. \]

(c) \[ q_x^* = -25 \frac{W}{m \cdot K} \times 200 \frac{K}{m} = -5000 \text{ W/m}^2 \]

\[ T_2 = 80^\circ C \cdot 0.5m \left[ 200 \frac{K}{m} \right] = -20^\circ C. \]

(d) \( \frac{dT}{dx} = \frac{q_x^*}{k} = \frac{-4000 \text{ W/m}^2}{25 \text{ W/m} \cdot \text{K}} = -160 \frac{K}{m} \)

\[ T_1 = L \left[ \frac{dT}{dx} \right] + T_2 = 0.5m \left[ -160 \frac{K}{m} \right] + (-5^\circ C) \sqrt{a^2 + b^2} \]

\[ T_1 = -85^\circ C. \]

(e) \( \frac{dT}{dx} = \frac{q_x^*}{k} = \frac{-3000 \text{ W/m}^2}{25 \text{ W/m} \cdot \text{K}} = 120 \frac{K}{m} \)

\[ T_2 = 30^\circ C \cdot 0.5m \left[ 120 \frac{K}{m} \right] = -30^\circ C. \]
**PROBLEM 2.8**

**KNOWN:** One-dimensional system with prescribed thermal conductivity and thickness.

**FIND:** Unknowns for various temperature conditions and sketch distribution.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional conduction, (3) No internal heat generation, (4) Constant properties.

**ANALYSIS:** The rate equation and temperature gradient for this system are

\[ q_x = -k \frac{dT}{dx} \quad \text{and} \quad \frac{dT}{dx} = \frac{T_2 - T_1}{L}. \tag{1,2} \]

Using Eqs. (1) and (2), the unknown quantities for each case can be determined.

(a) \[ \frac{dT}{dx} = \frac{(-20 - 50) K}{0.25 m} = -280 K/m \]

\[ q_x = -50 \frac{W}{m \cdot K} \times \left[ -280 \frac{K}{m} \right] = 14.0 \text{ kW/m}^2. \]

(b) \[ \frac{dT}{dx} = \frac{(-10 - (-30)) K}{0.25 m} = 80 K/m \]

\[ q_x = -50 \frac{W}{m \cdot K} \times \left[ 80 \frac{K}{m} \right] = -4.0 \text{ kW/m}^2. \]

(c) \[ q_x = -50 \frac{W}{m \cdot K} \times \left[ 160 \frac{K}{m} \right] = -8.0 \text{ kW/m}^2 \]

\[ T_2 = L \cdot \frac{dT}{dx} + T_1 = 0.25 m \times \left[ 160 \frac{K}{m} \right] + 70^\circ C. \]

\[ T_2 = 110^\circ C. \]

(d) \[ q_x = -50 \frac{W}{m \cdot K} \times \left[ -80 \frac{K}{m} \right] = 4.0 \text{ kW/m}^2 \]

\[ T_1 = T_2 - L \cdot \frac{dT}{dx} = 40^\circ C - 0.25 m \left[ -80 \frac{K}{m} \right]. \]

\[ T_1 = 60^\circ C. \]

(e) \[ q_x = -50 \frac{W}{m \cdot K} \times \left[ 200 \frac{K}{m} \right] = -10.0 \text{ kW/m}^2 \]

\[ T_1 = T_2 - L \cdot \frac{dT}{dx} = 30^\circ C - 0.25 m \left[ 200 \frac{K}{m} \right] = -20^\circ C. \]
PROBLEM 2.9

KNOWN: Plane wall with prescribed thermal conductivity, thickness, and surface temperatures.

FIND: Heat flux, \( q''_x \), and temperature gradient, \( \frac{dT}{dx} \), for the three different coordinate systems shown.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional heat flow, (2) Steady-state conditions, (3) No internal generation, (4) Constant properties.

ANALYSIS: The rate equation for conduction heat transfer is

\[
q''_x = -k \frac{dT}{dx},
\]

where the temperature gradient is constant throughout the wall and of the form

\[
\frac{dT}{dx} = \frac{T(L) - T(0)}{L}.
\]

Substituting numerical values, find the temperature gradients,

(a) \[ \frac{dT}{dx} = \frac{T_2 - T_1}{L} = \frac{(600 - 400)K}{0.100m} = 2000 K/m \]

(b) \[ \frac{dT}{dx} = \frac{T_1 - T_2}{L} = \frac{(400 - 600)K}{0.100m} = -2000 K/m \]

(c) \[ \frac{dT}{dx} = \frac{T_2 - T_1}{L} = \frac{(600 - 400)K}{0.100m} = 2000 K/m. \]

The heat rates, using Eq. (1) with \( k = 100 \text{ W/m-K} \), are

(a) \[ q''_x = -100 \frac{W}{m \cdot K} \times 2000 \text{ K/m} = -200 \text{ kW/m}^2 \]

(b) \[ q''_x = -100 \frac{W}{m \cdot K} (-2000 \text{ K/m}) = +200 \text{ kW/m}^2 \]

(c) \[ q''_x = -100 \frac{W}{m \cdot K} \times 2000 \text{ K/m} = -200 \text{ kW/m}^2 \]
PROBLEM 2.10

KNOWN: Temperature distribution in solid cylinder and convection coefficient at cylinder surface.

FIND: Expressions for heat rate at cylinder surface and fluid temperature.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, radial conduction, (2) Steady-state conditions, (3) Constant properties.

ANALYSIS: The heat rate from Fourier’s law for the radial (cylindrical) system has the form

\[ q_r = -k A_r \frac{dT}{dr}. \]

Substituting for the temperature distribution, \( T(r) = a + br^2 \),

\[ q_r = -k(2\pi L) 2br = -4\pi kbLr^2. \]

At the outer surface ( \( r = r_o \) ), the conduction heat rate is

\[ q_{r=r_o} = -4\pi kbLr_o^2. \]

From a surface energy balance at \( r = r_o \),

\[ q_{r=r_o} = q_{\text{conv}} = h(2\pi r_o L) \left[ T(r_o) - T_\infty \right]. \]

Substituting for \( q_{r=r_o} \) and solving for \( T_\infty \),

\[ T_\infty = T(r_o) + \frac{2kb r_o}{h} \]

\[ T_\infty = a + br_o^2 + \frac{2kb r_o}{h} \]

\[ T_\infty = a + br_o \left[ r_o + \frac{2k}{h} \right] \]

<
PROBLEM 2.11

KNOWN: Two-dimensional body with specified thermal conductivity and two isothermal surfaces of prescribed temperatures; one surface, A, has a prescribed temperature gradient.

FIND: Temperature gradients, $\frac{\partial T}{\partial x}$ and $\frac{\partial T}{\partial y}$, at the surface B.

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional conduction, (2) Steady-state conditions, (3) No heat generation, (4) Constant properties.

ANALYSIS: At the surface A, the temperature gradient in the x-direction must be zero. That is, $(\partial T/\partial x)_A = 0$. This follows from the requirement that the heat flux vector must be normal to an isothermal surface. The heat rate at the surface A is given by Fourier’s law written as

$$q'_{y,A} = -k \cdot w_A \frac{\partial T}{\partial y}_A = -10 \text{W/m} \times 2\text{m} \times 30 \text{K/m} = -600 \text{W/m}.$$  

On the surface B, it follows that

$$\frac{\partial T}{\partial y}_B = 0$$

in order to satisfy the requirement that the heat flux vector be normal to the isothermal surface B. Using the conservation of energy requirement, Eq. 1.11a, on the body, find

$$q'_{y,A} - q'_{x,B} = 0 \quad \text{or} \quad q'_{x,B} = q'_{y,A}.$$  

Note that,

$$q'_{x,B} = -k \cdot w_B \frac{\partial T}{\partial x}_B$$

and hence

$$\frac{\partial T}{\partial x}_B = \frac{-q'_{y,A}}{k \cdot w_B} = \frac{-(-600 \text{W/m})}{10 \text{W/m} \cdot \text{K} \times 1\text{m}} = 60 \text{K/m}.$$  

COMMENTS: Note that, in using the conservation requirement, $q'_{\text{in}} = +q'_{y,A}$ and $q'_{\text{out}} = +q'_{x,B}$. 

<
PROBLEM 2.12

KNOWN: Length and thermal conductivity of a shaft. Temperature distribution along shaft.

FIND: Temperature and heat rates at ends of shaft.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in x, (3) Constant properties.

ANALYSIS: Temperatures at the top and bottom of the shaft are, respectively,

\[ T(0) = 100^\circ C \quad T(L) = -40^\circ C. \]

Applying Fourier’s law, Eq. 2.1,

\[ q_x = -kA \frac{dT}{dx} = -25 \text{ W} \cdot \text{m/K} \cdot (0.005 \text{ m}^2)(-150 + 20x)^\circ C/\text{m} \]

\[ q_x = 0.125(150 - 20x)\text{W}. \]

Hence,

\[ q_x(0) = 18.75 \text{ W} \quad q_x(L) = 16.25 \text{ W}. \]

The difference in heat rates, \( q_x(0) > q_x(L) \), is due to heat losses \( q_\ell \) from the side of the shaft.

COMMENTS: Heat loss from the side requires the existence of temperature gradients over the shaft cross-section. Hence, specification of T as a function of only x is an approximation.
PROBLEM 2.13

KNOWN: A rod of constant thermal conductivity \( k \) and variable cross-sectional area \( A_x(x) = A_0e^{ax} \) where \( A_0 \) and \( a \) are constants.

FIND: (a) Expression for the conduction heat rate, \( q_x(x) \); use this expression to determine the temperature distribution, \( T(x) \); and sketch of the temperature distribution, (b) Considering the presence of volumetric heat generation rate, \( \dot{q} = \dot{q}_0 \exp(-ax) \), obtain an expression for \( q_x(x) \) when the left face, \( x = 0 \), is well insulated.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in the rod, (2) Constant properties, (3) Steady-state conditions.

ANALYSIS: Perform an energy balance on the control volume, \( A(x) \cdot dx \),

\[
\dot{E}_{\text{in}} - \dot{E}_{\text{out}} + \dot{E}_g = 0
\]

\[
q_x - q_{x+dx} + \dot{q} \cdot A(x) \cdot dx = 0
\]

The conduction heat rate terms can be expressed as a Taylor series and substituting expressions for \( \dot{q} \) and \( A(x) \),

\[
-\frac{d}{dx}(q_x) + \dot{q}_0 \exp(-ax) \cdot A_0 \exp(ax) = 0
\]  
(1)

\[
q_x = -k \cdot A(x) \frac{dT}{dx}
\]  
(2)

(a) With no internal generation, \( \dot{q}_0 = 0 \), and from Eq. (1) find

\[
-\frac{d}{dx}(q_x) = 0
\]

indicating that the heat rate is constant with \( x \). By combining Eqs. (1) and (2)

\[
-\frac{d}{dx}\left(-k \cdot A(x) \frac{dT}{dx}\right) = 0 \quad \text{or} \quad A(x) \frac{dT}{dx} = C_1
\]  
(3)

Continued...
That is, the product of the cross-sectional area and the temperature gradient is a constant, independent of $x$. Hence, with $T(0) > T(L)$, the temperature distribution is exponential, and as shown in the sketch above. Separating variables and integrating Eq. (3), the general form for the temperature distribution can be determined,

$$A_o \exp(ax) \frac{dT}{dx} = C_1$$

$$dT = C_1 A_o^{-1} \exp(-ax) dx$$

$$T(x) = -C_1 A_o a \exp(-ax) + C_2$$

We could use the two temperature boundary conditions, $T_o = T(0)$ and $T_L = T(L)$, to evaluate $C_1$ and $C_2$ and, hence, obtain the temperature distribution in terms of $T_o$ and $T_L$.

(b) With the internal generation, from Eq. (1),

$$-\frac{d}{dx}(q_x) + q_o A_o = 0 \quad \text{or} \quad q_x = \dot{q}_o A_o x$$

That is, the heat rate increases linearly with $x$.

**COMMENTS:** In part (b), you could determine the temperature distribution using Fourier’s law and knowledge of the heat rate dependence upon the $x$-coordinate. Give it a try!
**PROBLEM 2.14**

**KNOWN:** Dimensions and end temperatures of a cylindrical rod which is insulated on its side.

**FIND:** Rate of heat transfer associated with different rod materials.

**SCHEMATIC:**

![Cylindrical Rod Schematic](attachment:image.png)

**ASSUMPTIONS:** (1) One-dimensional conduction along cylinder axis, (2) Steady-state conditions, (3) Constant properties.

**PROPERTIES:** The properties may be evaluated from *Tables A-1 to A-3* at a mean temperature of 50°C = 323K and are summarized below.

**ANALYSIS:** The heat transfer rate may be obtained from Fourier’s law. Since the axial temperature gradient is linear, this expression reduces to

\[
q = kA \frac{T_1 - T_2}{L} = k \frac{\pi(0.025m)^2}{4} \frac{(100 - 0)\degree C}{0.1m} = 0.491(\text{m} \cdot \degree \text{C}) \cdot k
\]

<table>

**COMMENTS:** The k values of Cu and Al were obtained by linear interpolation; the k value of St.St. was obtained by linear extrapolation, as was the value for SiN; the value for magnesia was obtained by linear interpolation; and the values for oak and pyrex are for 300 K.
PROBLEM 2.15

KNOWN: One-dimensional system with prescribed surface temperatures and thickness.

FIND: Heat flux through system constructed of these materials: (a) pure aluminum, (b) plain carbon steel, (c) AISI 316, stainless steel, (d) pyroceram, (e) teflon and (f) concrete.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) No heat generation, (4) Constant thermal properties.

PROPERTIES: The thermal conductivity is evaluated at the average temperature of the system, \( T = \frac{T_1 + T_2}{2} = \frac{(325 + 275) \text{K}}{2} = 300 \text{K} \). Property values and table identification are shown below.

ANALYSIS: For this system, Fourier’s law can be written as

\[
q_x'' = -k \frac{dT}{dx} = -k \frac{T_2 - T_1}{L}.
\]

Substituting numerical values, the heat flux is

\[
q_x'' = -k \frac{(275 - 325) \text{K}}{20 \times 10^{-3} \text{ m}} = +2500 \frac{\text{K}}{\text{m}} \cdot \text{k}
\]

where \( q_x'' \) will have units \( \text{W/m}^2 \) if \( k \) has units \( \text{W/m-K} \). The heat fluxes for each system follow.

COMMENTS: Recognize that the thermal conductivity of these solid materials varies by more than two orders of magnitude.
**PROBLEM 2.16**

**KNOWN:** Different thicknesses of three materials: rock, 18 ft; wood, 15 in; and fiberglass insulation, 6 in.

**FIND:** The insulating quality of the materials as measured by the R-value.

**PROPERTIES:** Table A-3 (300K):

<table>
<thead>
<tr>
<th>Material</th>
<th>Thermal conductivity, W/m-K</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limestone</td>
<td>2.15</td>
</tr>
<tr>
<td>Softwood</td>
<td>0.12</td>
</tr>
<tr>
<td>Blanket (glass, fiber 10 kg/m³)</td>
<td>0.048</td>
</tr>
</tbody>
</table>

**ANALYSIS:** The R-value, a quantity commonly used in the construction industry and building technology, is defined as

\[
R \equiv \frac{L (\text{in})}{k (\text{Btu in} / \text{h ft}^2 \cdot ^\circ \text{F})}.
\]

The R-value can be interpreted as the thermal resistance of a 1 ft² cross section of the material. Using the conversion factor for thermal conductivity between the SI and English systems, the R-values are:

Rock, Limestone, 18 ft:

\[
R = \frac{18 \text{ ft} \times 12 \text{ in}}{2.15 \frac{\text{W}}{\text{m} \cdot \text{K}} \times 0.5778 \frac{\text{Btu/h ft} \cdot ^\circ \text{F}}{\text{W/m K}} \times 12 \text{ in}} = 14.5 \left(\frac{\text{Btu/h ft}^2 \cdot ^\circ \text{F}}{\text{W/m K}}\right)^{-1}
\]

Wood, Softwood, 15 in:

\[
R = \frac{15 \text{ in}}{0.12 \frac{\text{W}}{\text{m} \cdot \text{K}} \times 0.5778 \frac{\text{Btu/h ft} \cdot ^\circ \text{F}}{\text{W/m K}} \times 12 \text{ in}} = 18 \left(\frac{\text{Btu/h ft}^2 \cdot ^\circ \text{F}}{\text{W/m K}}\right)^{-1}
\]

Insulation, Blanket, 6 in:

\[
R = \frac{6 \text{ in}}{0.048 \frac{\text{W}}{\text{m} \cdot \text{K}} \times 0.5778 \frac{\text{Btu/h ft} \cdot ^\circ \text{F}}{\text{W/m K}} \times 12 \text{ in}} = 18 \left(\frac{\text{Btu/h ft}^2 \cdot ^\circ \text{F}}{\text{W/m K}}\right)^{-1}
\]

**COMMENTS:** The R-value of 19 given in the advertisement is reasonable.
PROBLEM 2.17

KNOWN: Electrical heater sandwiched between two identical cylindrical (30 mm dia. × 60 mm length) samples whose opposite ends contact plates maintained at $T_0$.

FIND: (a) Thermal conductivity of SS316 samples for the prescribed conditions (A) and their average temperature, (b) Thermal conductivity of Armco iron sample for the prescribed conditions (B), (c) Comment on advantages of experimental arrangement, lateral heat losses, and conditions for which $\Delta T_1 \neq \Delta T_2$.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional heat transfer in samples, (2) Steady-state conditions, (3) Negligible contact resistance between materials.

PROPERTIES: Table A.2, Stainless steel 316 ($\bar{T} = 400$ K): $k_{ss} = 15.2$ W / m·K; Armco iron ($\bar{T} = 380$ K): $k_{iron} = 71.6$ W / m·K.

ANALYSIS: (a) For Case A recognize that half the heater power will pass through each of the samples which are presumed identical. Apply Fourier’s law to a sample

$$ q = kA_c \frac{\Delta T}{\Delta x} $$

$$ k = \frac{q\Delta x}{A_c\Delta T} = \frac{0.5(100\text{V} \times 0.353\text{A}) \times 0.015\text{m}}{\pi(0.030\text{m})^2 / 4 \times 25.0^\circ C} = 15.0\text{ W} / \text{m} \cdot \text{K}. $$

The total temperature drop across the length of the sample is $\Delta T_1 (L/\Delta x) = 25^\circ C$ (60 mm/15 mm) = 100°C. Hence, the heater temperature is $T_h = 177^\circ C$. Thus the average temperature of the sample is $\bar{T} = (T_0 + T_h) / 2 = 127^\circ C = 400$ K

We compare the calculated value of $k$ with the tabulated value (see above) at 400 K and note the good agreement.

(b) For Case B, we assume that the thermal conductivity of the SS316 sample is the same as that found in Part (a). The heat rate through the Armco iron sample is

Continued …..
PROBLEM 2.17 (CONT.)

\[ q_{\text{iron}} = q_{\text{heater}} - q_{ss} = 100 \times 0.601A - 15.0 \text{ W/m.K} \times \frac{\pi (0.030 \text{ m})^2}{4} \times \frac{15^\circ \text{C}}{0.015 \text{ m}} \]

\[ q_{\text{iron}} = (60.1 - 10.6) \text{W} = 49.5 \text{ W} \]

where

\[ q_{ss} = k_{ss} A_c \Delta T_2 / \Delta x_2. \]

Applying Fourier’s law to the iron sample,

\[ k_{\text{iron}} = \frac{q_{\text{iron}} \Delta x_2}{A_c \Delta T_2} = \frac{49.5 \text{ W} \times 0.015 \text{ m}}{\pi (0.030 \text{ m})^2 / 4 \times 15^\circ \text{C}} = 70.0 \text{ W/m.K}. \]

The total drop across the iron sample is 15°C(60/15) = 60°C; the heater temperature is (77 + 60)°C = 137°C. Hence the average temperature of the iron sample is

\[ T = \frac{(137 + 77)^\circ \text{C}}{2} = 107^\circ \text{C} = 380 \text{ K}. \]

We compare the computed value of \( k \) with the tabulated value (see above) at 380 K and note the good agreement.

(c) The principal advantage of having two identical samples is the assurance that all the electrical power dissipated in the heater will appear as equivalent heat flows through the samples. With only one sample, heat can flow from the backside of the heater even though insulated.

Heat leakage out the lateral surfaces of the cylindrically shaped samples will become significant when the sample thermal conductivity is comparable to that of the insulating material. Hence, the method is suitable for metallics, but must be used with caution on nonmetallic materials.

For any combination of materials in the upper and lower position, we expect \( \Delta T_1 = \Delta T_2 \). However, if the insulation were improperly applied along the lateral surfaces, it is possible that heat leakage will occur, causing \( \Delta T_1 \neq \Delta T_2 \).
PROBLEM 2.18

KNOWN: Comparative method for measuring thermal conductivity involving two identical samples stacked with a reference material.

FIND: (a) Thermal conductivity of test material and associated temperature, (b) Conditions for which $\Delta T_{t,1} \neq \Delta T_{t,2}$

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat transfer through samples and reference material, (3) Negligible thermal contact resistance between materials.

PROPERTIES: Table A.2, Armco iron ($\bar{T} = 350$ K): $k_r = 69.2$ W / m · K.

ANALYSIS: (a) Recognizing that the heat rate through the samples and reference material, all of the same diameter, is the same, it follows from Fourier’s law that

$$k_t \frac{\Delta T_{t,1}}{\Delta x} = k_r \frac{\Delta T_r}{\Delta x} = k_t \frac{\Delta T_{t,2}}{\Delta x}$$

$$k_t = k_t \frac{\Delta T_{t}}{\Delta T_{t}} = 69.2 \text{ W / m} \cdot \text{K} \frac{2.49^\circ\text{C}}{3.32^\circ\text{C}} = 51.9 \text{ W / m} \cdot \text{K}.$$ <

We should assign this value a temperature of 350 K. <

(b) If the test samples are identical in every respect, $\Delta T_{t,1} \neq \Delta T_{t,2}$ if the thermal conductivity is highly dependent upon temperature. Also, if there is heat leakage out the lateral surface, we can expect $\Delta T_{t,2} < \Delta T_{t,1}$. Leakage could be influential, if the thermal conductivity of the test material were less than an order of magnitude larger than that of the insulating material.
**PROBLEM 2.19**

**KNOWN:** Identical samples of prescribed diameter, length and density initially at a uniform temperature $T_i$, sandwich an electric heater which provides a uniform heat flux $q_o$ for a period of time $\Delta t_o$. Conditions shortly after energizing and a long time after de-energizing heater are prescribed.

**FIND:** Specific heat and thermal conductivity of the test sample material. From these properties, identify type of material using Table A.1 or A.2.

**SCHEMATIC:**

![Diagram showing the setup of the problem with insulation, heater, and samples.](image)

**ASSUMPTIONS:** (1) One dimensional heat transfer in samples, (2) Constant properties, (3) Negligible heat loss through insulation, (4) Negligible heater mass.

**ANALYSIS:** Consider a control volume about the samples and heater, and apply conservation of energy over the time interval from $t = 0$ to $\infty$

$$E_{in} - E_{out} = \Delta E = E_f - E_i$$

$$P\Delta t_o = 0 = M c_p \left[ T(\infty) - T_i \right]$$

where energy inflow is prescribed by the Case A power condition and the final temperature $T_f$ by Case B. Solving for $c_p$,

$$c_p = \frac{P\Delta t_o}{M \left[ T(\infty) - T_i \right]} = \frac{15 \text{ W} \times 120 \text{ s}}{2 \times 3965 \text{ kg} / \text{m}^3 \left( \pi \times 0.060^2 / 4 \right) \text{m}^2 \times 0.010 \text{ m} \left[ 33.50 - 23.00 \right] \text{C}}$$

$$c_p = 765 \text{ J} / \text{kg} \cdot \text{K}$$

where $M = \rho V = 2\rho(\pi D^2/4)L$ is the mass of both samples. For Case A, the transient thermal response of the heater is given by

Continued .....
PROBLEM 2.19 (Cont.)

\[ T_0(t) - T_i = 2q_0' \left[ \frac{t}{\pi \rho c_p k} \right]^{1/2} \]

\[ k = \frac{t}{\pi \rho c_p} \left[ \frac{2q_0''}{T_0(t) - T_i} \right]^2 \]

\[ k = \frac{30 \text{ s}}{\pi \times 3965 \text{ kg/m}^3 \times 765 \text{ J/kg} \cdot \text{K}} \left[ \frac{2 \times 2653 \text{ W/m}^2}{(24.57 - 23.00)^{\circ} \text{C}} \right]^2 = 36.0 \text{ W/m} \cdot \text{K} \]

where

\[ q_0'' = \frac{P}{2A_s} = \frac{P}{2\left(\pi D^2 / 4\right)} = \frac{15 \text{ W}}{2\left(\pi \times 0.060^2 / 4\right) \text{m}^2} = 2653 \text{ W/m}^2. \]

With the following properties now known,

\[ \rho = 3965 \text{ kg/m}^3 \quad c_p = 765 \text{ J/kg} \cdot \text{K} \quad k = 36 \text{ W/m} \cdot \text{K} \]

entries in Table A.1 are scanned to determine whether these values are typical of a metallic material. Consider the following,

- metallics with low \( \rho \) generally have higher thermal conductivities,
- specific heats of both types of materials are of similar magnitude,
- the low \( k \) value of the sample is typical of poor metallic conductors which generally have much higher specific heats,
- more than likely, the material is nonmetallic.

From Table A.2, the second entry, polycrystalline aluminum oxide, has properties at 300 K corresponding to those found for the samples.
PROBLEM 2.20

KNOWN: Temperature distribution, T(x,y,z), within an infinite, homogeneous body at a given instant of time.

FIND: Regions where the temperature changes with time.

SCHEMATIC:

\[ T(x,y,z) = x^2 - 2y^2 + z^2 - xy + 2yz \]

Infinite medium

ASSUMPTIONS: (1) Constant properties of infinite medium and (2) No internal heat generation.

ANALYSIS: The temperature distribution throughout the medium, at any instant of time, must satisfy the heat equation. For the three-dimensional cartesian coordinate system, with constant properties and no internal heat generation, the heat equation, Eq. 2.15, has the form

\[ \frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2} + \frac{\partial^2 T}{\partial z^2} = \frac{1}{\alpha} \frac{\partial T}{\partial t}. \]  

(1)

If T(x,y,z) satisfies this relation, conservation of energy is satisfied at every point in the medium. Substituting T(x,y,z) into the Eq. (1), first find the gradients, \( \frac{\partial T}{\partial x}, \frac{\partial T}{\partial y}, \text{ and } \frac{\partial T}{\partial z} \).

\[ \frac{\partial}{\partial x} (2x - y) + \frac{\partial}{\partial y} (-4y - x + 2z) + \frac{\partial}{\partial z} (2z + 2y) = \frac{1}{\alpha} \frac{\partial T}{\partial t}. \]

Performing the differentiations,

\[ 2 - 4 + 2 = \frac{1}{\alpha} \frac{\partial T}{\partial t}. \]

Hence,

\[ \frac{\partial T}{\partial t} = 0 \]

which implies that, at the prescribed instant, the temperature is everywhere independent of time.

COMMENTS: Since we do not know the initial and boundary conditions, we cannot determine the temperature distribution, T(x,y,z), at any future time. We can only determine that, for this special instant of time, the temperature will not change.
PROBLEM 2.21

KNOWN: Diameter D, thickness L and initial temperature $T_i$ of pan. Heat rate from stove to bottom of pan. Convection coefficient $h$ and variation of water temperature $T_\infty(t)$ during Stage 1. Temperature $T_L$ of pan surface in contact with water during Stage 2.

FIND: Form of heat equation and boundary conditions associated with the two stages.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in pan bottom, (2) Heat transfer from stove is uniformly distributed over surface of pan in contact with the stove, (3) Constant properties.

ANALYSIS:

Stage 1

Heat Equation:
\[
\frac{\partial^2 T}{\partial x^2} = \frac{1}{\alpha} \frac{\partial T}{\partial t}
\]

Boundary Conditions:
\[
-k \frac{\partial T}{\partial x} \bigg|_{x=0} = q_0 = \frac{q_0}{\pi D^2 / 4}
\]
\[
-k \frac{\partial T}{\partial x} \bigg|_{x=L} = h \left[ T(L, t) - T_\infty(t) \right]
\]

Initial Condition: $T(x, 0) = T_i$

Stage 2

Heat Equation:
\[
\frac{d^2 T}{dx^2} = 0
\]

Boundary Conditions:
\[
-k \frac{dT}{dx} \bigg|_{x=0} = q_0^*
\]
\[
T(L) = T_L
\]

COMMENTS: Stage 1 is a transient process for which $T_\infty(t)$ must be determined separately. As a first approximation, it could be estimated by neglecting changes in thermal energy storage by the pan bottom and assuming that all of the heat transferred from the stove acted to increase thermal energy storage within the water. Hence, with $q \approx M c_p \frac{dT_\infty}{dt}$, where $M$ and $c_p$ are the mass and specific heat of the water in the pan, $T_\infty(t) = (q/Mc_p) t$. 

PROBLEM 2.22

KNOWN: Steady-state temperature distribution in a cylindrical rod having uniform heat generation of \( q_1 = 5 \times 10^7 \text{ W/m}^3 \).

FIND: (a) Steady-state centerline and surface heat transfer rates per unit length, \( q_r' \). (b) Initial time rate of change of the centerline and surface temperatures in response to a change in the generation rate from \( q_1 \) to \( q_2 = 10^8 \text{ W/m}^3 \).

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in the \( r \) direction, (2) Uniform generation, and (3) Steady-state for \( q_1 = 5 \times 10^7 \text{ W/m}^3 \).

ANALYSIS: (a) From the rate equations for cylindrical coordinates,

\[
q_r'' = -k \frac{\partial T}{\partial r} \quad q = -kA_r \frac{\partial T}{\partial r}.
\]

Hence,

\[
q_r = -k(2\pi L) \frac{\partial T}{\partial r}
\]

or

\[
q'_r = -2\pi kr \frac{\partial T}{\partial r}
\]

where \( \frac{\partial T}{\partial r} \) may be evaluated from the prescribed temperature distribution, \( T(r) \).

At \( r = 0 \), the gradient is \( (\partial T/\partial r) = 0 \). Hence, from Eq. (1) the heat rate is

\[
q'_r(0) = 0.
\]

At \( r = r_0 \), the temperature gradient is

\[
\left. \frac{\partial T}{\partial r} \right|_{r=r_0} = -2\left( 4.167 \times 10^5 \text{ K/m}^2 \right)(0.025\text{m}) = -2(4.167 \times 10^5)(0.025\text{m})
\]

\[
\left. \frac{\partial T}{\partial r} \right|_{r=r_0} = -0.208 \times 10^5 \text{ K/m}.
\]

Continued ....
Hence, the heat rate at the outer surface \((r = r_o)\) per unit length is

\[
q_r'(r_o) = -2\pi \left[30 \text{ W m}^{-1} \cdot \text{K} \right] \left[0.025 \text{m} \right] \left[-0.208 \times 10^5 \text{ K m}^{-1} \right]
\]

\[
q_r'(r_o) = 0.980 \times 10^5 \text{ W m}.
\]

(b) Transient (time-dependent) conditions will exist when the generation is changed, and for the prescribed assumptions, the temperature is determined by the following form of the heat equation, Eq. 2.20

\[
\frac{1}{r} \frac{\partial}{\partial r} \left[ k r \frac{\partial T}{\partial r} \right] + \dot{q}_2 = \rho c_p \frac{\partial T}{\partial t}
\]

Hence

\[
\frac{\partial T}{\partial t} = \frac{1}{\rho c_p} \left( \frac{1}{r} \frac{\partial}{\partial r} \left[ k r \frac{\partial T}{\partial r} \right] + \dot{q}_2 \right).
\]

However, initially (at \(t = 0\)), the temperature distribution is given by the prescribed form, \(T(r) = 800 - 4.167 \times 10^5 r^2\), and

\[
\frac{1}{r} \frac{\partial}{\partial r} \left[ k r \frac{\partial T}{\partial r} \right] = \frac{k}{r} \left( -8.334 \times 10^5 \cdot r \right)
\]

\[
= \frac{k}{r} \left( -16.668 \times 10^5 \cdot r \right)
\]

\[
= 30 \text{ W m}^{-1} \cdot \text{K} \left[ -16.668 \times 10^5 \text{ K m}^{-2} \right]
\]

\[
= -5 \times 10^7 \text{ W m}^{-3} \text{ (the original } \dot{q} = \dot{q}_1)\).
\]

Hence, everywhere in the wall,

\[
\frac{\partial T}{\partial t} = \frac{1}{1100 \text{ kg m}^{-3} \times 800 \text{ J kg}^{-1} \cdot \text{K}} \left[-5 \times 10^7 + 10^8 \right] \text{ W m}^{-3}
\]

or

\[
\frac{\partial T}{\partial t} = 56.82 \text{ K s}^{-1}
\]

COMMENTS: (1) The value of \((\partial T/\partial t)\) will decrease with increasing time, until a new steady-state condition is reached and once again \((\partial T/\partial t) = 0\).

(2) By applying the energy conservation requirement, Eq. 1.11a, to a unit length of the rod for the steady-state condition, \(\dot{E}_{in} - \dot{E}_{out} + \dot{E}_{gen} = 0\). Hence \(q_r'(0) - q_r'(r_o) = -\dot{q}_1 (\pi r_o^2)\).
**PROBLEM 2.23**

**KNOWN:** Temperature distribution in a one-dimensional wall with prescribed thickness and thermal conductivity.

**FIND:** (a) The heat generation rate, \( q \), in the wall, (b) Heat fluxes at the wall faces and relation to \( q \).

**SCHEMATIC:**

![Schematic](image)

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional heat flow, (3) Constant properties.

**ANALYSIS:** (a) The appropriate form of the heat equation for steady-state, one-dimensional conditions with constant properties is Eq. 2.15 re-written as

\[
\dot{q} = -k \frac{dT}{dx} = -k \frac{d}{dx}(a + bx^2) = -2bk
\]

Substituting the prescribed temperature distribution,

\[
\dot{q} = -2\left(-2000 \text{°C/m}^2\right) \times 50 \text{ W/m·K} = 2.0 \times 10^5 \text{ W/m}^2.
\]

(b) The heat fluxes at the wall faces can be evaluated from Fourier’s law,

\[
q_x(x) = -k \frac{dT}{dx}.
\]

Using the temperature distribution \( T(x) \) to evaluate the gradient, find

\[
q_x(x) = -k \frac{d}{dx}(a + bx^2) = -2kbx.
\]

The fluxes at \( x = 0 \) and \( x = L \) are then

\[
q_x(0) = 0
\]

\[
q_x(L) = -2kbL = -2 \times 50 \text{ W/m·K} \times 0.050 \text{m} = 10,000 \text{ W/m}^2.
\]

**COMMENTS:** From an overall energy balance on the wall, it follows that, for a unit area,

\[
\dot{E}_{in} - \dot{E}_{out} + \dot{E}_g = 0 \quad \Rightarrow \quad q_x(0) - q_x(L) + qL = 0
\]

\[
\dot{q} = \frac{q_x(L) - q_x(0)}{L} = \frac{10,000 \text{ W/m}^2 - 0}{0.050 \text{m}} = 2.0 \times 10^5 \text{ W/m}^3.
\]
PROBLEM 2.24

KNOWN: Wall thickness, thermal conductivity, temperature distribution, and fluid temperature.

FIND: (a) Surface heat rates and rate of change of wall energy storage per unit area, and (b) Convection coefficient.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in x, (2) Constant k.

ANALYSIS: (a) From Fourier’s law,

\[ q_x'' = -k \frac{\partial T}{\partial x} = (200 - 60x) \cdot k \]

\[ q_{in}'' = q_{x=0}'' = 200 \frac{\degree C}{m} \times 1 \frac{W}{m \cdot K} = 200 \frac{W}{m^2} \]

\[ q_{out}'' = q_{x=L}'' = (200 - 60 \times 0.3) \frac{\degree C}{m} \times 1 \frac{W}{m \cdot K} = 182 \frac{W}{m^2}. \]

Applying an energy balance to a control volume about the wall, Eq. 1.11a,

\[ \dot{E}_{in}'' - \dot{E}_{out}'' = \dot{E}_{st}'' \]

\[ \dot{E}_{st}'' = q_{in}'' - q_{out}'' = 18 \frac{W}{m^2}. \]

(b) Applying a surface energy balance at \( x = L \),

\[ q_{out}'' = h[T(L) - T_\infty] \]

\[ h = \frac{q_{out}''}{T(L) - T_\infty} = \frac{182 \frac{W}{m^2}}{(142.7 - 100) \degree C} \]

\[ h = 4.3 \frac{W}{m^2 \cdot K}. \]

COMMENTS: (1) From the heat equation,

\[ (\partial T/\partial t) = \frac{k}{\rho c_p} \frac{\partial^2 T}{\partial x^2} = 60(\frac{k}{\rho c_p}). \]

it follows that the temperature is increasing with time at every point in the wall.

(2) The value of \( h \) is small and is typical of free convection in a gas.
**PROBLEM 2.25**

**KNOWN:** Analytical expression for the steady-state temperature distribution of a plane wall experiencing uniform volumetric heat generation \( \dot{q} \) while convection occurs at both of its surfaces.

**FIND:** (a) Sketch the temperature distribution, \( T(x) \), and identify significant physical features, (b) Determine \( \dot{q} \), (c) Determine the surface heat fluxes, \( q'_x(-L) \) and \( q'_x(+L) \); how are these fluxes related to the generation rate; (d) Calculate the convection coefficients at the surfaces \( x = L \) and \( x = +L \), (e) Obtain an expression for the heat flux distribution, \( q'_x(x) \); explain significant features of the distribution; (f) If the source of heat generation is suddenly deactivated (\( \dot{q} = 0 \)), what is the rate of change of energy stored at this instant; (g) Determine the temperature that the wall will reach eventually with \( \dot{q} = 0 \); determine the energy that must be removed by the fluid per unit area of the wall to reach this state.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Uniform volumetric heat generation, (3) Constant properties.

**ANALYSIS:** (a) Using the analytical expression in the Workspace of IHT, the temperature distribution appears as shown below. The significant features include (1) parabolic shape, (2) maximum does not occur at the mid-plane, \( T(-5.25 \text{ mm}) = 83.3°C \), (3) the gradient at the \( x = +L \) surface is greater than at \( x = -L \). Find also that \( T(-L) = 78.2°C \) and \( T(+L) = 69.8°C \) for use in part (d).

(b) Substituting the temperature distribution expression into the appropriate form of the heat diffusion equation, Eq. 2.15, the rate of volumetric heat generation can be determined.

\[
\frac{d}{dx}\left(\frac{dT}{dx}\right) + \frac{\dot{q}}{k} = 0 \quad \text{where} \quad T(x) = a + bx + cx^2
\]

\[
\frac{d}{dx}(0 + b + 2cx) + \frac{\dot{q}}{k} = (0 + 2c) + \frac{\dot{q}}{k} = 0
\]

Continued …..
PROBLEM 2.25 (Cont.)

\[ \dot{q} = -2ck = -2\left(-2 \times 10^4 \text{C} / \text{m}^2 \right)5 \text{ W} / \text{m} \cdot \text{K} = 2 \times 10^5 \text{ W} / \text{m}^3 \]  

(c) The heat fluxes at the two boundaries can be determined using Fourier’s law and the temperature distribution expression.

\[ q_x^* (x) = -k \frac{dT}{dx} \quad \text{where} \quad T(x) = a + bx + cx^2 \]

\[ q_x^* (-L) = -k \left[ 0 + b + 2cx \right]_{x=-L} = -\left[ b - 2cL \right]k \]

\[ q_x^* (-L) = -\left[ -210^\circ \text{C} / \text{m} - 2\left(-2 \times 10^4 \text{C} / \text{m}^2 \right)0.020 \text{m} \right] \times 5 \text{ W} / \text{m} \cdot \text{K} = -2950 \text{ W} / \text{m}^2 \]

\[ q_x^* (+L) = -(b + 2cL)k = +5050 \text{ W} / \text{m}^2 \]

From an overall energy balance on the wall as shown in the sketch below, \( \dot{E}_{in} - \dot{E}_{out} + \dot{E}_{gen} = 0 \),

\[ +q_x^* (-L) - q_x^* (+L) + 2\dot{q}_L = 0 \quad \text{or} \quad -2950 \text{ W} / \text{m}^2 - 5050 \text{ W} / \text{m}^2 + 8000 \text{ W} / \text{m}^2 = 0 \]

where \( 2\dot{q}_L = 2 \times 2 \times 10^5 \text{ W} / \text{m}^3 \times 0.020 \text{ m} = 8000 \text{ W} / \text{m}^2 \), so the equality is satisfied.

(d) The convection coefficients, \( h_l \) and \( h_r \), for the left- and right-hand boundaries (\( x = -L \) and \( x = +L \), respectively), can be determined from the convection heat fluxes that are equal to the conduction fluxes at the boundaries. See the surface energy balances in the sketch above. See also part (a) result for \( T(-L) \) and \( T(+L) \).

\[ q_{cv,l} = q_x^* (-L) \]

\[ h_l \left[ T_{\infty} - T(-L) \right] = h_l \left[ 20 - 78.2 \right] \text{K} = -2950 \text{ W} / \text{m}^2 \quad h_l = 51 \text{ W} / \text{m}^2 \cdot \text{K} \]

\[ q_{cv,r} = q_x^* (+L) \]

\[ h_r \left[ T(+L) - T_{\infty} \right] = h_r \left[ 69.8 - 20 \right] \text{K} = +5050 \text{ W} / \text{m}^2 \quad h_r = 101 \text{ W} / \text{m}^2 \cdot \text{K} \]

(e) The expression for the heat flux distribution can be obtained from Fourier’s law with the temperature distribution

\[ q_x^* (x) = -k \frac{dT}{dx} = -k \left[ 0 + b + 2cx \right] \]

\[ q_x^* (x) = -5 \text{ W} / \text{m} \cdot \text{K} \left[ -210^\circ \text{C} / \text{m} + 2\left(-2 \times 10^4 \text{C} / \text{m}^2 \right) \right] x = 1050 + 2 \times 10^5 x \]

Continued.....
PROBLEM 2.25 (Cont.)

The distribution is linear with the x-coordinate. The maximum temperature will occur at the location where \(q^*_x(x_{\text{max}}) = 0\),

\[
x_{\text{max}} = -\frac{1050 \text{ W/m}^2}{2 \times 10^5 \text{ W/m}^3} = -5.25 \times 10^{-3} \text{ m} = -5.25 \text{ mm}
\]

(f) If the source of the heat generation is suddenly deactivated so that \(q = 0\), the appropriate form of the heat diffusion equation for the ensuing transient conduction is

\[
k \frac{\partial}{\partial x} \left( \frac{\partial T}{\partial x} \right) = \rho c_p \frac{\partial T}{\partial t}
\]

At the instant this occurs, the temperature distribution is still \(T(x) = a + bx + cx^2\). The right-hand term represents the rate of energy storage per unit volume,

\[
\dot{E}_{\text{st}}^* = k \frac{\partial}{\partial x} [0 + b + 2cx] = k [0 + 2c] = 5 \text{ W/m/K} \times 2 \left(-2 \times 10^4 \text{C/m}^2\right) = -2 \times 10^5 \text{ W/m}^3
\]

(g) With no heat generation, the wall will eventually \((t \to \infty)\) come to equilibrium with the fluid, \(T(x, \infty) = T_\infty = 20^\circ\text{C}\). To determine the energy that must be removed from the wall to reach this state, apply the conservation of energy requirement over an interval basis, Eq. 1.11b. The “initial” state is that corresponding to the steady-state temperature distribution, \(T_i\), and the “final” state has \(T_f = 20^\circ\text{C}\).

We’ve used \(T_\infty\) as the reference condition for the energy terms.

\[
E_{\text{in}}^* - E_{\text{out}}^* = \Delta E_{\text{st}}^* = E_f^* - E_i^* \quad \text{with} \quad E_{\text{in}}^* = 0.
\]

\[
E_{\text{out}}^* = \rho c_p 2L (T_f - T_\infty) - \rho c_p \int_{-L}^{+L} (T_i - T_\infty) \, dx
\]

\[
E_{\text{out}}^* = \rho c_p \int_{-L}^{+L} \left( a + bx + cx^2 - T_\infty \right) \, dx = \rho c_p \left[ ax + bx^2 / 2 + cx^3 / 3 - T_\infty x \right]_{-L}^{+L}
\]

\[
E_{\text{out}}^* = \rho c_p \left[ 2aL + 0 + 2cx^3 / 3 - 2T_\infty L \right]
\]

\[
E_{\text{out}}^* = 2600 \text{ kg/m}^3 \times 800 \text{ J/kg} \cdot \text{K} \left[ 2 \times 82^\circ\text{C} \times 0.020 \text{ m} + 2 \left(-2 \times 10^4 \text{C/m}^2\right) \right]
\]

\[
(0.020 \text{ m})^3 / 3 - 2 \times (20^\circ\text{C}) \times 0.020 \text{ m}
\]

\[
E_{\text{out}}^* = 4.94 \times 10^6 \text{ J/m}^2
\]

COMMENTS: (1) In part (a), note that the temperature gradient is larger at \(x = + L\) than at \(x = - L\). This is consistent with the results of part (c) in which the conduction heat fluxes are evaluated.
(2) In evaluating the conduction heat fluxes, $q_x(x)$, it is important to recognize that this flux is in the positive x-direction. See how this convention is used in formulating the energy balance in part (c).

(3) It is good practice to represent energy balances with a schematic, clearly defining the system or surface, showing the CV or CS with dashed lines, and labeling the processes. Review again the features in the schematics for the energy balances of parts (c & d).

(4) Re-writing the heat diffusion equation introduced in part (b) as

$$\frac{d}{dx}\left(-k \frac{dT}{dx}\right) + \dot{q} = 0$$

recognize that the term in parenthesis is the heat flux. From the differential equation, note that if the differential of this term is a constant $(\dot{q}/k)$, then the term must be a linear function of the x-coordinate. This agrees with the analysis of part (e).

(5) In part (f), we evaluated $\dot{E}_{st}$, the rate of energy change stored in the wall at the instant the volumetric heat generation was deactivated. Did you notice that $\dot{E}_{st} = -2 \times 10^5 \text{ W/m}^3$ is the same value of the deactivated $\dot{q}$? How do you explain this?
PROBLEM 2.26

KNOWN: Steady-state conduction with uniform internal energy generation in a plane wall; temperature distribution has quadratic form. Surface at \( x=0 \) is prescribed and boundary at \( x = L \) is insulated.

FIND: (a) Calculate the internal energy generation rate, \( \dot{q} \), by applying an overall energy balance to the wall, (b) Determine the coefficients \( a, b, \) and \( c \), by applying the boundary conditions to the prescribed form of the temperature distribution; plot the temperature distribution and label as Case 1, (c) Determine new values for \( a, b, \) and \( c \) for conditions when the convection coefficient is halved, and the generation rate remains unchanged; plot the temperature distribution and label as Case 2; (d) Determine new values for \( a, b, \) and \( c \) for conditions when the generation rate is doubled, and the convection coefficient remains unchanged (\( h = 500 \text{ W/m}^2\text{K} \)); plot the temperature distribution and label as Case 3.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction with constant properties and uniform internal generation, and (3) Boundary at \( x = L \) is adiabatic.

ANALYSIS: (a) The internal energy generation rate can be calculated from an overall energy balance on the wall as shown in the schematic below.

\[
\dot{E}_{in}^* - \dot{E}_{out}^* + \dot{E}_{gen}^* = 0 \quad \text{where} \quad \dot{E}_{in}^* = \dot{q}_{conv}^*
\]

\[
h \left( T_\infty - T_0 \right) + \dot{q} \cdot L = 0
\]

\[
\dot{q} = -h \left( T_\infty - T_0 \right) / L = -500 \text{ W/m}^2\text{K} (20-120)^\circ \text{C} / 0.050 \text{ m} = 1.0 \times 10^6 \text{ W/m}^3 <
\]

(b) The coefficients of the temperature distribution, \( T(x) = a + bx + cx^2 \), can be evaluated by applying the boundary conditions at \( x = 0 \) and \( x = L \). See Table 2.1 for representation of the boundary conditions, and the schematic above for the relevant surface energy balances.

Boundary condition at \( x = 0 \), convection surface condition

\[
\dot{E}_{in}^* - \dot{E}_{out}^* = \dot{q}_{conv}^* - \dot{q}_x \left( 0 \right) = 0 \quad \text{where} \quad \dot{q}_x \left( 0 \right) = -k \frac{dT}{dx} \bigg|_{x=0}
\]

\[
h \left( T_\infty - T_0 \right) - \left[ -k \left( 0 + b + 2cx \right) \right]_{x=0} = 0
\]

Continued .....
PROBLEM 2.26 (Cont.)

\[ b = -h(T_\infty - T_o) / k = -500 \text{ W/m}^2 \cdot \text{K} (20 - 120) \text{C}/5 \text{ W/m} \cdot \text{K} = 1.0 \times 10^4 \text{K/m} \]  

Boundary condition at \( x = L \), adiabatic or insulated surface

\[ \dot{E}_{in} - \dot{E}_{out} = -q_x(L) = 0 \quad \text{where} \quad q_x(L) = -k \frac{dT}{dx} \bigg|_{x=L} \]

\[ k[0 + b + 2cx]_{x=L} = 0 \quad \text{(3)} \]

\[ c = -b / 2L = -1.0 \times 10^4 \text{K/m} / (2 \times 0.050\text{m}) = -1.0 \times 10^5 \text{K/m}^2 \]  

Since the surface temperature at \( x = 0 \) is known, \( T(0) = T_o = 120^\circ \text{C} \), find

\[ T(0) = 120^\circ \text{C} = a + b \cdot 0 + c \cdot 0 \quad \text{or} \quad a = 120^\circ \text{C} \quad \text{(4)} \]

Using the foregoing coefficients with the expression for \( T(x) \) in the Workspace of IHT, the temperature distribution can be determined and is plotted as Case 1 in the graph below.

(c) Consider Case 2 when the convection coefficient is halved, \( h_2 = h / 2 = 250 \text{ W/m}^2 \cdot \text{K} \), \( q = 1 \times 10^6 \text{ W/m}^3 \) and other parameters remain unchanged except that \( T_o \neq 120^\circ \text{C} \). We can determine \( a, b, \) and \( c \) for the temperature distribution expression by repeating the analyses of parts (a) and (b).

Overall energy balance on the wall, see Eqs. (1,4)

\[ a = T_o = qL / h + T_\infty = 1 \times 10^6 \text{W} / \text{m}^3 \times 0.050\text{m} / 250 \text{ W/m}^2 \cdot \text{K} + 20^\circ \text{C} = 220^\circ \text{C} \]

Surface energy balance at \( x = 0 \), see Eq. (2)

\[ b = -h(T_\infty - T_o) / k = -250 \text{ W/m}^2 \cdot \text{K} (20 - 220) \text{C}/5 \text{ W/m} \cdot \text{K} = 1.0 \times 10^4 \text{K/m} \]

Surface energy balance at \( x = L \), see Eq. (3)

\[ c = -b / 2L = -1.0 \times 10^4 \text{K/m} / (2 \times 0.050\text{m}) = -1.0 \times 10^5 \text{K/m}^2 \]

The new temperature distribution, \( T_2(x) \), is plotted as Case 2 below.

(d) Consider Case 3 when the internal energy volumetric generation rate is doubled, \( q_3 = 2q = 2 \times 10^6 \text{ W/m}^3 \), \( h = 500 \text{ W/m}^2 \cdot \text{K} \), and other parameters remain unchanged except that \( T_o \neq 120^\circ \text{C} \). Following the same analysis as part (c), the coefficients for the new temperature distribution, \( T(x) \), are

\[ a = 220^\circ \text{C} \quad b = 2 \times 10^4 \text{K/m} \quad c = -2 \times 10^5 \text{K/m}^2 \]

and the distribution is plotted as Case 3 below.

Continued .....
PROBLEM 2.26 (Cont.)

**COMMENTS:** Note the following features in the family of temperature distributions plotted above.
The temperature gradients at $x = L$ are zero since the boundary is insulated (adiabatic) for all cases. The shapes of the distributions are all quadratic, with the maximum temperatures at the insulated boundary.

By halving the convection coefficient for Case 2, we expect the surface temperature $T_o$ to increase relative to the Case 1 value, since the same heat flux is removed from the wall ($q_L$) but the convection resistance has increased.

By doubling the generation rate for Case 3, we expect the surface temperature $T_o$ to increase relative to the Case 1 value, since double the amount of heat flux is removed from the wall ($2q_L$).

Can you explain why $T_o$ is the same for Cases 2 and 3, yet the insulated boundary temperatures are quite different? Can you explain the relative magnitudes of $T(L)$ for the three cases?
PROBLEM 2.27

KNOWN: Temperature distribution and distribution of heat generation in central layer of a solar pond.

FIND: (a) Heat fluxes at lower and upper surfaces of the central layer, (b) Whether conditions are steady or transient, (c) Rate of thermal energy generation for the entire central layer.

SCHEMATIC:

ASSUMPTIONS: (1) Central layer is stagnant, (2) One-dimensional conduction, (3) Constant properties

ANALYSIS: (a) The desired fluxes correspond to conduction fluxes in the central layer at the lower and upper surfaces. A general form for the conduction flux is

\[ q_{\text{cond}}'' = -k \frac{\partial T}{\partial x} = -k \left[ \frac{A}{ka} e^{-ax} + B \right]. \]

Hence,

\[ q_1'' = q_{\text{cond}(x=L)}'' = -k \left[ \frac{A}{ka} e^{-aL} + B \right] \quad q_u'' = q_{\text{cond}(x=0)}'' = -k \left[ \frac{A}{ka} + B \right]. \]

(b) Conditions are steady if \( \partial T/\partial t = 0 \). Applying the heat equation,

\[ \frac{\partial^2 T}{\partial x^2} + \frac{q}{k} = \frac{1}{\alpha} \frac{\partial T}{\partial t} \quad - \frac{A}{k} e^{-ax} + \frac{A}{k} e^{ax} = \frac{1}{\alpha} \frac{\partial T}{\partial t} \]

Hence conditions are steady since

\( \partial T/\partial t = 0 \) (for all \( 0 \leq x \leq L \)).

(c) For the central layer, the energy generation is

\[ \dot{E}_g'' = \int_0^L q'' \, dx = \int_0^L A e^{-ax} \, dx \]

\[ \dot{E}_g = -\frac{A}{a} e^{-ax} \bigg|_0^L = -\frac{A}{a} (e^{-aL} - 1) = \frac{A}{a} (1 - e^{-aL}). \]

Alternatively, from an overall energy balance,

\[ q_2'' - q_1'' + \dot{E}_g'' = q''_1 - q''_2 + \left(-q_{\text{cond}(x=0)}''\right) - \left(-q_{\text{cond}(x=L)}''\right) \]

\[ \dot{E}_g = k \left[ \frac{A}{ka} + B \right] - k \left[ \frac{A}{ka} e^{-aL} + B \right] = \frac{A}{a} (1 - e^{-aL}). \]

COMMENTS: Conduction is in the negative x-direction, necessitating use of minus signs in the above energy balance.
PROBLEM 2.28

KNOWN: Temperature distribution in a semi-transparent medium subjected to radiative flux.

FIND: (a) Expressions for the heat flux at the front and rear surfaces, (b) Heat generation rate \( \dot{q}(x) \), (c) Expression for absorbed radiation per unit surface area in terms of A, a, B, C, L, and k.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in medium, (3) Constant properties, (4) All laser irradiation is absorbed and can be characterized by an internal volumetric heat generation term \( \dot{q}(x) \).

ANALYSIS: (a) Knowing the temperature distribution, the surface heat fluxes are found using Fourier’s law,

\[
q''_x = -k \left[ \frac{dT}{dx} \right] = -k \left[ -\frac{A}{ka}(-a)e^{-ax} + B \right]
\]

Front Surface, \( x=0 \):

\[
q''_x(0) = -k \left[ +\frac{A}{ka} \cdot 1 + B \right] = -\left[ \frac{A}{a} + kB \right]
\]

Rear Surface, \( x=L \):

\[
q''_x(L) = -k \left[ +\frac{A}{ka}e^{-aL} + B \right] = -\left[ \frac{A}{a} e^{-aL} + kB \right].
\]

(b) The heat diffusion equation for the medium is

\[
\frac{d}{dx} \left( \frac{dT}{dx} \right) = \frac{\dot{q}}{k} = 0 \quad \text{or} \quad \dot{q} = -k \frac{d}{dx} \left( \frac{dT}{dx} \right)
\]

\[
\dot{q}(x) = -k \frac{d}{dx} \left[ +\frac{A}{ka}e^{-ax} + B \right] = Ae^{-ax}.
\]

(c) Performing an energy balance on the medium,

\[
\dot{E}_{\text{in}} - \dot{E}_{\text{out}} + \dot{E}_g = 0
\]

recognize that \( \dot{E}_g \) represents the absorbed irradiation. On a unit area basis

\[
\dot{E}_g'' = -\dot{E}'_{\text{in}} + \dot{E}'_{\text{out}} = -q''_x(0) + q''_x(L) = +\frac{A}{a} \left( 1 - e^{-aL} \right).
\]

Alternatively, evaluate \( \dot{E}_g'' \) by integration over the volume of the medium,

\[
\dot{E}_g'' = \int_0^L \dot{q}(x)dx = \int_0^L Ae^{-ax}dx = \frac{A}{a} \left[ e^{-ax} \right]_0^L = \frac{A}{a} \left( 1 - e^{-aL} \right).
\]
PROBLEM 2.29

KNOWN: Steady-state temperature distribution in a one-dimensional wall of thermal conductivity, \( T(x) = Ax^3 + Bx^2 + Cx + D \).

FIND: Expressions for the heat generation rate in the wall and the heat fluxes at the two wall faces (x = 0, L).

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat flow, (3) Homogeneous medium.

ANALYSIS: The appropriate form of the heat diffusion equation for these conditions is

\[
\frac{d^2T}{dx^2} + \frac{\dot{q}}{k} = 0 \quad \text{or} \quad \dot{q} = -k \frac{d^2T}{dx^2}.
\]

Hence, the generation rate is

\[
\dot{q} = -k \frac{d}{dx} \left[ \frac{dT}{dx} \right] = -k \frac{d}{dx} \left[ 3Ax^2 + 2Bx + C + 0 \right]
\]

\[
\dot{q} = -k[6Ax + 2B]
\]

which is linear with the coordinate \( x \). The heat fluxes at the wall faces can be evaluated from Fourier’s law,

\[
q_x'' = -k \frac{dT}{dx} = -k \left[ 3Ax^2 + 2Bx + C \right]
\]

using the expression for the temperature gradient derived above. Hence, the heat fluxes are:

Surface \( x=0 \):

\[
q_x''(0) = -kC
\]

Surface \( x=L \):

\[
q_x''(L) = -k \left[ 3AL^2 + 2BL + C \right]
\]

COMMENTS: (1) From an overall energy balance on the wall, find

\[
\dot{E}_{in}'' - \dot{E}_{out}'' + \dot{E}_g'' = 0
\]

\[
q_x''(0) - q_x''(L) + \dot{E}_g'' = (-kC) - (-k) \left[ 3AL^2 + 2BL + C \right] + \dot{E}_g'' = 0
\]

\[
\dot{E}_g'' = -3AkL^2 - 2BkL.
\]

From integration of the volumetric heat rate, we can also find \( \dot{E}_g'' \) as

\[
\dot{E}_g'' = \int_0^L \dot{q}(x)dx = \int_0^L -k[6Ax + 2B]dx = -k \left[ 3Ax^2 + 2Bx \right]_0^L
\]

\[
\dot{E}_g'' = -3AkL^2 - 2BkL.
\]
PROBLEM 2.30

KNOWN: Plane wall with no internal energy generation.

FIND: Determine whether the prescribed temperature distribution is possible; explain your reasoning. With the temperatures $T(0) = 0^\circ C$ and $T_\infty = 20^\circ C$ fixed, compute and plot the temperature $T(L)$ as a function of the convection coefficient for the range $10 \leq h \leq 100 \text{ W/m}^2\text{K}$.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) No internal energy generation, (3) Constant properties, (4) No radiation exchange at the surface $x = L$, and (5) Steady-state conditions.

ANALYSIS: (a) Is the prescribed temperature distribution possible? If so, the energy balance at the surface $x = L$ as shown above in the Schematic, must be satisfied.

$$\dot{E}_\text{in} - \dot{E}_\text{out} = 0 \quad q_x(L) - q_{cv} = 0 \quad \text{(1,2)}$$

where the conduction and convection heat fluxes are, respectively,

$$q_x(L) = -k \frac{dT}{dx} \bigg|_{x=L} = -k \frac{T(L) - T(0)}{L} = -4.5 \text{ W/m} \cdot \text{K} \times (120 - 0)^\circ C / 0.18 \text{ m} = -3000 \text{ W/m}^2$$

$$q_{cv} = h \left[ T(L) - T_\infty \right] = 30 \text{ W/m}^2 \cdot \text{K} \times (120 - 20)^\circ C = 3000 \text{ W/m}^2$$

Substituting the heat flux values into Eq. (2), find $(-3000) - (3000) = 0$ and therefore, the temperature distribution is not possible.

(b) With $T(0) = 0^\circ C$ and $T_\infty = 20^\circ C$, the temperature at the surface $x = L$, $T(L)$, can be determined from an overall energy balance on the wall as shown above in the Schematic,

$$\dot{E}_\text{in} - \dot{E}_\text{out} = 0 \quad q_x(0) - q_{cv} = 0 \quad -k \frac{T(L) - T(0)}{L} - h \left[ T(L) - T_\infty \right] = 0$$

$$-4.5 \text{ W/m} \cdot \text{K} \left[ T(L) - 0^\circ C \right] / 0.18 \text{ m} - 30 \text{ W/m}^2 \cdot \text{K} \left[ T(L) - 20^\circ C \right] = 0$$

$$T(L) = 10.9^\circ C$$

Using this same analysis, $T(L)$ as a function of the convection coefficient can be determined and plotted. We don’t expect $T(L)$ to be linearly dependent upon $h$. Note that as $h$ increases to larger values, $T(L)$ approaches $T_\infty$. To what value will $T(L)$ approach as $h$ decreases?
**PROBLEM 2.31**

**KNOWN:** Coal pile of prescribed depth experiencing uniform volumetric generation with convection, absorbed irradiation and emission on its upper surface.

**FIND:** (a) The appropriate form of the heat diffusion equation (HDE) and whether the prescribed temperature distribution satisfies this HDE; conditions at the bottom of the pile, \( x = 0 \); sketch of the temperature distribution with labeling of key features; (b) Expression for the conduction heat rate at the location \( x = L \); expression for the surface temperature \( T_s \) based upon a surface energy balance at \( x = L \); evaluate \( T_s \) and \( T(0) \) for the prescribed conditions; (c) Based upon typical daily averages for \( G_s \) and \( h \), compute and plot \( T_s \) and \( T(0) \) for (1) \( h = 5 \text{ W/m}^2\text{K} \) with \( 50 \leq G_s \leq 500 \text{ W/m}^2 \), (2) \( G_s = 400 \text{ W/m}^2 \) with \( 5 \leq h \leq 50 \text{ W/m}^2\text{K} \).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional conduction, (2) Uniform volumetric heat generation, (3) Constant properties, (4) Negligible irradiation from the surroundings, and (5) Steady-state conditions.

**PROPERTIES:** Table A.3, Coal (300K): \( k = 0.26 \text{ W/m.K} \)

**ANALYSIS:** (a) For one-dimensional, steady-state conduction with uniform volumetric heat generation and constant properties the heat diffusion equation (HDE) follows from Eq. 2.16,

\[
\frac{d}{dx} \left( \frac{d T}{dx} \right) + \frac{\dot{q}}{k} = 0
\]

Substituting the temperature distribution into the HDE, Eq. (1),

\[
T(x) = T_s + \frac{\dot{q} L^2}{2k} \left(1 - \frac{x^2}{L^2}\right)
\]

\[
\frac{d}{dx} \left[ 0 + \frac{\dot{q} L^2}{2k} \left(0 - \frac{2x}{L^2}\right) \right] + \frac{\dot{q}}{k} = 0
\]

we find that it does indeed satisfy the HDE for all values of \( x \).

From Eq. (2), note that the temperature distribution must be quadratic, with maximum value at \( x = 0 \). At \( x = 0 \), the heat flux is

\[
q^*_x (0) = -k \frac{dT}{dx} \bigg|_{x=0} = -k \left[ 0 + \frac{\dot{q} L^2}{2k} \left(0 - \frac{2x}{L^2}\right) \right] \bigg|_{x=0} = 0
\]

so that the gradient at \( x = 0 \) is zero. Hence, the bottom is insulated.

(b) From an overall energy balance on the pile, the conduction heat flux at the surface must be

\[
q^*_x (L) = \dot{E}^*_g = \dot{q} L
\]
PROBLEM 2.31 (Cont.)

From a surface energy balance per unit area shown in the Schematic above,

\[ 
\dot{E}_{in} - \dot{E}_{out} + \dot{E}_g = 0 \quad \text{and} \quad q_x^* (L) - q_{cv}^* + G_{S,abs} - E = 0 
\]

\[ 
\dot{q}L - h(T_s - T_\infty) + 0.95G_S - \varepsilon\sigma T_s^4 = 0 \tag{4} 
\]

\[ 
20 \text{ W/m}^2 \times 4 \text{ m} = 5 \text{ W/m}^2 \text{ K} \times (T_s - 298 \text{ K}) + 0.95 \times 400 \text{ W/m}^2 - 0.95 \times 5.67 \times 10^{-8} \text{ W/m}^2 \text{ K}^4 T_s^4 = 0 
\]

\[ 
T_s = 295.7 \text{ K} = 22.7^\circ \text{C} \] <

From Eq. (2) with \( x = 0 \), find

\[ 
T(0) = T_s + \frac{\dot{q}L^2}{2k} = 22.7^\circ \text{C} + \frac{30 \text{ W/m}^2 \times (1 \text{ m})^2}{2 \times 0.26 \text{ W/m} \cdot \text{K}} = 61.1^\circ \text{C} \tag{5} <
\]

where the thermal conductivity for coal was obtained from Table A.3.

(c) Two plots are generated using Eq. (4) and (5) for \( T_s \) and \( T(0) \), respectively: (1) with \( h = 5 \text{ W/m}^2 \cdot \text{K} \) for \( 50 \leq G_S \leq 500 \text{ W/m}^2 \) and (2) with \( G_s = 400 \text{ W/m}^2 \) for \( 5 \leq h \leq 50 \text{ W/m}^2 \cdot \text{K} \).

From the \( T \) vs. \( h \) plot with \( G_s = 400 \text{ W/m}^2 \), note that the convection coefficient does not have a major influence on the surface or bottom coal pile temperatures. From the \( T \) vs. \( G_s \) plot with \( h = 5 \text{ W/m}^2 \cdot \text{K} \), note that the solar irradiation has a very significant effect on the temperatures. The fact that \( T_s \) is less than the ambient air temperature, \( T_\infty \), and, in the case of very low values of \( G_s \), below freezing, is a consequence of the large magnitude of the emissive power \( E \).

**COMMENTS:** In our analysis we ignored irradiation from the sky, an environmental radiation effect you’ll consider in Chapter 12. Treated as large isothermal surroundings, \( G_{sky} = \sigma T_{sky}^4 \) where \( T_{sky} = -30^\circ \text{C} \) for very clear conditions and nearly air temperature for cloudy conditions. For low \( G_s \) conditions we should consider \( G_{sky} \), the effect of which will be to predict higher values for \( T_s \) and \( T(0) \).
**PROBLEM 2.32**

**KNOWN:** Cylindrical system with negligible temperature variation in the r,z directions.

**FIND:** (a) Heat equation beginning with a properly defined control volume, (b) Temperature distribution \( T(\phi) \) for steady-state conditions with no internal heat generation and constant properties, (c) Heat rate for Part (b) conditions.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) \( T \) is independent of \( r,z \), (2) \( \Delta r = (r_o - r_i) \ll r_i \).

**ANALYSIS:** (a) Define the control volume as \( V = r_i d\phi \Delta r \cdot L \) where \( L \) is length normal to page. Apply the conservation of energy requirement, Eq. 1.11a,

\[
\dot{E}_{in} - \dot{E}_{out} + \dot{E}_g = \dot{E}_{st} \quad q_\phi - q_{\phi+d\phi} + \dot{q}V = \rho V c \frac{\partial T}{\partial t} \tag{1,2}
\]

where \( q_\phi = -k(\Delta r \cdot L) \frac{\partial T}{r_i \partial \phi} \quad q_{\phi+d\phi} = q_\phi + \frac{\partial}{\partial \phi} (q_\phi) d\phi. \tag{3,4} \)

Eqs. (3) and (4) follow from Fourier’s law, Eq. 2.1, and from Eq. 2.7, respectively. Combining Eqs. (3) and (4) with Eq. (2) and canceling like terms, find

\[
\frac{1}{r_i^2} \frac{\partial}{\partial \phi} \left( k \frac{\partial T}{\partial \phi} \right) + \dot{q} = \rho c \frac{\partial T}{\partial t}. \tag{5} <
\]

Since temperature is independent of \( r \) and \( z \), this form agrees with Eq. 2.20.

(b) For steady-state conditions with \( \dot{q} = 0 \), the heat equation, (5), becomes

\[
\frac{d}{d\phi} \left[ k \frac{dT}{d\phi} \right] = 0. \tag{6}
\]

With constant properties, it follows that \( dT/d\phi \) is constant which implies \( T(\phi) \) is linear in \( \phi \). That is,

\[
\frac{dT}{d\phi} = \frac{T_2 - T_1}{\phi_2 - \phi_1} = \frac{1}{\pi} (T_2 - T_1) \quad \text{or} \quad T(\phi) = T_1 + \frac{1}{\pi} (T_2 - T_1) \phi. \tag{7,8} <
\]

(c) The heat rate for the conditions of Part (b) follows from Fourier’s law, Eq. (3), using the temperature gradient of Eq. (7). That is,

\[
q_\phi = -k(\Delta r \cdot L) \left[ \frac{1}{r_i} + \frac{1}{\pi} (T_2 - T_1) \right] = -k \left[ \frac{r_o - r_i}{\pi r_i^2} \right] L (T_2 - T_1). \tag{9} <
\]

**COMMENTS:** Note the expression for the temperature gradient in Fourier’s law, Eq. (3), is \( \partial T/r_i \partial \phi \) not \( \partial T/\partial \phi \). For the conditions of Parts (b) and (c), note that \( q_\phi \) is independent of \( \phi \); this is first indicated by Eq. (6) and confirmed by Eq. (9).
PROBLEM 2.33

KNOWN: Heat diffusion with internal heat generation for one-dimensional cylindrical, radial coordinate system.

FIND: Heat diffusion equation.

SCHEMATIC:

ASSUMPTIONS: (1) Homogeneous medium.

ANALYSIS: Control volume has volume, $V = A_r \cdot dr = 2\pi r \cdot dr \cdot 1$, with unit thickness normal to page. Using the conservation of energy requirement, Eq. 1.11a,

$$
\dot{E}_{in} - \dot{E}_{out} + \dot{E}_{gen} = \dot{E}_{st}
$$

$$
q_r - q_{r+dr} + \dot{q}V = \rho V c_p \frac{\partial T}{\partial t}.
$$

Fourier’s law, Eq. 2.1, for this one-dimensional coordinate system is

$$
q_r = -kA_r \frac{\partial T}{\partial r} = -k \times 2\pi r \times 1 \times \frac{\partial T}{\partial r}.
$$

At the outer surface, $r+dr$, the conduction rate is

$$
q_{r+dr} = q_r + \frac{\partial}{\partial r} (q_r)dr = q_r + \frac{\partial}{\partial r} \left[ -k \cdot 2\pi r \cdot \frac{\partial T}{\partial r} \right]dr.
$$

Hence, the energy balance becomes

$$
q_r - \left[ q_r + \frac{\partial}{\partial r} \left[ -k \cdot 2\pi r \cdot \frac{\partial T}{\partial r} \right]dr \right] + \dot{q} \cdot 2\pi rdr = \rho \cdot 2\pi rdr \cdot c_p \frac{\partial T}{\partial t}.
$$

Dividing by the factor $2\pi r \, dr$, we obtain

$$
\frac{1}{r} \frac{\partial}{\partial r} \left[ kr \frac{\partial T}{\partial r} \right] + \dot{q} = \rho c_p \frac{\partial T}{\partial t}.
$$

COMMENTS: (1) Note how the result compares with Eq. 2.20 when the terms for the $\phi, z$ coordinates are eliminated. (2) Recognize that we did not require $\dot{q}$ and $k$ to be independent of $r$. 
PROBLEM 2.34

KNOWN: Heat diffusion with internal heat generation for one-dimensional spherical, radial coordinate system.

FIND: Heat diffusion equation.

SCHEMATIC:

ASSUMPTIONS: (1) Homogeneous medium.

ANALYSIS: Control volume has the volume, \( V = A_r \cdot dr = 4\pi r^2 \cdot dr \). Using the conservation of energy requirement, Eq. 1.11a,

\[
\dot{E}_{\text{in}} - \dot{E}_{\text{out}} + \dot{E}_{\text{gen}} = \dot{E}_{\text{st}}
\]

\[
q_r - q_{r+dr} + \dot{q} V = \rho V c_p \frac{\partial T}{\partial t}.
\]

Fourier’s law, Eq. 2.1, for this coordinate system has the form

\[
q_r = -k A_r \frac{\partial T}{\partial r} = -k \cdot 4\pi r^2 \cdot \frac{\partial T}{\partial r}.
\]

At the outer surface, \( r+dr \), the conduction rate is

\[
q_{r+dr} = q_r + \frac{\partial}{\partial r} (q_r) dr = q_r + \frac{\partial}{\partial r} \left[ -k \cdot 4\pi r^2 \cdot \frac{\partial T}{\partial r} \right] dr.
\]

Hence, the energy balance becomes

\[
q_r = q_r + \frac{\partial}{\partial r} \left[ -k \cdot 4\pi r^2 \cdot \frac{\partial T}{\partial r} \right] dr + \dot{q} \cdot 4\pi r^2 dr = \rho c_p \frac{\partial T}{\partial t}.
\]

Dividing by the factor \( 4\pi r^2 dr \), we obtain

\[
\frac{1}{r^2} \frac{\partial}{\partial r} \left[ k r^2 \frac{\partial T}{\partial r} \right] + \dot{q} = \rho c_p \frac{\partial T}{\partial t}.
\] <

COMMENTS: (1) Note how the result compares with Eq. 2.23 when the terms for the \( \theta, \phi \) directions are eliminated.

(2) Recognize that we did not require \( \dot{q} \) and \( k \) to be independent of the coordinate \( r \).
**PROBLEM 2.35**

**KNOWN:** Three-dimensional system – described by cylindrical coordinates \((r, \phi, z)\) – experiences transient conduction and internal heat generation.

**FIND:** Heat diffusion equation.

**SCHEMATIC:** See also Fig. 2.9.

**ASSUMPTIONS:** (1) Homogeneous medium.

**ANALYSIS:** Consider the differential control volume identified above having a volume given as \(V = dr \cdot rd\phi \cdot dz\). From the conservation of energy requirement,

\[
q_r - q_r + dr + q_\phi - q_\phi + d\phi + q_z - q_z + dz + \dot{E}_g = \dot{E}_{st}.
\]

The generation and storage terms, both representing volumetric phenomena, are

\[
\dot{E}_g = \dot{q} V = \dot{q} (dr \cdot rd\phi \cdot dz) \quad \dot{E}_{st} = \rho \nu c \partial T / \partial t = \rho (dr \cdot rd\phi \cdot dz) c \partial T / \partial t.
\]

Using a Taylor series expansion, we can write

\[
q_{r+dr} = q_r + \frac{\partial}{\partial r} (q_r) dr, \quad q_{\phi+d\phi} = q_\phi + \frac{\partial}{\partial \phi} (q_\phi) d\phi, \quad q_{z+dz} = q_z + \frac{\partial}{\partial z} (q_z) dz.
\]

Using Fourier’s law, the expressions for the conduction heat rates are

\[
q_r = -kA_r \partial T / \partial r = -k (rd\phi \cdot dz) \partial T / \partial r
\]

\[
q_\phi = -kA_\phi \partial T / \partial \phi = -k (dr \cdot dz) \partial T / \partial \phi
\]

\[
q_z = -kA_z \partial T / \partial z = -k (dr \cdot rd\phi) \partial T / \partial z.
\]

Note from the above, right schematic that the gradient in the \(\phi\)-direction is \(\partial T / \partial \phi\) and not \(\partial T / \partial \phi\). Substituting Eqs. (2), (3) and (4), (5), (6) into Eq. (1),

\[
-\frac{\partial}{\partial r} (q_r) dr - \frac{\partial}{\partial \phi} (q_\phi) d\phi - \frac{\partial}{\partial z} (q_z) dz + \dot{q} dr \cdot rd\phi \cdot dz = \rho (dr \cdot rd\phi \cdot dz) c \frac{\partial T}{\partial t}.
\]

Substituting Eqs. (7), (8) and (9) for the conduction rates, find

\[
-\frac{\partial}{\partial r} \left[ -k (rd\phi \cdot dz) \frac{\partial T}{\partial r} \right] dr - \frac{\partial}{\partial \phi} \left[ -k (drdz) \frac{\partial T}{\partial \phi} \right] d\phi - \frac{\partial}{\partial z} \left[ -k (dr \cdot rd\phi) \frac{\partial T}{\partial z} \right] dz + \dot{q} dr \cdot rd\phi \cdot dz = \rho (dr \cdot rd\phi \cdot dz) c \frac{\partial T}{\partial t}.
\]

Dividing Eq. (11) by the volume of the CV, Eq. 2.20 is obtained.

\[
\frac{1}{r} \frac{\partial}{\partial r} \left[ kr \frac{\partial T}{\partial r} \right] + \frac{1}{r^2} \frac{\partial}{\partial \phi} \left[ k \frac{\partial T}{\partial \phi} \right] + \frac{\partial}{\partial z} \left[ k \frac{\partial T}{\partial z} \right] + \dot{q} = \rho c \frac{\partial T}{\partial t}
\]
**PROBLEM 2.36**

**KNOWN:** Three-dimensional system – described by cylindrical coordinates \((r, \phi, \theta)\) – experiences transient conduction and internal heat generation.

**FIND:** Heat diffusion equation.

**SCHEMATIC:** See Figure 2.10.

**ASSUMPTIONS:** (1) Homogeneous medium.

**ANALYSIS:** The differential control volume is \(V = dr \cdot r \sin \theta d\phi \cdot r d\theta\), and the conduction terms are identified in Figure 2.10. Conservation of energy requires

\[
q_r - q_r + dr + q_\phi - q_\phi + d\phi + q_\theta - q_\theta + d\theta + \dot{E}_g = \dot{E}_{st}.
\]  
(1)

The generation and storage terms, both representing volumetric phenomena, are

\[
\dot{E}_g = \dot{q}V = \dot{q}[dr \cdot r \sin \theta d\phi \cdot r d\theta], \quad \dot{E}_{st} = \rho V c \frac{\partial T}{\partial t} = \rho [dr \cdot r \sin \theta d\phi \cdot r d\theta] c \frac{\partial T}{\partial t}.
\]  
(2,3)

Using a Taylor series expansion, we can write

\[
q_r + dr = q_r + \frac{\partial}{\partial r}(q_r)dr, \quad q_\phi + d\phi = q_\phi + \frac{\partial}{\partial \phi}(q_\phi)d\phi, \quad q_\theta + d\theta = q_\theta + \frac{\partial}{\partial \theta}(q_\theta)d\theta.
\]  
(4,5,6)

From Fourier’s law, the conduction heat rates have the following forms.

\[
q_r = -kA_r \frac{\partial T}{\partial r} = -k[dr \cdot r \sin \theta d\phi \cdot r d\theta] \frac{\partial T}{\partial r}
\]  
(7)

\[
q_\phi = -kA_\phi \frac{\partial T}{r \sin \theta \partial \phi} = -k[dr \cdot r d\theta] \frac{\partial T}{r \sin \theta \partial \phi}
\]  
(8)

\[
q_\theta = -kA_\theta \frac{\partial T}{r \partial \theta} = -k[dr \cdot r \sin \theta d\phi] \frac{\partial T}{r \partial \theta}.
\]  
(9)

Substituting Eqs. (2), (3) and (4), (5), (6) into Eq. (1), the energy balance becomes

\[
-\frac{\partial}{\partial r}(q_r)dr - \frac{\partial}{\partial \phi}(q_\phi)d\phi - \frac{\partial}{\partial \theta}(q_\theta)d\theta + \dot{q}[dr \cdot r \sin \theta d\phi \cdot r d\theta] = \rho [dr \cdot r \sin \theta d\phi \cdot r d\theta] c \frac{\partial T}{\partial t}.
\]  
(10)

Substituting Eqs. (7), (8) and (9) for the conduction rates, find

\[
-\frac{\partial}{\partial \theta} \left[ -k[dr \cdot r \sin \theta d\phi] \frac{\partial T}{r \partial \theta} \right] d\theta + \dot{q}[dr \cdot r \sin \theta d\phi \cdot r d\theta] = \rho [dr \cdot r \sin \theta d\phi \cdot r d\theta] c \frac{\partial T}{\partial t}.
\]  
(11)

Dividing Eq. (11) by the volume of the control volume, \(V\), Eq. 2.23 is obtained.

\[
\frac{1}{r^2 \frac{\partial}{\partial r}} \left[ kr^2 \frac{\partial T}{\partial r} \right] + \frac{1}{r^2 \sin^2 \theta \frac{\partial}{\partial \phi}} \left[ k \frac{\partial T}{\partial \phi} \right] + \frac{1}{r^2 \sin \theta \frac{\partial}{\partial \theta}} \left[ k \sin \theta \frac{\partial T}{\partial \theta} \right] + \dot{q} = \rho c \frac{\partial T}{\partial t}.
\]

**COMMENTS:** Note how the temperature gradients in Eqs. (7) - (9) are formulated. The numerator is always \(\partial T\) while the denominator is the dimension of the control volume in the specified coordinate direction.
PROBLEM 2.37

KNOWN: Temperature distribution in steam pipe insulation.

FIND: Whether conditions are steady-state or transient. Manner in which heat flux and heat rate vary with radius.

SCHEMATIC:

\[ T(r) = C_1 \ln \frac{r}{r_0} + C_2 \]

ASSUMPTIONS: (1) One-dimensional conduction in r, (2) Constant properties.

ANALYSIS: From Equation 2.20, the heat equation reduces to

\[
\frac{1}{r} \frac{\partial}{\partial r} \left( r \frac{\partial T}{\partial r} \right) = \frac{1}{\alpha} \frac{\partial T}{\partial t}.
\]

Substituting for \( T(r) \),

\[
\frac{1}{\alpha} \frac{\partial T}{\partial t} = \frac{1}{r} \frac{\partial}{\partial r} \left( r \frac{C_1}{r} \right) = 0.
\]

Hence, steady-state conditions exist.

From Equation 2.19, the radial component of the heat flux is

\[ q_r'' = -k \frac{\partial T}{\partial r} = -k \frac{C_1}{r}. \]

Hence, \( q_r'' \) decreases with increasing \( r/\alpha 1/r \).

At any radial location, the heat rate is

\[ q_r = 2\pi L q_r'' = -2\pi k C_1 L \]

Hence, \( q_r \) is independent of \( r \).

COMMENTS: The requirement that \( q_r \) is invariant with \( r \) is consistent with the energy conservation requirement. If \( q_r \) is constant, the flux must vary inversely with the area perpendicular to the direction of heat flow. Hence, \( q_r'' \) varies inversely with \( r \).
PROBLEM 2.38

KNOWN: Inner and outer radii and surface temperatures of a long circular tube with internal energy generation.

FIND: Conditions for which a linear radial temperature distribution may be maintained.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, steady-state conduction, (2) Constant properties.

ANALYSIS: For the assumed conditions, Eq. 2.20 reduces to

\[
\frac{k}{r} \frac{d}{dr} \left( r \frac{dT}{dr} \right) + \dot{q} = 0
\]

If \( \dot{q} = 0 \) or \( \dot{q} = \text{constant} \), it is clearly impossible to have a linear radial temperature distribution. However, we may use the heat equation to infer a special form of \( \dot{q}(r) \) for which \( dT/dr \) is a constant (call it \( C_1 \)). It follows that

\[
\frac{k}{r} \frac{d}{dr} (rC_1) + \dot{q} = 0
\]

\[
\dot{q} = -\frac{C_1 k}{r}
\]

where \( C_1 = (T_2 - T_1)/(r_2 - r_1) \). Hence, if the generation rate varies inversely with radial location, the radial temperature distribution is linear.

COMMENTS: Conditions for which \( \dot{q} \propto (1/r) \) would be unusual.
PROBLEM 2.39

KNOWN: Radii and thermal conductivity of conducting rod and cladding material. Volumetric rate of thermal energy generation in the rod. Convection conditions at outer surface.

FIND: Heat equations and boundary conditions for rod and cladding.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in r, (3) Constant properties.

ANALYSIS: From Equation 2.20, the appropriate forms of the heat equation are

Conducting Rod:

\[
\frac{k_r}{r} \frac{d}{dr} \left( r \frac{dT_r}{dr} \right) + \dot{q} = 0
\]

Cladding:

\[
\frac{d}{dr} \left( r \frac{dT_c}{dr} \right) = 0.
\]

Appropriate boundary conditions are:

(a) \( \frac{dT_r}{dr} \big|_{r=r_i} = 0 \)

(b) \( T_r(r_i) = T_c(r_i) \)

(c) \( k_r \frac{dT_r}{dr} \big|_{r=r_i} = k_c \frac{dT_c}{dr} \big|_{r=r_i} \)

(d) \( k_c \frac{dT_c}{dr} \big|_{r=r_o} = h[T_c(r_o) - T_\infty] \)

COMMENTS: Condition (a) corresponds to symmetry at the centerline, while the interface conditions at \( r = r_i \) (b,c) correspond to requirements of thermal equilibrium and conservation of energy. Condition (d) results from conservation of energy at the outer surface.
PROBLEM 2.40

KNOWN: Steady-state temperature distribution for hollow cylindrical solid with volumetric heat generation.

FIND: (a) Determine the inner radius of the cylinder, \( r_i \), (b) Obtain an expression for the volumetric rate of heat generation, \( \dot{q} \), (c) Determine the axial distribution of the heat flux at the outer surface, \( q_r^* \), and the heat rate at this outer surface; is the heat rate in or out of the cylinder; (d) Determine the radial distribution of the heat flux at the end faces of the cylinder, \( q_z^* \), and the corresponding heat rates; are the heat rates in or out of the cylinder; (e) Determine the relationship of the surface heat rates to the heat generation rate; is an overall energy balance satisfied?

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction with constant properties and volumetric heat generation.

ANALYSIS: (a) Since the inner boundary, \( r = r_i \), is adiabatic, then \( q_r^* (r_i, z) = 0 \). Hence the temperature gradient in the \( r \)-direction must be zero.

\[
\frac{\partial T}{\partial r} \bigg|_{r_i} = 0 + 2b r_i + c / r_i + 0 = 0
\]

\[ r_i = \left( -\frac{c}{2b} \right)^{1/2} = \left( -\frac{-12^\circ C}{2 \times 150^\circ C / m^2} \right)^{1/2} = 0.2 \text{ m} \]

(b) To determine \( \dot{q} \), substitute the temperature distribution into the heat diffusion equation, Eq. 2.20, for two-dimensional \((r,z)\), steady-state conduction

\[
\frac{1}{r} \frac{\partial}{\partial r} \left( r \frac{\partial T}{\partial r} \right) + \frac{\partial^2 T}{\partial z^2} + \frac{\dot{q}}{k} = 0
\]

\[
\frac{1}{r} \left[ 4b r + 0 \right] + 2d + \frac{\dot{q}}{k} = 0
\]

\[
\dot{q} = -k \left[ 4b r - 2d \right] = -16 \text{ W} / \text{m} \cdot \text{K} \left[ 4 \times 150^\circ C / m^2 - 2 \left( -300^\circ C / m^2 \right) \right]
\]

\[
\dot{q} = 0 \text{ W} / \text{m}^3
\]

(c) The heat flux and the heat rate at the outer surface, \( r = r_o \), may be calculated using Fourier’s law. Note that the sign of the heat flux in the positive \( r \)-direction is negative, and hence the heat flow is into the cylinder.

\[
q_r^* (r_o, z) = -k \frac{\partial T}{\partial r} \bigg|_{r_o} = -k \left[ 0 + 2b r_o + c / r_o + 0 \right]
\]

Continued …..
PROBLEM 2.40 (Cont.)

\[ q_r(r_0, z) = -16 \text{ W/m·K} \left[ 2 \times 150^\circ \text{C/m}^2 \times 1 \text{ m} - 12^\circ \text{C/1 m} \right] = -4608 \text{ W/m}^2 \]

\[ q_r(r_0) = A_r q_r(r_0, z) \quad \text{where} \quad A_r = 2\pi r_0 (2z_0) \]

\[ q_r(r_0) = -4\pi \times 1 \text{ m} \times 2.5 \text{ m} \times 4608 \text{ W/m}^2 = -144,765 \text{ W} \]

(d) The heat fluxes and the heat rates at end faces, \( z = +z_o \) and \(-z_o \), may be calculated using Fourier's law. The direction of the heat rate in or out of the end face is determined by the sign of the heat flux in the positive \( z \)-direction.

**At the upper end face, \( z = +z_o \):** heat rate is out of the cylinder

\[ q_z(r, +z_o) = -k \frac{\partial T}{\partial z} \bigg|_{+z_o} = -k \left[ 0 + 0 + 2dz_o \right] \]

\[ q_z(r, +z_o) = -16 \text{ W/m·K} \left( -300^\circ \text{C/m}^2 \right) 2.5 \text{ m} = +24,000 \text{ W/m}^2 \]

\[ q_z(+z_o) = A_z q_z(r, +z_o) \quad \text{where} \quad A_z = \pi \left( r_o^2 - r_i^2 \right) \]

\[ q_z(+z_o) = \pi \left( 1^2 - 0.2^2 \right) \text{ m}^2 \times 24,000 \text{ W/m}^2 = +72,382 \text{ W} \]

**At the lower end face, \( z = -z_o \):** heat rate is out of the cylinder

\[ q_z(r, -z_o) = -k \frac{\partial T}{\partial z} \bigg|_{-z_o} = -k \left[ 0 + 0 + 2dz_o \right] \]

\[ q_z(r, -z_o) = -16 \text{ W/m·K} \left( -300^\circ \text{C/m}^2 \right) (-2.5 \text{ m}) = -24,000 \text{ W/m}^2 \]

\[ q_z(-z_o) = -72,382 \text{ W} \]

(e) The heat rates from the surfaces and the volumetric heat generation can be related through an overall energy balance on the cylinder as shown in the sketch.

\[ \dot{E}_{in} - \dot{E}_{out} + \dot{E}_{gen} = 0 \quad \text{where} \quad \dot{E}_{gen} = \dot{q} \forall = 0 \]

\[ \dot{E}_{in} = -q_r(r_0) = -(-144,765 \text{ W}) = +144,765 \text{ W} \]

\[ \dot{E}_{out} = +q_z(-z_o) - q_z(z_o) = \left[ 72,382 - (-72,382) \right] \text{ W} = +144,764 \text{ W} \]

The overall energy balance is satisfied.

**COMMENTS:** When using Fourier’s law, the heat flux \( q_z \) denotes the heat flux in the positive \( z \)-direction. At a boundary, the sign of the numerical value will determine whether heat is flowing into or out of the boundary.
PROBLEM 2.41

KNOWN: An electric cable with an insulating sleeve experiences convection with adjoining air and radiation exchange with large surroundings.

FIND: (a) Verify that prescribed temperature distributions for the cable and insulating sleeve satisfy their appropriate heat diffusion equations; sketch temperature distributions labeling key features; (b) Applying Fourier’s law, verify the conduction heat rate expression for the sleeve, \( q_{r,1}' \), in terms of \( T_{s,1} \) and \( T_{s,2} \); apply a surface energy balance to the cable to obtain an alternative expression for \( q_{r,1}' \) in terms of \( \dot{q} \) and \( r_1 \); (c) Apply surface energy balance around the outer surface of the sleeve to obtain an expression for which \( T_{s,2} \) can be evaluated; (d) Determine \( T_{s,1}, T_{s,2}, \) and \( T_o \) for the specified geometry and operating conditions; and (e) Plot \( T_{s,1}, T_{s,2}, \) and \( T_o \) as a function of the outer radius for the range 15.5 ≤ \( r_2 \) ≤ 20 mm.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, radial conduction, (2) Uniform volumetric heat generation in cable, (3) Negligible thermal contact resistance between the cable and sleeve, (4) Constant properties in cable and sleeve, (5) Surroundings large compared to the sleeve, and (6) Steady-state conditions.

ANALYSIS: (a) The appropriate forms of the heat diffusion equation (HDE) for the insulation and cable are identified. The temperature distributions are valid if they satisfy the relevant HDE.

Insulation: The temperature distribution is given as

\[
T(r) = T_{s,2} + \left( T_{s,1} - T_{s,2} \right) \frac{\ln(r/r_2)}{\ln(\eta_1/r_2)}
\]

and the appropriate HDE (radial coordinates, SS, \( \dot{q} = 0 \)), Eq. 2.20,

\[
\frac{d}{dr} \left( r \frac{dT}{dr} \right) = 0
\]

\[
\frac{d}{dr} \left[ r \left( T_{s,1} - T_{s,2} \right) \frac{1}{\ln(\eta_1/r_2)} \right] = \frac{d}{dr} \left( \frac{T_{s,1} - T_{s,2}}{\ln(\eta_1/r_2)} \right) = 0
\]

Hence, the temperature distribution satisfies the HDE.

Cable: The temperature distribution is given as

\[
T(r) = T_{s,1} + \frac{\dot{q} r_1^2}{4k_c} \left( 1 - \frac{r^2}{r_1^2} \right)
\]

and the appropriate HDE (radial coordinates, SS, \( \dot{q} \) uniform), Eq. 2.20,

Continued...
PROBLEM 2.41 (Cont.)

\[
\frac{1}{r} \frac{d}{dr} \left( r \frac{dT}{dr} \right) + \frac{\dot{q}}{k_c} = 0
\]

\[
\frac{1}{r} \frac{d}{dr} \left( r \left[ \frac{\dot{q} \eta^2}{4k_c} \left( 0 - \frac{2r}{\eta^2} \right) \right] \right) + \frac{\dot{q}}{k_c} = 0
\]

\[
\frac{1}{r} \left( \frac{\dot{q} \eta^2}{4k_c} \frac{2r^2}{\eta^2} \right) + \frac{\dot{q}}{k_c} = 0
\]

\[
\frac{1}{r} \left( \frac{\dot{q} \eta^2}{4k_c} \frac{4r}{\eta^2} \right) + \frac{\dot{q}}{k_c} = 0
\]

Hence the temperature distribution satisfies the HDE.

The temperature distributions in the cable, \(0 \leq r \leq r_1\), and sleeve, \(r_1 \leq r \leq r_2\), and their key features are as follows:

1. Zero gradient, symmetry condition,
2. Increasing gradient with increasing radius, \(r\), because of \(\dot{q}\),
3. Discontinuous \(T(r)\) across cable-sleeve interface because of different thermal conductivities,
4. Decreasing gradient with increasing radius, \(r\), since heat rate is constant.

(b) Using Fourier’s law for the radial-cylindrical coordinate, the heat rate through the insulation (sleeve) per unit length is

\[
q'_r = -kA_r \frac{dT}{dr} = -k2\pi r \frac{dT}{dr}
\]

and substituting for the temperature distribution, Eq. (1),

\[
q'_r = -k_s 2\pi r \left[ 0 + \left( T_{s,1} - T_{s,2} \right) \frac{1/r}{\ln (\eta/r_2)} \right] = 2\pi k_s \frac{\left( T_{s,1} - T_{s,2} \right)}{\ln (r_2/\eta)}
\]

Applying an energy balance to a control surface placed around the cable,

\[
\dot{E}_{in} - \dot{E}_{out} = q'_r + \dot{q}'_{\text{c}} - q'_r = 0
\]

where \(\dot{q}'_{\text{c}}\) represents the dissipated electrical power in the cable

Continued...
PROBLEM 2.41 (Cont.)

\[ \dot{q} \left( \pi \eta^2 \right) - q_r' = 0 \quad \text{or} \quad q_r' = \pi \dot{q} \eta^2 \quad (4) \]

(c) Applying an energy balance to a control surface placed around the outer surface of the sleeve,

\[ \dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0 \]

\[ q_r' - q_{cv}' - q_{rad}' = 0 \]

\[ \pi \dot{q} \eta^2 - h \left( 2\pi r_2 \right) \left( T_{s,2} - T_{\infty} \right) - \varepsilon \left( 2\pi r_2 \right) \sigma \left( T_{s,2}^4 - T_{\text{sur}}^4 \right) = 0 \quad (5) \]

This relation can be used to determine \( T_{s,2} \) in terms of the variables \( \dot{q} \), \( r_1 \), \( r_2 \), \( h \), \( T_{\infty} \), \( \varepsilon \) and \( T_{\text{sur}} \).

(d) Consider a cable-sleeve system with the following prescribed conditions:

\begin{align*}
 r_1 & = 15 \text{ mm} & k_c & = 200 \text{ W/m-K} & h & = 25 \text{ W/m}^2\text{K} & \varepsilon & = 0.9 \\
 r_2 & = 15.5 \text{ mm} & k_s & = 0.15 \text{ W/m-K} & T_{\infty} & = 25^\circ \text{C} & T_{\text{sur}} & = 35^\circ \text{C}
\end{align*}

For 250 A with \( R'_c = 0.005 \Omega/\text{m} \), the volumetric heat generation rate is

\[ \dot{q} = I^2 R'_c \pi^2 / \pi^2 = I^2 R'_c \pi^2 = (250 \text{ A})^2 \times 0.005 \Omega/\text{m} \times \pi \times 0.015^2 \text{ m}^2 = 4.42 \times 10^5 \text{ W/m}^3 \]

Substituting numerical values in appropriate equations, we can evaluate \( T_{s,1} \), \( T_{s,2} \) and \( T_{o} \).

**Sleeve outer surface temperature, \( T_{s,2} \):** Using Eq. (5),

\[ \pi \times 4.42 \times 10^5 \text{ W/m}^3 \times (0.015 \text{ m})^2 - 25 \text{ W/m}^2\cdot\text{K} \times (2\pi \times 0.0155 \text{ m}) \left( T_{s,2} - 298 \text{K} \right) \\
-0.9 \times (2\pi \times 0.0155 \text{ m}) \times 5.67 \times 10^{-8} \text{ W/m}^2\cdot\text{K} \times K^4 \left( T_{s,2}^4 - 308^4 \right) K^4 = 0 \\
T_{s,2} = 395 \text{ K} = 122^\circ \text{C} \]

**Sleeve-cable interface temperature, \( T_{s,1} \):** Using Eqs. (3) and (4), with \( T_{s,2} = 395 \text{ K} , \\
\pi \dot{q} \eta^2 = 2\pi k_s \frac{\left( T_{s,1} - T_{s,2} \right)}{\ln \left( r_2 / \eta \right)} \\
\pi \times 4.42 \times 10^5 \text{ W/m}^3 \times (0.015 \text{ m})^2 = 2\pi \times 0.15 \text{ W/m-K} \times \left( T_{s,1} - 395 \text{ K} \right) \ln \left( 15.5/15.0 \right) \\
T_{s,1} = 406 \text{ K} = 133^\circ \text{C} \]

Continued...
PROBLEM 2.41 (Cont.)

Cable centerline temperature, $T_o$: Using Eq. (2) with $T_{s,1} = 133^\circ$C,

$$T_o = T(0) = T_{s,1} + \frac{4q^2}{4k_c}$$

$$T_o = 133^\circ$C + $4.42 \times 10^5$ W/m$^3 \times (0.015$ m$)^2 / (4 \times 200$ W/m$ \cdot$ K) = 133.1$°C 

(e) With all other conditions remaining the same, the relations of part (d) can be used to calculate $T_o$, $T_{s,1}$ and $T_{s,2}$ as a function of the sleeve outer radius $r_2$ for the range $15.5 \leq r_2 \leq 20$ mm.

On the plot above $T_o$ would show the same behavior as $T_{s,1}$ since the temperature rise between cable center and its surface is 0.12°C. With increasing $r_2$, we expect $T_{s,2}$ to decrease since the heat flux decreases with increasing $r_2$. We expect $T_{s,1}$ to increase with increasing $r_2$ since the thermal resistance of the sleeve increases.
PROBLEM 2.42

KNOWN: Temperature distribution in a spherical shell.

FIND: Whether conditions are steady-state or transient. Manner in which heat flux and heat rate vary with radius.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in r, (2) Constant properties.

ANALYSIS: From Equation 2.23, the heat equation reduces to

\[ \frac{1}{r^2} \frac{\partial}{\partial r} \left( r^2 \frac{\partial T}{\partial r} \right) = \frac{1}{\alpha} \frac{\partial T}{\partial t} \]

Substituting for \( T(r) \),

\[ \frac{1}{\alpha} \frac{\partial T}{\partial t} = - \frac{1}{r^2} \frac{\partial}{\partial r} \left( r^2 \frac{C_1}{r^2} \right) = 0. \]

Hence, steady-state conditions exist.

From Equation 2.22, the radial component of the heat flux is

\[ q_r'' = -k \frac{\partial T}{\partial r} = -k \frac{C_1}{r^2}. \]

Hence, \( q_r'' \) decreases with increasing \( r^2(q_r'' \propto 1/r^2) \).

At any radial location, the heat rate is

\[ q_r = 4\pi r^2 q_r'' = 4\pi k C_1. \]

Hence, \( q_r \) is independent of \( r \).

COMMENTS: The fact that \( q_r \) is independent of \( r \) is consistent with the energy conservation requirement. If \( q_r \) is constant, the flux must vary inversely with the area perpendicular to the direction of heat flow. Hence, \( q_r'' \) varies inversely with \( r^2 \).
PROBLEM 2.43

KNOWN: Spherical container with an exothermic reaction enclosed by an insulating material whose outer surface experiences convection with adjoining air and radiation exchange with large surroundings.

FIND: (a) Verify that the prescribed temperature distribution for the insulation satisfies the appropriate form of the heat diffusion equation; sketch the temperature distribution and label key features; (b) Applying Fourier's law, verify the conduction heat rate expression for the insulation layer, \( q_r \), in terms of \( T_{s,1} \) and \( T_{s,2} \); apply a surface energy balance to the container and obtain an alternative expression for \( q_r \) in terms of \( \dot{q} \) and \( r_1 \); (c) Apply a surface energy balance around the outer surface of the insulation to obtain an expression to evaluate \( T_{s,2} \); (d) Determine \( T_{s,2} \) for the specified geometry and operating conditions; (e) Compute and plot the variation of \( T_{s,2} \) as a function of the outer radius for the range \( 201 \leq r_2 \leq 210 \) mm; explore approaches for reducing \( T_{s,2} \leq 45^\circ \)C to eliminate potential risk for burn injuries to personnel.

SCHEMATIC: 

ASSUMPTIONS: (1) One-dimensional, radial spherical conduction, (2) Isothermal reaction in container so that \( T_o = T_{s,1} \), (3) Negligible thermal contact resistance between the container and insulation, (3) Constant properties in the insulation, (4) Surroundings large compared to the insulated vessel, and (5) Steady-state conditions.

ANALYSIS: The appropriate form of the heat diffusion equation (HDE) for the insulation follows from Eq. 2.23,

\[
\frac{1}{r^2} \frac{d}{dr} \left( r^2 \frac{dT}{dr} \right) = 0
\]  

(1) <

The temperature distribution is given as

\[
T(r) = T_{s,1} - \left( T_{s,1} - T_{s,2} \right) \left[ \frac{1 - \left( \eta_1/r \right)}{1 - \left( \eta_1/r_2 \right)} \right]
\]  

(2)

Substitute \( T(r) \) into the HDE to see if it is satisfied:

\[
\frac{1}{r^2} \frac{d}{dr} \left( r^2 \left[ 0 - \left( T_{s,1} - T_{s,2} \right) \frac{0 + \left( \eta_1/r^2 \right)}{1 - \left( \eta_1/r_2 \right)} \right] \right) = 0
\]

\[
\frac{1}{r^2} \frac{d}{dr} \left( + \left( T_{s,1} - T_{s,2} \right) \frac{\eta_1}{1 - \left( \eta_1/r_2 \right)} \right) = 0
\]

<

and since the expression in parenthesis is independent of \( r \), \( T(r) \) does indeed satisfy the HDE. The temperature distribution in the insulation and its key features are as follows:

Continued...
PROBLEM 2.43 (Cont.)

(1) \( T_{s,1} > T_{s,2} \)

(2) Decreasing gradient with increasing radius, \( r \), since the heat rate is constant through the insulation.

(b) Using Fourier’s law for the radial-spherical coordinate, the heat rate through the insulation is

\[
q_r = -kA_r \frac{dT}{dr} = -k \left( 4\pi r^2 \right) \frac{dT}{dr}
\]

and substituting for the temperature distribution, Eq. (2),

\[
q_r = -k\pi r^2 \left[ 0 - \left( T_{s,1} - T_{s,2} \right) \frac{0 + \left( \eta_1 / r^2 \right)}{1 - \left( \eta_1 / r_2 \right)} \right]
\]

\[
q_r = \frac{4\pi k \left( T_{s,1} - T_{s,2} \right)}{1/\eta_1 - 1/\eta_2}
\]

(3) Applying an energy balance to a control surface about the container at \( r = r_1 \),

\[
\dot{E}_{in} - \dot{E}_{out} = 0
\]

\[
\dot{q} \text{\forall} - q_r = 0
\]

where \( \dot{q} \text{\forall} \) represents the generated heat in the container,

\[
q_r = \left( \frac{4}{3} \right) \pi \eta_1^3 \dot{q}
\]

(4) Applying an energy balance to a control surface placed around the outer surface of the insulation,

\[
\dot{E}_{in} - \dot{E}_{out} = 0
\]

\[
q_r - q_{cv} - q_{rad} = 0
\]

\[
q_r - hA_s \left( T_{s,2} - T_\infty \right) - \varepsilon A_s \sigma \left( T_{s,2}^4 - T_{sur}^4 \right) = 0
\]

(5) Continued...
PROBLEM 2.43 (Cont.)

where

\[ A_s = 4\pi r_2^2 \]  

(6)

These relations can be used to determine \( T_{s,2} \) in terms of the variables \( \dot{q}, r_1, r_2, h, T_\infty, \varepsilon \) and \( T_{\text{sur}} \).

(d) Consider the reactor system operating under the following conditions:

\[
\begin{align*}
r_1 &= 200 \text{ mm} & h &= 5 \text{ W/m}^2\cdot\text{K} \\
r_2 &= 208 \text{ mm} & T_\infty &= 25^\circ\text{C} \\
k &= 0.05 \text{ W/m} \cdot \text{K} & T_{\text{sur}} &= 35^\circ\text{C} \\
\end{align*}
\]

The heat generated by the exothermic reaction provides for a volumetric heat generation rate,

\[ \dot{q} = \dot{q}_0 \exp \left( -A/T_0 \right) \quad \dot{q}_0 = 5000 \text{ W/m}^3 \quad A = 75 \text{ K} \]  

(7)

where the temperature of the reaction is that of the inner surface of the insulation, \( T_o = T_{s,1} \). The following system of equations will determine the operating conditions for the reactor.

**Conduction rate equation, insulation, Eq. (3),**

\[ q_r = \frac{4\pi \times 0.05 \text{ W/m} \cdot \text{K} \left( T_{s,1} - T_{s,2} \right)}{(1/0.200 \text{ m} - 1/0.208 \text{ m})} \]  

(8)

**Heat generated in the reactor, Eqs. (4) and (7),**

\[ q_r = \frac{4/3 \pi \left( 0.200 \text{ m} \right)^3 \dot{q}}{} \]  

(9)

\[ \dot{q} = 5000 \text{ W/m}^3 \exp \left( -75 \text{ K}/T_{s,1} \right) \]  

(10)

**Surface energy balance, insulation, Eqs. (5) and (6),**

\[ q_r - 5 \text{ W/m}^2 \cdot \text{K} A_s \left( T_{s,2} - 298 \text{ K} \right) - 0.9 A_s 5.67 \times 10^{-8} \text{ J/m}^2 \cdot \text{K}^4 \left( T_{s,2}^4 - (308 \text{ K})^4 \right) = 0 \]  

(11)

\[ A_s = 4\pi \left( 0.208 \text{ m} \right)^2 \]  

(12)

Solving these equations simultaneously, find that

\[ T_{s,1} = 94.3^\circ\text{C} \quad T_{s,2} = 52.5^\circ\text{C} \]  

That is, the reactor will be operating at \( T_o = T_{s,1} = 94.3^\circ\text{C} \), very close to the desired 95°C operating condition.

(e) From the above analysis, we found the outer surface temperature \( T_{s,2} = 52.5^\circ\text{C} \) represents a potential burn risk to plant personnel. Using the above system of equations, Eqs. (8)-(12), we have explored the effects of changes in the convection coefficient, \( h \), and the insulation thermal conductivity, \( k \), as a function of insulation thickness, \( t = r_2 - r_1 \).
In the $T_{s,2}$ vs. $(r_2 - r_1)$ plot, note that decreasing the thermal conductivity from 0.05 to 0.01 W/m·K slightly increases $T_{s,2}$ while increasing the convection coefficient from 5 to 15 W/m²·K markedly decreases $T_{s,2}$. Insulation thickness only has a minor effect on $T_{s,2}$ for either option. In the $T_o$ vs. $(r_2 - r_1)$ plot, note that, for all the options, the effect of increased insulation is to increase the reaction temperature. With $k = 0.01$ W/m·K, the reaction temperature increases beyond 95°C with less than 2 mm insulation. For the case with $h = 15$ W/m²·K, the reaction temperature begins to approach 95°C with insulation thickness around 10 mm. We conclude that by selecting the proper insulation thickness and controlling the convection coefficient, the reaction could be operated around 95°C such that the outer surface temperature would not exceed 45°C.
PROBLEM 2.44

KNOWN: One-dimensional system, initially at a uniform temperature $T_i$, is suddenly exposed to a uniform heat flux at one boundary, while the other boundary is insulated.

FIND: (a) Proper form of heat equation and boundary and initial conditions, (b) Temperature distributions for following conditions: initial condition ($t \leq 0$), and several times after heater is energized; will a steady-state condition be reached; (c) Heat flux at $x = 0$, $L/2$, $L$ as a function of time; (d) Expression for uniform temperature, $T_f$, reached after heater has been switched off following an elapsed time, $t_c$, with the heater on.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) No internal heat generation, (3) Constant properties.

ANALYSIS: (a) The appropriate form of the heat equation follows from Eq. 2.15. Also, the appropriate boundary and initial conditions are:

Initial condition: $T(x,0) = T_i$      Uniform temperature

$$\frac{\partial^2 T}{\partial x^2} = \frac{1}{\alpha} \frac{\partial T}{\partial t}$$

Boundary conditions:

$x = 0$ \quad $q_o'' = -k \frac{\partial T}{\partial x}{0}$

$x = L$ \quad $\frac{\partial T}{\partial x}{L} = 0$

(b) The temperature distributions are as follows:

No steady-state condition will be reached since $\dot{E}_{in} = \dot{E}_{st}$ and $\dot{E}_{in}$ is constant.

(c) The heat flux as a function of time for positions $x = 0$, $L/2$ and $L$ is as follows:

(d) If the heater is energized until $t = t_c$ and then switched off, the system will eventually reach a uniform temperature, $T_f$. Perform an energy balance on the system, Eq. 1.11b, for an interval of time $\Delta t = t_c$.

$$E_{in} = E_{st} \quad E_{in} = Q_{in} = \int_0^{t_c} q_o''A_s dt = q_o''A_s t_c \quad E_{st} = Mc(T_f - T_i)$$

It follows that $q_o''A_s t_c = Mc(T_f - T_i)$ or $T_f = T_i + \frac{q_o''A_s t_c}{Mc}$. 

PROBLEM 2.45

KNOWN: Plate of thickness $2L$, initially at a uniform temperature of $T_i = 200^\circ C$, is suddenly quenched in a liquid bath of $T_{\infty} = 20^\circ C$ with a convection coefficient of 100 W/m$^2$·K.

FIND: (a) On $T$-$x$ coordinates, sketch the temperature distributions for the initial condition ($t \leq 0$), the steady-state condition ($t \to \infty$), and two intermediate times; (b) On $q_x^* - t$ coordinates, sketch the variation with time of the heat flux at $x = L$, (c) Determine the heat flux at $x = L$ and for $t = 0$; what is the temperature gradient for this condition; (d) By performing an energy balance on the plate, determine the amount of energy per unit surface area of the plate (J/m$^2$) that is transferred to the bath over the time required to reach steady-state conditions; and (e) Determine the energy transferred to the bath during the quenching process using the exponential-decay relation for the surface heat flux.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, and (3) No internal heat generation.

ANALYSIS: (a) The temperature distributions are shown in the sketch below.

(b) The heat flux at the surface $x = L$, $q_x^*(L, t)$, is initially a maximum value, and decreases with increasing time as shown in the sketch above.

(c) The heat flux at the surface $x = L$ at time $t = 0$, $q_x^*(L, 0)$, is equal to the convection heat flux with the surface temperature as $T(L,0) = T_i$.

$$q_x^*(L, 0) = q_{\text{conv}}(t = 0) = h(T_i - T_{\infty}) = 100 \text{ W/m}^2\cdot\text{K}(200 - 20)^\circ C = 18.0 \text{ kW/m}^2$$

From a surface energy balance as shown in the sketch considering the conduction and convection fluxes at the surface, the temperature gradient can be calculated.

Continued …
PROBLEM 2.45 (Cont.)

\[
\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0
\]

\[
q^*_{x}(L,0) - q^*_{\text{conv}}(t = 0) = 0 \quad \text{with} \quad q^*_{x}(L,0) = -k \frac{\partial T}{\partial x} \bigg|_{x=L}
\]

\[
\frac{\partial T}{\partial x} \bigg|_{L,0} = -q^*_{\text{conv}}(t = 0)/k = -18 \times 10^3 \text{ W/m}^2 / 50 \text{ W/m} \cdot \text{K} = -360 \text{ K/m} < \]

(d) The energy transferred from the plate to the bath over the time required to reach steady-state conditions can be determined from an energy balance on a time interval basis, Eq. 1.11b. For the initial state, the plate has a uniform temperature \( T_i \); for the final state, the plate is at the temperature of the bath, \( T_\infty \).

\[
E^*_{\text{in}} - E^*_{\text{out}} = \Delta E^*_{\text{st}} = E^*_{f} - E^*_{i} \quad \text{with} \quad E^*_{\text{in}} = 0,
\]

\[
-E^*_{\text{out}} = \rho c_p (2L)[T_\infty - T_i]
\]

\[
E^*_{\text{out}} = -2770 \text{ kg/m}^3 \times 875 \text{ J/kg} \cdot \text{K} \left(2 \times 0.010 \text{ m}\right) \left[20 - 200\right] \text{K} = +8.73 \times 10^6 \text{ J/m}^2 <
\]

(e) The energy transfer from the plate to the bath during the quenching process can be evaluated from knowledge of the surface heat flux as a function of time. The area under the curve in the \( q^*_{x}(L, t) \) vs. time plot (see schematic above) represents the energy transferred during the quench process.

\[
E^*_{\text{out}} = 2 \int_{t=0}^{\infty} q^*_{x}(L, t) \, dt = 2 \int_{t=0}^{\infty} A e^{-Bt} \, dt
\]

\[
E^*_{\text{out}} = 2A \left[-\frac{1}{B} e^{-Bt} \right]_0^{\infty} = 2A \left[-\frac{1}{B} (0-1) \right] = 2A / B
\]

\[
E^*_{\text{out}} = 2 \times 1.80 \times 10^4 \text{ W/m}^2 / 4.126 \times 10^{-3} \text{ s}^{-1} = 8.73 \times 10^6 \text{ J/m}^2 <
\]

COMMENTS: (1) Can you identify and explain the important features in the temperature distributions of part (a)?

(2) The maximum heat flux from the plate occurs at the instant the quench process begins and is equal to the convection heat flux. At this instant, the gradient in the plate at the surface is a maximum. If the gradient is too large, excessive thermal stresses could be induced and cracking could occur.

(3) In this thermodynamic analysis, we were able to determine the energy transferred during the quenching process. We cannot determine the rate at which cooling of the plate occurs without solving the heat diffusion equation.
**PROBLEM 2.46**

**KNOWN:** Plane wall, initially at a uniform temperature, is suddenly exposed to convective heating.

**FIND:** (a) Differential equation and initial and boundary conditions which may be used to find the temperature distribution, $T(x,t)$; (b) Sketch $T(x,t)$ for these conditions: initial ($t \leq 0$), steady-state, $t \to \infty$, and two intermediate times; (c) Sketch heat fluxes as a function of time for surface locations; (d) Expression for total energy transferred to wall per unit volume (J/m$^3$).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional conduction, (2) Constant properties, (3) No internal heat generation.

**ANALYSIS:** (a) For one-dimensional conduction with constant properties, the heat equation has the form,

$$\frac{\partial^2 T}{\partial x^2} = \frac{1}{\alpha} \frac{\partial T}{\partial t}$$

and the conditions are:

- **Initial, $t \leq 0$:** $T(x,0) = T_i$ uniform
- **Boundaries:** $x = 0$ $\frac{\partial T}{\partial x} = 0$ adiabatic
- $x = L$ $-k \frac{\partial T}{\partial x} = h[T(L,t) - T_\infty]$ convection

(b) The temperature distributions are shown on the sketch.

Note that the gradient at $x = 0$ is always zero, since this boundary is adiabatic. Note also that the gradient at $x = L$ decreases with time.

(c) The heat flux, $q_x(x,t)$, as a function of time, is shown on the sketch for the surfaces $x = 0$ and $x = L$.

Continued  .....
For the surface at \( x = 0 \), \( q''_x(0, t) = 0 \) since it is adiabatic. At \( x = L \) and \( t = 0 \), \( q''_x(L, 0) \) is a maximum

\[
q''_x(L, 0) = h\left[T(L, 0) - T_\infty\right]
\]

where \( T(L, 0) = T_i \). The gradient, and hence the flux, decrease with time.

(d) The total energy transferred to the wall may be expressed as

\[
E_{in} = \int_0^\infty q''_{x_{\text{conv}}}A_x dt
\]

\[
E_{in} = hA_s\int_0^\infty (T_\infty - T(L, t)) dt
\]

Dividing both sides by \( A_s L \), the energy transferred per unit volume is

\[
\frac{E_{in}}{V} = \frac{h}{L} \int_0^\infty \left[T_\infty - T(L, t)\right] dt \quad \left[ \text{J/m}^3 \right]
\]

**COMMENTS:** Note that the heat flux at \( x = L \) is into the wall and is hence in the negative \( x \) direction.
**PROBLEM 2.47**

**KNOWN:** Plane wall, initially at a uniform temperature \( T_i \), is suddenly exposed to convection with a fluid at \( T_\infty \) at one surface, while the other surface is exposed to a constant heat flux \( q_o'' \).

**FIND:** (a) Temperature distributions, \( T(x,t) \), for initial, steady-state and two intermediate times, (b) Corresponding heat fluxes on \( q''_x - x \) coordinates, (c) Heat flux at locations \( x = 0 \) and \( x = L \) as a function of time, (d) Expression for the steady-state temperature of the heater, \( T(0,\infty) \), in terms of \( q_o'' \), \( T_\infty \), \( k \), \( h \) and \( L \).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional conduction, (2) No heat generation, (3) Constant properties.

**ANALYSIS:** (a) For \( T_i < T_\infty \), the temperature distributions are

Note the constant gradient at \( x = 0 \) since \( q_x''(0) = q_o'' \).

(b) The heat flux distribution, \( q''_x(x,t) \), is determined from knowledge of the temperature gradients, evident from Part (a), and Fourier’s law.

(c) On \( q''_x(x,t) - t \) coordinates, the heat fluxes at the boundaries are shown above.

(d) Perform a surface energy balance at \( x = L \) and an energy balance on the wall:

\[
q''_{\text{cond}} = q''_{\text{conv}} = h[T(L,\infty) - T_\infty] \quad (1), \quad q''_{\text{cond}} = q_o''. \quad (2)
\]

For the wall, under steady-state conditions, Fourier’s law gives

\[
q_o'' = -k \frac{dT}{dx} = k \frac{T(0,\infty) - T(L,\infty)}{L}. \quad (3)
\]

Combine Eqs. (1), (2), (3) to find:

\[
T(0,\infty) = T_\infty + \frac{q_o''}{1/h + L/k}.
\]
PROBLEM 2.48

KNOWN: Plane wall, initially at a uniform temperature $T_o$, has one surface ($x = L$) suddenly exposed to a convection process ($T_\infty > T_o, h$), while the other surface ($x = 0$) is maintained at $T_o$. Also, wall experiences uniform volumetric heating $\dot{q}$ such that the maximum steady-state temperature will exceed $T_\infty$.

FIND: (a) Sketch temperature distribution ($T$ vs. $X$) for following conditions: initial ($t \leq 0$), steady-state ($t \to \infty$), and two intermediate times; also show distribution when there is no heat flow at the $x = L$ boundary, (b) Sketch the heat flux ($q''_x$ vs. $t$) at the boundaries $x = 0$ and $L$.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, (3) Uniform volumetric generation, (4) $T_\infty$ and $q_0$ large enough that $T(x, \infty) > T_\infty$.

ANALYSIS: (a) The initial and boundary conditions for the wall can be written as

- **Initial ($t \leq 0$):** $T(x, 0) = T_o$ Uniform temperature
- **Boundary:** $x = 0, T(0, t) = T_o$ Constant temperature
  
  $$x = L \quad -k \frac{\partial T}{\partial x} \bigg|_{x=L} = h \left[ T(L, t) - T_\infty \right]$$

  Convection process.

The temperature distributions are shown on the T-x coordinates below. Note the special condition when the heat flux at ($x = L$) is zero.

(b) The heat flux as a function of time at the boundaries, $q''_x(0, t)$ and $q''_x(L, t)$, can be inferred from the temperature distributions using Fourier's law.

COMMENTS: Since $T(x, \infty) > T_\infty$ and $T_\infty > T_o$, heat transfer at both boundaries must be out of the wall. Hence, it follows from an overall energy balance on the wall that $+q''_x(0, \infty) - q''_x(L, \infty) + \dot{q}L = 0$. 
**PROBLEM 2.49**

**KNOWN:** Plane wall, initially at a uniform temperature $T_o$, has one surface ($x = L$) suddenly exposed to a convection process ($T_\infty < T_o$, $h$), while the other surface ($x = 0$) is maintained at $T_o$. Also, wall experiences uniform volumetric heating $\dot{q}$ such that the maximum steady-state temperature will exceed $T_\infty$.

**FIND:** (a) Sketch temperature distribution ($T$ vs. $x$) for following conditions: initial ($t \leq 0$), steady-state ($t \to \infty$), and two intermediate times; identify key features of the distributions, (b) Sketch the heat flux ($q_x''$ vs. $t$) at the boundaries $x = 0$ and $L$; identify key features of the distributions.

**SCHEMATIC:**

![Temperature Distribution and Heat Flux](image)

**ASSUMPTIONS:** (1) One-dimensional conduction, (2) Constant properties, (3) Uniform volumetric generation, (4) $T_\infty < T_o$ and $\dot{q}$ large enough that $T(x, \infty) > T_o$.

**ANALYSIS:** (a) The initial and boundary conditions for the wall can be written as

- **Initial** ($t \leq 0$): $T(x,0) = T_o$ Uniform temperature
- **Boundary:** $x = 0$ $T(0,t) = T_o$ Constant temperature
  
  $x = L$ $-k \frac{\partial T}{\partial x} \bigg|_{x=L} = h[T(L,t) - T_\infty]$ Convection process.

  The temperature distributions are shown on the T-x coordinates below. Note that the maximum temperature occurs under steady-state conditions not at the midplane, but to the right toward the surface experiencing convection. The temperature gradients at $x = L$ increase for $t > 0$ since the convection heat rate from the surface increases as the surface temperature increases.

(b) The heat flux as a function of time at the boundaries, $q_x''(0,t)$ and $q_x''(L,t)$, can be inferred from the temperature distributions using Fourier’s law. At the surface $x = L$, the convection heat flux at $t = 0$ is $q_x''(L,0) = h(T_o - T_\infty)$. Because the surface temperature dips slightly at early times, the convection heat flux decreases slightly, and then increases until the steady-state condition is reached. For the steady-state condition, heat transfer at both boundaries must be out of the wall. It follows from an overall energy balance on the wall that $+q_x''(0,\infty) - q_x''(L,\infty) + \dot{q}L = 0$. 

![Temperature and Heat Flux Diagrams](image)
PROBLEM 2.50

KNOWN: Interfacial heat flux and outer surface temperature of adjoining, equivalent plane walls.

FIND: (a) Form of temperature distribution at representative times during the heating process, (b) Variation of heat flux with time at the interface and outer surface.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties.

ANALYSIS: (a) With symmetry about the interface, consideration of the temperature distribution may be restricted to $0 \leq x \leq L$. During early stages of the process, heat transfer is into the material from the outer surface, as well as from the interface. During later stages and the eventual steady state, heat is transferred from the material at the outer surface. At steady-state, $dT/dx = -(q^o_o/2)/k = \text{const.}$ and $T(0,t) = T_o + (q^o_o/2)L/k$.

(b) At the outer surface, the heat flux is initially negative, but increases with time, approaching $q^o_o/2$. It is zero when $dT/dx|_{x=L} = 0$. 
**PROBLEM 2.51**

**KNOWN:** Temperature distribution in a plane wall of thickness L experiencing uniform volumetric heating $\dot{q}$ having one surface ($x = 0$) insulated and the other exposed to a convection process characterized by $T_\infty$ and $h$. Suddenly the volumetric heat generation is deactivated while convection continues to occur.

**FIND:** (a) Determine the magnitude of the volumetric energy generation rate associated with the initial condition, (b) On $T-x$ coordinates, sketch the temperature distributions for the initial condition ($T \leq 0$), the steady-state condition ($t \to \infty$), and two intermediate times; (c) On $q_x - t$ coordinates, sketch the variation with time of the heat flux at the boundary exposed to the convection process, $q_x(L, t)$; calculate the corresponding value of the heat flux at $t = 0$; and (d) Determine the amount of energy removed from the wall per unit area ($J/m^2$) by the fluid stream as the wall cools from its initial to steady-state condition.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional conduction, (2) Constant properties, and (3) Uniform internal volumetric heat generation for $t < 0$.

**ANALYSIS:** (a) The volumetric heating rate can be determined by substituting the temperature distribution for the initial condition into the appropriate form of the heat diffusion equation.

\[
\frac{d}{dx}\left(\frac{dT}{dx}\right) + \frac{\dot{q}}{k} = 0 \quad \text{where} \quad T(x, 0) = a + bx^2
\]

\[
\frac{d}{dx}\left(0 + 2bx\right) + \frac{\dot{q}}{k} = 0 + 2b + \frac{\dot{q}}{k} = 0
\]

\[
\dot{q} = -2kb = -2 \times 90 \text{ W/m·K} \left(-1.0 \times 10^4 \text{ °C/m}^2\right) = 1.8 \times 10^6 \text{ W/m}^3
\]

(b) The temperature distributions are shown in the sketch below.
PROBLEM 2.51 (Cont.)

(c) The heat flux at the exposed surface $x = L$, $q_x^* (L, 0)$, is initially a maximum value and decreases with increasing time as shown in the sketch above. The heat flux at $t = 0$ is equal to the convection heat flux with the surface temperature $T(L,0)$. See the surface energy balance represented in the schematic.

\[
q_x^* (L, 0) = q_{\text{conv}}^* (t = 0) = h (T(L,0) - T_{\infty}) = 1000 \text{W/m}^2 \cdot \text{K} (200 - 20) \text{°C} = 1.80 \times 10^5 \text{W/m}^2 < \]

where $T(L,0) = a + bL^2 = 300 \text{°C} - 1.0 \times 10^4 \text{C/m}^2 \left(0.1 \text{m}\right)^2 = 200 \text{°C}$.

\[T(L,0) = a + bx^2\]

\[q_{\text{conv}}^*(t=0)\]

\[T_{\infty}, h\]

(d) The energy removed from the wall to the fluid as it cools from its initial to steady-state condition can be determined from an energy balance on a time interval basis, Eq. 1.11b. For the initial state, the wall has the temperature distribution $T(x,0) = a + bx^2$; for the final state, the wall is at the temperature of the fluid, $T_f = T_{\infty}$. We have used $T_{\infty}$ as the reference condition for the energy terms.

\[
E_{\text{in}}^* - E_{\text{out}}^* = \Delta E_{\text{st}}^* = E_{f}^* - E_{i}^*(\text{with} \ E_{\text{in}}^* = 0)
\]

\[-E_{\text{out}}^* = \rho c_p L [T_f - T_{\infty}] - \rho c_p \int_{x=0}^{x=L} [T(x,0) - T_{\infty}] \text{dx}\]

\[E_{\text{out}}^* = \rho c_p \int_{x=0}^{x=L} [a + bx^2 - T_{\infty}] \text{dx} = \rho c_p \left[ a + bx^3 / 3 - T_{\infty}x \right]_0^L\]

\[E_{\text{out}}^* = 7000 \text{kg/m}^3 \times 450 \text{J/kg K} \times 300 \times 0.1 - 1.0 \times 10^4 (0.1)^3 / 3 - 20 \times 0.1 \text{K m} < \]

\[E_{\text{out}}^* = 7.77 \times 10^7 \text{ J/m}^2\]

COMMENTS:  
(1) In the temperature distributions of part (a), note these features: initial condition has quadratic form with zero gradient at the adiabatic boundary; for the steady-state condition, the wall has reached the temperature of the fluid; for all distributions, the gradient at the adiabatic boundary is zero; and, the gradient at the exposed boundary decreases with increasing time.

(2) In this thermodynamic analysis, we were able to determine the energy transferred during the cooling process. However, we cannot determine the rate at which cooling of the wall occurs without solving the heat diffusion equation.
**PROBLEM 2.52**

**KNOWN:** Temperature as a function of position and time in a plane wall suddenly subjected to a change in surface temperature, while the other surface is insulated.

**FIND:** (a) Validate the temperature distribution, (b) Heat fluxes at \( x = 0 \) and \( x = L \), (c) Sketch of temperature distribution at selected times and surface heat flux variation with time, (d) Effect of thermal diffusivity on system response.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional conduction in \( x \), (2) Constant properties.

**ANALYSIS:** (a) To be valid, the temperature distribution must satisfy the appropriate forms of the heat equation and boundary conditions. Substituting the distribution into Equation 2.15, it follows that

\[
\frac{\partial^2 T}{\partial x^2} = \frac{1}{\alpha} \frac{\partial T}{\partial t}
\]

\[
-C_1(T_i - T_s)\exp\left(-\frac{\pi^2 \alpha t}{4L^2}\right)\pi^2 - \frac{\pi}{2L} \cos\left(\frac{\pi x}{2L}\right)
\]

\[
= -\frac{C_1}{\alpha}(T_i - T_s)\left(\frac{\pi^2 \alpha}{4L^2}\right)\exp\left(-\frac{\pi^2 \alpha t}{4L^2}\right)\cos\left(\frac{\pi x}{2L}\right) <
\]

Hence, the heat equation is satisfied. Applying boundary conditions at \( x = 0 \) and \( x = L \), it follows that

\[
\frac{\partial T}{\partial x}\bigg|_{x=0} = -\frac{C_1\pi}{2L}(T_i - T_s)\exp\left(-\frac{\pi^2 \alpha t}{4L^2}\right)\sin\left(\frac{\pi x}{2L}\right)\bigg|_{x=0} = 0 <
\]

and

\[
T(L, t) = T_s + C_1(T_i - T_s)\exp\left(-\frac{\pi^2 \alpha t}{4L^2}\right)\cos\left(\frac{\pi x}{2L}\right)\bigg|_{x=L} = T_s.<
\]

Hence, the boundary conditions are also satisfied.

(b) The heat flux has the form

\[
q''_x = -k \frac{\partial T}{\partial x} = +kC_1\pi(T_i - T_s)\exp\left(-\frac{\pi^2 \alpha t}{4L^2}\right)\sin\left(\frac{\pi x}{2L}\right).
\]

Continued …..
Hence, 

\[ q''_x(0) = 0, \]

\[ q''_x(L) = \frac{kC_L \pi}{2L} (T_i - T_s) \exp \left( -\frac{\pi^2 \alpha}{4L^2} \right), \]

(c) The temperature distribution and surface heat flux variations are:

(d) For materials A and B of different \( \alpha \),

\[
\frac{[T(x,t) - T_s]_A}{[T(x,t) - T_s]_B} = \exp \left[ -\frac{\pi^2}{4L^2} (\alpha_A - \alpha_B) t \right]
\]

Hence, if \( \alpha_A > \alpha_B \), \( T(x,t) \rightarrow T_s \) more rapidly for Material A. If \( \alpha_A < \alpha_B \), \( T(x,t) \rightarrow T_s \) more rapidly for Material B.

**COMMENTS:** Note that the prescribed function for \( T(x,t) \) does not reduce to \( T_i \) for \( t \rightarrow 0 \). For times at or close to zero, the function is not a valid solution of the problem. At such times, the solution for \( T(x,t) \) must include additional terms. The solution is considered in Section 5.5.1 of the text.
PROBLEM 2.53

KNOWN: Thin electrical heater dissipating 4000 W/m² sandwiched between two 25-mm thick plates whose surfaces experience convection.

FIND: (a) On T-x coordinates, sketch the steady-state temperature distribution for \(-L \leq x \leq +L\); calculate values for the surfaces \(x = L\) and the mid-point, \(x = 0\); label this distribution as Case 1 and explain key features; (b) Case 2: sudden loss of coolant causing existence of adiabatic condition on the \(x = +L\) surface; sketch temperature distribution on same T-x coordinates as part (a) and calculate values for \(x = 0, \pm L\); explain key features; (c) Case 3: further loss of coolant and existence of adiabatic condition on the \(x = -L\) surface; situation goes undetected for 15 minutes at which time power to the heater is deactivated; determine the eventual \((t \to \infty)\) uniform, steady-state temperature distribution; sketch temperature distribution on same T-x coordinates as parts (a,b); and (d) On T-t coordinates, sketch the temperature-time history at the plate locations \(x = 0, \pm L\) during the transient period between the steady-state distributions for Case 2 and Case 3; at what location and when will the temperature in the system achieve a maximum value?

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, (3) No internal volumetric generation in plates, and (3) Negligible thermal resistance between the heater surfaces and the plates.

ANALYSIS: (a) Since the system is symmetrical, the heater power results in equal conduction fluxes through the plates. By applying a surface energy balance on the surface \(x = +L\) as shown in the schematic, determine the temperatures at the mid-point, \(x = 0\), and the exposed surface, \(x + L\).

\[
\dot{E}_{in} - \dot{E}_{out} = 0
\]
\[
q^*_x (+L) - q^*_\text{conv} = 0 \quad \text{where} \quad q^*_x (+L) = q^*_o / 2
\]
\[
q^*_o / 2 - h \left[ T (+L) - T_\infty \right] = 0
\]
\[
T_1 (+L) = q^*_o / 2h + T_\infty = 4000 \text{ W/m}^2 / \left(2 \times 400 \text{ W/m}^2 \cdot \text{K} \right) + 20^\circ \text{C} = 25^\circ \text{C}
\]

From Fourier’s law for the conduction flux through the plate, find \(T(0)\).

\[
q^*_x = q^*_o / 2 = k \left[ T(0) - T(+L) \right] / L
\]
\[
T_1 (0) = T_1 (+L) + q^*_o L / 2k = 25^\circ \text{C} + 4000 \text{ W/m}^2 \cdot \text{K} \times 0.025 \text{m} / (2 \times 5 \text{ W/m} \cdot \text{K}) = 35^\circ \text{C}
\]

The temperature distribution is shown on the T-x coordinates below and labeled Case 1. The key features of the distribution are its symmetry about the heater plane and its linear dependence with distance.

Continued …..
b) Case 2: sudden loss of coolant with the existence of an adiabatic condition on surface x = +L. For this situation, all the heater power will be conducted to the coolant through the left-hand plate. From a surface energy balance and application of Fourier’s law as done for part (a), find

\[
\begin{align*}
T_2 (-L) & = q_o^* / h + T_\infty = 4000 \text{ W/m}^2 / 400 \text{ W/m}^2 \cdot K + 20 \text{°C} = 30 \text{°C} \\
T_2 (0) & = T_2 (-L) + q_o^* L / k = 30 \text{°C} + 4000 \text{ W/m}^2 \times 0.025 \text{ m} / 5 \text{ W/m} \cdot K = 50 \text{°C}
\end{align*}
\]

The temperature distribution is shown on the T-x coordinates above and labeled Case 2. The distribution is linear in the left-hand plate, with the maximum value at the mid-point. Since no heat flows through the right-hand plate, the gradient must zero and this plate is at the maximum temperature as well. The maximum temperature is higher than for Case 1 because the heat flux through the left-hand plate has increased two-fold.

c) Case 3: sudden loss of coolant occurs at the x = -L surface also. For this situation, there is no heat transfer out of either plate, so that for a 15-minute period, \( \Delta t_o \), the heater dissipates 4000 W/m\(^2\) and then is deactivated. To determine the eventual, uniform steady-state temperature distribution, apply the conservation of energy requirement on a time-interval basis, Eq. 1.11b. The initial condition corresponds to the temperature distribution of Case 2, and the final condition will be a uniform, elevated temperature \( T_f = T_3 \) representing Case 3. We have used \( T_\infty \) as the reference condition for the energy terms.

\[
E_{\text{in}}^* - E_{\text{out}}^* + E_{\text{gen}}^* = \Delta E_{\text{st}}^* = E_f^* - E_i^*
\]

(1)

Note that \( E_{\text{in}}^* - E_{\text{out}}^* = 0 \), and the dissipated electrical energy is

\[
E_{\text{gen}}^* = q_o^* \Delta t_o = 4000 \text{ W/m}^2 \times (15 \times 60) \text{s} = 3.600 \times 10^6 \text{ J/m}^2
\]

(2)

For the final condition,

\[
E_f^* = \rho c (2L)[T_f - T_\infty] = 2500 \text{ kg/m}^3 \times 700 \text{ J/kg} \cdot \text{K} \times (2 \times 0.025 \text{ m})[T_f - 20] \text{°C}
\]

\[
E_f^* = 8.75 \times 10^4 [T_f - 20] \text{ J/m}^2
\]

(3)

where \( T_f = T_3 \), the final uniform temperature, Case 3. For the initial condition,

\[
E_i^* = \rho c \int_{-L}^{+L} [T_2 (x) - T_\infty] dx = \rho c \left\{ \int_{-L}^{0} [T_2 (x) - T_\infty] dx + \int_{0}^{+L} [T_2 (0) - T_\infty] dx \right\}
\]

(4)

where \( T_2 (x) \) is linear for \(-L \leq x \leq 0\) and constant at \( T_2 (0) \) for \( 0 \leq x \leq +L\).

\[
T_2 (x) = T_2 (0) + \left[ T_2 (0) - T_2 (L) \right] x / L, \quad -L \leq x \leq 0
\]

\[
T_2 (x) = 50 \text{°C} + [50 - 30] \text{°C} x / 0.025 \text{m}
\]

\[
T_2 (x) = 50 \text{°C} + 800 x
\]

(5)

Substituting for \( T_2 (x) \), Eq. (5), into Eq. (4)
PROBLEM 2.53 (Cont.)

\[
E_1^r = \rho c \left\{ \int_{-L}^{0} \left[ 50 + 800x - T_\infty \right] dx + \left[ T_2(0) - T_\infty \right] L \right\}
\]

\[
E_2^r = \rho c \left\{ \int_{-L}^{0} \left[ 50x + 400x^2 - T_\infty x \right] dx + \left[ T_2(0) - T_\infty \right] L \right\}
\]

\[
E_3^r = \rho c \left\{ \left[ -50L + 400L^2 + T_\infty L \right] + \left[ T_2(0) - T_\infty \right] L \right\}
\]

\[
E_4^r = \rho c L \left\{ +50 - 400L - T_\infty + T_2(0) - T_\infty \right\}
\]

\[
E_5^r = 2500 \text{ kg/m}^3 \times 700 \text{ J/kg K} \times 0.025 \text{ m} \{+50 - 400 \times 0.025 - 20 + 50 - 20\} \text{ K}
\]

\[
E_6^r = 2.188 \times 10^6 \text{ J/m}^2
\]

Returning to the energy balance, Eq. (1), and substituting Eqs. (2), (3) and (6), find \(T_f = T_3\).

\[
3.600 \times 10^6 \text{ J/m}^2 = 8.75 \times 10^4 [T_3 - 20] - 2.188 \times 10^6 \text{ J/m}^2
\]

\[
T_3 = (66.1 + 20) ^\circ C = 86.1 ^\circ C
\]

The temperature distribution is shown on the T-x coordinates above and labeled Case 3. The distribution is uniform, and considerably higher than the maximum value for Case 2.

(d) The temperature-time history at the plate locations \(x = 0, \pm L\) during the transient period between the distributions for Case 2 and Case 3 are shown on the T-t coordinates below.

Note the temperatures for the locations at time \(t = 0\) corresponding to the instant when the surface \(x = -L\) becomes adiabatic. These temperatures correspond to the distribution for Case 2. The heater remains energized for yet another 15 minutes and then is deactivated. The midpoint temperature, \(T(0,t)\), is always the hottest location and the maximum value slightly exceeds the final temperature \(T_3\).
PROBLEM 2.54

KNOWN: Radius and length of coiled wire in hair dryer. Electric power dissipation in the wire, and temperature and convection coefficient associated with air flow over the wire.

FIND: (a) Form of heat equation and conditions governing transient, thermal behavior of wire during start-up, (b) Volumetric rate of thermal energy generation in the wire, (c) Sketch of temperature distribution at selected times during start-up, (d) Variation with time of heat flux at \( r = 0 \) and \( r = r_0 \).

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, radial conduction, (2) Constant properties, (3) Uniform volumetric heating, (4) Negligible radiation from surface of wire.

ANALYSIS: (a) The general form of the heat equation for cylindrical coordinates is given by Eq. 2.20. For one-dimensional, radial conduction and constant properties, the equation reduces to

\[
\frac{1}{r} \frac{\partial}{\partial r} \left( r \frac{\partial T}{\partial r} \right) + q = \frac{\rho c_p}{k} \frac{\partial T}{\partial t} = \frac{1}{\alpha} \frac{\partial T}{\partial t}
\]

The initial condition is

\[
T(r, 0) = T_i
\]

The boundary conditions are:

\[
-k \frac{\partial T}{\partial r} \bigg|_{r=r_0} = h[T(r_0, t) - T_\infty]
\]

(b) The volumetric rate of thermal energy generation is

\[
\dot{q} = \dot{E}_g = \frac{P_{\text{elec}}}{2 \pi r_0 L} = \frac{500 \text{ W}}{\pi (0.001 \text{ m})^2 (0.5 \text{ m})} = 3.18 \times 10^8 \text{ W/m}^3
\]

Under steady-state conditions, all of the thermal energy generated within the wire is transferred to the air by convection. Performing an energy balance for a control surface about the wire, \(-\dot{E}_{\text{out}} + \dot{E}_g = 0\), it follows that

\[
-2\pi r_0 L q^* (r_0, t \to \infty) + P_{\text{elec}} = 0.
\]

Hence,

\[
q^* (r_0, t \to \infty) = \frac{P_{\text{elec}}}{2\pi r_0 L} = \frac{500 \text{ W}}{2\pi (0.001 \text{ m}) (0.5 \text{ m})} = 1.59 \times 10^5 \text{ W/m}^2
\]

COMMENTS: The symmetry condition at \( r = 0 \) imposes the requirement that \( \frac{\partial T}{\partial r} \bigg|_{r=0} = 0 \), and hence \( q^*(0, t) = 0 \) throughout the process. The temperature at \( r_0 \), and hence the convection heat flux, increases steadily during the start-up, and since conduction to the surface must be balanced by convection from the surface at all times, \( \frac{\partial T}{\partial r} \bigg|_{r=r_0} \) also increases during the start-up.
PROBLEM 3.1

KNOWN: One-dimensional, plane wall separating hot and cold fluids at $T_{\infty,1}$ and $T_{\infty,2}$, respectively.

FIND: Temperature distribution, $T(x)$, and heat flux, $q''_x$, in terms of $T_{\infty,1}$, $T_{\infty,2}$, $h_1$, $h_2$, $k$ and $L$.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) Steady-state conditions, (3) Constant properties, (4) Negligible radiation, (5) No generation.

ANALYSIS: For the foregoing conditions, the general solution to the heat diffusion equation is of the form, Equation 3.2,

$$ T(x) = C_1x + C_2. \quad (1) $$

The constants of integration, $C_1$ and $C_2$, are determined by using surface energy balance conditions at $x = 0$ and $x = L$, Equation 2.23, and as illustrated above,

$$ -k \left. \frac{dT}{dx} \right|_{x=0} = h_1 \left[ T_{\infty,1} - T(0) \right] \quad \text{and} \quad -k \left. \frac{dT}{dx} \right|_{x=L} = h_2 \left[ T(L) - T_{\infty,2} \right]. \quad (2,3) $$

For the BC at $x = 0$, Equation (2), use Equation (1) to find

$$ -k (C_1 + 0) = h_1 \left[ T_{\infty,1} - (C_1 \cdot 0 + C_2) \right] $$

and for the BC at $x = L$ to find

$$ -k (C_1 + 0) = h_2 \left[ (C_1 L + C_2) - T_{\infty,2} \right]. \quad (5) $$

Multiply Eq. (4) by $h_2$ and Eq. (5) by $h_1$, and add the equations to obtain $C_1$. Then substitute $C_1$ into Eq. (4) to obtain $C_2$. The results are

$$ C_1 = - \frac{\left( T_{\infty,1} - T_{\infty,2} \right)}{k \left[ \frac{1}{h_1} + \frac{1}{h_2} + \frac{L}{k} \right]} \quad \text{and} \quad C_2 = - \frac{\left( T_{\infty,1} - T_{\infty,2} \right)}{h_1 \left[ \frac{1}{h_1} + \frac{1}{h_2} + \frac{L}{k} \right]} + T_{\infty,1} $$

$$ T(x) = - \frac{\left( T_{\infty,1} - T_{\infty,2} \right)}{1 \left[ \frac{1}{h_1} + \frac{1}{h_2} + \frac{L}{k} \right]} \left[ \frac{x}{k} + \frac{1}{h_1} \right] + T_{\infty,1}. \quad \text{<} $$

From Fourier’s law, the heat flux is a constant and of the form

$$ q''_x = -k \left. \frac{dT}{dx} \right|_{x=L} = -k C_1 = \frac{\left( T_{\infty,1} - T_{\infty,2} \right)}{1 \left[ \frac{1}{h_1} + \frac{1}{h_2} + \frac{L}{k} \right]} \quad \text{<} $$
**PROBLEM 3.2**

**KNOWN:** Temperatures and convection coefficients associated with air at the inner and outer surfaces of a rear window.

**FIND:** (a) Inner and outer window surface temperatures, $T_{s,i}$ and $T_{s,o}$, and (b) $T_{s,i}$ and $T_{s,o}$ as a function of the outside air temperature $T_{\infty,o}$ and for selected values of outer convection coefficient, $h_o$.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional conduction, (3) Negligible radiation effects, (4) Constant properties.

**PROPERTIES:** *Table A-3*, Glass (300 K): $k = 1.4 \text{ W/m}\cdot\text{K}$.

**ANALYSIS:** (a) The heat flux may be obtained from Eqs. 3.11 and 3.12,

$$q^* = \frac{T_{\infty,i} - T_{\infty,o}}{\frac{1}{h_o} + \frac{1}{L} + \frac{1}{h_i}} = \frac{40^\circ\text{C} - (-10^\circ\text{C})}{\frac{1}{h_o} + \frac{1}{0.004\text{m}} + \frac{1}{30\text{ W/m}^2\cdot\text{K}} + \frac{1}{65\text{ W/m}^2\cdot\text{K}}}$$

$$q^* = \frac{50^\circ\text{C}}{(0.0154 + 0.0029 + 0.0333)\text{m}^2\cdot\text{K}/\text{W}} = 968\text{ W/m}^2.$$  

Hence, with $q^* = h_i \left(T_{s,i} - T_{\infty,o}\right)$, the inner surface temperature is

$$T_{s,i} = T_{\infty,i} - \frac{q^*}{h_i} = 40^\circ\text{C} - \frac{968\text{ W/m}^2}{30\text{ W/m}^2\cdot\text{K}} = 7.7^\circ\text{C}$$

Similarly for the outer surface temperature with $q^* = h_o \left(T_{s,o} - T_{\infty,o}\right)$ find

$$T_{s,o} = T_{\infty,o} - \frac{q^*}{h_o} = -10^\circ\text{C} - \frac{968\text{ W/m}^2}{65\text{ W/m}^2\cdot\text{K}} = 4.9^\circ\text{C}$$

(b) Using the same analysis, $T_{s,i}$ and $T_{s,o}$ have been computed and plotted as a function of the outside air temperature, $T_{\infty,o}$, for outer convection coefficients of $h_o = 2, 65, \text{ and } 100\text{ W/m}^2\cdot\text{K}$. As expected, $T_{s,i}$ and $T_{s,o}$ are linear with changes in the outside air temperature. The difference between $T_{s,i}$ and $T_{s,o}$ increases with increasing convection coefficient, since the heat flux through the window likewise increases. This difference is larger at lower outside air temperatures for the same reason. Note that with $h_o = 2\text{ W/m}^2\cdot\text{K}$, $T_{s,i} - T_{s,o}$ is too small to show on the plot.

Continued …..
COMMENTS: (1) The largest resistance is that associated with convection at the inner surface. The values of $T_{s,i}$ and $T_{s,o}$ could be increased by increasing the value of $h_i$.

(2) The IHT Thermal Resistance Network Model was used to create a model of the window and generate the above plot. The Workspace is shown below.

```plaintext
// Thermal Resistance Network Model:
// The Network:

// Heat rates into node j, q_j, through thermal resistance R_ij
q21 = (T2 - T1) / R21
q32 = (T3 - T2) / R32
q43 = (T4 - T3) / R43

// Nodal energy balances
q1 + q21 = 0
q2 - q21 + q32 = 0
q3 - q32 + q43 = 0
q4 - q43 = 0

/* Assigned variables list: deselect the qi, Rij and Ti which are unknowns; set qi = 0 for embedded nodal points at which there is no external source of heat. */
T1 = Tinfo // Outside air temperature, C
q1 = // Heat rate, W
T2 = Tso // Outer surface temperature, C
q2 = 0 // Heat rate, W; node 2, no external heat source

R32 = L / (k * As) // Conduction thermal resistance, K/W; glass
R43 = 1 / (hi * As) // Convection thermal resistance, K/W; inner surface

// Other Assigned Variables:
Tinfo = -10 // Outside air temperature, C
ho = 65 // Convection coefficient, W/m^2.K; outer surface
L = 0.004 // Thickness, m; glass
k = 1.4 // Thermal conductivity, W/m.K; glass
Tinfi = 40 // Inside air temperature, C
hi = 30 // Convection coefficient, W/m^2.K; inner surface
As = 1 // Cross-sectional area, m^2; unit area
```
PROBLEM 3.3

KNOWN: Desired inner surface temperature of rear window with prescribed inside and outside air conditions.

FIND: (a) Heater power per unit area required to maintain the desired temperature, and (b) Compute and plot the electrical power requirement as a function of $T_{\infty,o}$ for the range $-30 \leq T_{\infty,o} \leq 0^\circ C$ with $h_o$ of 2, 20, 65 and 100 W/m$^2$·K. Comment on heater operation needs for low $h_o$. If $h \sim V^n$, where $V$ is the vehicle speed and $n$ is a positive exponent, how does the vehicle speed affect the need for heater operation?

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat transfer, (3) Uniform heater flux, $q_h$, (4) Constant properties, (5) Negligible radiation effects, (6) Negligible film resistance.

PROPERTIES: Table A-3, Glass (300 K): $k = 1.4$ W/m·K.

ANALYSIS: (a) From an energy balance at the inner surface and the thermal circuit, it follows that for a unit surface area,

$$\frac{T_{\infty,i} - T_{s,i}}{1/h_i} + q_h = \frac{T_{s,i} - T_{\infty,o}}{L/k + 1/h_o}$$

$$q_h = \frac{T_{s,i} - T_{\infty,o}}{L/k + 1/h_o} \cdot \frac{15^\circ C - (-15^\circ C)}{1.4 \text{ W/m} \cdot \text{K}} + \frac{1}{65 \text{ W/m}^2 \cdot \text{K}} - \frac{1}{10 \text{ W/m}^2 \cdot \text{K}}$$

$$q_h = (1370 - 100) \text{ W/m}^2 = 1270 \text{ W/m}^2$$

(b) The heater electrical power requirement as a function of the exterior air temperature for different exterior convection coefficients is shown in the plot. When $h_o = 2$ W/m$^2$·K, the heater is unnecessary, since the glass is maintained at $15^\circ C$ by the interior air. If $h \sim V^n$, we conclude that, with higher vehicle speeds, the exterior convection will increase, requiring increased heat power to maintain the $15^\circ C$ condition.

COMMENTS: With $q_h = 0$, the inner surface temperature with $T_{\infty,o} = -10^\circ C$ would be given by
\[
\frac{T_{\infty,i} - T_{s,i}}{T_{\infty,i} - T_{\infty,0}} = \frac{1/h_i}{1/h_i + L/k + 1/h_o} = \frac{0.10}{0.118} = 0.846, \quad \text{or} \quad T_{s,i} = 25^\circ C - 0.846 \left(35^\circ C\right) = -4.6^\circ C.
\]
PROBLEM 3.4

KNOWN: Curing of a transparent film by radiant heating with substrate and film surface subjected to known thermal conditions.

FIND: (a) Thermal circuit for this situation, (b) Radiant heat flux, \( q_o^* \) (W/m\(^2\)), to maintain bond at curing temperature, \( T_o \). (c) Compute and plot \( q_o^* \) as a function of the film thickness for \( 0 \leq L_f \leq 1 \) mm, and (d) If the film is not transparent, determine \( q_o^* \) required to achieve bonding; plot results as a function of \( L_f \).

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat flow, (3) All the radiant heat flux \( q_o^* \) is absorbed at the bond, (4) Negligible contact resistance.

ANALYSIS: (a) The thermal circuit for this situation is shown at the right. Note that terms are written on a per unit area basis.

(b) Using this circuit and performing an energy balance on the film-substrate interface,

\[
q_o^* = q_1^* + q_2^*
\]

where the thermal resistances are

\[
R_{cv}^* = \frac{1}{h} = 1/50 \text{ W/m}^2 \cdot \text{K} = 0.020 \text{ m}^2 \cdot \text{K/W}
\]

\[
R_f^* = \frac{L_f}{k_f} = 0.00025 \text{ m/0.025 W/m} \cdot \text{K} = 0.010 \text{ m}^2 \cdot \text{K/W}
\]

\[
R_s^* = \frac{L_s}{k_s} = 0.001 \text{ m/0.05 W/m} \cdot \text{K} = 0.020 \text{ m}^2 \cdot \text{K/W}
\]

\[
q_o^* = \frac{(60 - 20) \text{ C}}{[0.020 + 0.010] \text{ m}^2 \cdot \text{K/W}} + \frac{(60 - 30) \text{ C}}{0.020 \text{ m}^2 \cdot \text{K/W}} = (133 + 1500) \text{ W/m}^2 = 2833 \text{ W/m}^2
\]

(c) For the transparent film, the radiant flux required to achieve bonding as a function of film thickness \( L_f \) is shown in the plot below.

(d) If the film is opaque (not transparent), the thermal circuit is shown below. In order to find \( q_o^* \), it is necessary to write two energy balances, one around the \( T_s \) node and the second about the \( T_o \) node.

The results of the analyses are plotted below.

Continued...
COMMENTS: (1) When the film is transparent, the radiant flux is absorbed on the bond. The flux required decreases with increasing film thickness. Physically, how do you explain this? Why is the relationship not linear?

(2) When the film is opaque, the radiant flux is absorbed on the surface, and the flux required increases with increasing thickness of the film. Physically, how do you explain this? Why is the relationship linear?

(3) The IHT Thermal Resistance Network Model was used to create a model of the film-substrate system and generate the above plot. The Workspace is shown below.

```plaintext
// Thermal Resistance Network
Model:
// The Network:

// Heat rates into node j,qij, through thermal resistance Rij
q21 = (T2 - T1) / R21
q32 = (T3 - T2) / R32
q43 = (T4 - T3) / R43

// Nodal energy balances
q1 + q21 = 0
q2 - q21 + q32 = 0
q3 - q32 + q43 = 0
q4 - q43 = 0

/* Assigned variables list: deselect the qi, Rij and Ti which are unknowns; set qi = 0 for embedded nodal points at which there is no external source of heat. */
T1 = Tinf // Ambient air temperature, C
//q1 = // Heat rate, W; film side
T2 = Ts // Film surface temperature, C
q2 = 0 // Radiant flux, W/m^2; zero for part (a)
T3 = To // Bond temperature, C
q3 = qo // Radiant flux, W/m^2; part (a)
T4 = Tsub // Substrate temperature, C
//q4 = // Heat rate, W; substrate side

// Thermal Resistances:
R21 = 1 / ( h * As ) // Convection resistance, K/W
R32 = Lf / (kf * As) // Conduction resistance, K/W; film
R43 = Ls / (ks * As) // Conduction resistance, K/W; substrate

// Other Assigned Variables:
Tinf = 20 // Ambient air temperature, C
h = 50 // Convection coefficient, W/m^2.K
Lf = 0.00025 // Thickness, m; film

To = 60 // Cure temperature, C
Ls = 0.001 // Thickness, m; substrate
ks = 0.05 // Thermal conductivity, W/m.K; substrate
Tsub = 30 // Substrate temperature, C
As = 1 // Cross-sectional area, m^2; unit area
```
PROBLEM 3.5

KNOWN: Thicknesses and thermal conductivities of refrigerator wall materials. Inner and outer air temperatures and convection coefficients.

FIND: Heat gain per surface area.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional heat transfer, (2) Steady-state conditions, (3) Negligible contact resistance, (4) Negligible radiation, (5) Constant properties.

ANALYSIS: From the thermal circuit, the heat gain per unit surface area is

\[
q'' = \frac{T_{\infty,0} - T_{\infty,i}}{\left( \frac{1}{h_i} \right) + \left( \frac{L_p}{k_p} \right) + \left( \frac{L_i}{k_i} \right) + \left( \frac{L_p}{k_p} \right) + \left( \frac{1}{h_o} \right)}
\]

\[
q'' = \frac{(25 - 4) ^{\circ}C}{2(1/5 \text{ W/m}^2 \cdot \text{K}) + 2(0.003 \text{ m/60 W/m} \cdot \text{K}) + (0.050 \text{ m/0.046 W/m} \cdot \text{K})}
\]

\[
q'' = \frac{21 ^{\circ}C}{(0.4 + 0.0001 + 1.087) \text{ m}^2 \cdot \text{K/W}} = 14.1 \text{ W/m}^2 <
\]

COMMENTS: Although the contribution of the panels to the total thermal resistance is negligible, that due to convection is not inconsequential and is comparable to the thermal resistance of the insulation.
PROBLEM 3.6

KNOWN:  Design and operating conditions of a heat flux gage.

FIND:  (a) Convection coefficient for water flow ($T_s = 27^\circ C$) and error associated with neglecting conduction in the insulation, (b) Convection coefficient for air flow ($T_s = 125^\circ C$) and error associated with neglecting conduction and radiation, (c) Effect of convection coefficient on error associated with neglecting conduction for $T_s = 27^\circ C$.

SCHEMATIC:

ASSUMPTIONS:  (1) Steady-state, (2) One-dimensional conduction, (3) Constant k.

ANALYSIS:  (a) The electric power dissipation is balanced by convection to the water and conduction through the insulation. An energy balance applied to a control surface about the foil therefore yields

$$P_{elec}^* = q_{conv}^* + q_{cond}^* = h(T_s - T_{\infty}) + k(T_s - T_b)/L$$

Hence,

$$h = \frac{P_{elec}^* - k(T_s - T_b)/L}{T_s - T_{\infty}} = \frac{2000 \text{ W/m}^2 - 0.04 \text{ W/m} \cdot \text{K} \cdot 2 \text{ K}}{0.01 \text{ m}}$$

$$h = \frac{(2000 - 8) \text{ W/m}^2}{2 \text{ K}} = 996 \text{ W/m}^2 \cdot \text{K}$$

If conduction is neglected, a value of $h = 1000 \text{ W/m}^2 \cdot \text{K}$ is obtained, with an attendant error of $(1000 - 996)/996 = 0.40\%$

(b) In air, energy may also be transferred from the foil surface by radiation, and the energy balance yields

$$P_{elec}^* = q_{conv}^* + q_{rad}^* + q_{cond}^* = h(T_s - T_{\infty}) + \varepsilon \sigma (T_s^4 - T_{sur}^4) + k(T_s - T_b)/L$$

Hence,

$$h = \frac{P_{elec}^* - \varepsilon \sigma (T_s^4 - T_{sur}^4) - k(T_s - T_{\infty})/L}{T_s - T_{\infty}}$$

$$= \frac{2000 \text{ W/m}^2 - 0.15 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left(398^4 - 298^4\right) \text{ K}^4 - 0.04 \text{ W/m} \cdot \text{K} \cdot (100 \text{ K})}{0.01 \text{ m} \cdot 100 \text{ K}}$$

$$= \frac{(2000 - 146 - 400) \text{ W/m}^2}{100 \text{ K}} = 14.5 \text{ W/m}^2 \cdot \text{K}$$

Continued...
PROBLEM 3.6 (Cont.)

If conduction, radiation, or conduction and radiation are neglected, the corresponding values of \( h \) and the percentage errors are 18.5 W/m\(^2\)-K (27.6%), 16 W/m\(^2\)-K (10.3%), and 20 W/m\(^2\)-K (37.9%).

(c) For a fixed value of \( T_s = 27 ^\circ C \), the conduction loss remains at \( q_{cond} = 8 \) W/m\(^2\), which is also the fixed difference between \( P_{elec} \) and \( q_{conv} \). Although this difference is not clearly shown in the plot for \( 10 \leq h \leq 1000 \) W/m\(^2\)-K, it is revealed in the subplot for \( 10 \leq 100 \) W/m\(^2\)-K.

![Graphs showing power dissipation vs. convection coefficient with and without conduction](image)

Errors associated with neglecting conduction decrease with increasing \( h \) from values which are significant for small \( h \) (\( h < 100 \) W/m\(^2\)-K) to values which are negligible for large \( h \).

**COMMENTS:** In liquids (large \( h \)), it is an excellent approximation to neglect conduction and assume that all of the dissipated power is transferred to the fluid.
PROBLEM 3.7

KNOWN: A layer of fatty tissue with fixed inside temperature can experience different outside convection conditions.

FIND: (a) Ratio of heat loss for different convection conditions, (b) Outer surface temperature for different convection conditions, and (c) Temperature of still air which achieves same cooling as moving air (wind chill effect).

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction through a plane wall, (2) Steady-state conditions, (3) Homogeneous medium with constant properties, (4) No internal heat generation (metabolic effects are negligible), (5) Negligible radiation effects.

PROPERTIES: Table A-3, Tissue, fat layer: $k = 0.2 \text{ W/m·K}$.

ANALYSIS: The thermal circuit for this situation is

\[
\begin{align*}
&\frac{T_{s_1}}{L/kA} \quad \frac{T_{s_2}}{1/hA} \quad \frac{T_\infty}{Q}
\end{align*}
\]

Hence, the heat rate is

\[
q = \frac{T_{s_1} - T_\infty}{R_{\text{tot}}} = \frac{T_{s_1} - T_\infty}{L/kA + 1/hA}.
\]

Therefore,

\[
\begin{align*}
q_{\text{calm}} & = \left[ \frac{L}{k} + \frac{1}{h} \right]_{\text{calm}} \\
q_{\text{windy}} & = \left[ \frac{L}{k} + \frac{1}{h} \right]_{\text{windy}}
\end{align*}
\]

Applying a surface energy balance to the outer surface, it also follows that

\[
q_{\text{cond}} = q_{\text{conv}}.
\]

Continued …..
PROBLEM 3.7 (Cont.)

Hence,

\[
\frac{k}{L} (T_{s,1} - T_{s,2}) = h \left( T_{s,2} - T_\infty \right) \\
T_{s,2} = \frac{T_\infty + \frac{k}{hL} T_{s,1}}{1 + \frac{k}{hL}}.
\]

To determine the wind chill effect, we must determine the heat loss for the windy day and use it to evaluate the hypothetical ambient air temperature, \( T_\infty \), which would provide the same heat loss on a calm day, Hence,

\[
q^* = \frac{T_{s,1} - T_\infty}{L + \frac{k}{h}} = \frac{T_{s,1} - T_\infty'}{L + \frac{k}{h}}.
\]

From these relations, we can now find the results sought:

(a) 
\[
\frac{q_{\text{calm}}^*}{q_{\text{windy}}} = \frac{0.003 \text{ m} + \frac{1}{0.2 \text{ W/m} \cdot \text{K}}} {0.003 \text{ m} + \frac{1}{25 \text{ W/m}^2 \cdot \text{K}}} = \frac{0.015 + 0.0154}{0.015 + 0.04} \]
\[
\frac{q_{\text{calm}}}{q_{\text{windy}}} = 0.553
\]

(b) 
\[
T_{s,2} \Big|_{\text{calm}} = \frac{-15^\circ \text{C} + \frac{0.2 \text{ W/m} \cdot \text{K}}{25 \text{ W/m}^2 \cdot \text{K}}(0.003 \text{ m})}{1 + \frac{0.2 \text{ W/m} \cdot \text{K}}{25 \text{ W/m}^2 \cdot \text{K}}(0.003 \text{ m})} = 22.1^\circ \text{C}
\]

\[
T_{s,2} \Big|_{\text{windy}} = \frac{-15^\circ \text{C} + \frac{0.2 \text{ W/m} \cdot \text{K}}{65 \text{ W/m}^2 \cdot \text{K}}(0.003 \text{ m})}{1 + \frac{0.2 \text{ W/m} \cdot \text{K}}{65 \text{ W/m}^2 \cdot \text{K}}(0.003 \text{ m})} = 10.8^\circ \text{C}
\]

(c) 
\[
T_\infty = 36^\circ \text{C} - (36 + 15)^\circ \text{C} \frac{0.003/0.2 + 1/25}{0.003/0.2 + 1/65} = -56.3^\circ \text{C}
\]

**COMMENTS:** The wind chill effect is equivalent to a decrease of \( T_{s,2} \) by 11.3°C and increase in the heat loss by a factor of \((0.553)^{-1} = 1.81\).
**PROBLEM 3.8**

**KNOWN:** Dimensions of a thermopane window. Room and ambient air conditions.

**FIND:** (a) Heat loss through window, (b) Effect of variation in outside convection coefficient for double and triple pane construction.

**SCHEMATIC (Double Pane):**

![Diagram of a thermopane window with thermal circuit](image)

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional heat transfer, (3) Constant properties, (4) Negligible radiation effects, (5) Air between glass is stagnant.

**PROPERTIES:** Table A-3, Glass (300 K): \( k_g = 1.4 \text{ W/m} \cdot \text{K} \); Table A-4, Air (\( T = 278 \) K): \( k_a = 0.0245 \text{ W/m} \cdot \text{K} \).

**ANALYSIS:** (a) From the thermal circuit, the heat loss is

\[
q = \frac{1}{A} \left( \frac{1}{h_i} \frac{L}{k_g A} + \frac{L}{k_a A} + \frac{L}{k_g A} + \frac{1}{h_o} \right)

\]

\[
q = \frac{1}{0.4 \text{ m}^2} \left( \frac{1}{10 \text{ W/m}^2 \cdot \text{K}} + \frac{0.007 \text{ m}}{1.4 \text{ W/m} \cdot \text{K}} + \frac{0.007 \text{ m}}{0.0245 \text{ W/m} \cdot \text{K}} + \frac{1}{1.021 \text{ W/m}^2 \cdot \text{K}} \right)

q = \frac{30 \text{ C}}{(0.25 + 0.0125 + 0.715 + 0.0125 + 0.03125) \text{K/W}} = \frac{30 \text{ C}}{1.021 \text{ K/W}} = 29.4 \text{ W}

(b) For the triple pane window, the additional pane and airspace increase the total resistance from 1.021 K/W to 1.749 K/W, thereby reducing the heat loss from 29.4 to 17.2 W. The effect of \( h_o \) on the heat loss is plotted as follows.

![Graph showing the effect of outside convection coefficient on heat loss](image)

Continued...
Changes in $h_o$ influence the heat loss at small values of $h_o$, for which the outside convection resistance is not negligible relative to the total resistance. However, the resistance becomes negligible with increasing $h_o$, particularly for the triple pane window, and changes in $h_o$ have little effect on the heat loss.

**COMMENTS:** The largest contribution to the thermal resistance is due to conduction across the enclosed air. Note that this air could be in motion due to free convection currents. If the corresponding convection coefficient exceeded $3.5 \text{ W/m}^2\cdot\text{K}$, the thermal resistance would be less than that predicted by assuming conduction across stagnant air.
**PROBLEM 3.9**

**KNOWN:** Thicknesses of three materials which form a composite wall and thermal conductivities of two of the materials. Inner and outer surface temperatures of the composite; also, temperature and convection coefficient associated with adjoining gas.

**FIND:** Value of unknown thermal conductivity, $k_B$.

**SCHEMATIC:**

![Composite Wall Schematic](image)

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties, (4) Negligible contact resistance, (5) Negligible radiation effects.

**ANALYSIS:** Referring to the thermal circuit, the heat flux may be expressed as

$$q^* = \frac{T_{s,i} - T_{s,o}}{L_A + L_B + L_C} = \frac{600 - 20} {0.3 + \frac{0.15}{k_B} + \frac{0.15}{50}} \text{W/m}^2 \text{K}$$

$$q^* = \frac{580}{0.018 + 0.15/k_B} \text{W/m}^2.$$  \hspace{1cm} (1)

The heat flux may be obtained from

$$q^* = h(T_\infty - T_{s,i}) = 25 \text{ W/m}^2 \cdot \text{K} (800 - 600)^\circ \text{C}$$

$$q^* = 5000 \text{ W/m}^2.$$  \hspace{1cm} (2)

Substituting for the heat flux from Eq. (2) into Eq. (1), find

$$\frac{0.15}{k_B} = \frac{580}{q^*} - 0.018 = \frac{580}{5000} - 0.018 = 0.098$$

$$k_B = 1.53 \text{ W/m} \cdot \text{K}.$$ <

**COMMENTS:** Radiation effects are likely to have a significant influence on the net heat flux at the inner surface of the oven.
**PROBLEM 3.10**

**KNOWN:** Properties and dimensions of a composite oven window providing an outer surface safe-to-touch temperature \( T_{s,o} = 43^\circ C \) with outer convection coefficient \( h_o = 30 \text{ W/m}^2\cdot\text{K} \) and \( \varepsilon = 0.9 \) when the oven wall air temperatures are \( T_w = T_a = 400^\circ C \). See Example 3.1.

**FIND:** Values of the outer convection coefficient \( h_o \) required to maintain the safe-to-touch condition when the oven wall-air temperature is raised to 500°C or 600°C.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional conduction in window with no contact resistance and constant properties, (3) Negligible absorption in window material, (4) Radiation exchange processes are between small surface and large isothermal surroundings.

**ANALYSIS:** From the analysis in the Ex. 3.1 Comment 2, the surface energy balances at the inner and outer surfaces are used to determine the required value of \( h_o \) when \( T_{s,o} = 43^\circ C \) and \( T_{w,i} = T_a = 500 \) or 600°C.

\[
\varepsilon \sigma \left( T_{w,i}^4 - T_{s,i}^4 \right) + h_i \left( T_a - T_{s,i} \right) = \frac{T_{s,i} - T_{s,o}}{\left( L_A / k_A \right) + \left( L_B / k_B \right)}
\]

\[
\frac{T_{s,i} - T_{s,o}}{\left( L_A / k_A \right) + \left( L_B / k_B \right)} = \varepsilon \sigma \left( T_{s,o}^4 - T_{w,o}^4 \right) + h_o \left( T_{s,o} - T_\infty \right)
\]

Using these relations in IHT, the following results were calculated:

<table>
<thead>
<tr>
<th>( T_{w,i} ) (°C)</th>
<th>( T_{s,i} ) (°C)</th>
<th>( h_o ) (W/m²·K)</th>
</tr>
</thead>
<tbody>
<tr>
<td>400</td>
<td>392</td>
<td>30</td>
</tr>
<tr>
<td>500</td>
<td>493</td>
<td>40.4</td>
</tr>
<tr>
<td>600</td>
<td>594</td>
<td>50.7</td>
</tr>
</tbody>
</table>

**COMMENTS:** Note that the window inner surface temperature is closer to the oven air-wall temperature as the outer convection coefficient increases. Why is this so?
**PROBLEM 3.11**

**KNOWN:** Drying oven wall having material with known thermal conductivity sandwiched between thin metal sheets. Radiation and convection conditions prescribed on inner surface; convection conditions on outer surface.

**FIND:** (a) Thermal circuit representing wall and processes and (b) Insulation thickness required to maintain outer wall surface at \( T_o = 40^\circ C \).

**SCHEMATIC:**

![Thermal Circuit Diagram]

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional conduction in wall, (3) Thermal resistance of metal sheets negligible.

**ANALYSIS:**

(a) The thermal circuit is shown above. Note labels for the temperatures, thermal resistances and the relevant heat fluxes.

(b) Perform energy balances on the i- and o- nodes finding

\[
\begin{align*}
\frac{T_{\infty,i} - T_i}{R_{cv,i}'} &= \frac{T_o - T_i}{R_{cd}'} + q_{rad}' = 0 \quad (1) \\
\frac{T_i - T_o}{R_{cd}'} &= \frac{T_{\infty,o} - T_o}{R_{cv,o}'} = 0 \quad (2)
\end{align*}
\]

where the thermal resistances are

\[
\begin{align*}
R_{cv,i}' &= \frac{1}{h_i} = 0.0333 \text{ m}^2 \cdot \text{K} / \text{W} \quad (3) \\
R_{cd}' &= \frac{L}{k} = \frac{L}{0.05} \text{ m}^2 \cdot \text{K} / \text{W} \quad (4) \\
R_{cv,o}' &= \frac{1}{h_o} = 0.0100 \text{ m}^2 \cdot \text{K} / \text{W} \quad (5)
\end{align*}
\]

Substituting numerical values, and solving Eqs. (1) and (2) simultaneously, find

\[ L = 86 \text{ mm} \]

**COMMENTS:**

(1) The temperature at the inner surface can be found from an energy balance on the i-node using the value found for \( L \).

\[
\frac{T_{\infty,i} - T_i}{R_{cv,o}'} + \frac{T_{\infty,o} - T_i}{R_{cd}' + R_{cv,i}'} + q_{rad}' = 0 \]

\[ T_i = 298.3^\circ C \]

It follows that \( T_i \) is close to \( T_{\infty,i} \) since the wall represents the dominant resistance of the system.

(2) Verify that \( q_i' = 50 \text{ W} / \text{m}^2 \) and \( q_o' = 150 \text{ W} / \text{m}^2 \). Is the overall energy balance on the system satisfied?
PROBLEM 3.12

KNOWN: Configurations of exterior wall. Inner and outer surface conditions.

FIND: Heating load for each of the three cases.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) One-dimensional conduction, (3) Constant properties, (4) Negligible radiation effects.

PROPERTIES: (T = 300 K): Table A.3: plaster board, $k_p = 0.17 \text{ W/m} \cdot \text{K}$; urethane, $k_f = 0.026 \text{ W/m} \cdot \text{K}$; wood, $k_w = 0.12 \text{ W/m} \cdot \text{K}$; glass, $k_g = 1.4 \text{ W/m} \cdot \text{K}$. Table A.4: air, $k_a = 0.0263 \text{ W/m} \cdot \text{K}$.

ANALYSIS: (a) The heat loss may be obtained by dividing the overall temperature difference by the total thermal resistance. For the composite wall of unit surface area, $A = 1 \text{ m}^2$,

$$q = \frac{T_{\infty,i} - T_{\infty,o}}{\left[\left(1/h_i\right) + \left(L_p/k_p\right) + \left(L_f/k_f\right) + \left(L_w/k_w\right) + \left(1/h_o\right)\right]/A}\biggm|_{20^\circ \text{C} - (-15^\circ \text{C})}$$

$$q = \frac{35^\circ \text{C} - (-15^\circ \text{C})}{\left[\left(1/h_i\right) + \left(L_p/k_p\right) + \left(L_f/k_f\right) + \left(L_w/k_w\right) + \left(1/h_o\right)\right]/A}\biggm|_{20^\circ \text{C} - (-15^\circ \text{C})} = 15.0 \text{ W}$$

(b) For the single pane of glass,

$$q = \frac{T_{\infty,i} - T_{\infty,o}}{\left[\left(1/h_i\right) + \left(L_g/k_g\right) + \left(1/h_o\right)\right]/A}\biggm|_{20^\circ \text{C} - (-15^\circ \text{C})}$$

$$q = \frac{35^\circ \text{C}}{\left[\left(1/h_i\right) + \left(L_g/k_g\right) + \left(1/h_o\right)\right]/A}\biggm|_{20^\circ \text{C} - (-15^\circ \text{C})} = 0.269 \text{ K/ W}$$

(c) For the double pane window,

$$q = \frac{T_{\infty,i} - T_{\infty,o}}{\left[\left(1/h_i\right) + 2\left(L_g/k_g\right) + \left(L_a/k_a\right) + \left(1/h_o\right)\right]/A}\biggm|_{20^\circ \text{C} - (-15^\circ \text{C})}$$

$$q = \frac{35^\circ \text{C}}{\left[\left(1/h_i\right) + 2\left(L_g/k_g\right) + \left(L_a/k_a\right) + \left(1/h_o\right)\right]/A}\biggm|_{20^\circ \text{C} - (-15^\circ \text{C})} = 0.461 \text{ K/ W}$$

COMMENTS: The composite wall is clearly superior from the standpoint of reducing heat loss, and the dominant contribution to its total thermal resistance (82%) is associated with the foam insulation. Even with double pane construction, heat loss through the window is significantly larger than that for the composite wall.
**PROBLEM 3.13**

**KNOWN:** Composite wall of a house with prescribed convection processes at inner and outer surfaces.

**FIND:** (a) Expression for thermal resistance of house wall, $R_{\text{tot}}$; (b) Total heat loss, $q(W)$; (c) Effect on heat loss due to increase in outside heat transfer convection coefficient, $h_o$; and (d) Controlling resistance for heat loss from house.

**SCHEMATIC:**

**ASSUMPTIONS:**
1. One-dimensional conduction,
2. Steady-state conditions,
3. Negligible contact resistance.

**PROPERTIES:**

<table>
<thead>
<tr>
<th>Material</th>
<th>$k$ (W/m·K)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fiberglass blanket</td>
<td>0.038</td>
</tr>
<tr>
<td>Plywood siding</td>
<td>0.12</td>
</tr>
<tr>
<td>Plasterboard</td>
<td>0.17</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Temperature</th>
</tr>
</thead>
<tbody>
<tr>
<td>$T_i = 20^\circ\text{C}$</td>
</tr>
<tr>
<td>$T_o = -15^\circ\text{C}$</td>
</tr>
</tbody>
</table>

**ANALYSIS:**

(a) The expression for the total thermal resistance of the house wall follows from Eq. 3.18.

$$R_{\text{tot}} = \frac{1}{h_i A} + \frac{L_p}{k_p A} + \frac{L_b}{k_b A} + \frac{L_s}{k_s A} + \frac{1}{h_o A}.$$  

(b) The total heat loss through the house wall is

$$q = \Delta T/R_{\text{tot}} = (T_i - T_o)/R_{\text{tot}}.$$

Substituting numerical values, find

$$R_{\text{tot}} = \frac{1}{30 \text{W/m}^2 \cdot \text{K} \times 350 \text{m}^2} + \frac{0.01\text{m}}{0.17 \text{W/m} \cdot \text{K} \times 350 \text{m}^2} + \frac{0.10\text{m}}{0.038 \text{W/m} \cdot \text{K} \times 350 \text{m}^2} + \frac{0.12 \text{W/m} \cdot \text{K} \times 350 \text{m}^2}{60 \text{W/m}^2 \cdot \text{K} \times 350 \text{m}^2}$$

$$R_{\text{tot}} = [9.52 + 16.8 + 752 + 47.6 + 4.76] \times 10^{-5} \text{ C/W} = 831 \times 10^{-5} \text{ C/W}$$

The heat loss is then,

$$q = \left[20 - (-15)\right]^\circ\text{C}/831 \times 10^{-5} \text{ C/W} = 4.21 \text{ kW}.$$  

(c) If $h_o$ changes from 60 to 300 W/m$^2$·K, $R_o = 1/h_o A$ changes from $4.76 \times 10^{-5} \text{ C/W}$ to $0.95 \times 10^{-5} \text{ C/W}$. This reduces $R_{\text{tot}}$ to $826 \times 10^{-5} \text{ C/W}$, which is a 0.5% decrease and hence a 0.5% increase in $q$.

(d) From the expression for $R_{\text{tot}}$ in part (b), note that the insulation resistance, $L_b/k_b A$, is $752/830 = 90\%$ of the total resistance. Hence, this material layer controls the resistance of the wall. From part (c) note that a 5-fold decrease in the outer convection resistance due to an increase in the wind velocity has a negligible effect on the heat loss.
PROBLEM 3.14

KNOWN: Composite wall of a house with prescribed convection processes at inner and outer surfaces.

FIND: Daily heat loss for prescribed diurnal variation in ambient air temperature.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, steady-state conduction (negligible change in wall thermal energy storage over 24h period), (2) Negligible contact resistance.

PROPERTIES: Table A-3, $T = 300$ K: Fiberglass blanket ($28$ kg/m$^3$), $k_b = 0.038$ W/m·K; Plywood, $k_s = 0.12$ W/m·K; Plasterboard, $k_p = 0.17$ W/m·K.

ANALYSIS: The heat loss may be approximated as $Q = \int_0^{24h} \frac{T_{\infty,i} - T_{\infty,o}}{R_{tot}} dt$ where

$$R_{tot} = \frac{1}{A} \left[ \frac{L_p}{k_p} + \frac{L_b}{k_b} + \frac{L_s}{k_s} + \frac{1}{h_o} \right]$$

$$R_{tot} = \frac{1}{200m^2} \left[ \frac{1}{30 W/m^2-K} \cdot 0.01m + \frac{0.01m}{0.12 W/m·K} + \frac{0.02m}{0.038 W/m·K} + \frac{1}{60 W/m^2-K} \right]$$

Hence the heat rate is

$$Q = \frac{1}{R_{tot}} \left\{ \frac{12h}{0} \left[ 293 - \left[ 273 + 5 \sin \frac{2\pi t}{24} \right] \right] dt + \frac{24h}{12} \left[ 293 - \left[ 273 + 11 \sin \frac{2\pi t}{24} \right] \right] dt \right\}$$

$$Q = 68.8 \frac{W}{K} \left[ \left[ 20t + 5 \left[ \frac{24}{2\pi} \cos \frac{2\pi t}{24} \right] \right]_0^{12} + \left[ 20t + 11 \left[ \frac{24}{2\pi} \cos \frac{2\pi t}{24} \right] \right]_0^{12} \right] K·h$$

$$Q = 68.8 \left[ 240 + \frac{60}{\pi} (-1-1) \right] + \left[ 480 - 240 + \frac{132}{\pi} (1+1) \right] W·h$$

$$Q = 68.8 \{ 480-38.2+84.03 \} W·h$$

$$Q = 36.18 kW·h = 1.302 \times 10^8 J.$$ 

<

COMMENTS: From knowledge of the fuel cost, the total daily heating bill could be determined. For example, at a cost of $0.10$/kW·h, the heating bill would be $3.62/day.
PROBLEM 3.15

KNOWN: Dimensions and materials associated with a composite wall (2.5m × 6.5m, 10 studs each 2.5m high).

FIND: Wall thermal resistance.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Temperature of composite depends only on x (surfaces normal to x are isothermal), (3) Constant properties, (4) Negligible contact resistance.

PROPERTIES: Table A-3 (T = 300K): Hardwood siding, $k_A = 0.094$ W/m·K; Hardwood, $k_B = 0.16$ W/m·K; Gypsum, $k_C = 0.17$ W/m·K; Insulation (glass fiber paper faced, 28 kg/m$^3$), $k_D = 0.038$ W/m·K.

ANALYSIS: Using the isothermal surface assumption, the thermal circuit associated with a single unit (enclosed by dashed lines) of the wall is:

\[
\begin{align*}
(L_A / k_A A_A) &= \frac{0.008m}{0.094 \text{ W/m·K} \times (0.65\text{m} \times 2.5\text{m})} = 0.0524 \text{ K/W} \\
(L_B / k_B A_B) &= \frac{0.13m}{0.16 \text{ W/m·K} \times (0.04\text{m} \times 2.5\text{m})} = 8.125 \text{ K/W} \\
(L_D / k_D A_D) &= \frac{0.13m}{0.038 \text{ W/m·K} \times (0.61\text{m} \times 2.5\text{m})} = 2.243 \text{ K/W} \\
(L_C / k_C A_C) &= \frac{0.012m}{0.17 \text{ W/m·K} \times (0.65\text{m} \times 2.5\text{m})} = 0.0434 \text{ K/W}.
\end{align*}
\]

The equivalent resistance of the core is

\[
R_{eq} = \left(1/R_B + 1/R_D\right)^{-1} = \left(1/8.125 + 1/2.243\right)^{-1} = 1.758 \text{ K/W}
\]

and the total unit resistance is

\[
R_{tot,1} = R_A + R_{eq} + R_C = 1.854 \text{ K/W}.
\]

With 10 such units in parallel, the total wall resistance is

\[
R_{tot} = \left(10 \times 1/R_{tot,1}\right)^{-1} = 0.1854 \text{ K/W}.
\]

COMMENTS: If surfaces parallel to the heat flow direction are assumed adiabatic, the thermal circuit and the value of $R_{tot}$ will differ.
PROBLEM 3.16

KNOWN: Conditions associated with maintaining heated and cooled conditions within a refrigerator compartment.

FIND: Coefficient of performance (COP).

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state operating conditions, (2) Negligible radiation, (3) Compartment completely sealed from ambient air.

ANALYSIS: The Case (a) experiment is performed to determine the overall thermal resistance to heat transfer between the interior of the refrigerator and the ambient air. Applying an energy balance to a control surface about the refrigerator, it follows from Eq. 1.11a that, at any instant,

\[ \dot{E}_g - \dot{E}_{\text{out}} = 0 \]

Hence,

\[ q_{\text{elec}} - q_{\text{out}} = 0 \]

where \( q_{\text{out}} = \left( T_{\infty,i} - T_{\infty,o} \right) / R_t \). It follows that

\[ R_t = \frac{T_{\infty,i} - T_{\infty,o}}{q_{\text{elec}}} = \frac{(90 - 25) \degree C}{20 \, \text{W}} = 3.25 \degree C/\text{W} \]

For Case (b), heat transfer from the ambient air to the compartment (the heat load) is balanced by heat transfer to the refrigerant (\( q_{\text{in}} = q_{\text{out}} \)). Hence, the thermal energy transferred from the refrigerator over the 12 hour period is

\[ Q_{\text{out}} = q_{\text{out}} \Delta t = q_{\text{in}} \Delta t = \frac{T_{\infty,i} - T_{\infty,o}}{R_t} \Delta t \]

\[ Q_{\text{out}} = \frac{(25 - 5) \degree C}{3.25 \degree C/\text{W}} \times (12 \, \text{h} \times 3600 \, \text{s/h}) = 266,000 \, \text{J} \]

The coefficient of performance (COP) is therefore

\[ \text{COP} = \frac{Q_{\text{out}}}{W_{\text{in}}} = \frac{266,000}{125,000} = 2.13 \]

COMMENTS: The ideal (Carnot) COP is

\[ \text{COP}_{\text{ideal}} = \frac{T_c}{T_h - T_c} = \frac{278 \, \text{K}}{(298 - 278) \, \text{K}} = 13.9 \]

and the system is operating well below its peak possible performance.
PROBLEM 3.17

KNOWN: Total floor space and vertical distance between floors for a square, flat roof building.

FIND: (a) Expression for width of building which minimizes heat loss, (b) Width and number of floors which minimize heat loss for a prescribed floor space and distance between floors. Corresponding heat loss, percent heat loss reduction from 2 floors.

SCHEMATIC:

ASSUMPTIONS: Negligible heat loss to ground.

ANALYSIS: (a) To minimize the heat loss \( q \), the exterior surface area, \( A_s \), must be minimized. From Fig. (a)

\[
A_s = W^2 + 4WH = W^2 + 4W N_f H_f
\]

where

\[ N_f = A_f / W^2 \]

Hence,

\[
A_s = W^2 + 4WA_f H_f / W^2 = W^2 + 4A_f H_f / W
\]

The optimum value of \( W \) corresponds to

\[
\frac{dA_s}{dW} = 2W - \frac{4A_f H_f}{W^2} = 0
\]

or

\[
W_{op} = \left(2A_f H_f \right)^{1/3}
\]

The competing effects of \( W \) on the areas of the roof and sidewalls, and hence the basis for an optimum, is shown schematically in Fig. (b).

(b) For \( A_f = 32,768 \text{ m}^2 \) and \( H_f = 4 \text{ m} \),

\[
W_{op} = \left(2 \times 32,768 \text{ m}^2 \times 4 \text{ m} \right)^{1/3} = 64 \text{ m}
\]

Continued …..
PROBLEM 3.17 (Cont.)

Hence,
\[
N_f = \frac{A_f}{W^2} = \frac{32,768 \text{ m}^2}{(64 \text{ m})^2} = 8
\]

and
\[
q = UA_s \Delta T = 1 \text{ W/m}^2 \cdot K \left[ (64 \text{ m})^2 + \frac{4 \times 32,768 \text{ m}^2 \times 4 \text{ m}}{64 \text{ m}} \right]_{25^\circ \text{ C}} = 307,200 \text{ W}
\]

For \( N_f = 2 \),
\[
W = (A_f/N_f)^{1/2} = (32,768 \text{ m}^2/2)^{1/2} = 128 \text{ m}
\]
\[
q = 1 \text{ W/m}^2 \cdot K \left[ (128 \text{ m})^2 + \frac{4 \times 32,768 \text{ m}^2 \times 4 \text{ m}}{128 \text{ m}} \right]_{25^\circ \text{ C}} = 512,000 \text{ W}
\]

\% reduction in q = \( \frac{512,000 - 307,200}{512,000} = 40\% \)

COMMENTS: Even the minimum heat loss is excessive and could be reduced by reducing U.
PROBLEM 3.18

KNOWN: Concrete wall of 150 mm thickness experiences a flash-over fire with prescribed radiant flux and hot-gas convection on the fire-side of the wall. Exterior surface condition is 300°C, typical ignition temperature for most household and office materials.

FIND: (a) Thermal circuit representing wall and processes and (b) Temperature at the fire-side of the wall; comment on whether wall is likely to experience structural collapse for these conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in wall, (3) Constant properties.

PROPERTIES: Table A-3, Concrete (stone mix, 300 K): \( k = 1.4 \text{ W/m} \cdot \text{K} \).

ANALYSIS: (a) The thermal circuit is shown above. Note labels for the temperatures, thermal resistances and the relevant heat fluxes.

(b) To determine the fire-side wall surface temperatures, perform an energy balance on the o-node.

\[
\frac{T_\infty - T_o}{R_{cv}^\prime} + q_{rad} = \frac{T_L - T_o}{R_{cd}^\prime}
\]

where the thermal resistances are

\[
R_{cv}^\prime = \frac{1}{h} = \frac{1}{1/200 \text{ W/m}^2 \cdot \text{K}} = 0.00500 \text{ m}^2 \cdot \text{K} / \text{W}
\]

\[
R_{cd}^\prime = \frac{L}{k} = \frac{0.150 \text{ m}}{1.4 \text{ W/m} \cdot \text{K}} = 0.107 \text{ m}^2 \cdot \text{K} / \text{W}
\]

Substituting numerical values,

\[
\frac{(400 - T_o) K}{0.005 \text{ m}^2 \cdot \text{K} / \text{W}} + 25,000 \text{ W/m}^2 - \frac{(300 - T_o) K}{0.107 \text{ m}^2 \cdot \text{K} / \text{W}} = 0
\]

\[T_o = 515^\circ \text{C} \quad < \]

COMMENTS: (1) The fire-side wall surface temperature is within the 350 to 600°C range for which explosive spalling could occur. It is likely the wall will experience structural collapse for these conditions.

(2) This steady-state condition is an extreme condition, as the wall may fail before near steady-state conditions can be met.
**PROBLEM 3.19**

**KNOWN:** Representative dimensions and thermal conductivities for the layers of fire-fighter’s protective clothing, a turnout coat.

**FIND:** (a) Thermal circuit representing the turnout coat; tabulate thermal resistances of the layers and processes; and (b) For a prescribed radiant heat flux on the fire-side surface and temperature of $T_i = 60^\circ C$ at the inner surface, calculate the fire-side surface temperature, $T_o$.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional conduction through the layers, (3) Heat is transferred by conduction and radiation exchange across the stagnant air gaps, (3) Constant properties.

**PROPERTIES:** Table A-4, Air (470 K, 1 atm): $k_{ab} = k_{cd} = 0.0387$ W/m-K.

**ANALYSIS:** (a) The thermal circuit is shown with labels for the temperatures and thermal resistances.

The conduction thermal resistances have the form $R_{cd} = L/k$ while the radiation thermal resistances across the air gaps have the form

\[ R_{rad}^* = \frac{1}{h_{rad}} = \frac{1}{4\sigma T_{avg}^3} \]

The linearized radiation coefficient follows from Eqs. 1.8 and 1.9 with $\varepsilon = 1$ where $T_{avg}$ represents the average temperature of the surfaces comprising the gap

\[ h_{rad} = \sigma (T_1 + T_2)\left(T_1^2 + T_2^2\right) \approx 4\sigma T_{avg}^3 \]

For the radiation thermal resistances tabulated below, we used $T_{avg} = 470$ K.

Continued .....
PROBLEM 3.19 (Cont.)

<table>
<thead>
<tr>
<th>Shell (s)</th>

<td>0.01611</td>
<td>--</td>
</tr>
<tr>
<td>$R_{total}$</td>
<td>--</td>
<td>--</td>
<td>--</td>
<td>--</td>
<td>--</td>
</tr>
</tbody>
</table>

From the thermal circuit, the resistance across the gap for the conduction and radiation processes is

$$\frac{1}{R_{gap}^r} = \frac{1}{R_{cd}^r} + \frac{1}{R_{rad}^r}$$

and the total thermal resistance of the turn coat is

$$R_{tot}^r = R_{cd,s}^r + R_{gap,a-b}^r + R_{cd,mb}^r + R_{gap,c-d}^r + R_{cd,tl}^r$$

(b) If the heat flux through the coat is 0.25 W/cm$^2$, the fire-side surface temperature $T_o$ can be calculated from the rate equation written in terms of the overall thermal resistance.

$$q^r = \left(T_o - T_i\right)/R_{tot}^r$$

$$T_o = 66^\circ C + 0.25 \text{ W/cm}^2 \times \left(10^2 \text{ cm/m}\right)^2 \times 0.1043 \text{ m}^2 \cdot \text{K/W}$$

$$T_o = 327^\circ C$$

COMMENTS:  
(1) From the tabulated results, note that the thermal resistance of the moisture barrier (mb) is nearly 3 times larger than that for the shell or air gap layers, and 4.5 times larger than the thermal liner layer.

(2) The air gap conduction and radiation resistances were calculated based upon the average temperature of 470 K. This value was determined by setting $T_{avg} = (T_o + T_i)/2$ and solving the equation set using IHT with $k_{air} = k_{air}(T_{avg})$. 
PROBLEM 3.20

KNOWN: Materials and dimensions of a composite wall separating a combustion gas from a liquid coolant.

FIND: (a) Heat loss per unit area, and (b) Temperature distribution.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional heat transfer, (2) Steady-state conditions, (3) Constant properties, (4) Negligible radiation effects.

PROPERTIES: *Table A-1*, St. St. (304) \( T \approx 1000 \text{K} \): \( k = 25.4 \text{ W/m} \cdot \text{K} \); *Table A-2*, Beryllium Oxide \( T \approx 1500 \text{K} \): \( k = 21.5 \text{ W/m} \cdot \text{K} \).

ANALYSIS: (a) The desired heat flux may be expressed as

\[
q^* = \frac{T_{\infty,1} - T_{\infty,2}}{\frac{1}{h_1} + \frac{L_A}{k_A} + R_{t,c} + \frac{L_B}{k_B} + \frac{1}{h_2}} = \frac{(2600 - 100)\degree \text{C}}{\left[ \frac{1}{50} + \frac{0.01}{21.5} + \frac{0.05}{25.4} + \frac{1}{1000} \right] \text{m}^2 \cdot \text{K} / \text{W}}
\]

\[q^* = 34,600 \text{ W/m}^2.\]

(b) The composite surface temperatures may be obtained by applying appropriate rate equations. From the fact that \( q^* = h_1 (T_{\infty,1} - T_{s,1}) \), it follows that

\[T_{s,1} = T_{\infty,1} - \frac{q^*}{h_1} = 2600\degree \text{C} - \frac{34,600 \text{ W/m}^2}{50 \text{ W/m}^2 \cdot \text{K}} = 1908\degree \text{C}.\]

With \( q^* = (k_A / L_A)(T_{s,1} - T_{c,1}) \), it also follows that

\[T_{c,1} = T_{s,1} - \frac{L_A q^*}{k_A} = 1908\degree \text{C} - \frac{0.01 \text{m} \times 34,600 \text{ W/m}^2}{21.5 \text{ W/m} \cdot \text{K}} = 1892\degree \text{C}.\]

Similarly, with \( q^* = (T_{c,1} - T_{c,2}) / R_{t,c} \)

\[T_{c,2} = T_{c,1} - R_{t,c} q^* = 1892\degree \text{C} - 0.05 \text{ m}^2 \cdot \text{K} / \text{W} \times \frac{34,600 \text{ W}}{\text{m}^2} = 162\degree \text{C}\]

Continued .....
PROBLEM 3.20 (Cont.)

and with \( q^\prime\prime = (k_B / L_B) \left( T_{c,2} - T_{s,2} \right) \),

\[
T_{s,2} = T_{c,2} - \frac{L_B q^\prime\prime}{k_B} = 162^\circ \text{C} - \frac{0.02 \times 34,600 \text{ W/m}^2}{25.4 \text{ W/m} \cdot \text{K}} = 134.6^\circ \text{C}.
\]

The temperature distribution is therefore of the following form:

- \( T_{\infty,1} = 2600^\circ \text{C} \)
- \( T_{s,2} = 134.6^\circ \text{C} \)
- \( T_{c,2} = 162^\circ \text{C} \)
- \( T_{\infty,2} = 100^\circ \text{C} \)
- \( T_{c,1} = 1892^\circ \text{C} \)
- \( T_{s,1} = 1908^\circ \text{C} \)

**COMMENTS:**

1. The calculations may be checked by recomputing \( q^\prime\prime \) from

\[
q^\prime\prime = h_2 \left( T_{s,2} - T_{\infty,2} \right) = 10000 \text{ W/m}^2 \cdot \text{K} (134.6 - 100)^\circ \text{C} = 34,600 \text{ W/m}^2
\]

2. The initial *estimates* of the mean material temperatures are in error, particularly for the stainless steel. For improved accuracy the calculations should be repeated using \( k \) values corresponding to \( T \approx 1900^\circ \text{C} \) for the oxide and \( T \approx 115^\circ \text{C} \) for the steel.

3. The major contributions to the total resistance are made by the combustion gas boundary layer and the contact, where the temperature drops are largest.
PROBLEM 3.21

KNOWN: Thickness, overall temperature difference, and pressure for two stainless steel plates.

FIND: (a) Heat flux and (b) Contact plane temperature drop.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional heat transfer, (2) Steady-state conditions, (3) Constant properties.

PROPERTIES: Table A-1, Stainless Steel (T = 400K): $k = 16.6 \text{ W/m}\cdot\text{K}$.

ANALYSIS: (a) With $R_{t,c} = 15 \times 10^{-4} \text{ m}^2\cdot\text{K/W}$ from Table 3.1 and $k = 16.6 \text{ W/m}\cdot\text{K}$,

it follows that

$$R_{\text{tot}} = 2 \left( \frac{L}{k} \right) + R_{t,c} = 27 \times 10^{-4} \text{ m}^2\cdot\text{K/W};$$

hence

$$q = \frac{\Delta T}{R_{\text{tot}}} = \frac{100^\circ \text{C}}{27 \times 10^{-4} \text{ m}^2\cdot\text{K/W}} = 3.70 \times 10^4 \text{ W/m}^2. <$$

(b) From the thermal circuit,

$$\frac{\Delta T_c}{T_{s,1} - T_{s,2}} = \frac{R_{t,c}}{R_{\text{tot}}} = \frac{15 \times 10^{-4} \text{ m}^2\cdot\text{K/W}}{27 \times 10^{-4} \text{ m}^2\cdot\text{K/W}} = 0.556.$$

Hence,

$$\Delta T_c = 0.556 \left( T_{s,1} - T_{s,2} \right) = 0.556 \left( 100^\circ \text{C} \right) = 55.6^\circ \text{C}. <$$

COMMENTS: The contact resistance is significant relative to the conduction resistances. The value of $R_{t,c}$ would diminish, however, with increasing pressure.
**PROBLEM 3.22**

**KNOWN:** Temperatures and convection coefficients associated with fluids at inner and outer surfaces of a composite wall. Contact resistance, dimensions, and thermal conductivities associated with wall materials.

**FIND:** (a) Rate of heat transfer through the wall, (b) Temperature distribution.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional heat transfer, (3) Negligible radiation, (4) Constant properties.

**ANALYSIS:** (a) Calculate the total resistance to find the heat rate,

\[
R_{\text{tot}} = \frac{1}{h_1 A} + \frac{L_A}{k_A A} + R_{t,c} + \frac{L_B}{k_B A} + \frac{1}{h_2 A}
\]

\[
R_{\text{tot}} = \left[ \frac{1}{10 \times 5} + \frac{1}{0.1 \times 5} + \frac{0.3}{5} + \frac{0.02}{0.04 \times 5} + \frac{1}{20 \times 5} \right] \frac{\text{K}}{\text{W}}
\]

\[
R_{\text{tot}} = [0.02 + 0.02 + 0.06 + 0.10 + 0.01] \frac{\text{K}}{\text{W}} = 0.21 \frac{\text{K}}{\text{W}}
\]

\[
q = \frac{T_{\infty,1} - T_{\infty,2}}{R_{\text{tot}}} = \frac{(200 - 40) ^\circ \text{C}}{0.21 \text{ K/W}} = 762 \text{ W}
\]

(b) It follows that

\[
T_{s,1} = T_{\infty,1} - \frac{q}{h_1 A} = 200 ^\circ \text{C} - \frac{762 \text{ W}}{50 \text{ W/K}} = 184.8 ^\circ \text{C}
\]

\[
T_A = T_{s,1} - \frac{q L_A}{k_A A} = 184.8 ^\circ \text{C} - \frac{762 \text{ W} \times 0.01 \text{ m}}{0.1 \text{ W/m} \cdot \text{K} \times 5 \text{ m}^2} = 169.6 ^\circ \text{C}
\]

\[
T_B = T_A - q R_{t,c} = 169.6 ^\circ \text{C} - 762 \text{ W} \times 0.06 \text{ m} \cdot \text{K} = 123.8 ^\circ \text{C}
\]

\[
T_{s,2} = T_B - \frac{q L_B}{k_B A} = 123.8 ^\circ \text{C} - \frac{762 \text{ W} \times 0.02 \text{ m}}{0.04 \text{ W/m} \cdot \text{K} \times 5 \text{ m}^2} = 47.6 ^\circ \text{C}
\]

\[
T_{\infty,2} = T_{s,2} - \frac{q}{h_2 A} = 47.6 ^\circ \text{C} - \frac{762 \text{ W}}{100 \text{ W/K}} = 40 ^\circ \text{C}
\]
PROBLEM 3.23

KNOWN: Outer and inner surface convection conditions associated with zirconia-coated, Inconel turbine blade. Thicknesses, thermal conductivities, and interfacial resistance of the blade materials. Maximum allowable temperature of Inconel.

FIND: Whether blade operates below maximum temperature. Temperature distribution in blade, with and without the TBC.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, steady-state conduction in a composite plane wall, (2) Constant properties, (3) Negligible radiation.

ANALYSIS: For a unit area, the total thermal resistance with the TBC is

\[
R_{tot,w}^* = h_o^{-1} + (L/k)_{Zr} + R_{t,c}^* + (L/k)_{In} + h_i^{-1}
\]

\[
R_{tot,w}^* = \left(10^{-3} + 3.85 \times 10^{-4} + 10^{-4} + 2 \times 10^{-4} + 2 \times 10^{-3}\right) m^2 \cdot K/W = 3.69 \times 10^{-3} m^2 \cdot K/W
\]

With a heat flux of

\[
q_w^* = \frac{T_{\infty,o} - T_{\infty,i}}{R_{tot,w}^*} = \frac{1300 K}{3.69 \times 10^{-3} m^2 \cdot K/W} = 3.52 \times 10^5 W/m^2
\]

the inner and outer surface temperatures of the Inconel are

\[
T_{s,i(w)} = T_{\infty,i} + \left(q_w^*/h_i\right) = 400 K + \left(3.52 \times 10^5 W/m^2/500 W/m^2 \cdot K\right) = 1104 K
\]

\[
T_{s,o(w)} = T_{\infty,o} + \left((1/h_i) + (L/k)_{In}\right)q_w^* = 400 K + \left(2 \times 10^{-3} + 2 \times 10^{-4}\right) m^2 \cdot K/W \left(3.52 \times 10^5 W/m^2\right) = 1174 K
\]

Without the TBC, \(R_{tot,wo}^* = h_o^{-1} + (L/k)_{In} + h_i^{-1} = 3.20 \times 10^{-3} m^2 \cdot K/W\), and \(q_{wo}^* = \left(T_{\infty,o} - T_{\infty,i}\right)/R_{tot,wo}^* = (1300 K)/3.20 \times 10^{-3} m^2 \cdot K/W = 4.06 \times 10^5 W/m^2\). The inner and outer surface temperatures of the Inconel are then

\[
T_{s,i(wo)} = T_{\infty,i} + \left(q_{wo}^*/h_i\right) = 400 K + \left(4.06 \times 10^5 W/m^2/500 W/m^2 \cdot K\right) = 1212 K
\]

\[
T_{s,o(wo)} = T_{\infty,o} + \left((1/h_i) + (L/k)_{In}\right)q_{wo}^* = 400 K + \left(2 \times 10^{-3} + 2 \times 10^{-4}\right) m^2 \cdot K/W \left(4.06 \times 10^5 W/m^2\right) = 1293 K
\]

Continued...
Use of the TBC facilitates operation of the Inconel below $T_{\text{max}} = 1250$ K.

**COMMENTS:** Since the durability of the TBC decreases with increasing temperature, which increases with increasing thickness, limits to the thickness are associated with reliability considerations.
PROBLEM 3.24

KNOWN: Size and surface temperatures of a cubical freezer. Materials, thicknesses and interface resistances of freezer wall.

FIND: Cooling load.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) One-dimensional conduction, (3) Constant properties.

PROPERTIES: *Table A-1*, Aluminum 2024 (~267K): $k_{al} = 173 \text{ W/m·K}$. *Table A-1*, Carbon steel AISI 1010 (~295K): $k_{st} = 64 \text{ W/m·K}$. *Table A-3* (~300K): $k_{ins} = 0.039 \text{ W/m·K}$.

ANALYSIS: For a unit wall surface area, the total thermal resistance of the composite wall is

$$R_{tot}^* = \frac{L_{al}}{k_{al}} + R_{t,c}^* + \frac{L_{ins}}{k_{ins}} + R_{t,c}^* + \frac{L_{st}}{k_{st}}$$

$$R_{tot}^* = \frac{0.00635 \text{ m}}{173 \text{ W/m·K}} + 2.5 \times 10^{-4} \frac{\text{ m}^2 \cdot \text{K}}{\text{W}} + \frac{0.100 \text{ m}}{0.039 \text{ W/m·K}} + 2.5 \times 10^{-4} \frac{\text{ m}^2 \cdot \text{K}}{\text{W}} + \frac{0.00635 \text{ m}}{64 \text{ W/m·K}}$$

$$R_{tot}^* = \left(3.7 \times 10^{-5} + 2.5 \times 10^{-4} + 2.56 + 2.5 \times 10^{-4} + 9.9 \times 10^{-5}\right) \text{m}^2 \cdot \text{K/W}$$

Hence, the heat flux is

$$q^* = \frac{T_{s,o} - T_{s,i}}{R_{tot}^*} = \frac{[22 - (-6)] \degree C}{2.56 \text{ m}^2 \cdot \text{K/W}} = 10.9 \frac{\text{W}}{\text{m}^2}$$

and the cooling load is

$$q = A_s q^* = 6 \text{W}^2 q^* = 54 \text{m}^2 \times 10.9 \text{ W/m}^2 = 590 \text{W}$$

COMMENTS: Thermal resistances associated with the cladding and the adhesive joints are negligible compared to that of the insulation.
PROBLEM 3.25

FIND: (a) Reduction in heat loss associated with the insulation, (b) Heat losses for prescribed conditions, (c) Savings in fuel costs for 12 hour period.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) One-dimensional heat transfer, (3) Constant properties.

ANALYSIS: (a) The percentage reduction in heat loss is

\[ R_q = \frac{q_{\text{wo}} - q_{\text{with}}}{q_{\text{wo}}} \times 100\% = \left( 1 - \frac{q_{\text{with}}}{q_{\text{wo}}} \right) \times 100\% = \left( 1 - \frac{R_{\text{tot,wo}}^*}{R_{\text{tot,with}}^*} \right) \times 100\% \]

where the total thermal resistances without and with the insulation, respectively, are

\[ R_{\text{tot,wo}}^* = R_{\text{cnv,o}}^* + R_{\text{cnv,i}}^* + R_{\text{cnd,w}}^* + \frac{1}{h_i} \]

\[ R_{\text{tot,wo}} = (0.050 + 0.004 + 0.200) \text{ m}^2 \cdot \text{K} / \text{W} = 0.254 \text{ m}^2 \cdot \text{K} / \text{W} \]

\[ R_{\text{tot,with}}^* = R_{\text{cnv,o}}^* + R_{\text{cnv,i}}^* + R_{\text{cnd,w}}^* + R_{\text{t,c}}^* + \frac{1}{h_i} \]

\[ R_{\text{tot,with}} = (0.050 + 0.004 + 0.002 + 0.926 + 0.500) \text{ m}^2 \cdot \text{K} / \text{W} = 1.482 \text{ m}^2 \cdot \text{K} / \text{W} \]

\[ R_q = (1 - 0.254/1.482) \times 100\% = 82.9\% < \]

(b) With \( A_s = 12 \text{ m}^2 \), the heat losses without and with the insulation are

\[ q_{\text{wo}} = A_s \left( T_{\text{co,i}} - T_{\text{co,o}} \right) / R_{\text{tot,wo}}^* = 12 \text{ m}^2 \times 32^\circ \text{C} / 0.254 \text{ m}^2 \cdot \text{K} / \text{W} = 1512 \text{ W} < \]

\[ q_{\text{with}} = A_s \left( T_{\text{co,i}} - T_{\text{co,o}} \right) / R_{\text{tot,with}}^* = 12 \text{ m}^2 \times 32^\circ \text{C} / 1.482 \text{ m}^2 \cdot \text{K} / \text{W} = 259 \text{ W} < \]

(c) With the windows covered for 12 hours per day, the daily savings are

\[ S = \left( \frac{q_{\text{wo}} - q_{\text{with}}}{r_f} \right) \Delta t \times 10^{-6} \text{ MJ/J} = \left( \frac{(1512 - 259) \text{ W}}{0.8} \right) \times 12 \times 3600 \text{ s/h} \times 0.01 \text{ MJ/10}^{-6} \text{ MJ/J} = 0.677 \]

COMMENTS: (1) The savings may be insufficient to justify the cost of the insulation, as well as the daily tedium of applying and removing the insulation. However, the losses are significant and unacceptable. The owner of the building should install double pane windows. (2) The dominant contributions to the total thermal resistance are made by the insulation and convection at the inner surface.
PROBLEM 3.26

KNOWN: Surface area and maximum temperature of a chip. Thickness of aluminum cover and chip/cover contact resistance. Fluid convection conditions.

FIND: Maximum chip power.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat transfer, (3) Negligible heat loss from sides and bottom, (4) Chip is isothermal.

PROPERTIES: Table A.1, Aluminum ($T \approx 325$ K): $k = 238$ W/m·K.

ANALYSIS: For a control surface about the chip, conservation of energy yields

\[
\dot{E}_g - \dot{E}_{\text{out}} = 0
\]

or

\[
P_c = -\frac{(T_c - T_\infty)A}{\left[\left(\kappa/k\right) + R_{t,c} + \left(1/h\right)\right]} = 0
\]

\[
P_{c,\text{max}} = \frac{(85 - 25) \cdot C \cdot (10^{-4} \text{m}^2)}{(0.002/238) + 0.5 \times 10^{-4} + (1/1000)} \text{m}^2 \cdot \text{K/W}
\]

\[
P_{c,\text{max}} = \frac{60 \times 10^{-4} \cdot \text{C} \cdot \text{m}^2}{8.4 \times 10^{-6} + 0.5 \times 10^{-4} + 10^{-3}} \text{m}^2 \cdot \text{K/W}
\]

\[
P_{c,\text{max}} = 5.7 \text{ W.}
\]

COMMENTS: The dominant resistance is that due to convection ($R_{\text{conv}} > R_{t,c} >> R_{\text{cond}}$).
PROBLEM 3.27

KNOWN: Operating conditions for a board mounted chip.

FIND: (a) Equivalent thermal circuit, (b) Chip temperature, (c) Maximum allowable heat dissipation for dielectric liquid \((h_o = 1000 \text{ W/m}^2\cdot\text{K})\) and air \((h_o = 100 \text{ W/m}^2\cdot\text{K})\). Effect of changes in circuit board temperature and contact resistance.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Negligible chip thermal resistance, (4) Negligible radiation, (5) Constant properties.

PROPERTIES: Table A-3, Aluminum oxide (polycrystalline, 358 K): \(k_b = 32.4 \text{ W/m} \cdot \text{K}\).

ANALYSIS: (a)

(b) Applying conservation of energy to a control surface about the chip \((\dot{E}_{in} - \dot{E}_{out} = 0)\),

\[
q_c^* = q_i^* - q_o^* = 0
\]

\[
q_c^* = \frac{T_c - T_{\infty,i}}{1/h_i + (L/k)_b + R^*_{t,c}} + \frac{T_c - T_{\infty,o}}{1/h_o}
\]

With \(q_c^* = 3 \times 10^4 \text{ W/m}^2\), \(h_o = 1000 \text{ W/m}^2\cdot\text{K}\), \(k_b = 1 \text{ W/m} \cdot \text{K}\) and \(R^*_{t,c} = 10^{-4} \text{ m}^2 \cdot \text{K/W}\),

\[
3 \times 10^4 \text{ W/m}^2 = \frac{T_c - 20^\circ \text{C}}{\left(1/40 + 0.005/1 + 10^{-4}\right) \text{m}^2 \cdot \text{K/W}} + \frac{T_c - 20^\circ \text{C}}{(1/1000) \text{m}^2 \cdot \text{K/W}}
\]

\[
3 \times 10^4 \text{ W/m}^2 = (33.2T_c - 664 + 1000T_c - 20,000) \text{ W/m}^2 \cdot \text{K}
\]

1003\(T_c = 50,664\)

\(T_c = 49\^\circ \text{C}\).

(c) For \(T_c = 85^\circ \text{C}\) and \(h_o = 1000 \text{ W/m}^2\cdot\text{K}\), the foregoing energy balance yields

\[
q_c^* = 67,160 \text{ W/m}^2
\]

with \(q_o^* = 65,000 \text{ W/m}^2\) and \(q_i^* = 2160 \text{ W/m}^2\). Replacing the dielectric with air \((h_o = 100 \text{ W/m}^2\cdot\text{K})\), the following results are obtained for different combinations of \(k_b\) and \(R^*_{t,c}\).

Continued...

Comments:

1. For the conditions of part (b), the total internal resistance is 0.0301 m²·K/W, while the outer resistance is 0.001 m²·K/W. Hence

$$\frac{q_o^*}{q_i^*} = \left( \frac{T_c - T_{∞,o}}{R_o^*} \right) / \left( \frac{T_c - T_{∞,i}}{R_i^*} \right) = \frac{0.0301}{0.001} = 30.$$  

and only approximately 3% of the heat is dissipated through the board.

2. With $h_o = 100$ W/m²·K, the outer resistance increases to 0.01 m²·K/W, in which case $q_o^*/q_i^* = R_i^*/R_o^* = 0.0301/0.01 = 3.1$ and now almost 25% of the heat is dissipated through the board. Hence, although measures to reduce $R_i^*$ would have a negligible effect on $q_c^*$ for the liquid coolant, some improvement may be gained for air-cooled conditions. As shown in the table of part (b), use of an aluminum oxide board increase $q_i^*$ by 19% (from 2159 to 2574 W/m²) by reducing $R_i^*$ from 0.0301 to 0.0253 m²·K/W.

Because the initial contact resistance ($R_{t,c}^* = 10^{-4}$ m²·K/W) is already much less than $R_i^*$, any reduction in its value would have a negligible effect on $q_c^*$. The largest gain would be realized by increasing $h_o$, since the inside convection resistance makes the dominant contribution to the total internal resistance.
**PROBLEM 3.28**

**KNOWN:** Dimensions, thermal conductivity and emissivity of base plate. Temperature and convection coefficient of adjoining air. Temperature of surroundings. Maximum allowable temperature of transistor case. Case-plate interface conditions.

**FIND:** (a) Maximum allowable power dissipation for an air-filled interface, (b) Effect of convection coefficient on maximum allowable power dissipation.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Negligible heat transfer from the enclosure, to the surroundings. (3) One-dimensional conduction in the base plate, (4) Radiation exchange at surface of base plate is with large surroundings, (5) Constant thermal conductivity.

**PROPERTIES:** Aluminum-aluminum interface, air-filled, 10 µm roughness, $10^5$ N/m$^2$ contact pressure (Table 3.1): $R'_{t,c} = 2.75 \times 10^{-4}$ m$^2$ K/W.

**ANALYSIS:** (a) With all of the heat dissipation transferred through the base plate,

$$P_{elec} = q = \frac{T_{s,c} - T_\infty}{R_{tot}}$$

where

$$R_{tot} = R_{t,c} + R_{cnd} + \left[\left(\frac{1}{R_{cnv}}\right) + \left(\frac{1}{R_{rad}}\right)\right]^{-1}$$

$$R_{tot} = \frac{R'_{t,c}}{A_c} + \frac{L}{kW^2} + \frac{1}{W^2} \left(\frac{1}{h + h_r}\right)$$

and

$$h_r = \varepsilon \sigma (T_{s,p} + T_{sur}) \left(T_{s,p}^2 + T_{sur}^2\right)$$

To obtain $T_{s,p}$, the following energy balance must be performed on the plate surface,

$$q = T_{s,c} - T_{s,p} \frac{R_{t,c} + R_{cnd}}{R_{t,c} + R_{cnd}} = q_{cnv} + q_{rad} = hW^2 \left(T_{s,p} - T_\infty\right) + h_r W^2 \left(T_{s,p} - T_{sur}\right)$$

With $R_{t,c} = 2.75 \times 10^{-4}$ m$^2$ K/W, $R_{cnd} = 0.006$ m/(240 W/m$^2$K $\times 4 \times 10^{-4}$ m$^2$) = 0.0625 K/W, and the prescribed values of $h$, $W$, $T_\infty = T_{sur}$ and $\varepsilon$, Eq. (4) yields a surface temperature of $T_{s,p} = 357.6$ K = 84.6°C and a power dissipation of

Continued .....
The convection and radiation resistances are $R_{\text{conv}} = 625 \text{ m-K/W}$ and $R_{\text{rad}} = 345 \text{ m-K/W}$, where $h_r = 7.25 \text{ W/m}^2\cdot\text{K}$.

(b) With the major contribution to the total resistance made by convection, significant benefit may be derived by increasing the value of $h$.

For $h = 200 \text{ W/m}^2\cdot\text{K}$, $R_{\text{conv}} = 12.5 \text{ m-K/W}$ and $T_{s,p} = 351.6 \text{ K}$, yielding $R_{\text{rad}} = 355 \text{ m-K/W}$. The effect of radiation is then negligible.

**COMMENTS:**
1. The plate conduction resistance is negligible, and even for $h = 200 \text{ W/m}^2\cdot\text{K}$, the contact resistance is small relative to the convection resistance. However, $R_{t,c}$ could be rendered negligible by using indium foil, instead of an air gap, at the interface. From Table 3.1, $R_{t,c}^* = 0.07 \times 10^{-4} \text{ m}^2\cdot\text{K/W}$, in which case $R_{t,c} = 0.035 \text{ m-K/W}$.

2. Because $A_c < W^2$, heat transfer by conduction in the plate is actually two-dimensional, rendering the conduction resistance even smaller.
PROBLEM 3.29

KNOWN: Conduction in a conical section with prescribed diameter, D, as a function of x in the form \( D = ax^{1/2} \).

FIND: (a) Temperature distribution, \( T(x) \), (b) Heat transfer rate, \( q_x \).

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in x-direction, (3) No internal heat generation, (4) Constant properties.

PROPERTIES: Table A-2, Pure Aluminum (500K): \( k = 236 \text{ W/m-K} \).

ANALYSIS: (a) Based upon the assumptions, and following the same methodology of Example 3.3, \( q_x \) is a constant independent of x. Accordingly,

\[
q_x = -kA \frac{dT}{dx} = -k \left[ \pi \left( ax^{1/2} \right)^2 / 4 \right] \frac{dT}{dx}
\]

using \( A = \pi D^2/4 \) where \( D = ax^{1/2} \). Separating variables and identifying limits,

\[
\frac{4q_x}{\pi a^2 k} \int_{x_1}^{x} \frac{dx}{x} = -\int_{T_1}^{T_2} dT.
\]

Integrating and solving for \( T(x) \) and then for \( T_2 \),

\[
T(x) = T_1 - \frac{4q_x}{\pi a^2 k} \ln \frac{x}{x_1} \quad \text{and} \quad T_2 = T_1 - \frac{4q_x}{\pi a^2 k} \ln \frac{x_2}{x_1}.
\]

Solving Eq. (4) for \( q_x \) and then substituting into Eq. (3) gives the results,

\[
q_x = -\frac{\pi}{4} a^2 k \left( T_1 - T_2 \right) / \ln \left( x_1 / x_2 \right)
\]

(b) The heat rate follows from Eq. (5),

\[
q_x = \frac{\pi}{4} \times 0.5^2 \text{m} \times 236 \text{ W/m-K} \times (600 - 400) \text{K/ln} \frac{25}{125} = 5.76 \text{kW}.
\]
PROBLEM 3.30

KNOWN: Geometry and surface conditions of a truncated solid cone.

FIND: (a) Temperature distribution, (b) Rate of heat transfer across the cone.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in x, (3) Constant properties.

PROPERTIES: Table A-1, Aluminum (333K): k = 238 W/m·K.

ANALYSIS: (a) From Fourier's law, Eq. (2.1), with $A = \frac{\pi D^2}{4} = \left(\frac{\pi a^2}{4}\right)x^3$, it follows that

$$\frac{4q_x dx}{\pi a^2 x^3} = -kdT.\]$$

Hence, since $q_x$ is independent of $x$,

$$\frac{4q_x}{\pi a^2} \int_{x_1}^{x} \frac{dx}{x^3} = -k \int_{T_1}^{T} dT$$

or

$$\frac{4q_x}{\pi a^2} \left[ -\frac{1}{2x^2} \right]_{x_1}^{x} = -k (T - T_1).$$

Hence

$$T = T_1 + \frac{2q_x}{\pi a^2 k} \left[ \frac{1}{x^2} - \frac{1}{x_1^2} \right]. \quad <$$

(b) From the foregoing expression, it also follows that

$$q_x = \frac{\pi a^2 k}{2} \frac{T_2 - T_1}{\left[1/x_2^2 - 1/x_1^2\right]} \pi (1 m^{-1}) 238 \text{ W/m·K} \times \frac{(20-100) \circ C}{\left[(0.225)^{-2} - (0.075)^{-2}\right] m^{-2}}$$

$$q_x = 189 \text{ W}. \quad <$$

COMMENTS: The foregoing results are approximate due to use of a one-dimensional model in treating what is inherently a two-dimensional problem.
PROBLEM 3.31

KNOWN: Temperature dependence of the thermal conductivity, k.

FIND: Heat flux and form of temperature distribution for a plane wall.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction through a plane wall, (2) Steady-state conditions, (3) No internal heat generation.

ANALYSIS: For the assumed conditions, $q_x$ and $A(x)$ are constant and Eq. 3.21 gives

$$
q_x \int_0^L \! dx = -\int_{T_0}^{T_1} (k_0 + aT) dT
$$

$$
q_x^* = \frac{1}{L} \left[ k_0 (T_0 - T_1) + \frac{a}{2} (T_0^2 - T_1^2) \right].
$$

From Fourier’s law,

$$
q_x^* = -(k_0 + aT) \frac{dT}{dx}.
$$

Hence, since the product of $(k_0 + aT)$ and $dT/dx$ is constant, decreasing $T$ with increasing $x$ implies,

- $a > 0$: decreasing $(k_0 + aT)$ and increasing $|dT/dx|$ with increasing $x$
- $a = 0$: $k = k_0 \Rightarrow$ constant $(dT/dx)$
- $a < 0$: increasing $(k_0 + aT)$ and decreasing $|dT/dx|$ with increasing $x$.

The temperature distributions appear as shown in the above sketch.
PROBLEM 3.32

KNOWN: Temperature dependence of tube wall thermal conductivity.

FIND: Expressions for heat transfer per unit length and tube wall thermal (conduction) resistance.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional radial conduction, (3) No internal heat generation.

ANALYSIS: From Eq. 3.24, the appropriate form of Fourier’s law is

\[ q_r = -kA_T \frac{dT}{dr} = -k \left( 2\pi rL \right) \frac{dT}{dr} \]

\[ q_r' = -2\pi kr \frac{dT}{dr} \]

\[ q_r' = -2\pi r k_0 (1+aT) \frac{dT}{dr} \]

Separating variables,

\[ -\frac{q_r'}{2\pi r} dr = k_0 (1+aT) dT \]

and integrating across the wall, find

\[ -\frac{q_r'}{2\pi} \int_{r_i}^{r_o} \frac{dr}{r} = k_0 \int_{T_i}^{T_o} (1+aT) dT \]

\[ -\frac{q_r'}{2\pi} \ln \frac{r_o}{r_i} = k_0 \left[ T + \frac{aT^2}{2} \right] \bigg|_{T_i}^{T_o} \]

\[ -\frac{q_r'}{2\pi} \ln \frac{r_o}{r_i} = k_0 \left[ (T_o - T_i) + \frac{a}{2} (T_o^2 - T_i^2) \right] \]

\[ q_r' = -2\pi k_0 \left[ 1 + \frac{a}{2} (T_o + T_i) \right] \frac{(T_o - T_i)}{\ln \left( \frac{r_o}{r_i} \right)} \]

It follows that the overall thermal resistance per unit length is

\[ R'_t = \frac{\Delta T}{q_r'} = \frac{\ln \left( \frac{r_o}{r_i} \right)}{2\pi k_0 \left[ 1 + \frac{a}{2} (T_o + T_i) \right]} \]

COMMENTS: Note the necessity of the stated assumptions to treating \( q_r' \) as independent of \( r \).
**PROBLEM 3.33**

**KNOWN:** Steady-state temperature distribution of convex shape for material with \( k = k_0(1 + \alpha T) \) where \( \alpha \) is a constant and the mid-point temperature is \( \Delta T_0 \) higher than expected for a linear temperature distribution.

**FIND:** Relationship to evaluate \( \alpha \) in terms of \( \Delta T_0 \) and \( T_1, T_2 \) (the temperatures at the boundaries).

**SCHEMATIC:**

![Diagram of a convex shape with temperatures labeled](image)

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional conduction, (3) No internal heat generation, (4) \( \alpha \) is positive and constant.

**ANALYSIS:** At any location in the wall, Fourier’s law has the form

\[
q^*_x = -k_0(1 + \alpha T) \frac{dT}{dx}. \tag{1}
\]

Since \( q^*_x \) is a constant, we can separate Eq. (1), identify appropriate integration limits, and integrate to obtain

\[
\int_0^L q^*_x \, dx = -\int_{T_1}^{T_2} k_0(1 + \alpha T) \, dT \tag{2}
\]

\[
q^*_x = -\frac{k_0}{L} \left[ \left( T_2 + \frac{\alpha T_2^2}{2} \right) - \left( T_1 + \frac{\alpha T_1^2}{2} \right) \right]. \tag{3}
\]

We could perform the same integration, but with the upper limits at \( x = L/2 \), to obtain

\[
q^*_x = -\frac{2k_0}{L} \left[ \left( T_{L/2} + \frac{\alpha T_{L/2}^2}{2} \right) - \left( T_1 + \frac{\alpha T_1^2}{2} \right) \right]. \tag{4}
\]

where

\[
T_{L/2} = T(L/2) = \frac{T_1 + T_2}{2} + \Delta T_0. \tag{5}
\]

Setting Eq. (3) equal to Eq. (4), substituting from Eq. (5) for \( T_{L/2} \), and solving for \( \alpha \), it follows that

\[
\alpha = \frac{2\Delta T_0}{\left( T_2^2 + T_1^2 \right)/2 - \left[ (T_1 + T_2)/2 + \Delta T_0 \right]^2}. \tag{<}
\]
**PROBLEM 3.34**

**KNOWN:** Hollow cylinder of thermal conductivity $k$, inner and outer radii, $r_i$ and $r_o$, respectively, and length $L$.

**FIND:** Thermal resistance using the alternative conduction analysis method.

**SCHEMATIC:**

![Schematic of hollow cylinder](image)

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional radial conduction, (3) No internal volumetric generation, (4) Constant properties.

**ANALYSIS:** For the differential control volume, energy conservation requires that $q_r = q_{r+dr}$ for steady-state, one-dimensional conditions with no heat generation. With Fourier’s law,

$$q_r = -kA \frac{dT}{dr} = -k \left(2\pi rL\right) \frac{dT}{dr}$$

(1)

where $A = 2\pi rL$ is the area normal to the direction of heat transfer. Since $q_r$ is constant, Eq. (1) may be separated and expressed in integral form,

$$\frac{q_r}{2\pi L} \int_{r_i}^{r_o} \frac{dr}{r} = -\int_{T_i}^{T_o} k(T) dT.$$

Assuming $k$ is constant, the heat rate is

$$q_r = \frac{2\pi L k (T_i - T_o)}{\ln \left(r_o / r_i\right)}.$$

Remembering that the thermal resistance is defined as

$$R_t \equiv \frac{\Delta T}{q},$$

it follows that for the hollow cylinder,

$$R_t = \frac{\ln \left(r_o / r_i\right)}{2\pi L K}.$$  \[<\]

**COMMENTS:** Compare the *alternative* method used in this analysis with the *standard* method employed in Section 3.3.1 to obtain the same result.
PROBLEM 3.35

KNOWN: Thickness and inner surface temperature of calcium silicate insulation on a steam pipe. Convection and radiation conditions at outer surface.

FIND: (a) Heat loss per unit pipe length for prescribed insulation thickness and outer surface temperature. (b) Heat loss and radial temperature distribution as a function of insulation thickness.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties.

PROPERTIES: Table A-3, Calcium Silicate (T = 645 K): k = 0.089 W/m K.

ANALYSIS: (a) From Eq. 3.27 with T_{s,2} = 490 K, the heat rate per unit length is

\[ q' = \frac{2\pi k \left(T_{s,1} - T_{s,2}\right)}{\ln \left(\frac{r_2}{\eta}\right)} \]

\[ q' = 2\pi \left(0.089 \text{ W/m} \cdot \text{K}\right) (800 - 490) \text{ K} \frac{1}{\ln \left(\frac{0.08 \text{ m}}{0.06 \text{ m}}\right)} \]

\[ q' = 603 \text{ W/m} \]

(b) Performing an energy for a control surface around the outer surface of the insulation, it follows that

\[ q'_{\text{cond}} = q'_{\text{conv}} + q'_{\text{rad}} \]

\[ \frac{T_{s,1} - T_{s,2}}{\ln \left(\frac{r_2}{\eta}\right)} = \frac{1}{(2\pi r_2 h)} + \frac{T_{s,2} - T_{\text{sur}}}{1/(2\pi h r)} \]

where \( h_r = \varepsilon \sigma \left(T_{s,2} + T_{\text{sur}}\right) \left(T_{s,2}^2 + T_{\text{sur}}^2\right) \). Solving this equation for \( T_{s,2} \), the heat rate may be determined from

\[ q' = 2\pi r_2 \left[h \left(T_{s,2} - T_{\infty}\right) + h_r \left(T_{s,2} - T_{\text{sur}}\right)\right] \]

Continued...
and from Eq. 3.26 the temperature distribution is

\[ T(r) = \frac{T_{s,1} - T_{s,2}}{\ln (r_1 / r_2)} \left( \ln \frac{r}{r_2} \right) + T_{s,2} \]

As shown below, the outer surface temperature of the insulation \( T_{s,2} \) and the heat loss \( q' \) decay precipitously with increasing insulation thickness from values of \( T_{s,2} = T_{s,1} = 800 \) K and \( q' = 11,600 \) W/m, respectively, at \( r_2 = r_1 \) (no insulation).

![Graphs showing temperature and heat loss vs. insulation thickness](image)

When plotted as a function of a dimensionless radius, \((r - r_1)/(r_2 - r_1)\), the temperature decay becomes more pronounced with increasing \( r_2 \).

When plotted as a function of a dimensionless radius, \((r - r_1)/(r_2 - r_1)\), the temperature decay becomes more pronounced with increasing \( r_2 \).

Note that \( T(r_2) = T_{s,2} \) increases with decreasing \( r_2 \) and a linear temperature distribution is approached as \( r_2 \) approaches \( r_1 \).

**COMMENTS:** An insulation layer thickness of 20 mm is sufficient to maintain the outer surface temperature and heat rate below 350 K and 1000 W/m, respectively.
PROBLEM 3.36

KNOWN: Temperature and volume of hot water heater. Nature of heater insulating material. Ambient air temperature and convection coefficient. Unit cost of electric power.

FIND: Heater dimensions and insulation thickness for which annual cost of heat loss is less than $50.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, steady-state conduction through side and end walls, (2) Conduction resistance dominated by insulation, (3) Inner surface temperature is approximately that of the water \((T_{s,1} = 55^\circ C)\), (4) Constant properties, (5) Negligible radiation.

PROPERTIES: Table A.3, Urethane Foam \((T = 300 K)\): \(k = 0.026 \text{ W/m}\cdot\text{K}\).

ANALYSIS: To minimize heat loss, tank dimensions which minimize the total surface area, \(A_{s,t}\), should be selected. With \(L = 4\sqrt{\pi D^2}\), \(A_{s,t} = \pi D L + 2\left(\frac{\pi D^2}{4}\right) = 4\sqrt{\pi} D + \pi D^2/2\), and the tank diameter for which \(A_{s,t}\) is an extremum is determined from the requirement

\[
dA_{s,t}/dD = -4\sqrt{\pi} D^2 + \pi D = 0
\]

It follows that

\[
D = \left(4\sqrt{\pi}/\pi\right)^{1/3} \quad \text{and} \quad L = \left(4\sqrt{\pi}/\pi\right)^{1/3}
\]

With \(d^2A_{s,t}/dD^2 = 8\sqrt{\pi}/D^3 + \pi > 0\), the foregoing conditions yield the desired minimum in \(A_{s,t}\). Hence, for \(\forall = 100 \text{ gal} \times 0.00379 \text{ m}^3/\text{gal} = 0.379 \text{ m}^3\),

\[
D_{op} = L_{op} = 0.784 \text{ m}
\]

The total heat loss through the side and end walls is

\[
q = \frac{T_{s,1} - T_{\infty}}{\ln(r_2/\eta)} + \frac{2(T_{s,1} - T_{\infty})}{\delta} + \frac{1}{2\pi k L_{op}} \frac{1}{h2\pi r_2 L_{op}} + \frac{1}{\eta} \left(\frac{\pi D_{op}^2}{4}\right) + \frac{h}{\pi D_{op}^2/4}
\]

We begin by estimating the heat loss associated with a 25 mm thick layer of insulation. With \(r_1 = D_{op}/2 = 0.392 \text{ m}\) and \(r_2 = r_1 + \delta = 0.417 \text{ m}\), it follows that

Continued...
PROBLEM 3.36 (Cont.)

\[ q = \ln \left( \frac{0.417}{0.392} \right) + \frac{1}{2\pi (0.026 \text{ W/m·K}) 0.784 \text{ m}} \left[ 2 \left( \frac{0.417 \text{ m}}{0.784 \text{ m}} \right) \right] \\
+ \frac{1}{(0.026 \text{ W/m·K})\pi/4 (0.784 \text{ m})^2 + \left( \frac{2 \text{ W/m}^2 \cdot \text{K}}{0.784 \text{ m}} \right)\pi/4 (0.784 \text{ m})^2} \frac{2 \left(55 - 20\right)^\circ \text{C}}{2\pi (0.026 \text{ W/m·K}) 0.784 \text{ m}} \\
+ \frac{1}{\left( \frac{2 \text{ W/m}^2 \cdot \text{K}}{0.784 \text{ m}} \right)\pi/4 (0.784 \text{ m})^2} \frac{2 \left(55 - 20\right)^\circ \text{C}}{2\pi (0.026 \text{ W/m·K}) 0.784 \text{ m}} \\
+ \frac{1}{\left( \frac{2 \text{ W/m}^2 \cdot \text{K}}{0.784 \text{ m}} \right)\pi/4 (0.784 \text{ m})^2} \frac{2 \left(55 - 20\right)^\circ \text{C}}{2\pi (0.026 \text{ W/m·K}) 0.784 \text{ m}} \\
\]

The annual energy loss is therefore

\[ Q_{\text{annual}} = 71.3 \text{ W} \left( 365 \text{ days} \right) \left( 24 \text{ h/day} \right) \left( 10^{-3} \text{ kW/W} \right) = 625 \text{ kWh} \]

With a unit electric power cost of $0.08/kWh, the annual cost of the heat loss is

\[ C = \left( \frac{\$0.08}{\text{kWh}} \right)625 \text{ kWh} = \$50.00 \]

Hence, an insulation thickness of

\[ \delta = 25 \text{ mm} \]

will satisfy the prescribed cost requirement.

**COMMENTS:** Cylindrical containers of aspect ratio \( L/D = 1 \) are seldom used because of floor space constraints. Choosing \( L/D = 2 \), \( \forall = \pi D^{1/2} \) and \( D = (2\forall/\pi)^{1/3} = 0.623 \text{ m} \). Hence, \( L = 1.245 \text{ m}, r_1 = 0.312 \text{ m} \) and \( r_2 = 0.337 \text{ m} \). It follows that \( q = 76.1 \text{ W} \) and \( C = \$53.37 \). The 6.7% increase in the annual cost of the heat loss is small, providing little justification for using the optimal heater dimensions.
PROBLEM 3.37

KNOWN: Inner and outer radii of a tube wall which is heated electrically at its outer surface and is exposed to a fluid of prescribed h and T\(_\infty\). Thermal contact resistance between heater and tube wall and wall inner surface temperature.

FIND: Heater power per unit length required to maintain a heater temperature of 25°C.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties, (4) Negligible temperature drop across heater.

ANALYSIS: The thermal circuit has the form

\[
q' = q_a + q_b \quad q' = \frac{T_0 - T_i}{\ln \left( \frac{r_0}{r_i} \right)} + \frac{T_0 - T_\infty}{1/h\pi D_0} + R_{t,c}
\]

\[
q' = \frac{(25-5)°C}{\ln \left( \frac{75\text{mm}}{25\text{mm}} \right)} + \frac{25-(-10)°C}{0.01 \text{ m} \cdot \text{K/W}} + \frac{1/\left(100 \text{ W/m}^2 \cdot \text{K} \times \pi \times 0.15 \text{ m}\right)}{0.15 \text{ W/m} \cdot \text{K}}
\]

\[
q' = (728 + 1649) \text{ W/m} = 2377 \text{ W/m}
\]

COMMENTS: The conduction, contact and convection resistances are 0.0175, 0.01 and 0.021 m · K/W, respectively,
PROBLEM 3.38

KNOWN: Inner and outer radii of a tube wall which is heated electrically at its outer surface. Inner and outer wall temperatures. Temperature of fluid adjoining outer wall.

FIND: Effect of wall thermal conductivity, thermal contact resistance, and convection coefficient on total heater power and heat rates to outer fluid and inner surface.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties, (4) Negligible temperature drop across heater, (5) Negligible radiation.

ANALYSIS: Applying an energy balance to a control surface about the heater,

\[ q' = q_i + q_o \]

\[ q' = \frac{T_o - T_i}{\ln(r_o/r_i)} + \frac{T_o - T_\infty}{2\pi k + R'_{t,c} + (1/2\pi r_i h)} \]

Selecting nominal values of \( k = 10 \text{ W/m} \cdot \text{K}, \ R'_{t,c} = 0.01 \text{ m} \cdot \text{K}/\text{W} \) and \( h = 100 \text{ W/m}^2 \cdot \text{K} \), the following parametric variations are obtained.

Continued...
For a prescribed value of $h$, $q'_o$ is fixed, while $q'_i$, and hence $q'$, increase and decrease, respectively, with increasing $k$ and $R'_{t,c}$. These trends are attributable to the effects of $k$ and $R'_{t,c}$ on the total (conduction plus contact) resistance separating the heater from the inner surface. For fixed $k$ and $R'_{t,c}$, $q'_i$ is fixed, while $q'_o$, and hence $q'$, increase with increasing $h$ due to a reduction in the convection resistance.

**COMMENTS:** For the prescribed nominal values of $k$, $R'_{t,c}$ and $h$, the electric power requirement is $q' = 2377$ W/m. To maintain the prescribed heater temperature, $q'$ would increase with any changes which reduce the conduction, contact and/or convection resistances.
PROBLEM 3.39

KNOWN: Wall thickness and diameter of stainless steel tube. Inner and outer fluid temperatures and convection coefficients.

FIND: (a) Heat gain per unit length of tube, (b) Effect of adding a 10 mm thick layer of insulation to outer surface of tube.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional radial conduction, (3) Constant properties, (4) Negligible contact resistance between tube and insulation, (5) Negligible effect of radiation.

PROPERTIES: Table A-1, St. St. 304 (~280K): $k_{st} = 14.4 \text{ W/m} \cdot \text{K}$.

ANALYSIS: (a) Without the insulation, the total thermal resistance per unit length is

$$ R'_{\text{tot}} = R'_{\text{conv,i}} + R'_{\text{cond,st}} + R'_{\text{conv,o}} = \frac{1}{2\pi \eta_i h_i} + \frac{\ln\left(\frac{r_2}{\eta_i}\right)}{2\pi k_{st}} + \frac{1}{2\pi r_2 h_o} $$

$$ R'_{\text{tot}} = \frac{1}{2\pi (0.018) \text{m}} \left(\frac{400}{400} \text{ W/m}^2 \cdot \text{K} \right) + \frac{\ln\left(\frac{20}{18}\right)}{2\pi (14.4 \text{ W/m} \cdot \text{K})} + \frac{1}{2\pi (0.02) \text{m}} \left(\frac{6}{6} \text{ W/m}^2 \cdot \text{K} \right) $$

$$ R'_{\text{tot}} = \left(0.0221 + 1.16 \times 10^{-3} + 1.33\right)\text{m} \cdot \text{K} / \text{W} = 1.35 \text{ m} \cdot \text{K} / \text{W} $$

The heat gain per unit length is then

$$ q' = \frac{T_{\infty,o}}{R_{\text{tot}}} - \frac{T_{\infty,i}}{1.35 \text{ m} \cdot \text{K} / \text{W}} = 12.6 \text{ W/m} < $$

(b) With the insulation, the total resistance per unit length is now $R'_{\text{tot}} = R'_{\text{conv,i}} + R'_{\text{cond,st}} + R'_{\text{cond,ins}} + R'_{\text{conv,o}}$, where $R'_{\text{conv,i}}$ and $R'_{\text{cond,st}}$ remain the same. The thermal resistance of the insulation is

$$ R'_{\text{cond,ins}} = \frac{\ln\left(\frac{r_3}{r_2}\right)}{2\pi k_{\text{ins}}} = \frac{\ln\left(30/20\right)}{2\pi (0.05 \text{ W/m} \cdot \text{K})} = 1.29 \text{ m} \cdot \text{K} / \text{W} $$

and the outer convection resistance is now

$$ R'_{\text{conv,o}} = \frac{1}{2\pi r_2 h_o} = \frac{1}{2\pi (0.03) \text{m}} \left(\frac{6}{6} \text{ W/m}^2 \cdot \text{K} \right) = 0.88 \text{ m} \cdot \text{K} / \text{W} $$

The total resistance is now

$$ R'_{\text{tot}} = \left(0.0221 + 1.16 \times 10^{-3} + 1.29 + 0.88\right)\text{m} \cdot \text{K} / \text{W} = 2.20 \text{ m} \cdot \text{K} / \text{W} $$

Continued ….
and the heat gain per unit length is

\[ q' = \frac{T_{\infty,o} - T_{\infty,i}}{R_{\text{tot}}} = \frac{17^\circ C}{2.20 \text{ m} \cdot \text{K/W}} = 7.7 \text{ W/m} \]

**COMMENTS:** (1) The validity of assuming negligible radiation may be assessed for the worst case condition corresponding to the bare tube. Assuming a tube outer surface temperature of \( T_s = T_{\infty,i} = 279\text{K} \), large surroundings at \( T_{\text{sur}} = T_{\infty,o} = 296\text{K} \), and an emissivity of \( \varepsilon = 0.7 \), the heat gain due to net radiation exchange with the surroundings is

\[ q_{\text{rad}} = \varepsilon \sigma (2\pi r_2) \left(T_{\text{sur}}^4 - T_s^4\right) = 7.7 \text{ W/m} \].

Hence, the net rate of heat transfer by radiation to the tube surface is comparable to that by convection, and the assumption of negligible radiation is inappropriate.

(2) If heat transfer from the air is by natural convection, the value of \( h_o \) with the insulation would actually be less than the value for the bare tube, thereby further reducing the heat gain. Use of the insulation would also increase the outer surface temperature, thereby reducing net radiation transfer from the surroundings.

(3) The critical radius is \( r_{cr} = k_{\text{ins}}/h = 8 \text{ mm} < r_2 \). Hence, as indicated by the calculations, heat transfer is reduced by the insulation.
PROBLEM 3.40

KNOWN: Diameter, wall thickness and thermal conductivity of steel tubes. Temperature of steam flowing through the tubes. Thermal conductivity of insulation and emissivity of aluminum sheath. Temperature of ambient air and surroundings. Convection coefficient at outer surface and maximum allowable surface temperature.

FIND: (a) Minimum required insulation thickness \((r_3 - r_2)\) and corresponding heat loss per unit length, (b) Effect of insulation thickness on outer surface temperature and heat loss.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) One-dimensional radial conduction, (3) Negligible contact resistances at the material interfaces, (4) Negligible steam side convection resistance \((T_{\infty,i} = T_{s,i})\), (5) Negligible conduction resistance for aluminum sheath, (6) Constant properties, (7) Large surroundings.

ANALYSIS: (a) To determine the insulation thickness, an energy balance must be performed at the outer surface, where \(q' = q'_{\text{conv,o}} + q'_{\text{rad}}\). With \(q'_{\text{conv,o}} = 2\pi r_3 h_0 \left(T_{s,o} - T_{\infty,o}\right)\), \(q'_{\text{rad}} = 2\pi r_3 \varepsilon \sigma \left(T_{s,o} - T_{\text{sur}}\right)^4\)

\[
\left(T_{s,o} - T_{\text{sur}}\right)^4 = \frac{(T_{s,i} - T_{s,o})}{(R'_{\text{cond,sto}} + R'_{\text{cond,ins}})}, \quad R'_{\text{cond,sto}} = \frac{\ell n (r_2 / n)}{2\pi k_{st}}, \quad \text{and} \quad R'_{\text{cond,ins}} = \frac{\ell n (r_3 / r_2)}{2\pi k_{ins}}.
\]

it follows that

\[
\frac{2\pi \left(T_{s,i} - T_{s,o}\right)}{\ell n (r_2 / n) + \ell n (r_3 / r_2)} = 2\pi r_3 \left[h_0 \left(T_{s,o} - T_{\infty,o}\right) + \varepsilon \sigma \left(T_{s,o}^4 - T_{\text{sur}}^4\right)\right]
\]

\[
\frac{2\pi (848 - 323) K}{\ell n (0.18 / 0.15) + \ell n (0.394 / 0.18)} = 2\pi r_3 \left[6 \text{ W/m}^2 \cdot \text{K} (323 - 300) \text{K} + 0.20 \times 5.67 	imes 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (323^4 - 300^4) \text{K}^4\right]
\]

A trial-and-error solution yields \(r_3 = 0.394 \text{ m} = 394 \text{ mm}\), in which case the insulation thickness is

\[t_{\text{ins}} = r_3 - r_2 = 214 \text{ mm}\]

The heat rate is then

\[q' = \frac{2\pi (848 - 323) K}{\ell n (0.18 / 0.15) + \ell n (0.394 / 0.18)} = 420 \text{ W/m}\]

(b) The effects of \(r_3\) on \(T_{s,o}\) and \(q'\) have been computed and are shown below.
Beyond $r_3 \approx 0.40\text{m}$, there are rapidly diminishing benefits associated with increasing the insulation thickness.

**COMMENTS:** Note that the thermal resistance of the insulation is much larger than that for the tube wall. For the conditions of Part (a), the radiation coefficient is $h_r = 1.37 \text{ W/m}$, and the heat loss by radiation is less than 25% of that due to natural convection ($q'_{\text{rad}} = 78 \text{ W/m}$, $q'_{\text{conv,o}} = 342 \text{ W/m}$).

![Diagram of heat transfer components]

- $T_{\infty,o} = T_{s,i}$
- $q' = R'_{\text{cond, in}} R'_{\text{cond, st}} R_{\text{rad}}$
- $q_{\text{rad}}$
- $q_{\text{conv,o}}$
PROBLEM 3.41

KNOWN: Thin electrical heater fitted between two concentric cylinders, the outer surface of which experiences convection.

FIND: (a) Electrical power required to maintain outer surface at a specified temperature, (b) Temperature at the center

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, radial conduction, (2) Steady-state conditions, (3) Heater element has negligible thickness, (4) Negligible contact resistance between cylinders and heater, (5) Constant properties, (6) No generation.

ANALYSIS: (a) Perform an energy balance on the composite system to determine the power required to maintain \( T(r_2) = T_s = 5 \, ^\circ\text{C} \).

\[
\dot{E}_\text{in} - \dot{E}_\text{out} + \dot{E}_\text{gen} = \dot{E}_\text{st} + q'_{\text{elec}} - q'_{\text{conv}} = 0.
\]

Using Newton’s law of cooling,

\[
q'_{\text{elec}} = q'_{\text{conv}} = h \cdot 2\pi \cdot r_2 \cdot (T_s - T_\infty)
\]

\[
q'_{\text{elec}} = 50 \, \frac{W}{\text{m}^2 \cdot \text{K}} \times 2\pi \cdot (0.040\,\text{m}) \cdot [5 - (-15)]\,^\circ\text{C} = 251 \, \text{W/m}.
\]

(b) From a control volume about Cylinder A, we recognize that the cylinder must be isothermal, that is,

\[
T(0) = T(r_1).
\]

Represent Cylinder B by a thermal circuit:

For the cylinder, from Eq. 3.28,

\[
R'_B = \ln \frac{r_2}{\eta} / 2\pi \cdot k_B
\]

giving

\[
T(\eta) = T_s + q'R'_B = 5\,^\circ\text{C} + 253.1 \, \frac{W}{\text{m}^2 \cdot \text{K}} \ln \frac{40/20}{15} \, \text{W/m} \cdot \text{K} = 23.5\,^\circ\text{C}
\]

Hence, \( T(0) = T(r_1) = 23.5\,^\circ\text{C} \).

Note that \( k_A \) has no influence on the temperature \( T(0) \).
**PROBLEM 3.42**

**KNOWN:** Electric current and resistance of wire. Wire diameter and emissivity. Thickness, emissivity and thermal conductivity of coating. Temperature of ambient air and surroundings. Expression for heat transfer coefficient at surface of the wire or coating.

**FIND:** (a) Heat generation per unit length and volume of wire, (b) Temperature of uninsulated wire, (c) Inner and outer surface temperatures of insulation.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) One-dimensional radial conduction through insulation, (3) Constant properties, (4) Negligible contact resistance between insulation and wire, (5) Negligible radial temperature gradients in wire, (6) Large surroundings.

**ANALYSIS:** (a) The rates of energy generation per unit length and volume are, respectively,

\[ \dot{E}_g' = I^2 R_{\text{elec}} = (20 \text{ A})^2 (0.01 \Omega/\text{m}) = 4 \text{ W/m} \]

\[ \dot{q} = \dot{E}_g' / A_c = 4 \dot{E}_g' / \pi D^2 = 16 \text{ W/m} / \pi (0.002 \text{ m})^2 = 1.27 \times 10^6 \text{ W/m}^3 \]

(b) Without the insulation, an energy balance at the surface of the wire yields

\[ \dot{E}_g' = \dot{q} = q'_{\text{conv}} + q'_{\text{rad}} = \pi D h (T - T_\infty) + \pi D \varepsilon_w \sigma (T^4 - T_{\text{sur}}^4) \]

where \( h = 1.25 [(T - T_\infty)/D]^{1/4} \). Substituting,

\[ 4 \text{ W/m} = 1.25 \pi (0.002 \text{ m})^{3/4} (T - 293)^{5/4} + \pi (0.002 \text{ m})0.3 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot K (T^4 - 293^4)K^4 \]

and a trial-and-error solution yields

\[ T = 331 \text{ K} = 58^\circ \text{C} \]

(c) Performing an energy balance at the outer surface,

\[ \dot{E}_g' = q' = q'_{\text{conv}} + q'_{\text{rad}} = \pi D h (T_{s,2} - T_\infty) + \pi D \varepsilon_i \sigma (T_{s,2}^4 - T_{\text{sur}}^4) \]

\[ 4 \text{ W/m} = 1.25 \pi (0.006 \text{ m})^{3/4} (T_{s,2} - 293)^{5/4} + \pi (0.006 \text{ m})0.9 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot K (T_{s,2}^4 - 293^4)K^4 \]

and an iterative solution yields the following value of the surface temperature

\[ T_{s,2} = 307.8 \text{ K} = 34.8^\circ \text{C} \]

The inner surface temperature may then be obtained from the following expression for heat transfer by conduction in the insulation.

Continued ….
PROBLEM 3.42 (Cont.)

\[ q' = \frac{T_{s,i} - T_2}{R_{\text{cond}}} = \frac{T_{s,i} - T_{s,2}}{\ell \ln (r_2 / r_1) / 2\pi k_i} \]

\[ 4 W = \frac{2\pi (0.25 W / m \cdot K) (T_{s,i} - 307.8 K)}{\ell \ln 3} \]

\[ T_{s,i} = 310.6 K = 37.6^\circ C \]

As shown below, the effect of increasing the insulation thickness is to reduce, not increase, the surface temperatures.

This behavior is due to a reduction in the total resistance to heat transfer with increasing \( r_2 \). Although the convection, \( h \), and radiation, \( h_r = \varepsilon \sigma (T_{s,2} + T_{\text{sur}}) (T_{s,2}^2 + T_{\text{sur}}^2) \), coefficients decrease with increasing \( r_2 \), the corresponding increase in the surface area is more than sufficient to provide for a reduction in the total resistance. Even for an insulation thickness of \( t = 4 \text{ mm} \), \( h = h + h_r = (7.1 + 5.4) \text{ W/m}^2\text{K} = 12.5 \text{ W/m}^2\text{K} \), and \( r_{cr} = k/h = 0.25 \text{ W/m-K/12.5 W/m}^2\text{K} = 0.020m = 20 \text{ mm} > r_2 = 5 \text{ mm} \). The outer radius of the insulation is therefore well below the critical radius.
**PROBLEM 3.43**

**KNOWN:** Diameter of electrical wire. Thickness and thermal conductivity of rubberized sheath. Contact resistance between sheath and wire. Convection coefficient and ambient air temperature. Maximum allowable sheath temperature.

**FIND:** Maximum allowable power dissipation per unit length of wire. Critical radius of insulation.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) One-dimensional radial conduction through insulation, (3) Constant properties, (4) Negligible radiation exchange with surroundings.

**ANALYSIS:** The maximum insulation temperature corresponds to its inner surface and is independent of the contact resistance. From the thermal circuit, we may write

\[
\dot{E}_g' = q' = \frac{T_{in,i} - T_\infty}{R'_{\text{cond}} + R'_{\text{conv}}} = \frac{T_{in,i} - T_\infty}{\left[\frac{\ell_n\left(r_{in,o} / r_{in,i}\right)}{2\pi k}\right] + \left(1 / 2\pi r_{in,o} h\right)}
\]

where \(r_{in,i} = D / 2 = 0.001\text{m}, r_{in,o} = r_{in,i} + t = 0.003\text{m},\) and \(T_{in,i} = T_{\max} = 50^\circ\text{C}\) yields the maximum allowable power dissipation. Hence,

\[
\dot{E}_{g,\text{max}}' = \frac{\ell_n 3 (50 - 20)^\circ\text{C}}{2\pi \times 0.13 \text{W/m}\cdot\text{K}} + \frac{1}{2\pi \left(0.003\text{m}\right)10 \text{W/m}^2\cdot\text{K}} = \frac{30^\circ\text{C}}{1.35 + 5.31} \frac{\text{m} \cdot \text{K}}{\text{W}} = 4.51 \text{W/m} < \frac{4.51 \text{W/m}}{}\]

The critical insulation radius is also unaffected by the contact resistance and is given by

\[
r_{cr} = \frac{k}{h} = \frac{0.13 \text{W/m}\cdot\text{K}}{10 \text{W/m}^2\cdot\text{K}} = 0.013\text{m} = 13\text{mm}
\]

Hence, \(r_{in,o} < r_{cr}\) and \(E_{g,\text{max}}'\) could be increased by increasing \(r_{in,o}\) up to a value of 13 mm (\(t = 12\) mm).

**COMMENTS:** The contact resistance affects the temperature of the wire, and for \(q' = \dot{E}_{g,\text{max}}' = 4.51 \text{W/m}\), the outer surface temperature of the wire is \(T_{w,o} = T_{in,i} + q' R'_{t,c} = 50^\circ\text{C} + (4.51 \text{W/m}) \left(3 \times 10^{-4} \text{m}^2\cdot\text{K/W}\right)/\pi \left(0.002\text{m}\right) = 50.2^\circ\text{C}\). Hence, the temperature change across the contact resistance is negligible.
PROBLEM 3.44

KNOWN: Long rod experiencing uniform volumetric generation of thermal energy, \( q \), concentric with a hollow ceramic cylinder creating an enclosure filled with air. Thermal resistance per unit length due to radiation exchange between enclosure surfaces is \( R'_{\text{rad}} \). The free convection coefficient for the enclosure surfaces is \( h = 20 \text{ W/m}^2\cdot\text{K} \).

FIND: (a) Thermal circuit of the system that can be used to calculate the surface temperature of the rod, \( T_r \); label all temperatures, heat rates and thermal resistances; evaluate the thermal resistances; and (b) Calculate the surface temperature of the rod.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional, radial conduction through the hollow cylinder, (3) The enclosure surfaces experience free convection and radiation exchange.

ANALYSIS: (a) The thermal circuit is shown below. Note labels for the temperatures, thermal resistances and the relevant heat fluxes.

Enclosure, radiation exchange (given):
\[ R'_{\text{rad}} = 0.30 \text{ m} \cdot \text{K} / \text{W} \]

Enclosure, free convection:
\[ R'_{\text{cv,rod}} = \frac{1}{h \pi D_r} = \frac{1}{20 \text{ W/m}^2 \cdot \text{K} \times \pi \times 0.020\text{m}} = 0.80 \text{ m} \cdot \text{K} / \text{W} \]
\[ R'_{\text{cv,cer}} = \frac{1}{h \pi D_i} = \frac{1}{20 \text{ W/m}^2 \cdot \text{K} \times \pi \times 0.040\text{m}} = 0.40 \text{ m} \cdot \text{K} / \text{W} \]

Ceramic cylinder, conduction:
\[ R'_{\text{cd}} = \frac{\ln(D_o/D_i)}{2\pi k} = \frac{\ln(0.120/0.040)}{2\pi \times 1.75 \text{ W/m} \cdot \text{K}} = 0.10 \text{ m} \cdot \text{K} / \text{W} \]

The thermal resistance between the enclosure surfaces (r-i) due to convection and radiation exchange is
\[ \frac{1}{R'_{\text{enc}}} = \frac{1}{R'_{\text{rad}}} + \frac{1}{R'_{\text{cv,rod}} + R'_{\text{cv,cer}}} \]
\[ R'_{\text{enc}} = \left( \frac{1}{0.30} + \frac{1}{0.80+0.40} \right)^{-1} \text{ m} \cdot \text{K} / \text{W} = 0.24 \text{ m} \cdot \text{K} / \text{W} \]

The total resistance between the rod surface (r) and the outer surface of the cylinder (o) is
\[ R'_{\text{tot}} = R'_{\text{enc}} + R'_{\text{cd}} = (0.24+0.1) \text{ m} \cdot \text{K} / \text{W} = 0.34 \text{ m} \cdot \text{K} / \text{W} \]

Continued .....
(b) From an energy balance on the rod (see schematic) find $T_r$.

\[
\dot{E}_{in} - \dot{E}_{out} + \dot{E}_{gen} = 0
\]

\[-q + \dot{q} = 0
\]

\[-(T_r - T_i) / R_{tot} + \dot{q} (\pi D^2 / 4) = 0
\]

\[-(T_r - 25) K / 0.34 \text{ m} \cdot \text{K} / \text{W} + 2 \times 10^6 \text{ W} / \text{m}^3 (\pi \times 0.020 \text{m}^2 / 4) = 0
\]

\[T_r = 239 \degree C \]

**COMMENTS:** In evaluating the convection resistance of the air space, it was necessary to define an average air temperature ($T_\infty$) and consider the convection coefficients for each of the space surfaces. As you'll learn later in Chapter 9, correlations are available for directly estimating the convection coefficient ($h_{enc}$) for the enclosure so that $q_{cv} = h_{enc} (T_r - T_1)$. 
**PROBLEM 3.45**

**KNOWN:** Tube diameter and refrigerant temperature for evaporator of a refrigerant system. Convection coefficient and temperature of outside air.

**FIND:** (a) Rate of heat extraction without frost formation, (b) Effect of frost formation on heat rate, (c) Time required for a 2 mm thick frost layer to melt in ambient air for which \( h = 2 \text{ W/m}^2\cdot\text{K} \) and \( T_\infty = 20^\circ\text{C} \).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional, steady-state conditions, (2) Negligible convection resistance for refrigerant flow \( (T_{\infty,i} = T_{S,1}) \), (3) Negligible tube wall conduction resistance, (4) Negligible radiation exchange at outer surface.

**ANALYSIS:** (a) The cooling capacity in the defrosted condition \( (\delta = 0) \) corresponds to the rate of heat extraction from the airflow. Hence,

\[
q' = h \pi r_1 \left( T_{\infty,o} - T_{S,1} \right) = 100 \text{ W/m}^2\cdot\text{K} \left( 2\pi \times 0.005 \text{ m} \right) (-3 + 18)^\circ\text{C} \\
q' = 47.1 \text{ W/m}
\]

(b) With the frost layer, there is an additional (conduction) resistance to heat transfer, and the extraction rate is

\[
q' = \frac{T_{\infty,o} - T_{S,1}}{R'_{\text{conv}} + R'_{\text{cond}}} = \frac{T_{\infty,o} - T_{S,1}}{1/(h \pi r_2) + \ln \left( \frac{r_2}{\delta} \right)/2\pi k}
\]

For \( 5 \leq r_2 \leq 9 \text{ mm} \) and \( k = 0.4 \text{ W/m} \cdot \text{K} \), this expression yields

**Continued...**
PROBLEM 3.45 (Cont.)

The heat extraction, and hence the performance of the evaporator coil, decreases with increasing frost layer thickness due to an increase in the total resistance to heat transfer. Although the convection resistance decreases with increasing \( \delta \), the reduction is exceeded by the increase in the conduction resistance.

(c) The time \( t_m \) required to melt a 2 mm thick frost layer may be determined by applying an energy balance, Eq. 1.11b, over the differential time interval \( dt \) and to a differential control volume extending inward from the surface of the layer.

\[
\dot{E}_{in} dt = dE_{st} = dU_{lat}
\]

\[
h \left(2 \pi rL \right) (T_{\infty,o} - T_f) dt = -h_{sf} \rho \Delta \varphi = -h_{sf} \rho \left(2 \pi rL \right) dr
\]

\[
h \left(T_{\infty,o} - T_f \right) \int_0^{t_m} dt = -\rho h_{sf} \int_{r_2}^{r_1} \Delta \varphi \, dr
\]

\[
t_m = \frac{\rho h_{sf} (r_2 - r_1)}{h \left(T_{\infty,o} - T_f \right)} = \frac{700 \text{ kg/m}^3 \left(3.34 \times 10^5 \text{ J/kg} \right) (0.002 \text{ m})}{2 \text{ W/m}^2 \cdot \text{K} \left(20 - 0\right) \text{ C}}
\]

\[
t_m = 11,690 \text{ s} = 3.25 \text{ h}
\]

**COMMENTS:** The tube radius \( r_1 \) exceeds the critical radius \( r_{cr} = k/h = 0.4 \text{ W/m-K}/100 \text{ W/m}^2 \cdot \text{K} = 0.004 \text{ m} \), in which case any frost formation will reduce the performance of the coil.
PROBLEM 3.46

KNOWN: Conditions associated with a composite wall and a thin electric heater.

FIND: (a) Equivalent thermal circuit, (b) Expression for heater temperature, (c) Ratio of outer and inner heat flows and conditions for which ratio is minimized.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, steady-state conduction, (2) Constant properties, (3) Isothermal heater, (4) Negligible contact resistance(s).

ANALYSIS: (a) On the basis of a unit axial length, the circuit, thermal resistances, and heat rates are as shown in the schematic.

(b) Performing an energy balance for the heater, \( \hat{E}_{in} = \hat{E}_{out} \), it follows that

\[
q_h (2\pi r_2) = q'_i + q'_o = \frac{T_h - T_{\infty,i}}{(h_i2\pi\eta)^{-1} + \frac{\ln(r_2/\eta)}{2\pi k_B}} + \frac{T_h - T_{\infty,o}}{(h_o2\pi\eta)^{-1} + \frac{\ln(r_3/r_2)}{2\pi k_A}}
\]

(c) From the circuit,

\[
\frac{q'_o}{q'_i} = \frac{(T_h - T_{\infty,o})}{(h_i2\pi\eta)^{-1} + \frac{\ln(r_2/\eta)}{2\pi k_B}} \times \frac{(T_h - T_{\infty,i})}{(h_o2\pi\eta)^{-1} + \frac{\ln(r_3/r_2)}{2\pi k_A}}
\]

To reduce \( q'_o/q'_i \), one could increase \( k_B, h_i, \) and \( r_3/r_2 \), while reducing \( k_A, h_o \) and \( r_2/r_1 \).

COMMENTS: Contact resistances between the heater and materials A and B could be important.
PROBLEM 3.47

KNOWN: Electric current flow, resistance, diameter and environmental conditions associated with a cable.

FIND: (a) Surface temperature of bare cable, (b) Cable surface and insulation temperatures for a thin coating of insulation, (c) Insulation thickness which provides the lowest value of the maximum insulation temperature. Corresponding value of this temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in r, (3) Constant properties.

ANALYSIS: (a) The rate at which heat is transferred to the surroundings is fixed by the rate of heat generation in the cable. Performing an energy balance for a control surface about the cable, it follows that \( q' = I^2R'_e = (700A)^2(6 \times 10^{-4} \Omega/m) = 294 \text{ W/m} \), it follows that

\[
T_s = T_\infty + \frac{q'}{h\pi D_i} = 30^\circ C + \frac{294 \text{ W/m}}{25 \text{ W/m}^2 \cdot K \pi (0.005m)}
\]

\[T_s = 778.7^\circ C.\]

(b) With a thin coating of insulation, there exist contact and convection resistances to heat transfer from the cable. The heat transfer rate is determined by heating within the cable, however, and therefore remains the same.

\[
q = \frac{T_s - T_\infty}{R_{t,c} + \frac{1}{h\pi D_i L}} = \frac{T_s - T_\infty}{R'_{t,c} + \frac{1}{\pi D_i L} + \frac{1}{h\pi D_i L}}
\]

\[
q' = \frac{\pi D_i (T_s - T_\infty)}{R'_{t,c} + 1/h}
\]

and solving for the surface temperature, find

\[
T_s = \frac{q'}{\pi D_i \left[ R'_{t,c} + \frac{1}{h} \right]} + T_\infty = \frac{294 \text{ W/m}}{\pi (0.005m)} \left[ 0.02 \text{ m}^2 \cdot K/\text{W} + 0.04 \text{ m}^2 \cdot K/\text{W} \right] + 30^\circ C
\]

\[T_s = 1153^\circ C.\]

Continued …..
The insulation temperature is then obtained from
\[ q = \frac{T_s - T_i}{R_{t,c}} \]

or
\[ T_i = T_s - qR_{t,c} = 1153^\circ C - q \frac{R_{t,c}^*}{\pi D_i L} = 1153^\circ C - \frac{294 W \times 0.02 m^2 \cdot K}{\pi (0.005 m)} \]

\[ T_i = 778.7^\circ C. \]

(c) The maximum insulation temperature could be reduced by reducing the resistance to heat transfer from the outer surface of the insulation. Such a reduction is possible if \( D_i < D_{cr} \). From Example 3.4,
\[ r_{cr} = \frac{k}{h} = \frac{0.5 W/m \cdot K}{25 W/m^2 \cdot K} = 0.02 m. \]

Hence, \( D_{cr} = 0.04 m > D_i = 0.005 m \). To minimize the maximum temperature, which exists at the inner surface of the insulation, add insulation in the amount
\[ t = \frac{D_o - D_i}{2} = \frac{D_{cr} - D_i}{2} = \frac{(0.04 - 0.005) m}{2} \]

\[ t = 0.0175 m. \]

The cable surface temperature may then be obtained from
\[ q' = \frac{R_{t,c}}{\pi D_i} \left( \frac{T_s - T_{\infty}}{\ln (D_{cr} / D_i)} + \frac{1}{h \pi D_{cr}} \right) = \frac{T_s - 30^\circ C}{0.02 m^2 \cdot K/W} + \frac{\ln (0.04/0.005)}{2 \pi (0.005 m) + \left( \frac{1}{25 W/m^2 \cdot K} \right) \frac{W}{m^2 \pi (0.04 m)}} \]

Hence,
\[ 294 \frac{W}{m} = \frac{T_s - 30^\circ C}{(1.27+0.66+0.32) m \cdot K/W} = \frac{T_s - 30^\circ C}{2.25 m \cdot K/W} \]

\[ T_s = 692.5^\circ C \]

Recognizing that \( q = (T_s - T_i)/R_{t,c} \), find
\[ T_i = T_s - qR_{t,c} = T_s - q \frac{R_{t,c}^*}{\pi D_i L} = 692.5^\circ C - \frac{294 W \times 0.02 m^2 \cdot K}{\pi (0.005 m)} \]

\[ T_i = 318.2^\circ C. \]

**COMMENTS:** Use of the critical insulation thickness in lieu of a thin coating has the effect of reducing the maximum insulation temperature from 778.7°C to 318.2°C. Use of the critical insulation thickness also reduces the cable surface temperature to 692.5°C from 778.7°C with no insulation or from 1153°C with a thin coating.
PROBLEM 3.48

KNOWN: Saturated steam conditions in a pipe with prescribed surroundings.
FIND: (a) Heat loss per unit length from bare pipe and from insulated pipe, (b) Pay back period for insulation.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat transfer, (3) Constant properties, (4) Negligible pipe wall resistance, (5) Negligible steam side convection resistance (pipe inner surface temperature is equal to steam temperature), (6) Negligible contact resistance, (7) $T_{sur} = T_{\infty}$.

PROPERTIES: Table A-6, Saturated water ($p = 20$ bar): $T_{sat} = T_s = 486K$; Table A-3, Magnesia, 85% ($T = 392K$): $k = 0.058 \text{ W/m} \cdot \text{K}$.

ANALYSIS: (a) Without the insulation, the heat loss may be expressed in terms of radiation and convection rates,

$$q' = \varepsilon \pi D \sigma (T_s^4 - T_{sur}^4) + h (\pi D)(T_s - T_{\infty})$$

$$q' = 0.8 \pi (0.2m) 5.67 \times 10^{-8} \frac{W}{m^2 \cdot K^4} (486^4 - 298^4)K^4$$

$$+ 20 \frac{W}{m^2 \cdot K} (\pi \times 0.2m) (486-298)K$$

$$q' = (1365 + 2362) W/m = 3727 W/m. \quad \diamondsuit$$

With the insulation, the thermal circuit is of the form

Continued ....
From an energy balance at the outer surface of the insulation,

\[
\frac{q_{\text{cond}} - q_{\text{conv}} + q_{\text{rad}}}{T_{s,i} - T_{s,o}} = h \pi \frac{D_o}{D_i} \ln \left( \frac{D_o}{D_i} \right) / 2\pi k
\]

\[
= \frac{20}{\ln \left( \frac{0.3\text{m}}{0.2\text{m}} \right)} \frac{W}{m^2 \cdot K} \pi \left( T_{s,o} - 298\text{K} \right)
\]

\[
= +0.8 \times 5.67 \times 10^{-8} \frac{W}{m^2 \cdot K^4} \pi \left( T_{s,o} - 298^4 \right) K^4.
\]

By trial and error, we obtain

\[ T_{s,o} \approx 305\text{K} \]

in which case

\[
q' = \frac{(486-305)K}{\ln \left( \frac{0.3\text{m}}{0.2\text{m}} \right)} \frac{W}{2\pi (0.058\text{W/m} \cdot \text{K})} = 163 \text{ W/m.} <
\]

(b) The yearly energy savings per unit length of pipe due to use of the insulation is

\[
\frac{\text{Savings}}{\text{Yr} \cdot \text{m}} = \frac{\text{Energy Savings}}{\text{Yr} \cdot \text{Energy}} \times \frac{\text{Cost}}{\text{Yr}}
\]

\[
= (3727 - 163) \frac{J}{s \cdot m} \times 3600 \frac{s}{h} \times 7500 \frac{h}{\text{Yr}} \times \frac{4}{10^9 \text{J}}
\]

\[
= \frac{\text{Savings}}{\text{Yr} \cdot \text{m}} = \frac{\text{Cost}}{\text{Savings/Yr} \cdot \text{m}} = \frac{385}{\text{Yr} \cdot \text{m}}.
\]

The pay back period is then

\[
\text{Pay Back Period} = \frac{\text{Insulation Costs}}{\text{Savings/Yr} \cdot \text{m}} = \frac{100/\text{m}}{385/\text{Yr} \cdot \text{m}}
\]

\[
= \frac{0.26 \text{ Yr} = 3.1 \text{ mo.}}{<}
\]

COMMENTS: Such a low pay back period is more than sufficient to justify investing in the insulation.
**PROBLEM 3.49**

**KNOWN:** Temperature and convection coefficient associated with steam flow through a pipe of prescribed inner and outer diameters. Outer surface emissivity and convection coefficient. Temperature of ambient air and surroundings.

**FIND:** Heat loss per unit length.

**SCHEMATIC:**

![Schematic Diagram](image)

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional heat transfer, (3) Constant properties, (4) Surroundings form a large enclosure about pipe.

**PROPERTIES:** Table A-1, Steel, AISI 1010 (T ≈ 450 K): k = 56.5 W/m·K.

**ANALYSIS:** Referring to the thermal circuit, it follows from an energy balance on the outer surface that

\[
\frac{T_{\infty,i} - T_{s,o}}{R_{\text{conv},i} + R_{\text{cond}}} = \frac{T_{s,o} - T_{\infty,o}}{R_{\text{conv},o}} + \frac{T_{s,o} - T_{\text{sur}}}{R_{\text{rad}}}
\]

or from Eqs. 3.9, 3.28 and 1.7,

\[
\frac{T_{\infty,i} - T_{s,o}}{(1/\pi D_i h_i) + \ln (D_o/D_i)/2\pi k} = \frac{T_{s,o} - T_{\infty,o}}{(1/\pi D_o h_o)} + \varepsilon \pi D_o \sigma \left(T_{s,o}^4 - T_{\text{sur}}^4\right)
\]

\[
\frac{523 - T_{s,o}}{0.0106 + 0.0006} = \frac{T_{s,o} - 293}{0.170} + 1.07 \times 10^{-8} \left[T_{s,o}^4 - 293^4\right]\

From a trial-and-error solution, \(T_{s,o} \approx 502\)K. Hence the heat loss is

\[
q' = \pi D_o h_o \left(T_{s,o} - T_{\infty,o}\right) + \varepsilon \pi D_o \sigma \left(T_{s,o}^4 - T_{\text{sur}}^4\right)
\]

\[
q' = \pi (0.075m) 25 \text{ W/m}^2 \cdot \text{K} (502-293) + 0.8 \pi (0.075m) 5.67 \times 10^{-8} \frac{W}{\text{m}^2 \cdot \text{K}^4} \left[502^4 - 243^4\right] \text{K}^4
\]

\[q' = 1231 \text{ W/m} + 600 \text{ W/m} = 1831 \text{ W/m}.
\]

**COMMENTS:** The thermal resistance between the outer surface and the surroundings is much larger than that between the outer surface and the steam.
PROBLEM 3.50

KNOWN: Temperature and convection coefficient associated with steam flow through a pipe of prescribed inner and outer radii. Emissivity of outer surface magnesia insulation, and convection coefficient. Temperature of ambient air and surroundings.

FIND: Heat loss per unit length $q'$ and outer surface temperature $T_{s,o}$ as a function of insulation thickness. Recommended insulation thickness. Corresponding annual savings and temperature distribution.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat transfer, (3) Constant properties, (4) Surroundings form a large enclosure about pipe.

PROPERTIES: Table A-1, Steel, AISI 1010 ($T = 450$ K): $k_s = 56.5$ W/m$\cdot$K. Table A-3, Magnesia, 85% ($T = 365$ K): $k_m = 0.055$ W/m$\cdot$K.

ANALYSIS: Referring to the thermal circuit, it follows from an energy balance on the outer surface that

$$\frac{T_{\infty,i} - T_{s,o}}{R_{\text{conv,i}} + R_{\text{cond,s}} + R_{\text{cond,m}}} = \frac{T_{s,o} - T_{\infty,o}}{R_{\text{conv,o}}} + \frac{T_{s,o} - T_{\text{sur}}}{R_{\text{rad}}}$$

or from Eqs. 3.9, 3.28 and 1.7,

$$\frac{T_{\infty,i} - T_{s,o}}{(1/2\pi r_1 h_i) + \ln (r_2/\eta)}/2\pi k_s + \ln (r_3/r_2)/2\pi k_m = \frac{T_{s,o} - T_{\infty,o}}{(1/2\pi r_3 h_o)} + \frac{T_{s,o} - T_{\text{sur}}}{(2\pi r_3)\varepsilon\sigma (T_{s,o} + T_{\text{sur}})(T_{s,o}^2 + T_{\text{sur}}^2)^{-1}}$$

This expression may be solved for $T_{s,o}$ as a function of $r_3$, and the heat loss may then be determined by evaluating either the left- or right-hand side of the energy balance equation. The results are plotted as follows.
The rapid decay in $q'$ with increasing $r_3$ is attributable to the dominant contribution which the insulation begins to make to the total thermal resistance. The inside convection and tube wall conduction resistances are fixed at 0.0106 m·K/W and $6.29 \times 10^{-4}$ m·K/W, respectively, while the resistance of the insulation increases to approximately 2 m·K/W at $r_3 = 0.075$ m.

The heat loss may be reduced by almost 91% from a value of approximately 1830 W/m at $r_3 = r_2 = 0.0375$ m (no insulation) to 172 W/m at $r_3 = 0.0575$ m and by only an additional 3% if the insulation thickness is increased to $r_3 = 0.0775$ m. Hence, an insulation thickness of $(r_3 - r_2) = 0.020$ m is recommended, for which $q' = 172$ W/m. The corresponding annual savings (AS) in energy costs is therefore

$$\text{AS} = \left[ (1830 - 172) \text{ W/m} \right] \times \frac{\$4}{10^9 \text{ J}} \times 7000 \frac{\text{h}}{\text{y}} \times 3600 \frac{\text{s}}{\text{h}} = \$167 / \text{m}$$

The corresponding temperature distribution is

The temperature in the insulation decreases from $T(r) = T_2 = 521$ K at $r = r_2 = 0.0375$ m to $T(r) = T_3 = 309$ K at $r = r_3 = 0.0575$ m.
COMMENTS: 1. The annual energy and costs savings associated with insulating the steam line are substantial, as is the reduction in the outer surface temperature (from $T_{s,o} \approx 502$ K for $r_3 = r_2$, to $309$ K for $r_3 = 0.0575$ m).

2. The increase in $R'_{rad}$ to a maximum value of $0.63$ m-K/W at $r_3 = 0.0455$ m and the subsequent decay is due to the competing effects of $h_{rad}$ and $A_3' = \left(1/2\pi r_3\right)$. Because the initial decay in $T_3 = T_{s,o}$ with increasing $r_3$, and hence, the reduction in $h_{rad}$, is more pronounced than the increase in $A_3'$, $R'_{rad}$ increases with $r_3$. However, as the decay in $T_{s,o}$ and hence $h_{rad}$, becomes less pronounced, the increase in $A_3'$ becomes more pronounced and $R'_{rad}$ decreases with increasing $r_3$. 
**PROBLEM 3.51**

**KNOWN:** Pipe wall temperature and convection conditions associated with water flow through the pipe and ice layer formation on the inner surface.

**FIND:** Ice layer thickness $\delta$.

**SCHEMATIC:**

![Schematic of ice layer formation](image)

**ASSUMPTIONS:** (1) One-dimensional, steady-state conduction, (2) Negligible pipe wall thermal resistance, (3) negligible ice/wall contact resistance, (4) Constant $k$.

**PROPERTIES:** *Table A.3*, Ice ($T = 265$ K): $k \approx 1.94$ W/m$\cdot$K.

**ANALYSIS:** Performing an energy balance for a control surface about the ice/water interface, it follows that, for a unit length of pipe,

$$q'_{\text{conv}} = q'_{\text{cond}}$$

$$h_i (2\pi r_1) (T_{\infty,i} - T_{s,i}) = \frac{T_{s,i} - T_{s,o}}{\ln (r_2 / r_1) / 2\pi k}$$

Dividing both sides of the equation by $r_2$,

$$\frac{\ln (r_2 / r_1)}{(r_2 / \eta)} = \frac{k}{h_i r_2} \times \frac{T_{s,i} - T_{s,o}}{T_{\infty,i} - T_{s,i}} = \frac{1.94 \text{ W/m} \cdot \text{K}}{2000 \text{ W/m}^2 \cdot \text{K}} \times \frac{15^\circ \text{C}}{3^\circ \text{C}} = 0.097$$

The equation is satisfied by $r_2/r_1 = 1.114$, in which case $r_1 = 0.050$ m/1.114 = 0.045 m, and the ice layer thickness is

$$\delta = r_2 - \eta = 0.005 \text{ m} = 5 \text{ mm}$$

**COMMENTS:** With no flow, $h_i \to 0$, in which case $r_1 \to 0$ and complete blockage could occur. The pipe should be insulated.
PROBLEM 3.52

KNOWN: Inner surface temperature of insulation blanket comprised of two semi-cylindrical shells of different materials. Ambient air conditions.

FIND: (a) Equivalent thermal circuit, (b) Total heat loss and material outer surface temperatures.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional, radial conduction, (3) Infinite contact resistance between materials, (4) Constant properties.

ANALYSIS: (a) The thermal circuit is,
\[ R_{\text{conv},A} = R_{\text{conv},B} = \frac{1}{\pi r_2 h} \]

The conduction resistances follow from Section 3.3.1 and Eq. 3.28. Each resistance is larger by a factor of 2 than the result of Eq. 3.28 due to the reduced area.

(b) Evaluating the thermal resistances and the heat rate \( q' = q'_A + q'_B \),

\[ R'_{\text{conv}} = \left( \pi \times 0.1 \text{m} \times 25 \text{ W/m}^2 \cdot \text{K} \right)^{-1} = 0.1273 \text{ m} \cdot \text{K/W} \]

\[ R'_{\text{cond}(A)} = \frac{\ln \left( \frac{r_2}{r_1} \right)}{\pi k_A} = 0.1103 \text{ m} \cdot \text{K/W} \quad R'_{\text{cond}(B)} = 8 R'_{\text{cond}(A)} = 0.8825 \text{ m} \cdot \text{K/W} \]

\[ q' = \frac{T_{s,1} - T_{\infty}}{R'_{\text{cond}(A)} + R'_{\text{conv}}} + \frac{T_{s,1} - T_{\infty}}{R'_{\text{cond}(B)} + R'_{\text{conv}}} \]

\[ q' = \frac{(500 - 300) \text{K}}{(0.1103+0.1273) \text{m} \cdot \text{K/W}} + \frac{(500 - 300) \text{K}}{(0.8825+0.1273) \text{m} \cdot \text{K/W}} = (842 + 198) \text{W/m} = 1040 \text{ W/m}. \]

Hence, the temperatures are

\[ T_{s,2}(A) = T_{s,1} - q'A R'_{\text{cond}(A)} = 500\text{K} - 842 \frac{\text{W}}{\text{m}} \times 0.1103 \frac{\text{m} \cdot \text{K}}{\text{W}} = 407\text{K} \]

\[ T_{s,2}(B) = T_{s,1} - q'B R'_{\text{cond}(B)} = 500\text{K} - 198 \frac{\text{W}}{\text{m}} \times 0.8825 \frac{\text{m} \cdot \text{K}}{\text{W}} = 325\text{K}. \]

COMMENTS: The total heat loss can also be computed from \( q' = (T_{s,1} - T_{\infty})/R_{\text{equiv}} \),

where \[ R_{\text{equiv}} = \left[ \left( R'_{\text{cond}(A)} + R'_{\text{conv},A} \right)^{-1} + \left( R'_{\text{cond}(B)} + R'_{\text{conv},B} \right)^{-1} \right]^{-1} = 0.1923 \text{ m} \cdot \text{K/W} \]

Hence \( q' = (500 - 300) \text{K}/0.1923 \text{ m} \cdot \text{K/W} = 1040 \text{ W/m}. \)
**PROBLEM 3.53**

**KNOWN:** Surface temperature of a circular rod coated with bakelite and adjoining fluid conditions.

**FIND:** (a) Critical insulation radius, (b) Heat transfer per unit length for bare rod and for insulation at critical radius, (c) Insulation thickness needed for 25% heat rate reduction.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional conduction in r, (3) Constant properties, (4) Negligible radiation and contact resistance.

**PROPERTIES:** *Table A-3*, Bakelite (300K): \( k = 1.4 \text{ W/m} \cdot \text{K} \).

**ANALYSIS:**

(a) From Example 3.4, the critical radius is
\[
 r_{cr} = \frac{k}{h} = \frac{1.4 \text{ W/m} \cdot \text{K}}{140 \text{ W/m}^2 \cdot \text{K}} = 0.01 \text{m}. 
\]

(b) For the bare rod,
\[
 q' = h (\pi D_i) (T_i - T_\infty) 
= 140 \frac{W}{m^2 \cdot \text{K}} (\pi \times 0.01 \text{m}) (200 - 25) ^\circ \text{C} = 770 \text{ W/m} 
\]

For the critical insulation thickness,
\[
 q' = \frac{T_i - T_\infty}{1 + \frac{\ln \left( \frac{r_{cr}}{\eta} \right)}{2\pi k}} = \frac{(200 - 25) ^\circ \text{C}}{2\pi \times (0.01 \text{m}) \times 140 \text{ W/m}^2 \cdot \text{K} + \frac{\ln (0.01/0.005)}{2\pi \times 1.4 \text{ W/m} \cdot \text{K}}} 
= \frac{175 ^\circ \text{C}}{(0.1137 + 0.0788) \text{ m} \cdot \text{K/W}} = 909 \text{ W/m} 
\]

(c) The insulation thickness needed to reduce the heat rate to 577 W/m is obtained from
\[
 q' = \frac{T_i - T_\infty}{1 + \frac{\ln \left( \frac{r}{\eta} \right)}{2\pi k}} = \frac{(200 - 25) ^\circ \text{C}}{2\pi (r) 140 \text{ W/m}^2 \cdot \text{K} + \frac{\ln (r/0.005)}{2\pi \times 1.4 \text{ W/m} \cdot \text{K}}} = 577 \text{ W/m} 
\]

From a trial-and-error solution, find
\( r \approx 0.06 \text{ m} \).

The desired insulation thickness is then
\[
 \delta = (r - \eta) \approx (0.06 - 0.005) \text{m} = 55 \text{ mm}.
\]
PROBLEM 3.54

KNOWN: Geometry of an oil storage tank. Temperature of stored oil and environmental conditions.

FIND: Heater power required to maintain a prescribed inner surface temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in radial direction, (3) Constant properties, (4) Negligible radiation.

PROPERTIES: Table A-3, Pyrex (300K): $k = 1.4 \text{ W/m} \cdot \text{K}$.

ANALYSIS: The rate at which heat must be supplied is equal to the loss through the cylindrical and hemispherical sections. Hence,

$$q = q_{cyl} + 2q_{hemi} = q_{cyl} + q_{spher}$$

or, from Eqs. 3.28 and 3.36,

$$q = \frac{T_{s,i} - T_{\infty}}{\ln \left(\frac{D_o}{D_i}\right)} + \frac{1}{\pi D_o L h} \left[ \frac{1}{D_i} - \frac{1}{D_o} \right] + \frac{1}{\pi D_o^2 h} \left[ \frac{T_{s,i} - T_{\infty}}{L} \right]$$

$$q = \frac{(400 - 300) \text{K}}{2\pi (2 \text{m}) 1.4 \text{ W/m} \cdot \text{K}} + \frac{1}{\pi (1.04 \text{m}) 2 \text{m} \left(10 \text{ W/m}^2 \cdot \text{K}\right)} \left[ \frac{(400 - 300) \text{K}}{1.04 \text{m} - 0.962 \text{m}^{-1}} \right] + \frac{1}{\pi (1.04 \text{m})^2 10 \text{ W/m}^2 \cdot \text{K}} \left[ \frac{100 \text{K}}{2.23 \times 10^{-3} \text{ K/W}} + \frac{15.30 \times 10^{-3} \text{ K/W}}{4.32 \times 10^{-3} \text{ K/W}} + \frac{29.43 \times 10^{-3} \text{ K/W}}{4.32 \times 10^{-3} \text{ K/W}} \right]$$

$$q = 5705 \text{W} + 2963 \text{W} = 8668 \text{W}.$$
PROBLEM 3.55

KNOWN: Diameter of a spherical container used to store liquid oxygen and properties of insulating material. Environmental conditions.

FIND: (a) Reduction in evaporative oxygen loss associated with a prescribed insulation thickness, (b) Effect of insulation thickness on evaporation rate.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, one-dimensional conduction, (2) Negligible conduction resistance of container wall and contact resistance between wall and insulation, (3) Container wall at boiling point of liquid oxygen.

ANALYSIS: (a) Applying an energy balance to a control surface about the insulation, \( E_{\text{in}} - E_{\text{out}} = 0 \), it follows that \( q_{\text{conv}} + q_{\text{rad}} = q_{\text{cond}} = q \). Hence,

\[
\frac{T_{\infty} - T_{S,2}}{R_{t,\text{conv}}} + \frac{T_{\text{sur}} - T_{S,2}}{R_{t,\text{rad}}} = \frac{T_{S,2} - T_{S,1}}{R_{t,\text{cond}}} = q
\]

where

\[
R_{t,\text{conv}} = \left( \frac{4\pi r_2^2 h}{1} \right), \quad R_{t,\text{rad}} = \left( \frac{4\pi r_2^2 h_r}{1} \right), \quad R_{t,\text{cond}} = \left( \frac{1}{4\pi k} \right) \left[ \left( \frac{1}{\eta} \right) - \left( \frac{1}{r_2} \right) \right],
\]

and, from Eq. 1.9, the radiation coefficient is \( h_r = \epsilon \sigma \left( T_{S,2} + T_{\text{sur}} \right) \left( T_{S,2}^2 + T_{\text{sur}}^2 \right) \). With \( t = 10 \text{ mm} (r_2 = 260 \text{ mm}), \epsilon = 0.2 \) and \( T_{\infty} = T_{\text{sur}} = 298 \text{ K} \), an iterative solution of the energy balance equation yields \( T_{S,2} = 297.7 \text{ K} \), where \( R_{t,\text{conv}} = 0.118 \text{ K/W} \), \( R_{t,\text{rad}} = 0.982 \text{ K/W} \) and \( R_{t,\text{cond}} = 76.5 \text{ K/W} \). With the insulation, it follows that the heat gain is

\[
q_w \approx 2.72 \text{ W}
\]

Without the insulation, the heat gain is

\[
q_{w0} = \frac{T_{\infty} - T_{S,1}}{R_{t,\text{conv}}} + \frac{T_{\text{sur}} - T_{S,1}}{R_{t,\text{rad}}}
\]

where, with \( r_2 = r_1 \), \( T_{S,1} = 90 \text{ K} \), \( R_{t,\text{conv}} = 0.127 \text{ K/W} \) and \( R_{t,\text{rad}} = 3.14 \text{ K/W} \). Hence,

\[
q_{w0} = 1702 \text{ W}
\]

With the oxygen mass evaporation rate given by \( \dot{m} = \frac{q}{h_{fg}} \), the percent reduction in evaporated oxygen is

\[
\% \text{ Reduction} = \left( \frac{\dot{m}_{w0} - \dot{m}_w}{\dot{m}_{w0}} \right) \times 100\% = \left( \frac{q_{w0} - q_w}{q_{w0}} \right) \times 100\%
\]

Hence,

\[
\% \text{ Reduction} = \left( \frac{1702 - 2.7}{1702} \right) \times 100\% = 99.8\%
\]

Continued...
(b) Using Equation (1) to compute $T_{s,2}$ and $q$ as a function of $r_2$, the corresponding evaporation rate, $\dot{m} = q/h_g$, may be determined. Variations of $q$ and $\dot{m}$ with $r_2$ are plotted as follows.

Because of its extremely low thermal conductivity, significant benefits are associated with using even a thin layer of insulation. Nearly three-order magnitude reductions in $q$ and $\dot{m}$ are achieved with $r_2 = 0.26$ m. With increasing $r_2$, $q$ and $\dot{m}$ decrease from values of 1702 W and $8 \times 10^{-3}$ kg/s at $r_2 = 0.25$ m to 0.627 W and $2.9 \times 10^{-6}$ kg/s at $r_2 = 0.30$ m.

**COMMENTS:** Laminated metallic-foil/glass-mat insulations are extremely effective and corresponding conduction resistances are typically much larger than those normally associated with surface convection and radiation.
PROBLEM 3.56

KNOWN: Sphere of radius $r_i$, covered with insulation whose outer surface is exposed to a convection process.

FIND: Critical insulation radius, $r_{cr}$.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional radial (spherical) conduction, (3) Constant properties, (4) Negligible radiation at surface.

ANALYSIS: The heat rate follows from the thermal circuit shown in the schematic,

$$q = \frac{(T_i - T_\infty)}{R_{tot}}$$

where $R_{tot} = R_{t,conv} + R_{t,cond}$ and

$$R_{t,conv} = \frac{1}{hA_s} = \frac{1}{4\pi hr^2}$$

$$R_{t,cond} = \frac{1}{4\pi k} \left[ \frac{1}{r_i} - \frac{1}{r} \right]$$

If $q$ is a maximum or minimum, we need to find the condition for which

$$\frac{dR_{tot}}{dr} = 0.$$  

It follows that

$$\frac{d}{dr} \left[ \frac{1}{4\pi k} \left[ \frac{1}{r_i} - \frac{1}{r} \right] + \frac{1}{4\pi hr^2} \right] = \left[ \frac{1}{4\pi k} \frac{1}{r^2} - \frac{1}{2\pi h} \frac{1}{r^3} \right] = 0$$

giving

$$r_{cr} = 2 \frac{k}{h}$$

The second derivative, evaluated at $r = r_{cr}$, is

$$\frac{d}{dr} \left[ \frac{dR_{tot}}{dr} \right] = -\frac{1}{2\pi k} \frac{1}{r^3} + \frac{3}{2\pi h} \frac{1}{r^4} |_{r=r_{cr}}$$

$$= \frac{1}{(2k/h)^3} \left\{ -\frac{1}{2\pi k} + \frac{3}{2\pi h} \frac{1}{2k/h} \right\} = \frac{1}{(2k/h)^3} \frac{1}{2\pi k} \left\{ -1 + \frac{3}{2} \right\} > 0$$

Hence, it follows no optimum $R_{tot}$ exists. We refer to this condition as the critical insulation radius. See Example 3.4 which considers this situation for a cylindrical system.
PROBLEM 3.57

KNOWN: Thickness of hollow aluminum sphere and insulation layer. Heat rate and inner surface temperature. Ambient air temperature and convection coefficient.

FIND: Thermal conductivity of insulation.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional radial conduction, (3) Constant properties, (4) Negligible contact resistance, (5) Negligible radiation exchange at outer surface.

PROPERTIES: Table A-1, Aluminum (523K): $k \approx 230 \text{ W/m-K}$.

ANALYSIS: From the thermal circuit,

$$q = \frac{T_1 - T_\infty}{R_{\text{tot}}} = \frac{T_1 - T_\infty}{\frac{1}{r_1} - \frac{1}{r_2} + \frac{1}{r_2} - \frac{1}{r_3} + \frac{1}{h4\pi r_3^2}}$$

$$k_I = \frac{q}{\frac{1}{0.15} - \frac{1}{0.18} + \frac{1}{0.18} - \frac{1}{0.30} + \frac{1}{30(4\pi)(0.3)^2}} \approx 80 \text{ W}$$

or

$$3.84 \times 10^{-4} + \frac{0.177}{k_I} + 0.029 = \frac{230}{80} = 2.875.$$ 

Solving for the unknown thermal conductivity, find

$$k_I = 0.062 \text{ W/m-K}.$$ 

COMMENTS: The dominant contribution to the total thermal resistance is made by the insulation. Hence uncertainties in knowledge of $h$ or $k_{A1}$ have a negligible effect on the accuracy of the $k_I$ measurement.
**PROBLEM 3.58**

**KNOWN:** Dimensions of spherical, stainless steel liquid oxygen (LOX) storage container. Boiling point and latent heat of fusion of LOX. Environmental temperature.

**FIND:** Thermal isolation system which maintains boil-off below 1 kg/day.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional, steady-state conditions, (2) Negligible thermal resistances associated with internal and external convection, conduction in the container wall, and contact between wall and insulation, (3) Negligible radiation at exterior surface, (4) Constant insulation thermal conductivity.

**PROPERTIES:** *Table A.1*, 304 Stainless steel (T = 100 K): $k_s = 9.2 \text{ W/m} \cdot \text{K}$; *Table A.3*, Reflective, aluminum foil-glass paper insulation (T = 150 K): $k_i = 0.000017 \text{ W/m} \cdot \text{K}$.

**ANALYSIS:** The heat gain associated with a loss of 1 kg/day is

$$q = \frac{1 \text{ kg/day}}{86,400 \text{ s/day}} \times 2.13 \times 10^5 \frac{\text{J}}{\text{kg}} = 2.47 \text{ W}$$

With an overall temperature difference of $(T_{\infty} - T_{bp}) = 150 \text{ K}$, the corresponding total thermal resistance is

$$R_{tot} = \frac{\Delta T}{q} = \frac{150 \text{ K}}{2.47 \text{ W}} = 60.7 \text{ K/W}$$

Since the conduction resistance of the steel wall is

$$R_{t,\text{cond},s} = \frac{1}{4\pi k_s} \left( \frac{1}{r_1} - \frac{1}{r_2} \right) = \frac{1}{4\pi (9.2 \text{ W/m} \cdot \text{K})} \left( \frac{1}{0.35 \text{ m}} - \frac{1}{0.40 \text{ m}} \right) = 2.4 \times 10^{-3} \text{ K/W}$$

it is clear that exclusive reliance must be placed on the insulation and that a special insulation of very low thermal conductivity should be selected. The best choice is a highly reflective foil/glass matted insulation which was developed for cryogenic applications. It follows that

$$R_{t,\text{cond},i} = 60.7 \text{ K/W} = \frac{1}{4\pi k_i} \left( \frac{1}{r_2} - \frac{1}{r_3} \right) = \frac{1}{4\pi (0.000017 \text{ W/m} \cdot \text{K})} \left( \frac{1}{0.40 \text{ m}} - \frac{1}{r_3} \right)$$

which yields $r_3 = 0.4021 \text{ m}$. The minimum insulation thickness is therefore $\delta = (r_3 - r_2) = 2.1 \text{ mm}$.

**COMMENTS:** The heat loss could be reduced well below the maximum allowable by adding more insulation. Also, in view of weight restrictions associated with launching space vehicles, consideration should be given to fabricating the LOX container from a lighter material.
PROBLEM 3.59

KNOWN: Diameter and surface temperature of a spherical cryoprobe. Temperature of surrounding tissue and effective convection coefficient at interface between frozen and normal tissue.

FIND: Thickness of frozen tissue layer.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, steady-state conditions, (2) Negligible contact resistance between probe and frozen tissue, (3) Constant properties.

ANALYSIS: Performing an energy balance for a control surface about the phase front, it follows that

\[ q_{\text{conv}} - q_{\text{cond}} = 0 \]

Hence,

\[ h \left(4\pi r_2^2\right)\left(T_\infty - T_{s,2}\right) = \frac{T_{s,2} - T_{s,1}}{\left[\frac{1}{\eta} - \frac{1}{r_2}\right]/4\pi k} \]

\[ r_2^2 \left[\frac{1}{\eta} - \frac{1}{r_2}\right] = \frac{k}{h} \frac{T_{s,2} - T_{s,1}}{T_\infty - T_{s,2}} \]

\[ \left( \frac{r_2}{\eta} \right)^2 \left( \frac{r_2}{\eta} \right) - 1 = \frac{k}{h\eta} \frac{T_{s,2} - T_{s,1}}{T_\infty - T_{s,2}} = \frac{1.5 \text{ W/m·K}}{1.5 \text{ W/m·K}} \left( \frac{30}{37} \right) \]

\[ \left( \frac{r_2}{\eta} \right)^2 \left( \frac{r_2}{\eta} \right) - 1 = 16.2 \]

\[ (r_2/\eta) = 4.56 \]

It follows that \( r_2 = 6.84 \text{ mm} \) and the thickness of the frozen tissue is

\[ \delta = r_2 - \eta = 5.34 \text{ mm} \]
**PROBLEM 3.60**

**KNOWN:** Inner diameter, wall thickness and thermal conductivity of spherical vessel containing heat generating medium. Inner surface temperature without insulation. Thickness and thermal conductivity of insulation. Ambient air temperature and convection coefficient.

**FIND:** (a) Thermal energy generated within vessel, (b) Inner surface temperature of vessel with insulation.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) One-dimensional, radial conduction, (3) Constant properties, (4) Negligible contact resistance, (5) Negligible radiation.

**ANALYSIS:** (a) From an energy balance performed at an instant for a control surface about the pharmaceuticals, \( {\dot{E}_g} = q \), in which case, without the insulation

\[
{\dot{E}_g} = q = \frac{T_{s,1} - T_\infty}{\frac{1}{4\pi k_w} \left( \frac{1}{r_1} - \frac{1}{r_2} \right) + \frac{1}{4\pi r_2^2 h}} = \frac{(50 - 25) ^\circ C}{\frac{1}{4\pi k_w} \left( \frac{1}{0.50} - \frac{1}{0.51} \right) + \frac{1}{4\pi (0.51)^2 \cdot 6 W / m^2 \cdot K}}
\]

\[
{\dot{E}_g} = q = \frac{25 ^\circ C}{\left(1.84 \times 10^{-4} + 5.10 \times 10^{-2} \right)K / W} = 489 W <
\]

(b) With the insulation,

\[
T_{s,1} = T_\infty + q \left[ \frac{1}{4\pi k_w} \left( \frac{1}{r_1} - \frac{1}{r_2} \right) + \frac{1}{4\pi k_i} \left( \frac{1}{r_2} - \frac{1}{r_3} \right) + \frac{1}{4\pi r_3^2 h} \right]
\]

\[
T_{s,1} = 25 ^\circ C + 489 W \left[ \frac{1.84 \times 10^{-4} + \frac{1}{4\pi (0.04)} \left( \frac{1}{0.51} - \frac{1}{0.53} \right) + \frac{1}{4\pi (0.53)^2 \cdot 6} \right] K / W = 120 ^\circ C
\]

**COMMENTS:** The thermal resistance associated with the vessel wall is negligible, and without the insulation the dominant resistance is due to convection. The thermal resistance of the insulation is approximately three times that due to convection.
PROBLEM 3.61

KNOWN: Spherical tank of 1-m diameter containing an exothermic reaction and is at 200°C when the ambient air is at 25°C. Convection coefficient on outer surface is 20 W/m²·K.

FIND: Determine the thickness of urethane foam required to reduce the exterior temperature to 40°C. Determine the percentage reduction in the heat rate achieved using the insulation.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional, radial (spherical) conduction through the insulation, (3) Convection coefficient is the same for bare and insulated exterior surface, and (4) Negligible radiation exchange between the insulation outer surface and the ambient surroundings.

PROPERTIES: Table A-3, urethane, rigid foam (300 K): \( k = 0.026 \text{ W/m·K} \).

ANALYSIS: (a) The heat transfer situation for the heat rate from the tank can be represented by the thermal circuit shown above. The heat rate from the tank is

\[
q = \frac{T_t - T_\infty}{R_{cd} + R_{cv}}
\]

where the thermal resistances associated with conduction within the insulation (Eq. 3.35) and convection for the exterior surface, respectively, are

\[
R_{cd} = \frac{(1/\tilde{r}_t - 1/r_0)}{4\pi k} = \frac{(1/0.5 - 1/r_0)}{4\pi \times 0.026 \text{ W/m·K}} = 0.3267 \text{ K/W}
\]

\[
R_{cv} = \frac{1}{hA_s} = \frac{1}{4\pi hr_o^2} = \frac{1}{4\pi \times 20 \text{ W/m}^2\cdot\text{K} \times r_o^2} = 3.979 \times 10^{-3} r_o^{-2} \text{ K/W}
\]

To determine the required insulation thickness so that \( T_o = 40°C \), perform an energy balance on the o-node.

\[
\frac{T_t - T_o}{R_{cd}} + \frac{T_\infty - T_o}{R_{cv}} = 0
\]

\[
\frac{(200 - 40)}{(1/0.5 - 1/r_o)/0.3267 \text{ K/W}} + \frac{(25 - 40)}{3.979 \times 10^{-3} r_o^{-2}} \text{ K/W} = 0
\]

\[
r_o = 0.5135 \text{ m, } t = r_o - \tilde{r}_t = (0.5135 - 0.5000) \text{ m} = 13.5 \text{ mm}
\]

From the rate equation, for the bare and insulated surfaces, respectively,

\[
q_o = \frac{T_t - T_\infty}{1/4\pi hr_t^2} = \frac{(200 - 25)}{0.01592} \text{ K/W} = 10.99 \text{ kW}
\]

\[
q_{ins} = \frac{T_t - T_\infty}{R_{cd} + R_{cv}} = \frac{(200 - 25)}{(0.161 + 0.01592) \text{ K/W}} = 0.994 \text{ kW}
\]

Hence, the percentage reduction in heat loss achieved with the insulation is,

\[
\frac{q_{ins} - q_o}{q_o} \times 100 = \frac{0.994 - 10.99}{10.99} \times 100 = 91\%<
\]
**PROBLEM 3.62**

**KNOWN:** Dimensions and materials used for composite spherical shell. Heat generation associated with stored material.

**FIND:** Inner surface temperature, $T_1$, of lead (proposal is flawed if this temperature exceeds the melting point).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional conduction, (2) Steady-state conditions, (3) Constant properties at 300K, (4) Negligible contact resistance.

**PROPERTIES:** *Table A-1*, Lead: $k = 35.3 \text{ W/m} \cdot \text{K}$, $MP = 601\text{K}$; St.St.: 15.1 W/m·K.

**ANALYSIS:** From the thermal circuit, it follows that

$$q = \frac{T_1 - T_\infty}{R_{\text{tot}}} = \dot{q} \left[ \frac{4}{3} \pi r_1^3 \right]$$

Evaluate the thermal resistances,

$$R_{\text{Pb}} = \left[ \frac{1}{(4\pi \times 35.3 \text{ W/m} \cdot \text{K})} \right] \left[ \frac{1}{0.25\text{m}} - \frac{1}{0.30\text{m}} \right] = 0.00150 \text{ K/W}$$

$$R_{\text{St.St.}} = \left[ \frac{1}{(4\pi \times 15.1 \text{ W/m} \cdot \text{K})} \right] \left[ \frac{1}{0.30\text{m}} - \frac{1}{0.31\text{m}} \right] = 0.000567 \text{ K/W}$$

$$R_{\text{conv}} = \left[ \frac{1}{(4\pi \times 0.31^2 \text{ m}^2 \times 500 \text{ W/m}^2 \cdot \text{K})} \right] = 0.00166 \text{ K/W}$$

$$R_{\text{tot}} = 0.00372 \text{ K/W.}$$

The heat rate is $q = 5 \times 10^5 \text{ W/m}^3 \left(4\pi / 3\right)(0.25\text{m})^3 = 32,725 \text{ W}$. The inner surface temperature is

$$T_1 = T_\infty + R_{\text{tot}} q = 283\text{K} + 0.00372\text{K/W} \times 32,725 \text{ W}$$

$$T_1 = 405 \text{ K} < MP = 601\text{K.}$$

Hence, from the thermal standpoint, the proposal is adequate.

**COMMENTS:** In fabrication, attention should be given to maintaining a good thermal contact. A protective outer coating should be applied to prevent long term corrosion of the stainless steel.
PROBLEM 3.63

KNOWN: Dimensions and materials of composite (lead and stainless steel) spherical shell used to store radioactive wastes with constant heat generation. Range of convection coefficients \( h \) available for cooling.

FIND: (a) Variation of maximum lead temperature with \( h \). Minimum allowable value of \( h \) to maintain maximum lead temperature at or below 500 K. (b) Effect of outer radius of stainless steel shell on maximum lead temperature for \( h = 300, 500 \) and 1000 W/m\(^2\)-K.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) Steady-state conditions, (3) Constant properties at 300 K, (4) Negligible contact resistance.

PROPERTIES: Table A-1, Lead: \( k = 35.3 \) W/m-K, St. St.: 15.1 W/m-K.

ANALYSIS: (a) From the schematic, the maximum lead temperature \( T_1 \) corresponds to \( r = r_1 \), and from the thermal circuit, it may be expressed as

\[
T_1 = T_{\infty} + R_{\text{tot}} q
\]

where \( q = \dot{q} (4/3) \pi r_1^3 = 5 \times 10^5 \text{ W/m}^3 (4\pi/3)(0.25 \text{ m})^3 = 32,725 \text{ W} \). The total thermal resistance is

\[
R_{\text{tot}} = R_{\text{cond,Pb}} + R_{\text{cond,St,St}} + R_{\text{conv}}
\]

where expressions for the component resistances are provided in the schematic. Using the Resistance Network model and Thermal Resistance tool pad of IHT, the following result is obtained for the variation of \( T_1 \) with \( h \).
PROBLEM 3.63 (Cont.)

To maintain $T_1$ below 500 K, the convection coefficient must be maintained at

$$h \geq 181 \text{ W/m}^2\text{-K}$$

(b) The effect of varying the outer shell radius over the range $0.3 \leq r_3 \leq 0.5 \text{ m}$ is shown below.

For $h = 300, 500$ and $1000 \text{ W/m}^2\text{-K}$, the maximum allowable values of the outer radius are $r_3 = 0.365, 0.391$ and $0.408 \text{ m}$, respectively.

**COMMENTS:** For a maximum allowable value of $T_1 = 500 \text{ K}$, the maximum allowable value of the total thermal resistance is $R_{\text{tot}} = \frac{(T_1 - T_\infty)}{q}$, or $R_{\text{tot}} = \frac{(500 - 283)\text{K}}{32,725 \text{ W}} = 0.00663 \text{ K/W}$. Hence, any increase in $R_{\text{cond,St,St}}$ due to increasing $r_3$ must be accompanied by an equivalent reduction in $R_{\text{conv}}$. 
PROBLEM 3.64

KNOWN: Representation of the eye with a contact lens as a composite spherical system subjected to convection processes at the boundaries.

FIND: (a) Thermal circuits with and without contact lens in place, (b) Heat loss from anterior chamber for both cases, and (c) Implications of the heat loss calculations.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Eye is represented as 1/3 sphere, (3) Convection coefficient, $h_0$, unchanged with or without lens present, (4) Negligible contact resistance.

ANALYSIS: (a) Using Eqs. 3.9 and 3.36 to express the resistance terms, the thermal circuits are:

Without lens:

\[
\frac{q_{wo}}{T_{∞,i}} = \frac{3}{3h_i \pi r_1^2} + \frac{3}{4\pi k_1 (\frac{r_1}{r_2})} + \frac{3}{4\pi k_2 (\frac{r_2}{r_3})} + \frac{3}{4\pi h_0 (r_3)}
\]

With lens:

\[
\frac{q_w}{T_{∞,i}} = \frac{3}{3h_i \pi r_1^2} + \frac{3}{4\pi k_1 (\frac{r_1}{r_2})} + \frac{3}{4\pi k_2 (\frac{r_2}{r_3})} + \frac{3}{4\pi h_0 (r_3)}
\]

(b) The heat losses for both cases can be determined as $q = (T_{∞,i} - T_{∞,o})/R_t$, where $R_t$ is the thermal resistance from the above circuits.

Without lens:

\[
R_{t,wo} = \frac{3}{12W/m^2 \cdot K4\pi (10.2 \times 10^{-3} m)^2} + \frac{3}{4\pi \times 0.35 W/m \cdot K \left[ \frac{1}{10.2} - \frac{1}{12.7} \right]} \frac{1}{10^{-3} m}
\]

\[
= 191.2 \text{ K/W} + 13.2 \text{ K/W} + 246.7 \text{ K/W} = 451.1 \text{ K/W}
\]

With lens:

\[
R_{t,w} = 191.2 \text{ K/W} + 13.2 \text{ K/W} + \frac{3}{4\pi \times 0.80 W/m \cdot K \left[ \frac{1}{12.7} - \frac{1}{16.5} \right]} \frac{1}{10^{-3} m}
\]

\[
= 191.2 \text{ K/W} + 13.2 \text{ K/W} + 5.41 \text{ K/W} + 146.2 \text{ K/W} = 356.0 \text{ K/W}
\]

Hence the heat loss rates from the anterior chamber are

Without lens: $q_{wo} = (37 - 21)^o C/451.1 \text{ K/W} = 35.5 \text{ mW}$

With lens: $q_w = (37 - 21)^o C/356.0 \text{ K/W} = 44.9 \text{ mW}$

(c) The heat loss from the anterior chamber increases by approximately 20% when the contact lens is in place, implying that the outer radius, $r_3$, is less than the critical radius.
PROBLEM 3.65

KNOWN: Thermal conductivity and inner and outer radii of a hollow sphere subjected to a uniform heat flux at its outer surface and maintained at a uniform temperature on the inner surface.

FIND: (a) Expression for radial temperature distribution, (b) Heat flux required to maintain prescribed surface temperatures.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional radial conduction, (3) No generation, (4) Constant properties.

ANALYSIS: (a) For the assumptions, the temperature distribution may be obtained by integrating Fourier’s law, Eq. 3.33. That is,

$$\frac{q_r}{4\pi} \int_{r_1}^{r} \frac{dr}{r^2} = -k \int_{T_{s,1}}^{T} \frac{dT}{r} \quad \text{or} \quad -\frac{q_r}{4\pi} \frac{1}{r} \bigg|_{\eta}^{r} = -k \left( T - T_{s,1} \right).$$

Hence,

$$T(r) = T_{s,1} + \frac{q_r}{4\pi k} \left[ \frac{1}{r} \right]_0^{r} - \frac{1}{\eta} \left[ \frac{1}{r} \right]_0^{r}$$

or, with $q_2^r \equiv q_2 / 4\pi r_2^2$,

$$T(r) = T_{s,1} + \frac{q_2^r}{k} \left[ \frac{1}{r} \right]_0^{r} - \frac{1}{\eta} \left[ \frac{1}{r} \right]_0^{r}$$

(b) Applying the above result at $r_2$,

$$q_2^r = \frac{k \left( T_{s,2} - T_{s,1} \right)}{r_2^2 \left[ \frac{1}{r_2} \right] - \frac{1}{\eta} \left[ \frac{1}{r_2} \right]} = 10 \text{ W/m} \cdot \text{K} \left( 50 - 20 \right) \text{C} \left( 0.1 \text{m} \right)^2 \left[ \frac{1}{0.1} - \frac{1}{0.05} \right] \frac{1}{\text{m}} = -3000 \text{ W/m}^2.$$

COMMENTS: (1) The desired temperature distribution could also be obtained by solving the appropriate form of the heat equation,

$$\frac{d}{dr} \left[ r^2 \frac{dT}{dr} \right] = 0$$

and applying the boundary conditions $T(\eta) = T_{s,1}$ and $-k \left. \frac{dT}{dr} \right|_{r_2} = q_2^r$.

(2) The negative sign on $q_2^r$ implies heat transfer in the negative $r$ direction.
Problem 3.66

Known: Volumetric heat generation occurring within the cavity of a spherical shell of prescribed dimensions. Convection conditions at outer surface.

Find: Expression for steady-state temperature distribution in shell.

Schematic:

Assumptions: (1) One-dimensional radial conduction, (2) Steady-state conditions, (3) Constant properties, (4) Uniform generation within the shell cavity, (5) Negligible radiation.

Analysis: For the prescribed conditions, the appropriate form of the heat equation is

\[ \frac{d}{dr} \left[ r^2 \frac{dT}{dr} \right] = 0 \]

Integrate twice to obtain,

\[ r^2 \frac{dT}{dr} = C_1 \quad \text{and} \quad T = -\frac{C_1}{r} + C_2. \]  

The boundary conditions may be obtained from energy balances at the inner and outer surfaces. At the inner surface \( r_i \),

\[ \dot{E}_g = q \left( \frac{4}{3} \pi r_i^3 \right) = q_{\text{cond},i} = -k \left( 4\pi r_i^2 \right) \frac{dT}{dr} r_i \quad \text{and} \quad \frac{dT}{dr} r_i = -\frac{q_i}{3k}. \]  

At the outer surface \( r_o \),

\[ q_{\text{cond},o} = -k 4\pi r_o^2 \frac{dT}{dr} r_o = q_{\text{conv}} = h 4\pi r_o^2 \left[ T(r_o) - T_\infty \right] \]

\[ \frac{dT}{dr} r_o = -\left( \frac{h}{k} \right) \left[ T(r_o) - T_\infty \right]. \]  

From Eqs. (1) and (3), \( C_1 = -\frac{q_i^3}{3k} \). From Eqs. (1), (2) and (4)

\[ -\frac{q_i^3}{3kr_i^2} = -\left[ \frac{h}{k} \right] \left[ \frac{q_i^3}{3r_i k} + C_2 - T_\infty \right] \]

\[ C_2 = \frac{q_i^3}{3hr_i^2} - \frac{q_i^3}{3r_i k} + T_\infty. \]

Hence, the temperature distribution is

\[ T = \frac{q_i^3}{3k} \left[ \frac{1}{r} - \frac{1}{r_0} \right] + \frac{q_i^3}{3hr_0^2} + T_\infty. \]  

Comments: Note that \( \dot{E}_g = q_{\text{cond},i} = q_{\text{cond},o} = q_{\text{conv}} \).
PROBLEM 3.67

KNOWN: Spherical tank of 3-m diameter containing LP gas at -60°C with 250 mm thickness of insulation having thermal conductivity of 0.06 W/m·K. Ambient air temperature and convection coefficient on the outer surface are 20°C and 6 W/m²·K, respectively.

FIND: (a) Determine the radial position in the insulation at which the temperature is 0°C and (b) If the insulation is pervious to moisture, what conclusions can be reached about ice formation? What effect will ice formation have on the heat gain? How can this situation be avoided?

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional, radial (spherical) conduction through the insulation, and (3) Negligible radiation exchange between the insulation outer surface and the ambient surroundings.

ANALYSIS: (a) The heat transfer situation can be represented by the thermal circuit shown above. The heat gain to the tank is

\[
q = \frac{T_\infty - T_t}{R_{\text{ins}} + R_{\text{cv}}} = \frac{\left[20 - (-60)\right]K}{\left(0.1263 + 4.33 \times 10^{-3}\right)K/W} = 612.4 \text{ W}
\]

where the thermal resistances for the insulation (see Table 3.3) and the convection process on the outer surface are, respectively,

\[
R_{\text{ins}} = \frac{1}{\eta} - \frac{1}{r_0} = \frac{1}{1.50} - \frac{1}{1.75} \text{ m}^{-1} = 0.1263 \text{ K/W}
\]

\[
R_{\text{cv}} = \frac{1}{hA_s} = \frac{1}{h4\pi r_0^2} = \frac{1}{6 \text{ W/m}^2\cdot\text{K} \times 4\pi (1.75 \text{ m})^2} = 4.33 \times 10^{-3} \text{ K/W}
\]

To determine the location within the insulation where \(T_{\infty}(r_\infty) = 0°C\), use the conduction rate equation, Eq. 3.35,

\[
q = \frac{4\pi k (T_{\infty} - T_t)}{(1/\eta) - 1/r_\infty}
\]

and substituting numerical values, find

\[
r_\infty = \left[\frac{1}{\eta} - \frac{4\pi k (T_{\infty} - T_t)}{q}\right]^{-1}
\]

(b) With \(r_\infty = 1.687 \text{ m}\), we’d expect the region of the insulation \(r_i \leq r \leq r_\infty\) to be filled with ice formations if the insulation is pervious to water vapor. The effect of the ice formation is to substantially increase the heat gain since \(k_{\text{ice}}\) is nearly twice that of \(k_{\text{ins}}\), and the ice region is of thickness \((1.687 - 1.50)\text{ m} = 187 \text{ mm}\). To avoid ice formation, a vapor barrier should be installed at a radius larger than \(r_\infty\).
PROBLEM 3.68

KNOWN: Radius and heat dissipation of a hemispherical source embedded in a substrate of prescribed thermal conductivity. Source and substrate boundary conditions.

FIND: Substrate temperature distribution and surface temperature of heat source.

SCHEMATIC:

ASSUMPTIONS: (1) Top surface is adiabatic. Hence, hemispherical source in semi-infinite medium is equivalent to spherical source in infinite medium (with \( q = 8 \text{ W} \)) and heat transfer is one-dimensional in the radial direction, (2) Steady-state conditions, (3) Constant properties, (4) No generation.

ANALYSIS: Heat equation reduces to

\[
\frac{1}{r^2} \frac{d}{dr} \left(r^2 \frac{dT}{dr}\right) = 0 \quad r^2 \frac{dT}{dr} = C_1
\]

Boundary conditions:

\( T(\infty) = T_\infty \quad T(r_0) = T_s \)

Hence, \( C_2 = T_\infty \) and

\( T_s = -C_1/r_0 + T_\infty \quad \text{and} \quad C_1 = r_0 (T_\infty - T_s) \).

The temperature distribution has the form

\( T(r) = T_\infty + (T_s - T_\infty) r_0 / r \)

and the heat rate is

\( q = -k A \frac{dT}{dr} = -k 2\pi r^2 \left[ -\frac{(T_s - T_\infty)r_0}{r^2} \right] = k 2\pi r_0 (T_s - T_\infty) \)

It follows that

\( T_s - T_\infty = \frac{q}{k 2\pi r_0} = \frac{4 \text{ W}}{125 \text{ W/m·K} \cdot 2\pi \left(10^{-4} \text{ m} \right)} = 50.9^\circ \text{C} \)

\( T_s = 77.9^\circ \text{C}. \)

COMMENTS: For the semi-infinite (or infinite) medium approximation to be valid, the substrate dimensions must be much larger than those of the transistor.
**PROBLEM 3.69**

**KNOWN:** Critical and normal tissue temperatures. Radius of spherical heat source and radius of tissue to be maintained above the critical temperature. Tissue thermal conductivity.

**FIND:** General expression for radial temperature distribution in tissue. Heat rate required to maintain prescribed thermal conditions.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional, steady-state conduction, (2) Constant $k$.

**ANALYSIS:** The appropriate form of the heat equation is

$$\frac{1}{r^2} \frac{d}{dr} \left( r \frac{dT}{dr} \right) = 0$$

Integrating twice,

$$\frac{dT}{dr} = \frac{C_1}{r^2}$$

$$T(r) = -\frac{C_1}{r} + C_2$$

Since $T \to T_b$ as $r \to \infty$, $C_2 = T_b$. At $r = r_o$, $q = -k \left( 4\pi r_o^2 \right) \frac{dT}{dr} \bigg|_{r_o} = -4\pi kr_o^2 \frac{C_1}{r_o^2} = -4\pi k C_1$.

Hence, $C_1 = -q/4\pi k$ and the temperature distribution is

$$T(r) = \frac{q}{4\pi kr} + T_b$$

It follows that

$$q = 4\pi kr \left[ T(r) - T_b \right]$$

Applying this result at $r = r_c$,

$$q = 4\pi \left( 0.5 \text{ W/m} \cdot \text{K} \right) (0.005 \text{ m}) (42 - 37)^\circ \text{C} = 0.157 \text{ W}$$

**COMMENTS:** At $r_o = 0.0005 \text{ m}$, $T(r_o) = \left[ q/(4\pi kr_o) \right] + T_b = 92^\circ \text{C}$. Proximity of this temperature to the boiling point of water suggests the need to operate at a lower power dissipation level.
**PROBLEM 3.70**

**KNOWN:** Cylindrical and spherical shells with uniform heat generation and surface temperatures.

**FIND:** Radial distributions of temperature, heat flux and heat rate.

**SCHEMATIC:**

![Diagram showing cylindrical and spherical shells with surface temperatures and heat generation]

**ASSUMPTIONS:** (1) One-dimensional, steady-state conduction, (2) Uniform heat generation, (3) Constant k.

**ANALYSIS:** (a) For the **cylindrical shell**, the appropriate form of the heat equation is

\[
\frac{1}{r} \frac{d}{dr} \left( r \frac{dT}{dr} \right) + \frac{\dot{q}}{k} = 0
\]

The general solution is

\[
T(r) = -\frac{\dot{q}}{4k} r^2 + C_1 \ln r + C_2
\]

Applying the boundary conditions, it follows that

\[
T(r_1) = T_{s,1} = -\frac{\dot{q}}{4k} r_1^2 + C_1 \ln r_1 + C_2
\]

\[
T(r_2) = T_{s,2} = -\frac{\dot{q}}{4k} r_2^2 + C_1 \ln r_2 + C_2
\]

which may be solved for

\[
C_1 = \left[ \left( \frac{\dot{q}}{4k} \right) \left( r_2^2 - r_1^2 \right) + \left( T_{s,2} - T_{s,1} \right) \right] / \ln \left( \frac{r_2}{r_1} \right)
\]

\[
C_2 = T_{s,2} + \left( \frac{\dot{q}}{4k} \right) r_2^2 - C_1 \ln r_2
\]

Hence,

\[
T(r) = T_{s,2} + \left( \frac{\dot{q}}{4k} \right) \left( r_2^2 - r^2 \right) + \left[ \left( \frac{\dot{q}}{4k} \right) \left( r_2^2 - r_1^2 \right) + \left( T_{s,2} - T_{s,1} \right) \right] \frac{\ln \left( r/r_2 \right)}{\ln \left( r_2/r_1 \right)}
\]

With \( q^* = -k \frac{dT}{dr} \), the heat flux distribution is

\[
q^*(r) = \frac{\dot{q}}{2} \left( \frac{k}{r \ln \left( r_2/r_1 \right)} \right) \left[ \left( \frac{\dot{q}}{4k} \right) \left( r_2^2 - r_1^2 \right) + \left( T_{s,2} - T_{s,1} \right) \right] \frac{\ln \left( r/r_2 \right)}{\ln \left( r_2/r_1 \right)}
\]

Continued...
Similar to Problem 3.70, with \( q = q^* A(r) = q^* (2\pi r L) \), the heat rate distribution is

\[
q(r) = \pi L \dot{q} r^2 - \frac{2\pi L k}{\ln \left( \frac{r_2}{r_1} \right)} \left[ \left( \frac{\dot{q}}{4k} \right) \left( r_2^2 - r_1^2 \right) + \left( T_{s,2} - T_{s,1} \right) \right]
\]

(b) For the spherical shell, the heat equation and general solution are

\[
\frac{1}{r^2} \frac{d}{dr} \left( r^2 \frac{dT}{dr} \right) + \frac{\dot{q}}{k} = 0
\]

\[
T(r) = -\left( \frac{\dot{q}}{6k} \right) r^2 - \frac{C_1}{r} + C_2
\]

Applying the boundary conditions, it follows that

\[
T(r_1) = T_{s,1} = -\left( \frac{\dot{q}}{6k} \right) r_1^2 - \frac{C_1}{r_1} + C_2
\]

\[
T(r_2) = T_{s,2} = -\left( \frac{\dot{q}}{6k} \right) r_2^2 - \frac{C_1}{r_2} + C_2
\]

Hence,

\[
C_1 = \left[ \left( \frac{\dot{q}}{6k} \right) \left( r_2^2 - r_1^2 \right) + \left( T_{s,2} - T_{s,1} \right) \right] \left[ \frac{1}{r_1} - \frac{r_1}{r_2} \right]
\]

\[
C_2 = T_{s,2} + \left( \frac{\dot{q}}{6k} \right) r_2^2 + \frac{C_1}{r_2}
\]

and

\[
T(r) = T_{s,2} + \left( \frac{\dot{q}}{6k} \right) \left( r_2^2 - r^2 \right) - \left[ \left( \frac{\dot{q}}{6k} \right) \left( r_2^2 - r_1^2 \right) + \left( T_{s,2} - T_{s,1} \right) \right] \frac{1}{r_1} - \frac{r_1}{r_2}
\]

With \( q^* (r) = -k \frac{dT}{dr} \), the heat flux distribution is

\[
q^*(r) = \frac{\dot{q}}{3} r - \left[ \left( \frac{\dot{q}}{6} \right) \left( r_2^2 - r_1^2 \right) + k \left( T_{s,2} - T_{s,1} \right) \right] \frac{1}{r^2}
\]

and, with \( q = q^* \left( 4\pi r^2 \right) \), the heat rate distribution is

\[
q(r) = \frac{4\pi \dot{q}}{3} r^3 - \frac{4\pi}{(1/r_1) - (1/r_2)} \left[ \left( \frac{\dot{q}}{6} \right) \left( r_2^2 - r_1^2 \right) + k \left( T_{s,2} - T_{s,1} \right) \right]
\]
**PROBLEM 3.71**

**KNOWN:** Temperature distribution in a composite wall.

**FIND:** (a) Relative magnitudes of interfacial heat fluxes, (b) Relative magnitudes of thermal conductivities, and (c) Heat flux as a function of distance $x$.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties.

**ANALYSIS:** (a) For the prescribed conditions (one-dimensional, steady-state, constant $k$), the parabolic temperature distribution in C implies the existence of heat generation. Hence, since $dT/dx$ increases with decreasing $x$, the heat flux in C increases with decreasing $x$. Hence,

$q_3 > q_4$

However, the linear temperature distributions in A and B indicate no generation, in which case

$q_2 = q_3$

(b) Since conservation of energy requires that $q_{3,B} = q_{3,C}$ and $dT/dx)_B < dT/dx)_C$, it follows from Fourier’s law that

$k_B > k_C$.

Similarly, since $q_{2,A} = q_{2,B}$ and $dT/dx)_A > dT/dx)_B$, it follows that

$k_A < k_B$.

(c) It follows that the flux distribution appears as shown below.

**COMMENTS:** Note that, with $dT/dx)_{4,C} = 0$, the interface at 4 is adiabatic.
PROBLEM 3.72

KNOWN: Plane wall with internal heat generation which is insulated at the inner surface and subjected to a convection process at the outer surface.

FIND: Maximum temperature in the wall.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction with uniform volumetric heat generation, (3) Inner surface is adiabatic.

ANALYSIS: From Eq. 3.42, the temperature at the inner surface is given by Eq. 3.43 and is the maximum temperature within the wall,

\[ T_0 = \frac{qL^2}{2k} + T_s. \]

The outer surface temperature follows from Eq. 3.46,

\[ T_s = T_\infty + \frac{qL}{h}. \]

\[ T_s = 92^\circ C + 0.3 \times 10^6 \frac{W}{m^3} \times 0.1m/500W/m^2 \cdot K=92^\circ C+60^\circ C=152^\circ C. \]

It follows that

\[ T_0 = 0.3 \times 10^6 W/m^3 \times (0.1m)^2 / 2 \times 25W/m \cdot K+152^\circ C \]

\[ T_0 = 60^\circ C+152^\circ C=212^\circ C. \]

COMMENTS: The heat flux leaving the wall can be determined from knowledge of h, T_s and T_\infty using Newton’s law of cooling.

\[ q_{conv}^* = h(T_s - T_\infty) = 500W/m^2 \cdot K (152-92)^\circ C=30kW/m^2. \]

This same result can be determined from an energy balance on the entire wall, which has the form

\[ \dot{E}_g - \dot{E}_{out} = 0 \]

where

\[ \dot{E}_g = \dot{q}AL \quad \text{and} \quad \dot{E}_{out} = q_{conv}^* \cdot A. \]

Hence,

\[ q_{conv}^* = \dot{q}L=0.3 \times 10^6 W/m^3 \times 0.1m=30kW/m^2. \]
Problem 3.73

**KNOWN:** Composite wall with outer surfaces exposed to convection process.

**FIND:** (a) Volumetric heat generation and thermal conductivity for material B required for special conditions, (b) Plot of temperature distribution, (c) \( T_1 \) and \( T_2 \), as well as temperature distributions corresponding to loss of coolant condition where \( h = 0 \) on surface A.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, one-dimensional heat transfer, (2) Negligible contact resistance at interfaces, (3) Uniform generation in B; zero in A and C.

**ANALYSIS:**

(a) From an energy balance on wall B,

\[
\dot{E}_{in} - \dot{E}_{out} + \dot{E}_g = \dot{E}_{st}
\]

\[-q_1^* - q_2^* + 2q_B = 0\]

\[q_B = \left(q_1^* + q_2^*\right)/2L_B\, .\]

To determine the heat fluxes, \( q_1^* \) and \( q_2^* \), construct thermal circuits for A and C:

\[q_1^* = \left(T_1 - T_\infty\right)/(1/h + L_A/k_A)\]

\[q_2^* = \left(T_2 - T_\infty\right)/(L_C/k_C + 1/h)\]

\[q_1^* = \left(261 - 25\right)\, C/\left(1000\, W/m^2\cdot K + 0.030\, m \cdot 25\, W/m\cdot K\right)\]

\[q_2^* = \left(211 - 25\right)\, C/\left(0.020\, m \cdot 50\, W/m\cdot K + 1000\, W/m^2\cdot K\right)\]

\[q_1^* = 236\, C/\left(0.001 + 0.0012\right)\, m^2\cdot K/W\]

\[q_1^* = 107.273\, W/m^2\]

\[q_2^* = 186\, C/\left(0.0004 + 0.001\right)\, m^2\cdot K/W\]

\[q_2^* = 132.857\, W/m^2\]

Using the values for \( q_1^* \) and \( q_2^* \) in Eq. (1), find

\[\dot{q}_B = \left(106.818 + 132.143\, W/m^2\right)/2 \times 0.030\, m = 4.00 \times 10^6\, W/m^3\, .\]

To determine \( k_B \), use the general form of the temperature and heat flux distributions in wall B,

\[T(x) = -\frac{\dot{q}_B}{2k_B} x^2 + C_1 x + C_2\, \quad q_2^*(x) = -k_B\left[\left(-\frac{\dot{q}_B}{k_B} x + C_1\right)\right]\]

there are 3 unknowns, \( C_1 \), \( C_2 \) and \( k_B \), which can be evaluated using three conditions.

Continued...
PROBLEM 3.73 (Cont.)

\[
T(-L_B) = T_1 = -\frac{q_B}{2k_B}(-L_B)^2 - C_1 L_B + C_2 \quad \text{where } T_1 = 261°C \\
T(+L_B) = T_2 = -\frac{q_B}{2k_B}(+L_B)^2 + C_1 L_B + C_2 \quad \text{where } T_2 = 211°C \\
q_x'(-L_B) = -q_1' = -k_B \left[ -\frac{q_B}{k_B}(-L_B) + C_1 \right] \quad \text{where } q_1' = 107,273 \text{ W/m}^2
\]

Using IHT to solve Eqs. (3), (4) and (5) simultaneously with \( q_B = 4.00 \times 10^6 \text{ W/m}^3 \), find

\[ k_B = 15.3 \text{ W/m} \cdot \text{K} \]

(b) Following the method of analysis in the IHT Example 3.6, User-Defined Functions, the temperature distribution is shown in the plot below. The important features are (1) Distribution is quadratic in B, but non-symmetrical; linear in A and C; (2) Because thermal conductivities of the materials are different, discontinuities exist at each interface; (3) By comparison of gradients at \( x = -L_B \) and \( +L_B \), find \( q_2' > q_1' \).

(c) Using the same method of analysis as for Part (c), the temperature distribution is shown in the plot below when \( h = 0 \) on the surface of A. Since the left boundary is adiabatic, material A will be isothermal at \( T_1 \). Find

\[ T_1 = 835°C \quad T_2 = 360°C \]
**PROBLEM 3.74**

**KNOWN:** Composite wall exposed to convection process; inside wall experiences a uniform heat generation.

**FIND:** (a) Neglecting interfacial thermal resistances, determine \( T_1 \) and \( T_2 \), as well as the heat fluxes through walls A and C, and (b) Determine the same parameters, but consider the interfacial contact resistances. Plot temperature distributions.

**SCHEMATIC:**

- \( T_\infty = 25 \, ^\circ C \)
- \( h = 1000 \, \text{W/m}^2 \cdot \text{K} \)
- Walls: \( k_A = 25 \, \text{W/m} \cdot \text{K} \), \( L_A = 30 \, \text{mm} \)
- \( k_B = 15 \, \text{W/m} \cdot \text{K} \), \( L_B = 30 \, \text{mm} \)
- \( k_C = 50 \, \text{W/m} \cdot \text{K} \), \( L_C = 20 \, \text{mm} \)
- \( \dot{q}_B = 4 \times 10^6 \, \text{W/m}^2 \)

**ASSUMPTIONS:** (1) One-dimensional, steady-state heat flow, (2) Negligible contact resistance between walls, part (a), (3) Uniform heat generation in B, zero in A and C, (4) Uniform properties, (5) Negligible radiation at outer surfaces.

**ANALYSIS:** (a) The temperature distribution in wall B follows from Eq. 3.41,

\[
T(x) = \frac{\dot{q}_B L_B^2}{2k_B} \left(1 - \frac{x^2}{L_B^2}\right) + \frac{T_2 - T_1}{2} \frac{x}{L_B} + \frac{T_1 - T_2}{2}.
\]

The heat fluxes to the neighboring walls are found using Fourier’s law,

\[
q_x = -k \frac{dT}{dx}.
\]

At \( x = -L_B \):

\[
q_x (-L_B) = -k_B \left[ \frac{\dot{q}_B}{k_B} (L_B) + \frac{T_2 - T_1}{2 L_B} \right] = q_1
\]

At \( x = +L_B \):

\[
q_x (L_B) = -k_B \left[ -\frac{\dot{q}_B}{k_B} (L_B) + \frac{T_2 - T_1}{2 L_B} \right] = q_2
\]

The heat fluxes, \( q_1 \) and \( q_2 \), can be evaluated by thermal circuits.

Substituting numerical values, find

\[
q_1 = (T_\infty - T_1) \frac{C}{1/h + L_A/k_A} = (25 - T_1) \frac{C}{\left(1/1000 \, \text{W/m}^2 \cdot \text{K} + 0.03 \, \text{m}/25 \, \text{W/m} \cdot \text{K}\right)}
\]

\[
q_1 = (25 - T_1) \frac{C}{(0.001 + 0.0012) \, \text{K}/\text{W}} = 454.6 (25 - T_1)
\]

\[
q_2 = (T_2 - T_\infty) \frac{C}{1/h + L_C/k_C} = (T_2 - 25) \frac{C}{\left(1/1000 \, \text{W/m}^2 \cdot \text{K} + 0.02 \, \text{m}/50 \, \text{W/m} \cdot \text{K}\right)}
\]

\[
q_2 = (T_2 - 25) \frac{C}{(0.001 + 0.0004) \, \text{K}/\text{W}} = 714.3 (T_2 - 25).
\]

Continued...
PROBLEM 3.74 (Cont.)

Substituting the expressions for the heat fluxes, Eqs. (4) and (5), into Eqs. (2) and (3), a system of two equations with two unknowns is obtained.

Eq. (2): 

\[-4 \times 10^6 \text{ W/m}^3 \times 0.03 \text{ m} + 15 \text{ W/m} \cdot K \frac{T_2 - T_1}{2 \times 0.03 \text{ m}} = q_1^*\]

\[-1.2 \times 10^5 \text{ W/m}^2 - 2.5 \times 10^2 (T_2 - T_1) \text{ W/m}^2 = 454.6 (25 - T_1)\]

\[704.6 T_1 - 250 T_2 = 131,365\]  

(6)

Eq. (3): 

\[+4 \times 10^6 \text{ W/m}^3 \times 0.03 \text{ m} - 15 \text{ W/m} \cdot K \frac{T_2 - T_1}{2 \times 0.03 \text{ m}} = q_2^*\]

\[+1.2 \times 10^5 \text{ W/m}^2 - 2.5 \times 10^2 (T_2 - T_1) \text{ W/m}^2 = 714.3 (T_2 - 25)\]

\[250 T_1 - 964 T_2 = -137,857\]  

(7)

Solving Eqs. (6) and (7) simultaneously, find

\[T_1 = 260.9^\circ C\]  
\[T_2 = 210.0^\circ C\]

From Eqs. (4) and (5), the heat fluxes at the interfaces and through walls A and C are, respectively,

\[q_1^* = 454.6 (25 - 260.9) = -107,240 \text{ W/m}^2\]

\[q_2^* = 714.3 (210 - 25) = +132,146 \text{ W/m}^2\]

Note directions of the heat fluxes.

(b) Considering interfacial contact resistances, we will use a different approach. The general solution for the temperature and heat flux distributions in each of the materials is

\[T_A (x) = C_1 x + C_2\]

\[q_x = -k_A C_1 \quad - (L_A + L_B) \leq x \leq -L_B\]  

(1,2)

\[T_B (x) = \frac{-q_B}{2k_B} x^2 + C_3 x + C_4\]

\[q_x = \frac{-q_B}{k_B} x + C_3 \quad -L_B \leq x \leq L_B\]  

(3,4)

\[T_C (x) = C_5 x + C_6\]

\[q_x = -k_C C_5 \quad +L_B \leq x \leq (L_B + L_C)\]  

(5,6)

To determine \(C_1 \ldots C_6\) and the distributions, we need to identify boundary conditions using surface energy balances.

At \(x = -(L_A + L_B)\):

\[-q_x^* (-L_A - L_B) + q_{cv}^* = 0\]  

(7)

\[-(-k_A C_1) + h\left[T_\infty - T_A (-L_A - L_B)\right]\]  

(8)

At \(x = -L_B\). The heat flux must be continuous, but the temperature will be discontinuous across the contact resistance.

\[q_{x,A}^* (-L_B) = q_{x,B}^* (-L_B)\]  

(9)

\[q_{x,A} (-L_B) = \left[T_{1A} (-L_B) - T_{1B} (-L_B)\right]/R_{\infty,AB}^*\]  

(10)

PROBLEM 3.74 (Cont.)
At \( x = + L_B \): The same conditions apply as for \( x = -L_B \),

\[
q_{x,B}^* ( +L_B ) = q_{x,C}^* ( +L_B ) \quad (11)
\]

\[
q_{x,B}' ( +L_B ) = \left[ T_{2B} ( +L_B ) - T_{2C} ( +L_B ) \right] / R_{tc,BC}' \quad (12)
\]

At \( x = +(L_B + L_C) \):

\[
-q_{x,C} ( L_B + L_C ) - q_{cv} = 0 \quad (13)
\]

\[
-(k_C C_5) - h [ T_C ( L_B + L_C ) - T_\infty ] = 0 \quad (14)
\]

Following the method of analysis in IHT Example 3.6, User-Defined Functions, we solve the system of equations above for the constants \( C_1 \ldots C_6 \) for conditions with negligible and prescribed values for the interfacial constant resistances. The results are tabulated and plotted below; \( q_1^* \) and \( q_2^* \) represent heat fluxes leaving surfaces A and C, respectively.

<table>
<thead>
<tr>
<th>Conditions</th>
<th>( T_{1A} (\text{°C}) )</th>
<th>( T_{1B} (\text{°C}) )</th>
<th>( T_{2B} (\text{°C}) )</th>
<th>( T_{2C} (\text{°C}) )</th>
<th>( q_1^* ) (kW/m(^2))</th>
<th>( q_2^* ) (kW/m(^2))</th>
</tr>
</thead>
<tbody>
<tr>
<td>( R_{tc}^* = 0 )</td>
<td>260</td>
<td>260</td>
<td>210</td>
<td>210</td>
<td>106.8</td>

</tbody>
</table>

**COMMENTS:**

1. The results for part (a) can be checked using an energy balance on wall B,

\[
\hat{E}_{in} - \hat{E}_{out} = -\hat{E}_g
\]

\[
q_1^* - q_2^* = -\dot{q}_B \times 2L_B
\]

where

\[
q_1^* - q_2^* = -107,240 - 132,146 = 239,386 \text{ W/m}^2
\]

\[
-\dot{q}_B L_B = -4 \times 10^6 \text{ W/m}^3 \times 2 (0.03 \text{ m}) = -240,000 \text{ W/m}^2
\]

Hence, we have confirmed proper solution of Eqs. (6) and (7).

2. Note that the effect of the interfacial contact resistance is to increase the temperature at all locations. The total heat flux leaving the composite wall \( (q_1 + q_2) \) will of course be the same for both cases.
**PROBLEM 3.75**

**KNOWN:** Composite wall of materials A and B. Wall of material A has uniform generation, while wall B has no generation. The inner wall of material A is insulated, while the outer surface of material B experiences convection cooling. Thermal contact resistance between the materials is $R_{t,c}^* = 10^{-4} \text{ m}^2 \cdot \text{K} / \text{W}$. See Ex. 3.6 that considers the case without contact resistance.

**FIND:** Compute and plot the temperature distribution in the composite wall.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional conduction with constant properties, and (3) Inner surface of material A is adiabatic.

**ANALYSIS:** From the analysis of Ex. 3.6, we know the temperature distribution in material A is parabolic with zero slope at the inner boundary, and that the distribution in material B is linear. At the interface between the two materials, $x = L_A$, the temperature distribution will show a discontinuity.

- For material A:
  \[ T_A(x) = \frac{q_A L_A^2}{2k_A} \left( 1 - x^2 \right) + T_{1A} \quad 0 \leq x \leq L_A \]

- For material B:
  \[ T_B(x) = T_{1B} - \left( T_{1B} - T_2 \right) \frac{x - L_A}{L_B} \quad L_A \leq x \leq L_A + L_B \]

Considering the thermal circuit above (see also Ex. 3.6) including the thermal contact resistance, we find:
\[ \dot{q}^* = \dot{q}_A \frac{T_{1A} - T_\infty}{R_{\text{tot}}^*} = \frac{T_{1B} - T_\infty}{R_{\text{cond,B}}^* + R_{\text{conv}}^*} = \frac{T_2 - T_\infty}{R_{\text{conv}}^*} \]

find $T_A(0) = 147.5^\circ\text{C}$, $T_{1A} = 122.5^\circ\text{C}$, $T_{1B} = 115^\circ\text{C}$, and $T_2 = 105^\circ\text{C}$. Using the foregoing equations in IHT, the temperature distributions for each of the materials can be calculated and are plotted on the graph below.

**COMMENTS:**
(1) The effect of the thermal contact resistance between the materials is to increase the maximum temperature of the system.

(2) Can you explain why the temperature distribution in the material B is not affected by the presence of the thermal contact resistance at the materials’ interface?
**PROBLEM 3.76**

**KNOWN:** Plane wall of thickness 2L, thermal conductivity \( k \) with uniform energy generation \( \dot{q} \).

For case 1, boundary at \( x = -L \) is perfectly insulated, while boundary at \( x = +L \) is maintained at \( T_0 = 50^\circ C \). For case 2, the boundary conditions are the same, but a thin dielectric strip with thermal resistance \( R_t^* = 0.0005 \text{ m}^2 \cdot \text{K} / \text{W} \) is inserted at the mid-plane.

**FIND:** (a) Sketch the temperature distribution for case 1 on T-x coordinates and describe key features; identify and calculate the maximum temperature in the wall, (b) Sketch the temperature distribution for case 2 on the same T-x coordinates and describe the key features; (c) What is the temperature difference between the two walls at \( x = 0 \) for case 2? And (d) What is the location of the maximum temperature of the composite wall in case 2; calculate this temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional conduction in the plane and composite walls, and (3) Constant properties.

**ANALYSIS:** (a) For case 1, the temperature distribution, \( T_1(x) \) vs. \( x \), is parabolic as shown in the schematic below and the gradient is zero at the insulated boundary, \( x = -L \). From Eq. 3.43,

\[
T_1(-L) - T_1(+L) = \frac{\dot{q}(2L)^2}{2k} = \frac{5 \times 10^6 \text{ W/m}^3(2 \times 0.020 \text{ m})^2}{2 \times 50 \text{ W/m} \cdot \text{K}} = 80^\circ C
\]

and since \( T_1(+L) = T_0 = 50^\circ C \), the maximum temperature occurs at \( x = -L \),

\[
T_1(-L) = T_1(+L) + 80^\circ C = 130^\circ C
\]

(b) For case 2, the temperature distribution, \( T_2(x) \) vs. \( x \), is piece-wise parabolic, with zero gradient at \( x = -L \) and a drop across the dielectric strip, \( \Delta T_{AB} \). The temperature gradients at either side of the dielectric strip are equal.

(c) For case 2, the temperature drop across the thin dielectric strip follows from the surface energy balance shown above.

\[
q_x^*(0) = \frac{\Delta T_{AB}}{R_t^*} \quad q_x^*(0) = \dot{q}L
\]

\[
\Delta T_{AB} = \frac{\dot{q}L}{R_t^*} = 0.0005 \text{ m}^2 \cdot \text{K} / \text{W} \times 5 \times 10^6 \text{ W/m}^3 \times 0.020 \text{ m} = 50^\circ C.
\]

(d) For case 2, the maximum temperature in the composite wall occurs at \( x = -L \), with the value,

\[
T_2(-L) = T_1(-L) + \Delta T_{AB} = 130^\circ C + 50^\circ C = 180^\circ C
\]
PROBLEM 3.77

KNOWN: Geometry and boundary conditions of a nuclear fuel element.

FIND: (a) Expression for the temperature distribution in the fuel, (b) Form of temperature distribution for the entire system.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional heat transfer, (2) Steady-state conditions, (3) Uniform generation, (4) Constant properties, (5) Negligible contact resistance between fuel and cladding.

ANALYSIS: (a) The general solution to the heat equation, Eq. 3.39,

\[
\frac{d^2 T}{dx^2} + \frac{q}{k_f} = 0 \quad (-L \leq x \leq +L)
\]

is \(T = -\frac{q}{2k_f} x^2 + C_1 x + C_2\).

The insulated wall at \(x = -(L+b)\) dictates that the heat flux at \(x = -L\) is zero (for an energy balance applied to a control volume about the wall, \(\dot{E}_{in} = \dot{E}_{out} = 0\)). Hence

\[
\frac{dT}{dx}_{x=-L} = -\frac{q}{k_f} (-L) + C_1 = 0 \quad \text{or} \quad C_1 = -\frac{qL}{k_f}
\]

\(T = -\frac{q}{2k_f} x^2 - \frac{qL}{k_f} x + C_2\).

The value of \(T_{s,1}\) may be determined from the energy conservation requirement that \(\dot{E}_g = q_{cond} = q_{conv}\), or on a unit area basis.

\[
\dot{q}(2L) = \frac{k_s}{b} \left( T_{s,1} - T_{s,2} \right) = h \left( T_{s,2} - T_\infty \right).
\]

Hence,

\[
T_{s,1} = \frac{\dot{q} (2Lb)}{k_s} + T_{s,2} \quad \text{where} \quad T_{s,2} = \frac{\dot{q} (2L)}{h} + T_\infty
\]

\[
T_{s,1} = \frac{\dot{q} (2Lb)}{k_s} + \frac{\dot{q} (2L)}{h} + T_\infty.
\]

Continued …..
Hence from Eq. (1),

\[ T(L) = T_{s,1} = \frac{\dot{q}(2 L b)}{k_s} + \frac{\dot{q}(2 L)}{h} + T_\infty = -\frac{3}{2} \frac{\dot{q}L^2}{k_f} + C_2 \]

which yields

\[ C_2 = T_\infty + \dot{q}L \left[ \frac{2b}{k_s} + \frac{2}{h} + \frac{3}{2} \frac{L}{k_f} \right] \]

Hence, the temperature distribution for \((-L \leq x \leq +L)\) is

\[ T = -\frac{\dot{q}}{2k_f} x^2 - \frac{\dot{q}L}{k_f} x + \dot{q}L \left[ \frac{2b}{k_s} + \frac{2}{h} + \frac{3}{2} \frac{L}{k_f} \right] + T_\infty \]

(b) For the temperature distribution shown below,

\((-L-b) \leq x \leq -L:\) \quad dT/dx=0, \quad T=T_{\text{max}}

\(-L \leq x \leq +L:\) \quad |dT/dx| \uparrow \text{ with } \uparrow x

\(+L \leq x \leq +L+b:\) \quad (dT/dx) \text{ is const.}
PROBLEM 3.78

FIND: (a) Temperature distribution in fuel element with one surface insulated and the other cooled by convection. Largest and smallest temperatures and corresponding locations. (b) Same as part (a) but with equivalent convection conditions at both surfaces, (c) Plot of temperature distributions.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional heat transfer, (2) Steady-state, (3) Uniform generation, (4) Constant properties, (5) Negligible contact resistance.

ANALYSIS: (a) From Eq. C.1,
\[
T(x) = \frac{\dot{q} L^2}{2 k_f} \left(1 - \frac{x^2}{L^2}\right) + \frac{T_{s,2} - T_{s,1}}{2} \frac{x}{L} + \frac{T_{s,1} + T_{s,2}}{2}
\]

With an insulated surface at \(x = -L\), Eq. C.10 yields
\[
T_{s,1} - T_{s,2} = \frac{2 \dot{q} L^2}{k_f}
\]

and with convection at \(x = L + b\), Eq. C.13 yields
\[
U \left( T_{s,2} - T_{\infty} \right) - \frac{k_f}{2L} \left( T_{s,2} - T_{s,1} \right) = \dot{q} L - \frac{2 L U}{k_f} \left( T_{s,2} - T_{\infty} \right) - \frac{2 \dot{q} L^2}{k_f}
\]

Subtracting Eq. (2) from Eq. (3),
\[
0 = \frac{2 L U}{k_f} \left( T_{s,2} - T_{\infty} \right) - \frac{4 \dot{q} L^2}{k_f} - T_{s,2} - T_{\infty} = \frac{2 \dot{q} L}{U}
\]

Continued …..
and substituting into Eq. (2)

\[ T_{s,1} = T_{\infty} + 2qL \left( \frac{L}{k_f} + \frac{1}{U} \right) \]  

(5)

Substituting Eqs. (4) and (5) into Eq. (1),

\[ T(x) = -\frac{q}{2k_f}x^2 - \frac{qL}{k_f}x + qL \left( \frac{2}{U} + \frac{3L}{2k_f} \right) + T_{\infty} \]

or, with \( U^{-1} = h^{-1} + b/k_s \),

\[ T(x) = -\frac{q}{2k_f}x^2 - \frac{qL}{k_f}x + qL \left( \frac{2b}{k_s} + \frac{2}{h} + \frac{3L}{2k_f} \right) + T_{\infty} \]  

(6) \[<\]

The maximum temperature occurs at \( x = -L \) and is

\[ T(-L) = 2qL \left( \frac{b}{k_s} + \frac{1}{h} + \frac{L}{k_f} \right) + T_{\infty} \]

\[ T(-L) = 2 \times 2 \times 10^7 \text{ W/m}^3 \times 0.015 \text{ m} \times 0.003 \text{ m} + 10^4 \text{ W/m} \cdot \text{K} + \frac{2}{10 \times 10^5} + \frac{0.015 \text{ m}}{60^2 \text{ W/m} \cdot \text{K}} + 200^\circ \text{C} = 530^\circ \text{C} \]

The lowest temperature is at \( x = +L \) and is

\[ T(+L) = -\frac{3}{2} \frac{qL^2}{k_f} + qL \left( \frac{2b}{k_s} + \frac{2}{h} + \frac{3L}{2k_f} \right) + T_{\infty} = 380^\circ \text{C} \]

(b) If a convection condition is maintained at \( x = -L \), Eq. C.12 reduces to

\[ U \left( T_{\infty} - T_{s,1} \right) = -\frac{qL}{2L} \left( T_{s,2} - T_{s,1} \right) \]

\[ T_{s,1} - T_{s,2} = \frac{2LU}{k_f} \left( T_{s,1} - T_{\infty} \right) - \frac{2qL^2}{k_f} \]  

(7)

Subtracting Eq. (7) from Eq. (3),

\[ 0 = \frac{2LU}{k_f} \left( T_{s,2} - T_{\infty} - T_{s,1} + T_{\infty} \right) \quad \text{or} \quad T_{s,1} = T_{s,2} \]

Hence, from Eq. (7)

Continued …..
PROBLEM 3.78 (Cont.)

\[ T_{s,1} = T_{s,2} = \frac{qL}{U} + T_\infty = qL \left( \frac{1}{h} + \frac{b}{k_s} \right) + T_\infty \]  \hspace{1cm} (8)

Substituting into Eq. (1), the temperature distribution is

\[ T(x) = \frac{qL^2}{2k_f} \left( 1 - \frac{x^2}{L^2} \right) + qL \left( \frac{1}{h} + \frac{b}{k_s} \right) + T_\infty \]  \hspace{1cm} (9)

The maximum temperature is at \( x = 0 \) and is

\[ T(0) = \frac{2 \times 10^7 \text{ W/m}^3 (0.015 \text{ m})^2}{2 \times 60 \text{ W/m} \cdot \text{K}} + 2 \times 10^7 \text{ W/m}^3 \times 0.015 \text{ m} \left( \frac{1}{10,000 \text{ W/m}^2 \cdot \text{K}} + \frac{0.003 \text{ m}}{15 \text{ W/m} \cdot \text{K}} \right) + 200^\circ \text{C} \]

\[ T(0) = 37.5^\circ \text{C} + 90^\circ \text{C} + 200^\circ \text{C} = 327.5^\circ \text{C} \]

The minimum temperature at \( x = \pm L \) is

\[ T_{s,1} = T_{s,2} = 2 \times 10^7 \text{ W/m}^3 (0.015 \text{ m}) \left( \frac{1}{10,000 \text{ W/m}^2 \cdot \text{K}} + \frac{0.003 \text{ m}}{15 \text{ W/m} \cdot \text{K}} \right) + 200^\circ \text{C} = 290^\circ \text{C} \]

(c) The temperature distributions are as shown.

![Graph showing temperature distribution](image)

The amount of heat generation is the same for both cases, but the ability to transfer heat from both surfaces for case (b) results in lower temperatures throughout the fuel element.

COMMENTS: Note that for case (a), the temperature in the insulated cladding is constant and equivalent to \( T_{s,1} = 530^\circ \text{C} \).
**PROBLEM 3.79**

**KNOWN:** Wall of thermal conductivity \( k \) and thickness \( L \) with uniform generation \( \dot{q} \); strip heater with uniform heat flux \( q^* \); prescribed inside and outside air conditions \( (h_i, T_{\infty,i}, h_o, T_{\infty,o}) \).

**FIND:** (a) Sketch temperature distribution in wall if none of the heat generated within the wall is lost to the outside air, (b) Temperatures at the wall boundaries \( T(0) \) and \( T(L) \) for the prescribed condition, (c) Value of \( q^* \) required to maintain this condition, (d) Temperature of the outer surface, \( T(L) \), if \( \dot{q}=0 \) but \( q^* \) corresponds to the value calculated in (c).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional conduction, (3) Uniform volumetric generation, (4) Constant properties.

**ANALYSIS:** (a) If none of the heat generated within the wall is lost to the outside of the chamber, the gradient at \( x = 0 \) must be zero. Since \( \dot{q} \) is uniform, the temperature distribution is parabolic, with \( T(L) > T_{\infty,i} \).

(b) To find temperatures at the boundaries of wall, begin with the general solution to the appropriate form of the heat equation (Eq.3.40).

\[
T(x) = -\frac{\dot{q}}{2k}x^2 + C_1x + C_2
\]  

(1)

From the first boundary condition,

\[
\frac{dT}{dx} \bigg|_{x=0} = 0 \quad \Rightarrow \quad C_1 = 0.
\]  

(2)

Two approaches are possible using different forms for the second boundary condition.

*Approach No. 1:* With boundary condition \( T(0) = T_i \)

\[
T(x) = -\frac{\dot{q}}{2k}x^2 + T_i
\]  

(3)

To find \( T_1 \), perform an overall energy balance on the wall

\[
\dot{E}_{in} - \dot{E}_{out} + \dot{E}_g = 0
\]

\[
-h \left[ T(L) - T_{\infty,i} \right] + \dot{q}L = 0 \quad T(L) = T_2 = T_{\infty,i} + \frac{\dot{q}L}{h}
\]  

(4)

Continued …..
and from Eq. (3) with \( x = L \) and \( T(L) = T_2 \),

\[
T(L) = -\frac{\dot{q}}{2k} L^2 + T_1 \quad \text{or} \quad T_1 = T_2 + \frac{\dot{q}}{2k} L^2 = T_{\infty,i} + \frac{\dot{q}L}{h} + \frac{\dot{q}L^2}{2k} \quad (5,6)
\]

Substituting numerical values into Eqs. (4) and (6), find

\[
T_2 = 50^\circ C + 1000 \text{ W/m}^3 \times 0.200 \text{ m} / 20 \text{ W/m}^2 \cdot \text{K} = 50^\circ C + 10^\circ C = 60^\circ C
\]

\[
T_1 = 60^\circ C + 1000 \text{ W/m}^3 \times (0.200 \text{ m})^2 / 2 \times 4 \text{ W/m} \cdot \text{K} = 65^\circ C.
\]

**Approach No. 2:** Using the boundary condition

\[
-k \frac{dT}{dx} \bigg|_{x=L} = h \left[ T(L) - T_{\infty,i} \right]
\]

yields the following temperature distribution which can be evaluated at \( x = 0, L \) for the required temperatures,

\[
T(x) = -\frac{\dot{q}}{2k} \left( x^2 - L^2 \right) + \frac{\dot{q}L}{h} + T_{\infty,i}.
\]

(c) The value of \( q^* \) when \( T(0) = T_1 = 65^\circ C \) follows from the circuit

\[
q^* = \frac{T_1 - T_{\infty,0}}{1/h_o}
\]

\[ q^* = 5 \text{ W/m}^2 \cdot \text{K} (65-25)^\circ \text{C} = 200 \text{ W/m}^2. \]

(d) With \( \dot{q}=0 \), the situation is represented by the thermal circuit shown. Hence,

\[
q^*_a = q^*_a + q^*_b
\]

\[
q^*_a = \frac{T_1 - T_{\infty,0}}{1/h_o} + \frac{T_1 - T_{\infty,1}}{L/k+1/h_1}
\]

which yields

\[ T_1 = 55^\circ C. \]
KNOWN: Wall of thermal conductivity $k$ and thickness $L$ with uniform generation and strip heater with uniform heat flux $q_0''$; prescribed inside and outside air conditions ($T_{\infty,i}$, $h_i$, $T_{\infty,o}$, $h_o$). Strip heater acts to guard against heat losses from the wall to the outside.

FIND: Compute and plot $q_0''$ and $T(0)$ as a function of $\dot{q}$ for $200 \leq \dot{q} \leq 2000$ W/m$^3$ and $T_{\infty,i} = 30, 50$ and 70°C.

SCHEMATIC:

Assumptions: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Uniform volumetric generation, (4) Constant properties.

ANALYSIS: If no heat generated within the wall will be lost to the outside of the chamber, the gradient at the position $x = 0$ must be zero. Since $\dot{q}$ is uniform, the temperature distribution must be parabolic as shown in the sketch.

To determine the required heater flux $q_0''$ as a function of the operation conditions $\dot{q}$ and $T_{\infty,i}$, the analysis begins by considering the temperature distribution in the wall and then surface energy balances at the two wall surfaces. The analysis is organized for easy treatment with equation-solving software.

Temperature distribution in the wall, $T(x)$: The general solution for the temperature distribution in the wall is, Eq. 3.40,

$$T(x) = \frac{-\dot{q}}{2k} x^2 + C_1 x + C_2$$

and the guard condition at the outer wall, $x = 0$, requires that the conduction heat flux be zero. Using Fourier’s law,

$$q_x''(0) = -k \frac{dT}{dx} \bigg|_{x=0} = -kC_1 = 0 \quad (C_1 = 0) \quad (1)$$

At the outer wall, $x = 0$,

$$T(0) = C_2 \quad (2)$$

Surface energy balance, $x = 0$:

$$h_0 \left( T(0) - T_{\infty,o} \right) = 0$$

$$q_0'' - q_{cv,o}'' - q_x''(0) = 0 \quad (3)$$

$$q_{cv,o}'' = h \left( T(0) - T_{\infty,o} \right), q_x''(0) = 0 \quad (4a,b)$$

Continued...
PROBLEM 3.80 (Cont.)

Surface energy balance, \( x = L \):

\[
\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0
\]

\[
\dot{q}_x(L) - \dot{q}_{cv,i} = 0
\]  \( \text{(5)} \)

\[
\dot{q}_x(L) = -k \frac{dT}{dx} \bigg|_{x=L} = +\dot{q}L
\]  \( \text{(6)} \)

\[
\dot{q}_{cv,i} = h \left[ T(L) - T_{\infty,i} \right]
\]

\[
\dot{q}_{cv,i} = h \left[ -\frac{\dot{q}}{2k} L^2 + T(0) - T_{\infty,i} \right]
\]  \( \text{(7)} \)

Solving Eqs. (1) through (7) simultaneously with appropriate numerical values and performing the parametric analysis, the results are plotted below.

From the first plot, the heater flux \( \dot{q}_o \) is a linear function of the volumetric generation rate \( \dot{q} \). As expected, the higher \( \dot{q} \) and \( T_{\infty,i} \), the higher the heat flux required to maintain the guard condition \( (\dot{q}_x(0) = 0) \). Notice that for any \( \dot{q} \) condition, equal changes in \( T_{\infty,i} \) result in equal changes in the required \( \dot{q}_o \). The outer wall temperature \( T(0) \) is also linearly dependent upon \( \dot{q} \). From our knowledge of the temperature distribution, it follows that for any \( \dot{q} \) condition, the outer wall temperature \( T(0) \) will track changes in \( T_{\infty,i} \).
**PROBLEM 3.81**

**KNOWN:** Plane wall with prescribed nonuniform volumetric generation having one boundary insulated and the other isothermal.

**FIND:** Temperature distribution, \( T(x) \), in terms of \( x, L, k, \dot{q}_o \) and \( T_o \).

**SCHEMATIC:**

![Schematic Image](image)

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional conduction in \( x \)-direction, (3) Constant properties.

**ANALYSIS:** The appropriate form the heat diffusion equation is

\[
\frac{d}{dx} \left( \frac{dT}{dx} \right) + \frac{\dot{q}}{k} = 0.
\]

Noting that \( \dot{q} = \dot{q}(x) = \dot{q}_o \left( 1 - x/L \right) \), substitute for \( \dot{q}(x) \) into the above equation, separate variables and then integrate,

\[
dT = \frac{\dot{q}_o}{k} \left( 1 - \frac{x}{L} \right) dx \quad \Rightarrow \quad T(x) = -\frac{\dot{q}_o}{k} \left[ \frac{x^2}{2L} \right] + C_1.
\]

Separate variables and integrate again to obtain the general form of the temperature distribution in the wall,

\[
T(x) = -\frac{\dot{q}_o}{k} \left[ \frac{x^2}{2} - \frac{x^3}{6L} \right] + C_1x + C_2.
\]

Identify the boundary conditions at \( x = 0 \) and \( x = L \) to evaluate \( C_1 \) and \( C_2 \). At \( x = 0 \),

\[
T(0) = T_o = -\frac{\dot{q}_o}{k}(0-0) + C_1 \cdot 0 + C_2 \quad \text{hence, } C_2 = T_o
\]

At \( x = L \),

\[
\frac{dT}{dx} \bigg|_{x=L} = 0 = -\frac{\dot{q}_o}{k} \left[ L - \frac{L^2}{2L} \right] + C_1 \quad \text{hence, } C_1 = \frac{\dot{q}_o L}{2k}
\]

The temperature distribution is

\[
T(x) = -\frac{\dot{q}_o}{k} \left[ \frac{x^2}{2} - \frac{x^3}{6L} \right] + \frac{\dot{q}_o L}{2k} x + T_o.
\]

**COMMENTS:** It is good practice to test the final result for satisfying BCs. The heat flux at \( x = 0 \) can be found using Fourier’s law or from an overall energy balance

\[
\dot{E}_{out} = \dot{E}_g = \int_0^L \dot{q}dV \quad \text{to obtain} \quad q''_{out} = \dot{q}_o L/2.
\]
PROBLEM 3.82

KNOWN: Distribution of volumetric heating and surface conditions associated with a quartz window.

FIND: Temperature distribution in the quartz.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Negligible radiation emission and convection at inner surface \((x = 0)\) and negligible emission from outer surface, (4) Constant properties.

ANALYSIS: The appropriate form of the heat equation for the quartz is obtained by substituting the prescribed form of \(q\) into Eq. 3.39.

\[
\frac{d^2T}{dx^2} + \frac{\alpha (1-\beta) q_0^*}{k} e^{-\alpha x} = 0
\]

Integrating,

\[
\frac{dT}{dx} = \frac{(1-\beta) q_0^*}{k} e^{-\alpha x} + C_1 \quad \text{and} \quad T = -\frac{(1-\beta)}{k\alpha} q_0^* e^{-\alpha x} + C_1x + C_2
\]

Boundary Conditions:

\[
-k \left. \frac{dT}{dx} \right|_{x=0} = \beta q_0^* \\
-k \left. \frac{dT}{dx} \right|_{x=L} = h \left( T(L) - T_\infty \right)
\]

Hence, at \(x = 0\):

\[
-k \left[ \frac{(1-\beta)}{k} q_0^* + C_1 \right] = \beta q_0^* \\
C_1 = -q_0^*/k
\]

At \(x = L\):

\[
-k \left[ \frac{(1-\beta)}{k} q_0^* e^{-\alpha L} + C_1 \right] = h \left[ \frac{(1-\beta)}{k\alpha} q_0^* e^{-\alpha L} + C_1 L + C_2 - T_\infty \right]
\]

Substituting for \(C_1\) and solving for \(C_2\),

\[
C_2 = \frac{q_0^*}{h} \left[ 1 - (1-\beta) e^{-\alpha L} \right] + \frac{q_0^*}{k} + \frac{q_0^*(1-\beta)}{k\alpha} e^{-\alpha L} + T_\infty.
\]

Hence,

\[
T(x) = \frac{(1-\beta) q_0^*}{k\alpha} \left( e^{-\alpha x} - e^{-\alpha L} \right) + \frac{q_0^*}{k} (L-x) + \frac{q_0^*}{h} \left[ 1 - (1-\beta) e^{-\alpha L} \right] + T_\infty.
\]

COMMENTS: The temperature distribution depends strongly on the radiative coefficients, \(\alpha\) and \(\beta\). For \(\alpha \to \infty\) or \(\beta = 1\), the heating occurs entirely at \(x = 0\) (no volumetric heating).
PROBLEM 3.83

KNOWN: Radial distribution of heat dissipation in a cylindrical container of radioactive wastes. Surface convection conditions.

FIND: Radial temperature distribution.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties, (4) Negligible temperature drop across container wall.

ANALYSIS: The appropriate form of the heat equation is

\[
\frac{1}{r} \frac{d}{dr} \left( r \frac{dT}{dr} \right) = -\frac{\dot{q}}{k} = -\frac{\dot{q}_0}{k} \left( 1 - \frac{r^2}{r_0^2} \right)
\]

\[
r \frac{dT}{dr} = -\frac{\dot{q}_0 r^2}{2k} + \frac{\dot{q}_0^4}{4kr_0^2} + C_1 \quad T = -\frac{\dot{q}_0 r^2}{4k} + \frac{\dot{q}_0^4}{16kr_0^2} + C_1 \ln r + C_2.
\]

From the boundary conditions,

\[
\frac{dT}{dr} \bigg|_{r=0} = 0 \rightarrow C_1 = 0 \quad -k \frac{dT}{dr} \bigg|_{r=r_0} = h \left[ T(r_0) - T_\infty \right]
\]

\[
+ \frac{\dot{q}_0 r_0}{2} - \frac{\dot{q}_0 r_0^2}{4} = h \left[ -\frac{\dot{q}_0 r_0^2}{4k} + \frac{\dot{q}_0 r_0^2}{16k} + C_2 - T_\infty \right]
\]

\[
C_2 = \frac{\dot{q}_0 r_0}{4h} + \frac{3\dot{q}_0 r_0^2}{16k} + T_\infty.
\]

Hence

\[
T(r) = T_\infty + \frac{\dot{q}_0 r_0}{4h} + \frac{\dot{q}_0 r_0^2}{k} \left[ \frac{3}{16} - \frac{1}{4} \left( \frac{r}{r_0} \right)^2 + \frac{1}{16} \left( \frac{r}{r_0} \right)^4 \right].
\]

COMMENTS: Applying the above result at \( r_0 \) yields

\[ T_s = T(r_0) = T_\infty + (\dot{q}_0 r_0)/4h \]

The same result may be obtained by applying an energy balance to a control surface about the container, where \( E_g = q_{conv} \). The maximum temperature exists at \( r = 0 \).
PROBLEM 3.84

KNOWN: Cylindrical shell with uniform volumetric generation is insulated at inner surface and exposed to convection on the outer surface.

FIND: (a) Temperature distribution in the shell in terms of \( r_i, r_o, \dot{q}, h, T_\infty \) and \( k \), (b) Expression for the heat rate per unit length at the outer radius, \( q'(r_o) \).

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional radial (cylindrical) conduction in shell, (3) Uniform generation, (4) Constant properties.

ANALYSIS: (a) The general form of the temperature distribution and boundary conditions are

\[
T(r) = -\frac{\dot{q}}{4k} r^2 + C_1 \ln r + C_2
\]

at \( r = r_i \):

\[
\left. \frac{dT}{dr} \right|_{r_i} = 0 = -\frac{\dot{q}}{2k} r_i + C_1 \frac{1}{r_i} + 0 \quad C_1 = \frac{\dot{q}}{2k} r_i^2
\]

at \( r = r_o \):

\[
-k \left. \frac{dT}{dr} \right|_{r_o} = h \left[ T(r_o) - T_\infty \right] \quad \text{surface energy balance}
\]

\[
k \left[ -\frac{\dot{q}}{2k} r_o + \left( \frac{\dot{q}}{2k} r_i^2 \frac{1}{r_o} \right) \ln r_o \right] = h \left[ -\frac{\dot{q}}{4k} r_o^2 + \left( \frac{\dot{q}}{2k} r_i^2 \right) \ln r_o + C_2 - T_\infty \right]
\]

\[
C_2 = -\frac{\dot{q} r_o}{2h} \left[ 1 + \left( \frac{r_i}{r_o} \right)^2 \right] + \frac{\dot{q} r_o^2}{2k} \left[ \frac{1}{2} - \left( \frac{r_i}{r_o} \right)^2 \ln r_o \right] + T_\infty
\]

Hence,

\[
T(r) = \frac{\dot{q}}{4k} \left( r_o^2 - r^2 \right) + \frac{\dot{q} r_i^2}{2k} \ln \left( \frac{r}{r_o} \right) - \frac{\dot{q} r_o}{2h} \left[ 1 + \left( \frac{r_i}{r_o} \right)^2 \right] + T_\infty.
\]

(b) From an overall energy balance on the shell,

\[
\dot{q}'(r_o) = \dot{E}' = \dot{q} \pi \left( r_o^2 - r_i^2 \right).
\]

Alternatively, the heat rate may be found using Fourier’s law and the temperature distribution,

\[
\dot{q}'(r) = -k \left( 2\pi r_o \right) \left. \frac{dT}{dr} \right|_{r_o} = -2\pi kr_o \left[ -\frac{\dot{q}}{2k} r_o + \frac{\dot{q} r_i^2}{2k} \frac{1}{r_o} + 0 + 0 \right] = \dot{q} \pi \left( r_o^2 - r_i^2 \right)
\]
**PROBLEM 3.85**

**KNOWN:** The solid tube of Example 3.7 with inner and outer radii, 50 and 100 mm, and a thermal conductivity of 5 W/m·K. The inner surface is cooled by a fluid at 30°C with a convection coefficient of 1000 W/m²·K.

**FIND:** Calculate and plot the temperature distributions for volumetric generation rates of $1 \times 10^5$, $5 \times 10^5$, and $1 \times 10^6$ W/m³. Use Eq. (7) with Eq. (10) of the Example 3.7 in the *IHT Workspace*.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional radial conduction, (3) Constant properties and (4) Uniform volumetric generation.

**ANALYSIS:** From Example 3.7, the temperature distribution in the tube is given by Eq. (7),

$$ T(r) = T_{s,2} + \frac{q}{4k} \left( r_2^2 - r^2 \right) - \frac{q}{2k} \frac{r_2^2}{\ln \left( \frac{r_2}{r} \right)} \quad r_1 \leq r \leq r_2 $$

(1)

The temperature at the inner boundary, $T_{s,1}$, follows from the surface energy balance, Eq. (10),

$$ \pi q \left( r_2^2 - r_1^2 \right) = h 2\pi r_1 \left( T_{s,1} - T_{\infty} \right) $$

(2)

For the conditions prescribed in the schematic with $q = 1 \times 10^5$ W/m³, Eqs. (1) and (2), with $r = r_1$ and $T(r) = T_{s,1}$, are solved simultaneously to find $T_{s,2} = 69.3°C$. Eq. (1), with $T_{s,2}$ now a known parameter, can be used to determine the temperature distribution, $T(r)$. The results for different values of the generation rate are shown in the graph.

**COMMENTS:**

(1) The temperature distributions are parabolic with a zero gradient at the insulated outer boundary, $r = r_2$. The effect of increasing $q$ is to increase the maximum temperature in the tube, which always occurs at the outer boundary.

(2) The equations used to generate the graphical result in the *IHT Workspace* are shown below.

// The temperature distribution, from Eq. 7, Example 3.7
T(r) = Ts2 + qdot/(4*k) * (r2^2 - r^2) - qdot / (2*k) * r2^2 / ln (r2/r)

// The temperature at the inner surface, from Eq. 7
Ts1 = Ts2 + qdot / (4*k) * (r2^2 - r1^2) - qdot / (2*k) * r2^2 * ln (r2/r1)

// The energy balance on the surface, from Eq. 10
pi * qdot * (r2^2 - r1^2) = h * 2 * pi * r1 * (Ts1 - Tin)
PROBLEM 3.86

KNOWN: Diameter, resistivity, thermal conductivity, emissivity, voltage, and maximum temperature of heater wire. Convection coefficient and air exit temperature. Temperature of surroundings.

FIND: Maximum operating current, heater length and power rating.

SCHEMATIC:

Assumptions: (1) Steady-state, (2) Uniform wire temperature, (3) Constant properties, (4) Radiation exchange with large surroundings.

Analysis: Assuming a uniform wire temperature, \( T_{\text{max}} = T(r = 0) \equiv T_0 \approx T_s \), the maximum volumetric heat generation may be obtained from Eq. (3.55), but with the total heat transfer coefficient, \( h_t = h + h_r \), used in lieu of the convection coefficient \( h \). With

\[
\begin{align*}
\dot{q}_{\text{max}} &= \frac{2h_t}{r_o} (T_s - T_\infty) = \frac{2(296.3 \text{ W/m}^2 \cdot \text{K})}{0.0005 \text{ m}} (1150 \text{ C}) = 1.36 \times 10^9 \text{ W/m}^3 \\
\text{Hence, with} \quad \dot{q} &= \frac{l^2 \rho_e}{\pi^2} \left( \frac{\rho_e L/A_c}{A_c^2} \right) = \frac{l^2 \rho_e}{\pi D^2/4} = \frac{l^2 \rho_e}{\pi (D^2/4)} \\
I_{\text{max}} &= \left( \frac{\dot{q}_{\text{max}}}{\dot{q}} \right)^{1/2} = \left( \frac{1.36 \times 10^9 \text{ W/m}^3}{10^{-6} \text{ W} \cdot \text{m}^3} \right)^{1/2} \frac{\pi (0.001 \text{ m})^2}{4} = 29.0 \text{ A} \\
\text{Also, with} \quad \Delta E = I R_e = I (\rho_e L/A_c), \quad \text{and the power rating is} \quad P_{\text{elec}} = \Delta E \cdot I_{\text{max}} = 110 \text{ V} (29 \text{ A}) = 3190 \text{ W} = 3.19 \text{ kW}
\end{align*}
\]

Comments: To assess the validity of assuming a uniform wire temperature, Eq. (3.53) may be used to compute the centerline temperature corresponding to \( \dot{q}_{\text{max}} \) and a surface temperature of 1200°C. It follows that \( T_0 = \frac{q_{\text{max}}^2}{4k} + T_s = \frac{1.36 \times 10^9 \text{ W/m}^3 (0.0005 \text{ m})^2}{4 (25 \text{ W/m} \cdot \text{K})} + 1200 \text{ C} = 1203 \text{ C} \). With only a
3°C temperature difference between the centerline and surface of the wire, the assumption is excellent.
PROBLEM 3.87

KNOWN: Energy generation in an aluminum-clad, thorium fuel rod under specified operating conditions.

FIND: (a) Whether prescribed operating conditions are acceptable, (b) Effect of $\dot{q}$ and $h$ on acceptable operating conditions.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in r-direction, (2) Steady-state conditions, (3) Constant properties, (4) Negligible temperature gradients in aluminum and contact resistance between aluminum and thorium.

PROPERTIES: Table A-1, Aluminum, pure: M.P. = 933 K; Table A-1, Thorium: M.P. = 2023 K, $k \approx 60$ W/m·K.

ANALYSIS: (a) System failure would occur if the melting point of either the thorium or the aluminum were exceeded. From Eq. 3.53, the maximum thorium temperature, which exists at $r = 0$, is

$$T(0) = \frac{\dot{q}r_0^2}{4k} + T_s = T_{Th,max}$$

where, from the energy balance equation, Eq. 3.55, the surface temperature, which is also the aluminum temperature, is

$$T_s = T_\infty + \frac{\dot{q}r_0}{2h} = T_{Al}$$

Hence,

$$T_{Al} = T_s = 95^\circ C + \frac{7 \times 10^8 \text{ W/m}^3 \times 0.0125\text{ m}}{14,000 \text{ W/m}^2 \cdot \text{ K}} = 720^\circ C = 993\text{ K}$$

$$T_{Th,max} = \frac{7 \times 10^8 \text{ W/m}^3 (0.0125\text{ m})^2}{4 \times 60 \text{ W/m} \cdot \text{ K}} + 993\text{ K} = 1449\text{ K}$$

Although $T_{Th,max} < \text{M.P.}_{Th}$ and the thorium would not melt, $T_{al} > \text{M.P.}_{Al}$ and the cladding would melt under the proposed operating conditions. The problem could be eliminated by decreasing $\dot{q}$, increasing $h$ or using a cladding material with a higher melting point.

(b) Using the one-dimensional, steady-state conduction model (solid cylinder) of the IHT software, the following radial temperature distributions were obtained for parametric variations in $\dot{q}$ and $h$.

Continued...
For \( h = 10,000 \text{ W/m}^2\cdot\text{K} \), which represents a reasonable upper limit with water cooling, the temperature of the aluminum would be well below its melting point for \( \dot{q} = 7 \times 10^8 \text{ W/m}^3 \), but would be close to the melting point for \( \dot{q} = 8 \times 10^8 \text{ W/m}^3 \) and would exceed it for \( \dot{q} = 9 \times 10^8 \text{ W/m}^3 \). Hence, under the best of conditions, \( \dot{q} \approx 7 \times 10^8 \text{ W/m}^3 \) corresponds to the maximum allowable energy generation. However, if coolant flow conditions are constrained to provide values of \( h < 10,000 \text{ W/m}^2\cdot\text{K} \), volumetric heating would have to be reduced. Even for \( \dot{q} \) as low as \( 2 \times 10^8 \text{ W/m}^3 \), operation could not be sustained for \( h = 2000 \text{ W/m}^2\cdot\text{K} \).

The effects of \( \dot{q} \) and \( h \) on the centerline and surface temperatures are shown below.

For \( h = 2000 \) and \( 5000 \text{ W/m}^2\cdot\text{K} \), the melting point of thorium would be approached for \( \dot{q} \approx 4.4 \times 10^8 \) and \( 8.5 \times 10^8 \text{ W/m}^3 \), respectively. For \( h = 2000, 5000 \) and \( 10,000 \text{ W/m}^2\cdot\text{K} \), the melting point of aluminum would be approached for \( \dot{q} \approx 1.6 \times 10^8, 4.3 \times 10^8 \) and \( 8.7 \times 10^8 \text{ W/m}^3 \). Hence, the envelope of acceptable operating conditions must call for a reduction in \( \dot{q} \) with decreasing \( h \), from a maximum of \( \dot{q} \approx 7 \times 10^8 \text{ W/m}^3 \) for \( h = 10,000 \text{ W/m}^2\cdot\text{K} \).

**COMMENTS:** Note the problem which would arise in the event of a *loss of coolant*, for which case \( h \) would *decrease* drastically.
PROBLEM 3.88

FIND: (a) Expressions for temperature distributions in fuel and cladding, (b) Maximum fuel element temperature for prescribed conditions, (c) Effect of $h$ on temperature distribution.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Negligible contact resistance, (4) Constant properties.

ANALYSIS: (a) From Eqs. 3.49 and 3.23, the heat equations for the fuel ($f$) and cladding ($c$) are

$$\frac{1}{r} \frac{d}{dr} \left( r \frac{dT_f}{dr} \right) = - \frac{\dot{q}}{k_f} \quad (0 \leq r \leq \eta)$$

$$\frac{1}{r} \frac{d}{dr} \left( r \frac{dT_c}{dr} \right) = 0 \quad (\eta \leq r \leq r_2)$$

Hence, integrating both equations twice,

$$\frac{dT_f}{dr} = -\frac{\dot{q} r}{2k_f} + \frac{C_1}{k_f r} \quad T_f = -\frac{\dot{q} r^2}{4k_f} + \frac{C_1}{k_f} \ln r + C_2$$

(1.2)

$$\frac{dT_c}{dr} = \frac{C_3}{k_c r} \quad T_c = \frac{C_3}{k_c} \ln r + C_4$$

(3.4)

The corresponding boundary conditions are:

$$\frac{dT_f}{dr} \bigg|_{r=0} = 0 \quad T_f \bigg( \eta \bigg) = T_c \bigg( \eta \bigg)$$

(5.6)

$$-k_f \frac{dT_f}{dr} \bigg|_{r=\eta} = -k_c \frac{dT_c}{dr} \bigg|_{r=\eta} \quad -k_c \frac{dT_c}{dr} \bigg|_{r=r_2} = h \left[ T_c \bigg( r_2 \bigg) - T_\infty \right]$$

(7.8)

Note that Eqs. (7) and (8) are obtained from surface energy balances at $r_1$ and $r_2$, respectively. Applying Eq. (5) to Eq. (1), it follows that $C_1 = 0$. Hence,

$$T_f = -\frac{\dot{q} r^2}{4k_f} + C_2$$

(9)

From Eq. (6), it follows that

$$-\frac{\dot{q} \eta^2}{4k_f} + C_2 = \frac{C_3 \ln \eta}{k_c} + C_4$$

(10)

Continued...
Also, from Eq. (7),
\[ \frac{\dot{q}_n}{2} = -\frac{C_3}{\eta} \quad \text{or} \quad C_3 = -\frac{\dot{q}_n^2}{2} \]  
(11)

Finally, from Eq. (8),
\[ -\frac{C_3}{r_2} = h \left[ \frac{C_3}{k_c} \ln r_2 + C_4 - T_\infty \right] \] or, substituting for \( C_3 \) and solving for \( C_4 \)

\[ C_4 = -\frac{\dot{q}_n^2}{2r_2h} + \frac{\dot{q}_n^2}{2k_c} \ln r_2 + T_\infty \]  
(12)

Substituting Eqs. (11) and (12) into (10), it follows that
\[ C_2 = \frac{\dot{q}_n^2}{4k_f} - \frac{\dot{q}_n^2}{2k_c} \ln \eta + \frac{\dot{q}_n^2}{2r_2h} + \frac{\dot{q}_n^2}{2} \ln r_2 + T_\infty \]
\[ C_2 = \frac{\dot{q}_n^2}{4k_f} + \frac{\dot{q}_n^2}{2k_c} \ln \eta + \frac{\dot{q}_n^2}{2r_2h} + T_\infty \]  
(13)

Substituting Eq. (13) into (9),
\[ T_f = \frac{\dot{q}}{4k_f} \left( \eta^2 - r^2 \right) + \frac{\dot{q}_n^2}{2k_c} \ln \eta + \frac{\dot{q}_n^2}{2r_2h} + T_\infty \]  
(14)

Substituting Eqs. (11) and (12) into (4),
\[ T_c = \frac{\dot{q}_n^2}{2k_c} \frac{\ln r_2}{r} + \frac{\dot{q}_n^2}{2r_2h} + T_\infty . \]  
(15)

(b) Applying Eq. (14) at \( r = 0 \), the maximum fuel temperature for \( h = 2000 \text{ W/m}^2\cdot\text{K} \) is
\[ T_f (0) = \frac{2 \times 10^8 \text{ W/m}^3 \times (0.006 \text{ m})^2}{4 \times 2 \text{ W/m} \cdot \text{K}} + \frac{2 \times 10^8 \text{ W/m}^3 \times (0.006 \text{ m})^2}{2 \times 25 \text{ W/m} \cdot \text{K} \cdot \text{m}} \ln \frac{0.009 \text{ m}}{0.006 \text{ m}} \]
\[ + \frac{2 \times 10^8 \text{ W/m}^3 \times (0.006 \text{ m})^2}{2 \times (0.09 \text{ m}) \cdot 2000 \text{ W/m}^2 \cdot \text{K}} + 300 \text{ K} \]
\[ T_f (0) = (900 + 58.4 + 200 + 300) \text{ K} = 1458 \text{ K}. \]

(c) Temperature distributions for the prescribed values of \( h \) are as follows:
Clearly, the ability to control the maximum fuel temperature by increasing $h$ is limited, and even for $h\to\infty$, $T_f(0)$ exceeds 1000 K. The overall temperature drop, $T_f(0) - T_\infty$, is influenced principally by the low thermal conductivity of the fuel material.

**COMMENTS:** For the prescribed conditions, Eq. (14) yields, $T_f(0) - T_f(r_1) = \frac{q_1^2}{4k_f} = (2\times10^8 \text{ W/m}^3)(0.006 \text{ m})^3/8 \text{ W/m-K} = 900 \text{ K}$, in which case, with no cladding and $h\to\infty$, $T_f(0) = 1200 \text{ K}$. To reduce $T_f(0)$ below 1000 K for the prescribed material, it is necessary to reduce $q$. 

PROBLEM 3.89

**KNOWN:** Dimensions and properties of tubular heater and external insulation. Internal and external convection conditions. Maximum allowable tube temperature.

**FIND:** (a) Maximum allowable heater current for adiabatic outer surface, (3) Effect of internal convection coefficient on heater temperature distribution, (c) Extent of heat loss at outer surface.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional, steady-state conditions, (2) Constant properties, (3) Uniform heat generation, (4) Negligible radiation at outer surface, (5) Negligible contact resistance.

**ANALYSIS:** (a) From Eqs. 7 and 10, respectively, of Example 3.7, we know that

\[
T_{s,2} - T_{s,1} = \frac{\dot{q}}{2k} \frac{r_2}{\eta} \left[ \ln \frac{r_2}{\eta} - \frac{1}{4} \left( \frac{r_2^2 - \eta^2}{\eta^2} \right) \right]
\]

and

\[
T_{s,1} = T_{\infty,1} + \frac{\dot{q} \left( r_2^2 - \eta^2 \right)}{2h_1 \eta}
\]

Hence, eliminating \( T_{s,1} \), we obtain

\[
T_{s,2} - T_{\infty,1} = \frac{\dot{q} r_2^2}{2k} \left[ \ln \frac{r_2}{\eta} - \frac{1}{2} \left( 1 - \frac{\eta^2}{r_2^2} \right) + \frac{k}{h_1 \eta} \left( 1 - \frac{\eta^2}{r_2^2} \right) \right]
\]

Substituting the prescribed conditions (\( h_1 = 100 \text{ W/m}^2\cdot\text{K} \)),

\[
T_{s,2} - T_{\infty,1} = 1.237 \times 10^{-4} \left( \text{m}^3 \cdot \text{K/W} \right) \dot{q} \left( \text{W/m}^3 \right)
\]

Hence, with \( T_{\text{max}} \) corresponding to \( T_{s,2} \), the maximum allowable value of \( \dot{q} \) is

\[
\dot{q}_{\text{max}} = \frac{1400 - 400}{1.237 \times 10^{-4}} = 8.084 \times 10^6 \text{ W/m}^3
\]

with

\[
\dot{q} = \frac{I^2}{\eta} = \frac{I^2 \rho_e L/A_c}{\pi \left( r_2^2 - \eta^2 \right)^2}
\]

\[
I_{\text{max}} = \pi \left( r_2^2 - \eta^2 \right) \left( \frac{\dot{q}}{\rho_e} \right)^{1/2} = \pi \left( 0.035^2 - 0.025^2 \right) m^2 \left( 8.084 \times 10^6 \text{ W/m}^3 \right) \left( 0.7 \times 10^{-6} \Omega \cdot \text{m} \right)^{1/2} = 6406 \text{ A}
\]

Continued …..
PROBLEM 3.89 (Cont.)

(b) Using the one-dimensional, steady-state conduction model of IHT (hollow cylinder; convection at inner surface and adiabatic outer surface), the following temperature distributions were obtained.

The results are consistent with key implications of Eqs. (1) and (2), namely that the value of \( h_1 \) has no effect on the temperature drop across the tube \( (T_{s,2} - T_{s,1}) = 30 \text{ K}, \) irrespective of \( h_1 \), while \( T_{s,1} \) decreases with increasing \( h_1 \). For \( h_1 = 100, 500 \) and \( 1000 \text{ W/m}^2\text{K} \), respectively, the ratio of the temperature drop between the inner surface and the air to the temperature drop across the tube, \( (T_{s,1} - T_{\infty,1})/(T_{s,2} - T_{s,1}) \), decreases from \( 970/30 = 32.3 \) to \( 194/30 = 6.5 \) and \( 97/30 = 3.2 \). Because the outer surface is insulated, the heat rate to the airflow is fixed by the value of \( \dot{q}' \) and, irrespective of \( h_1 \),

\[
\dot{q}'(r_1) = \pi \left( r_2^2 - r_1^2 \right) \dot{q} = -15,240 \text{ W}
\]

(c) Heat loss from the outer surface of the tube to the surroundings depends on the total thermal resistance

\[
R_{\text{tot}} = \frac{\ln \left( r_3/r_2 \right)}{2\pi L k_2} + \frac{1}{2\pi r_3 L h_2}
\]

or, for a unit area on surface 2,

\[
R'_{\text{tot,2}} = (2\pi r_2 L) R_{\text{tot}} = \frac{r_2 \ln \left( r_3/r_2 \right)}{k_2} + \frac{r_2}{r_3 h_2}
\]

Again using the capabilities of IHT (hollow cylinder; convection at inner surface and heat transfer from outer surface through \( R'_{\text{tot,2}} \)), the following temperature distributions were determined for the tube and insulation.
PROBLEM 3.89 (Cont.)

Heat losses through the insulation, \( q'(r_2) \), are 4250 and 3890 W/m for \( \delta = 25 \) and 50 mm, respectively, with corresponding values of \( q'(r_1) \) equal to -10,990 and -11,350 W/m. Comparing the tube temperature distributions with those predicted for an adiabatic outer surface, it is evident that the losses reduce tube wall temperatures predicted for the adiabatic surface and also shift the maximum temperature from \( r = 0.035 \) m to \( r \approx 0.033 \) m. Although the tube outer and insulation inner surface temperatures, \( T_s,2 = T(r_2) \), increase with increasing insulation thickness, Fig. (c), the insulation outer surface temperature decreases.

COMMENTS: If the intent is to maximize heat transfer to the airflow, heat losses to the ambient should be reduced by selecting an insulation material with a significantly smaller thermal conductivity.
**PROBLEM 3.90**

**KNOWN:** Electric current I is passed through a pipe of resistance $R_e'$ to melt ice under steady-state conditions.

**FIND:** (a) Temperature distribution in the pipe wall, (b) Time to completely melt the ice.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional radial conduction, (3) Constant properties, (4) Uniform heat generation in the pipe wall, (5) Outer surface of the pipe is adiabatic, (6) Inner surface is at a constant temperature, $T_m$.

**PROPERTIES:** *Table A-3, Ice* (273K): $\rho = 920 \text{ kg/m}^3$; *Handbook Chem. & Physics, Ice*: Latent heat of fusion, $h_{sf} = 3.34 \times 10^5 \text{ J/kg}$.

**ANALYSIS:** (a) The appropriate form of the heat equation is Eq. 3.49, and the general solution, Eq. 3.51 is

$$T(r) = -\frac{\dot{q}}{4k} r^2 + C_1 \ln r + C_2$$

where

$$\dot{q} = \frac{I^2 R_e'}{\pi (r_2^2 - r_1^2)}.$$

Applying the boundary condition $(dT/dr)_{r_2} = 0$, it follows that

$$0 = \frac{\dot{q} r_2}{2k} + \frac{C_1}{r_2}.$$

Hence

$$C_1 = \frac{\dot{q} r_2^2}{2k}.$$

and

$$T(r) = -\frac{\dot{q}}{4k} r^2 + \frac{\dot{q} r_2^2}{2k} \ln r + C_2.$$

Continued …..
Applying the second boundary condition, \( T(\eta) = T_m \), it follows that

\[
T_m = -\frac{\dot{q} r^2}{4k \eta^2} + \frac{\dot{q} r^2}{2k} \ln \eta + C_2.
\]

Solving for \( C_2 \) and substituting into the expression for \( T(r) \), find

\[
T(r) = T_m + \frac{\dot{q} r^2}{2k} \ln \frac{r}{\eta} - \frac{\dot{q}}{4k} \left( r^2 - r^1 \right).
\]

(b) Conservation of energy dictates that the energy required to completely melt the ice, \( E_m \), must equal the energy which reaches the inner surface of the pipe by conduction through the wall during the melt period. Hence from Eq. 1.11b

\[
\Delta E_{\text{st}} = E_{\text{in}} - E_{\text{out}} + E_{\text{gen}}
\]

\[
\Delta E_{\text{st}} = E_m = t_m \cdot q_{\text{cond}, \eta}
\]

or, for a unit length of pipe,

\[
\rho \left( \pi \eta^2 \right) h_{sf} = t_m \left[ -k \left( 2\pi \eta \right) \left[ \frac{dT}{dr} \right]_{\eta} \right]
\]

\[
\rho \left( \pi \eta^2 \right) h_{sf} = -2\pi \eta k t_m \left[ \frac{\dot{q} r^2}{2k \eta} - \frac{\dot{q} \eta}{2k} \right]
\]

\[
\rho \left( \pi \eta^2 \right) h_{sf} = -t_m \dot{q} \pi \left( r^2 - r^1 \right).
\]

Dropping the minus sign, which simply results from the fact that conduction is in the negative \( r \) direction, it follows that

\[
t_m = \frac{\rho h_{sf} \eta^2}{\dot{q} \left( r^2 - r^1 \right)} = \frac{\rho h_{sf} \pi \eta^2}{I^2 R_e'}. \]

With \( r_1 = 0.05 \text{m}, I = 100 \text{ A} \) and \( R_e' = 0.30 \Omega/\text{m} \), it follows that

\[
t_m = \frac{920 \text{kg/m}^3 \times 3.34 \times 10^5 \text{J/kg} \times \pi \times (0.05 \text{m})^2}{(100 \text{A})^2 \times 0.30 \Omega/\text{m}}
\]

or

\[
t_m = 804 \text{s}.
\]

**COMMENTS:** The foregoing expression for \( t_m \) could also be obtained by recognizing that all of the energy which is generated by electrical heating in the pipe wall must be transferred to the ice. Hence,

\[
I^2 R_e' t_m = \rho h_{sf} \pi r_1^2.
\]
PROBLEM 3.91

KNOWN: Materials, dimensions, properties and operating conditions of a gas-cooled nuclear reactor.

FIND: (a) Inner and outer surface temperatures of fuel element, (b) Temperature distributions for different heat generation rates and maximum allowable generation rate.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties, (4) Negligible contact resistance, (5) Negligible radiation.

PROPERTIES: Table A.1, Thorium: \( T_{mp} \approx 2000 \text{ K} \); Table A.2, Graphite: \( T_{mp} \approx 2300 \text{ K} \).

ANALYSIS: (a) The outer surface temperature of the fuel, \( T_2 \), may be determined from the rate equation

\[
q' = \frac{T_2 - T_{\infty}}{R_{\text{tot}}^{'}}
\]

where

\[
R_{\text{tot}}^{'} = \frac{\ln (r_3 / r_2)}{2\pi k_g} + \frac{1}{2\pi r_2 h} = \frac{\ln (14/11)}{2\pi (3 \text{ W/m} \cdot \text{K})} + \frac{1}{2\pi (0.014 \text{ m})(2000 \text{ W/m}^2 \cdot \text{K})} = 0.0185 \text{ m} \cdot \text{K/W}
\]

and the heat rate per unit length may be determined by applying an energy balance to a control surface about the fuel element. Since the interior surface of the element is essentially adiabatic, it follows that

\[
q' = q\pi \left( r_2^2 - \eta_1^2 \right) = 10^8 \text{ W/m}^3 \times \pi \left( 0.011^2 - 0.008^2 \right) \text{m}^2 = 17,907 \text{ W/m}
\]

Hence,

\[
T_2 = q' R_{\text{tot}}^{' + T_{\infty} = 17,907 \text{ W/m}(0.0185 \text{ m} \cdot \text{K/W}) + 600 \text{ K} = 931 \text{ K}
\]

With zero heat flux at the inner surface of the fuel element, Eq. C.14 yields

\[
T_1 = T_2 + \frac{q\eta_1^2}{4k_t} \left( 1 - \frac{\eta_1^2}{r_1^2} \right) - \frac{q\eta_1^2}{2k_t} \ln \left( \frac{r_2}{\eta_1} \right)
\]

\[
T_1 = 931 \text{ K} + \frac{10^8 \text{ W/m}^3 (0.011 \text{ m})^2}{4 \times 57 \text{ W/m} \cdot \text{K}} \left[ 1 - \left( \frac{0.008}{0.011} \right)^2 \right] - \frac{10^8 \text{ W/m}^3 (0.008 \text{ m})^2}{2 \times 57 \text{ W/m} \cdot \text{K}} \ln \left( \frac{0.011}{0.008} \right)
\]

Continued...
(b) The temperature distributions may be obtained by using the IHT model for one-dimensional, steady-state conduction in a hollow tube. For the fuel element \((\dot{q} > 0)\), an adiabatic surface condition is prescribed at \(r_1\), while heat transfer from the outer surface at \(r_2\) to the coolant is governed by the thermal resistance \(R_{\text{tot},2} = 2\pi r_2 R'_{\text{tot}} = 2\pi (0.011 \text{ m}) 0.0185 \text{ m} \cdot \text{K/W} = 0.00128 \text{ m}^2 \cdot \text{K/W}\). For the graphite \((\dot{q} = 0)\), the value of \(T_2\) obtained from the foregoing solution is prescribed as an inner boundary condition at \(r_2\), while a convection condition is prescribed at the outer surface \((r_3)\). For \(1 \times 10^8 \leq \dot{q} \leq 5 \times 10^8 \text{ W/m}^3\), the following distributions are obtained.

The comparatively large value of \(k_t\) yields small temperature variations across the fuel element, while the small value of \(k_g\) results in large temperature variations across the graphite. Operation at \(\dot{q} = 5 \times 10^8 \text{ W/m}^3\) is clearly unacceptable, since the melting points of thorium and graphite are exceeded and approached, respectively. To prevent softening of the materials, which would occur below their melting points, the reactor should not be operated much above \(\dot{q} = 3 \times 10^8 \text{ W/m}^3\).

**COMMENTS:** A contact resistance at the thorium/graphite interface would increase temperatures in the fuel element, thereby reducing the maximum allowable value of \(\dot{q}\).
PROBLEM 3.92

KNOWN: Long rod experiencing uniform volumetric generation encapsulated by a circular sleeve exposed to convection.

FIND: (a) Temperature at the interface between rod and sleeve and on the outer surface, (b) Temperature at center of rod.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional radial conduction in rod and sleeve, (2) Steady-state conditions, (3) Uniform volumetric generation in rod, (4) Negligible contact resistance between rod and sleeve.

ANALYSIS: (a) Construct a thermal circuit for the sleeve,

where

\[ q' = q_{gen} = \frac{\dot{q}}{24,000 \text{ W/m}^3} \times \pi \times (0.20 \text{ m})^2 / 4 = 754.0 \text{ W/m} \]

\[ R_s' = \frac{\ln (r_2 / \eta)}{2 \pi k_s} = \frac{\ln (400/200)}{2 \pi \times 4 \text{ W/m} \cdot \text{K}} = 2.758 \times 10^{-2} \text{ m} \cdot \text{K/W} \]

\[ R_{conv} = \frac{1}{h \pi D_2} = \frac{1}{25 \text{ W/m}^2 \cdot \text{K} \times \pi \times 0.400 \text{ m}} = 3.183 \times 10^{-2} \text{ m} \cdot \text{K/W} \]

The rate equation can be written as

\[ q' = \frac{T_1 - T_\infty}{R_s + R_{conv}'} = \frac{T_2 - T_\infty}{R_{conv}'} \]

\[ T_1 = T_\infty + q' (R_s' + R_{conv}') = 27^\circ \text{C} + 754 \text{ W/m} \left( 2.758 \times 10^{-2} + 3.183 \times 10^{-2} \right) \text{ K/W} \cdot \text{m} = 71.8^\circ \text{C} < \]

\[ T_2 = T_\infty + q' R_{conv}' = 27^\circ \text{C} + 754 \text{ W/m} \times 3.183 \times 10^{-2} \text{ m} \cdot \text{K/W} = 51.0^\circ \text{C}. < \]

(b) The temperature at the center of the rod is

\[ T(0) = T_0 = \frac{\dot{q}_1^2}{4k_r} + T_1 = \frac{24,000 \text{ W/m}^3 (0.100 \text{ m})^2}{4 \times 0.5 \text{ W/m} \cdot \text{K}} + 71.8^\circ \text{C} = 192^\circ \text{C}. < \]

COMMENTS: The thermal resistances due to conduction in the sleeve and convection are comparable. Will increasing the sleeve outer diameter cause the surface temperature \( T_2 \) to increase or decrease?
PROBLEM 3.93

KNOWN: Radius, thermal conductivity, heat generation and convection conditions associated with a solid sphere.

FIND: Temperature distribution.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional radial conduction, (3) Constant properties, (4) Uniform heat generation.

ANALYSIS: Integrating the appropriate form of the heat diffusion equation,

\[ \frac{1}{r^2} \frac{d}{dr} \left[ kr^2 \frac{dT}{dr} \right] + \dot{q} = 0 \quad \text{or} \quad \frac{d}{dr} \left[ r^2 \frac{dT}{dr} \right] = -\frac{\dot{q}r^2}{k} \]

\[ r^2 \frac{dT}{dr} = -\frac{\dot{q}r^3}{3k} + C_1 \quad \frac{dT}{dr} = -\frac{\dot{q}r}{3k} \frac{C_1}{r^2} \]

\[ T(r) = -\frac{\dot{q}r^2}{6k} - \frac{C_1}{r} + C_2. \]

The boundary conditions are:

\[ \left. \frac{dT}{dr} \right|_{r=0} = 0 \quad \text{hence} \quad C_1 = 0, \text{ and} \]

\[ -k \left. \frac{dT}{dr} \right|_{r=r_0} = h[T(r_0) - T_\infty] . \]

Substituting into the second boundary condition \((r = r_0)\), find

\[ \frac{\dot{q}r_0^2}{3} = h \left[ -\frac{\dot{q}r_0^2}{6k} + C_2 - T_\infty \right] \quad C_2 = \frac{\dot{q}r_0}{3h} + \frac{\dot{q}r_0^2}{6k} - T_\infty . \]

The temperature distribution has the form

\[ T(r) = \frac{\dot{q}r}{6k} \left( r_0^2 - r^2 \right) + \frac{\dot{q}r_0^2}{6k} - T_\infty . \]

COMMENTS: To verify the above result, obtain \(T(r_0) = T_s\).

\[ T_s = \frac{\dot{q}r_0}{3h} + T_\infty \]

Applying energy balance to the control volume about the sphere,

\[ \dot{q} \left[ \frac{4}{3} \pi r_0^3 \right] = h4\pi r_0^2 (T_s - T_\infty) \quad \text{find} \quad T_s = \frac{\dot{q}r_0}{3h} + T_\infty . \]
PROBLEM 3.94

KNOWN: Radial distribution of heat dissipation of a spherical container of radioactive wastes. Surface convection conditions.

FIND: Radial temperature distribution.

SCHEMATIC: 

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties, (4) Negligible temperature drop across container wall.

ANALYSIS: The appropriate form of the heat equation is

\[
\frac{1}{r^2} \frac{d}{dr} \left( r^2 \frac{dT}{dr} \right) = -\frac{\dot{q}_0}{k} \left[ 1 - \left( \frac{r}{r_0} \right)^2 \right].
\]

Hence

\[
\frac{dT}{dr} = -\frac{\dot{q}_0}{k} \left( \frac{r^3}{3} - \frac{r^5}{5r_0^2} \right) + C_1.
\]

From the boundary conditions,

\[
\left. \frac{dT}{dr} \right|_{r=0} = 0 \quad \text{and} \quad -k \frac{dT}{dr} \big|_{r=r_0} = h \left( T(r_0) - T_\infty \right)
\]

it follows that \( C_1 = 0 \) and

\[
\dot{q}_0 \left( \frac{r_0 - r_0}{3} - \frac{r_0}{5} \right) = h \left[ -\dot{q}_0 \left( \frac{r_0^2}{6} - \frac{r_0^2}{20} \right) + C_2 - T_\infty \right]
\]

\[
C_2 = \frac{2r_0 \dot{q}_0}{15h} + \frac{7 \dot{q}_0 r_0^2}{60k} + T_\infty.
\]

Hence

\[
T(r) = T_\infty + \frac{2r_0 \dot{q}_0}{15h} + \frac{\dot{q}_0}{k} \left[ \frac{7}{60} - \frac{1}{6} \left( \frac{r}{r_0} \right)^2 + \frac{1}{20} \left( \frac{r}{r_0} \right)^4 \right].
\]

COMMENTS: Applying the above result at \( r_0 \) yields

\[
T_s = T(r_0) = T_\infty + \frac{2r_0 \dot{q}_0}{15h}.
\]

The same result may be obtained by applying an energy balance to a control surface about the container, where \( E_g = q_{\text{conv}} \). The maximum temperature exists at \( r = 0 \).
PROBLEM 3.95

KNOWN: Dimensions and thermal conductivity of a spherical container. Thermal conductivity and volumetric energy generation within the container. Outer convection conditions.

FIND: (a) Outer surface temperature, (b) Container inner surface temperature, (c) Temperature distribution within and center temperature of the wastes, (d) Feasibility of operating at twice the energy generation rate.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) One-dimensional radial conduction.

ANALYSIS: (a) For a control volume which includes the container, conservation of energy yields
\[ E_{\text{g}} - E_{\text{out}} = 0, \text{ or } \dot{q}V - q_{\text{conv}} = 0. \]
Hence
\[ \dot{q} \left( \frac{4}{3} \pi r_1^3 \right) = h 4 \pi r_0^2 \left( T_{s,o} - T_{\infty} \right) \]
and with \( \dot{q} = 10^5 \text{ W/m}^3 \),
\[ T_{s,o} = T_{\infty} + \frac{\dot{q} r_1^3}{3 h r_0^2} = 25^\circ\text{C} + \frac{10^5 \text{ W/m}^2 \left( 0.5 \text{ m} \right)^3}{3000 \text{ W/} \text{m}^2 \cdot \text{K} \left( 0.6 \text{ m} \right)^2} = 36.6^\circ\text{C}. \]

(b) Performing a surface energy balance at the outer surface, \( E_{\text{in}} - E_{\text{out}} = 0 \) or \( q_{\text{cond}} - q_{\text{conv}} = 0 \).
Hence
\[ \frac{4 \pi k_{s} \left( T_{s,i} - T_{s,o} \right) \left( 1/r_1 \right) - \left( 1/r_0 \right)}{\left( 1/r_1 \right) - \left( 1/r_0 \right)} = h 4 \pi r_0^2 \left( T_{s,o} - T_{\infty} \right) \]
\[ T_{s,i} = T_{s,o} + \frac{h}{k_{s} \left( r_1 \right)} \left( r_0 - 1 \right) r_0 \left( T_{s,o} - T_{\infty} \right) = 36.6^\circ\text{C} + \frac{1000 \text{ W/} \text{m}^2 \cdot \text{K}}{15 \text{ W/} \text{m} \cdot \text{K}} \left( 0.2 \right) 0.6 \text{ m} \left( 11.6^\circ\text{C} \right) = 129.4^\circ\text{C}. \]

(c) The heat equation in spherical coordinates is
\[ k_{rw} \frac{d}{dr} \left( r^2 \frac{dT}{dr} \right) + \dot{q} r^2 = 0. \]
Solving,
\[ r^2 \frac{dT}{dr} = - \frac{\dot{q} r^3}{3 k_{rw}} + C_1 \]
and
\[ T(r) = - \frac{\dot{q} r^2}{6 k_{rw}} - \frac{C_1}{r} + C_2 \]
Applying the boundary conditions,
\[ \frac{dT}{dr} \bigg|_{r=0} = 0 \quad \text{and} \quad T(r_1) = T_{s,i} \]
\[ C_1 = 0 \quad \text{and} \quad C_2 = T_{s,i} + \frac{\dot{q} r_1^2}{6 k_{rw}}. \]

Continued...
PROBLEM 3.95 (Cont.)

Hence
\[ T(r) = T_{s,i} + \frac{\dot{q}}{6k_{rw}} \left( \eta^2 - r^2 \right) \]

At \( r = 0 \),
\[ T(0) = T_{s,i} + \frac{\eta^2}{6k_{rw}} = 129.4^\circ C + \frac{10^5 \text{ W/m}^3 (0.5 \text{ m})^2}{6(20 \text{ W/m} \cdot \text{K})} = 337.7^\circ C \]

(d) The feasibility assessment may be performed by using the IHT model for one-dimensional, steady-state conduction in a solid sphere, with the surface boundary condition prescribed in terms of the total thermal resistance

\[ R^*_{tot,i} = \left( 4\pi \eta \right)^2 R^*_{tot} = R^*_{cnd,i} + R^*_{cnv,i} = \frac{\eta^2 \left( (1/\eta) - (1/r_o) \right)}{k_{ss}} + \frac{1}{h} \left( \frac{\eta}{r_o} \right)^2 \]

where, for \( r_o = 0.6 \text{ m} \) and \( h = 1000 \text{ W/m}^2 \cdot \text{K} \), \( R^*_{cnd,i} = 5.56 \times 10^{-3} \text{ m}^2 \cdot \text{K/W} \), \( R^*_{cnv,i} = 6.94 \times 10^{-4} \text{ m}^2 \cdot \text{K/W} \), and \( R^*_{tot,i} = 6.25 \times 10^{-3} \text{ m}^2 \cdot \text{K/W} \). Results for the center temperature are shown below.

Clearly, even with \( r_o = 0.54 \text{ m} = r_{o,min} \) and \( h = 10,000 \text{ W/m}^2 \cdot \text{K} \) (a practical upper limit), \( T(0) > 475^\circ C \) and the desired condition can not be met. The corresponding resistances are \( R^*_{cnd,i} = 2.47 \times 10^{-3} \text{ m}^2 \cdot \text{K/W} \), \( R^*_{cnv,i} = 8.57 \times 10^{-5} \text{ m}^2 \cdot \text{K/W} \), and \( R^*_{tot,i} = 2.56 \times 10^{-3} \text{ m}^2 \cdot \text{K/W} \). The conduction resistance remains dominant, and the effect of reducing \( R^*_{cnv,i} \) by increasing \( h \) is small. The proposed extension is not feasible.

COMMENTS: A value of \( \dot{q} = 1.79 \times 10^5 \text{ W/m}^3 \) would allow for operation at \( T(0) = 475^\circ C \) with \( r_o = 0.54 \text{ m} \) and \( h = 10,000 \text{ W/m}^2 \cdot \text{K} \).
PROBLEM 3.96

KNOWN: Carton of apples, modeled as 80-mm diameter spheres, ventilated with air at 5°C and experiencing internal volumetric heat generation at a rate of 4000 J/kg-day.

FIND: (a) The apple center and surface temperatures when the convection coefficient is 7.5 W/m²·K, and (b) Compute and plot the apple temperatures as a function of air velocity, V, for the range 0.1 ≤ V ≤ 1 m/s, when the convection coefficient has the form $h = C_1 V^{0.425}$, where $C_1 = 10.1$ W/m²·K·(m/s)$^{0.425}$.

SCHEMATIC:

ASSUMPTIONS: (1) Apples can be modeled as spheres, (2) Each apple experiences flow of ventilation air at $T_\infty = 5$°C, (3) One-dimensional radial conduction, (4) Constant properties and (5) Uniform heat generation.

ANALYSIS: (a) From Eq. C.24, the temperature distribution in a solid sphere (apple) with uniform generation is

$$T(r) = \frac{\dot{q} r_0^2}{6k} \left(1 - \frac{r^2}{r_0^2}\right) + T_s$$

(1)

To determine $T_s$, perform an energy balance on the apple as shown in the sketch above, with volume $V = \frac{4}{3} \pi r_0^3$,

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_{g} = 0 \quad \Rightarrow \quad -q_{cv} + \dot{q} V = 0$$

$$-h \left(4\pi r_0^2\right) \left(T_s - T_\infty\right) + \dot{q} \left(4/3 \pi r_0^3\right) = 0$$

(2)

$$-7.5 \text{ W/m}^2\cdot\text{K} \left(4\pi \times 0.040^2 \text{ m}^2\right) \left(T_s - 5^\circ\text{C}\right) + 38.9 \text{ W/m}^3 \left(4/3 \pi \times 0.040^3 \text{ m}^3\right) = 0$$

where the volumetric generation rate is

$$\dot{q} = 4000 \text{ J/kg} \cdot \text{day}$$

$$\dot{q} = 4000 \text{ J/kg} \cdot \text{day} \times 840 \text{ kg/m}^3 \times (1 \text{ day/24 hr}) \times (1 \text{ hr}/3600 \text{ s})$$

$$\dot{q} = 38.9 \text{ W/m}^3$$

and solving for $T_s$, find

$$T_s = 5.14^\circ\text{C}$$

From Eq. (1), at $r = 0$, with $T_s$, find

$$T(0) = \frac{38.9 \text{ W/m}^3 \times 0.040^2 \text{ m}^2}{6 \times 0.5 \text{ W/m} \cdot \text{K}} + 5.14^\circ\text{C} = 0.12^\circ\text{C} + 5.14^\circ\text{C} = 5.26^\circ\text{C}$$

Continued...
PROBLEM 3.96 (Cont.)

(b) With the convection coefficient depending upon velocity,

\[ h = C_1 V^{0.425} \]

with \( C_1 = 10.1 \text{ W/m}^2\cdot\text{K} \cdot (\text{m/s})^{0.425} \), and using the energy balance of Eq. (2), calculate and plot \( T_s \) as a function of ventilation air velocity \( V \). With very low velocities, the center temperature is nearly 0.5°C higher than the air. From our earlier calculation we know that \( T(0) - T_s = 0.12 \)°C and is independent of \( V \).

COMMENTS:
1. While the temperature within the apple is nearly isothermal, the center temperature will track the ventilation air temperature which will increase as it passes through stacks of cartons.
2. The IHT Workspace used to determine \( T_s \) for the base condition and generate the above plot is shown below.

```
// The temperature distribution, Eq (1),
T_r = qdot * ro^2 / (4 * k) * (1 - r^2/ro^2) + Ts

// Energy balance on the apple, Eq (2)
- qcv + qdot * Vol = 0
Vol = 4 / 3 * pi * ro^3

// Convection rate equation:
qcv = h * As * (Ts - Tinf)
As = 4 * pi * ro^2

// Generation rate:
qdot = qdotm * (1/24) * (1/3600) * rho  // Generation rate, W/m^3; Conversions: days/h and h/sec

// Assigned variables:
ro = 0.080  // Radius of apple, m
k = 0.5    // Thermal conductivity, W/m.K
qdotm = 4000  // Generation rate, J/kg.K
rho = 840   // Specific heat, J/kg.K
r = 0   // Center, m; location for T(0)
hs = 7.5  // Convection coefficient, W/m^2.K; base case, V = 0.5 m/s
//h = C1 * V^0.425  // Correlation
//C1 = 10.1
//V = 0.5
Tinf = 5  // Air temperature, °C
```
PROBLEM 3.97

KNOWN: Plane wall, long cylinder and sphere, each with characteristic length \( a \), thermal conductivity \( k \) and uniform volumetric energy generation rate \( \dot{q} \).

FIND: (a) On the same graph, plot the dimensionless temperature, \( \left( T(x) - T_s \right) / [\dot{q} a^2 / 2k] \), vs. the dimensionless characteristic length, \( x/a \) or \( r/a \), for each shape; (b) Which shape has the smallest temperature difference between the center and the surface? Explain this behavior by comparing the ratio of the volume-to-surface area; and (c) Which shape would be preferred for use as a nuclear fuel element? Explain why?

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties and (4) Uniform volumetric generation.

ANALYSIS: (a) For each of the shapes, with \( T(a) = T_s \), the dimensionless temperature distributions can be written by inspection from results in Appendix C.3.

Plane wall, Eq. C.22
\[
\frac{T(x) - T_s}{\dot{q} a^2 / 2k} = 1 - \left( \frac{x}{a} \right)^2
\]

Long cylinder, Eq. C.23
\[
\frac{T(r) - T_s}{\dot{q} a^2 / 2k} = \frac{1}{2} \left[ 1 - \left( \frac{r}{a} \right)^2 \right]
\]

Sphere, Eq. C.24
\[
\frac{T(r) - T_s}{\dot{q} a^2 / 2k} = \frac{1}{3} \left[ 1 - \left( \frac{r}{a} \right)^2 \right]
\]

The dimensionless temperature distributions using the foregoing expressions are shown in the graph below.

Continued …..
PROBLEM 3.97 (Cont.)

(b) The sphere shape has the smallest temperature difference between the center and surface, \( T(0) - T(a) \). The ratio of volume-to-surface-area, \( \forall/A_s \), for each of the shapes is

**Plane wall**

\[
\frac{\forall}{A_s} = \frac{a(1\times1)}{(1\times1)} = a
\]

**Long cylinder**

\[
\frac{\forall}{A_s} = \frac{\pi a^2 \times 1}{2\pi a \times 1} = \frac{a}{2}
\]

**Sphere**

\[
\frac{\forall}{A_s} = \frac{4\pi a^3 / 3}{4\pi a^2} = \frac{a}{3}
\]

The smaller the \( \forall/A_s \) ratio, the smaller the temperature difference, \( T(0) - T(a) \).

(c) The sphere would be the preferred element shape since, for a given \( \forall/A_s \) ratio, which controls the generation and transfer rates, the sphere will operate at the lowest temperature.
PROBLEM 3.98

KNOWN: Radius, thickness, and incident flux for a radiation heat gauge.

FIND: Expression relating incident flux to temperature difference between center and edge of gauge.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in $r$ (negligible temperature drop across foil thickness), (3) Constant properties, (4) Uniform incident flux, (5) Negligible heat loss from foil due to radiation exchange with enclosure wall, (6) Negligible contact resistance between foil and heat sink.

ANALYSIS: Applying energy conservation to a circular ring extending from $r$ to $r + dr$,

$$ q_i + q_i^r (2\pi r dr) = q_{r+dr}, \quad q_r = -k (2\pi r) \frac{dT}{dr}, \quad q_{r+dr} = q_r + \frac{ddr}{dr} dr. $$

Rearranging, find that

$$ q_i^r (2\pi r dr) = \frac{d}{dr} \left[ (-k 2\pi r) \frac{dT}{dr} \right] dr 
\frac{d}{dr} \left[ r \frac{dT}{dr} \right] = -\frac{q_i^r}{kt}. $$

Integrating,

$$ r \frac{dT}{dr} = -\frac{q_i r^2}{2kt} + C_1 \quad \text{and} \quad T(r) = -\frac{q_i r^2}{4kt} + C_1 \ln r + C_2. $$

With $dT/dr|_{r=0} = 0$, $C_1 = 0$ and with $T(r = R) = T(R)$,

$$ T(R) = -\frac{q_i R^2}{4kt} + C_2 \quad \text{or} \quad C_2 = T(R) + \frac{q_i R^2}{4kt}. $$

Hence, the temperature distribution is

$$ T(r) = \frac{q_i}{4kt} \left( R^2 - r^2 \right) + T(R). $$

Applying this result at $r = 0$, it follows that

$$ q_i^r = \frac{4kt}{R^2} \left[ T(0) - T(R) \right] = \frac{4kt}{R^2} \Delta T. $$

COMMENTS: This technique allows for determination of a radiation flux from measurement of a temperature difference. It becomes inaccurate if emission from the foil becomes significant.
PROBLEM 3.98

KNOWN: Radius, thickness, and incident flux for a radiation heat gauge.

FIND: Expression relating incident flux to temperature difference between center and edge of gauge.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in r (negligible temperature drop across foil thickness), (3) Constant properties, (4) Uniform incident flux, (5) Negligible heat loss from foil due to radiation exchange with enclosure wall, (6) Negligible contact resistance between foil and heat sink.

ANALYSIS: Applying energy conservation to a circular ring extending from r to r + dr,

\[ q_r + q_i^r (2\pi r \, dr) = q_{r+dr}, \quad q_r = -k (2\pi r) \frac{dT}{dr}, \quad q_{r+dr} = q_r + \frac{dr}{dr} dr. \]

Rearranging, find that

\[ q_i^r (2\pi r \, dr) = \frac{d}{dr} \left[ (-k2\pi r) \frac{dT}{dr} \right] dr \]

\[ \frac{d}{dr} \left[ r \frac{dT}{dr} \right] = -\frac{q_i^r}{kt}. \]

Integrating,

\[ r \frac{dT}{dr} = -\frac{q_i^r r^2}{2kt} + C_1 \quad \text{and} \quad T(r) = -\frac{q_i^r r^2}{4kt} + C_1 \ln r + C_2. \]

With \( dT/dr |_{r=0} = 0 \), \( C_1 = 0 \) and with \( T(r = R) = T(R) \),

\[ T(R) = -\frac{q_i^r R^2}{4kt} + C_2 \quad \text{or} \quad C_2 = T(R) + \frac{q_i^r R^2}{4kt}. \]

Hence, the temperature distribution is

\[ T(r) = \frac{q_i^r}{4kt} \left( R^2 - r^2 \right) + T(R). \]

Applying this result at \( r = 0 \), it follows that

\[ q_i^r = \frac{4kt}{R^2} \left[ T(0) - T(R) \right] = \frac{4kt}{R^2} \Delta T. \]

COMMENTS: This technique allows for determination of a radiation flux from measurement of a temperature difference. It becomes inaccurate if emission from the foil becomes significant.
PROBLEM 3.99

KNOWN: Net radiative flux to absorber plate.

FIND: (a) Maximum absorber plate temperature, (b) Rate of energy collected per tube.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional (x) conduction along absorber plate, (3) Uniform radiation absorption at plate surface, (4) Negligible losses by conduction through insulation, (5) Negligible losses by convection at absorber plate surface, (6) Temperature of absorber plate at \( x = 0 \) is approximately that of the water.

PROPERTIES: Table A-1, Aluminum alloy (2024-T6): \( k = 180 \) W/m\( \cdot \)K.

ANALYSIS: The absorber plate acts as an extended surface (a conduction-radiation system), and a differential equation which governs its temperature distribution may be obtained by applying Eq.1.11a to a differential control volume. For a unit length of tube

\[
q'_x + q_{rad}'(dx) - q'_{x+dx} = 0.
\]

With

\[
q'_{x+dx} = q'_x + \frac{dq'_x}{dx} dx
\]

and

\[
q'_x = -kt \frac{dT}{dx}
\]

it follows that,

\[
q_{rad}' = \frac{d}{dx} \left[-kt \frac{dT}{dx} \right] = 0
\]

\[
\frac{d^2T}{dx^2} + \frac{q_{rad}'}{kt} = 0
\]

Integrating twice it follows that, the general solution for the temperature distribution has the form,

\[
T(x) = -\frac{q_{rad}}{2kt} x^2 + C_1x + C_2.
\]

Continued …..
The boundary conditions are:

\[
T(0) = T_w \quad C_2 = T_w \\
\frac{dT}{dx} \bigg|_{x=L/2} = 0 \quad C_1 = \frac{q_{\text{rad}} L}{2kt}
\]

Hence,

\[
T(x) = \frac{q_{\text{rad}}}{2kt} x (L - x) + T_w.
\]

The maximum absorber plate temperature, which is at \( x = L/2 \), is therefore

\[
T_{\text{max}} = T(L/2) = \frac{q_{\text{rad}} L^2}{8kt} + T_w.
\]

The rate of energy collection per tube may be obtained by applying Fourier’s law at \( x = 0 \). That is, energy is transferred to the tubes via conduction through the absorber plate. Hence,

\[
q' = 2 \left[ -k \frac{dT}{dx} \right]_{x=0}
\]

where the factor of two arises due to heat transfer from both sides of the tube. Hence,

\[
q' = -L q_{\text{rad}}.
\]

Hence

\[
T_{\text{max}} = \frac{800 \frac{W}{m^2} (0.2m)^2}{8 \left[ 180 \frac{W}{m \cdot K} \right] (0.006m)} + 60^\circ C
\]

or

\[
T_{\text{max}} = 63.7^\circ C
\]

and

\[
q' = -0.2m \times 800 \text{ W/m}^2
\]

or

\[
q' = -160 \text{ W/m.}
\]

**COMMENTS:** Convection losses in the typical flat plate collector, which is not evacuated, would reduce the value of \( q' \).
**PROBLEM 3.100**

**KNOWN:** Surface conditions and thickness of a solar collector absorber plate. Temperature of working fluid.

**FIND:** (a) Differential equation which governs plate temperature distribution, (b) Form of the temperature distribution.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional conduction, (3) Adiabatic bottom surface, (4) Uniform radiation flux and convection coefficient at top, (5) Temperature of absorber plate at \( x = 0 \) corresponds to that of working fluid.

**ANALYSIS:** (a) Performing an energy balance on the differential control volume,

\[
q_{x} + dq_{\text{rad}} = q_{x+dx} + dq_{\text{conv}}
\]

where

\[
q_{x+dx} = q_{x} + (dq_{x}/dx) \, dx
\]

\[
dq_{\text{rad}} = q_{\text{rad}} \, dx
\]

\[
dq_{\text{conv}} = h(T - T_{\infty}) \, dx
\]

Hence,

\[
dq_{\text{rad}} dx = (dq_{x}/dx) \, dx + h(T - T_{\infty}) dx.
\]

From Fourier's law, the conduction heat rate per unit width is

\[
q_{x} = -k \, t \, dT/dx \quad \frac{d^{2}T}{dx^{2}} - \frac{h}{k} \left(T - T_{\infty}\right) + \frac{q_{\text{rad}}}{k} = 0.
\]

(b) Defining \( \theta = T - T_{\infty} \), \( d^{2}T/dx^{2} = d^{2}\theta/dx^{2} \) and the differential equation becomes,

\[
\frac{d^{2}\theta}{dx^{2}} - \frac{h}{k} \theta + \frac{q_{\text{rad}}}{k} = 0.
\]

It is a second-order, differential equation with constant coefficients and a source term, and its general solution is of the form

\[
\theta = C_{1} e^{+\lambda x} + C_{2} e^{-\lambda x} + S/\lambda^{2}
\]

where \( \lambda = (h/kt)^{1/2} \), \( S = q_{\text{rad}}/kt \).

Appropriate boundary conditions are:

\[
\theta(0) = T_{0} - T_{\infty} \equiv \theta_{0}, \quad d\theta/dx)_{x=L} = 0.
\]

Hence,

\[
\theta_{0} = C_{1} + C_{2} + S/\lambda^{2}
\]

\[
d\theta/dx)_{x=L} = C_{1} \lambda e^{+\lambda L} - C_{2} \lambda e^{-\lambda L} = 0 \quad C_{2} = C_{1} e^{2\lambda L}
\]

Hence,

\[
C_{1} = \left(\theta_{0} - S/\lambda^{2}\right)/(1 + e^{2\lambda L}) \quad C_{2} = \left(\theta_{0} - S/\lambda^{2}\right)/(1 + e^{-2\lambda L})
\]

\[
\theta = \left(\theta_{0} - S/\lambda^{2}\right) \left[\frac{e^{\lambda x}}{1 + e^{2\lambda L}} + \frac{e^{-\lambda x}}{1 + e^{-2\lambda L}}\right] + S/\lambda^{2}.
\]
PROBLEM 3.101

KNOWN: Dimensions of a plate insulated on its bottom and thermally joined to heat sinks at its ends. Net heat flux at top surface.

FIND: (a) Differential equation which determines temperature distribution in plate, (b) Temperature distribution and heat loss to heat sinks.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) One-dimensional conduction in x (W,L>>t), (3) Constant properties, (4) Uniform surface heat flux, (5) Adiabatic bottom, (6) Negligible contact resistance.

ANALYSIS: (a) Applying conservation of energy to the differential control volume, \( q_x + dq = q_x + dx \), where \( q_x + dx = q_x + (dq_x/dx) dx \) and \( dq_x = q_0 (W \cdot dx) \). Hence, \( (dq_x/dx) - q_0 W = 0 \).

From Fourier’s law, \( q_x = -k (t \cdot W) dT/dx \). Hence, the differential equation for the temperature distribution is

\[
-k \frac{dT}{dx} - q_0 W = 0 \quad \text{and} \quad \frac{d^2 T}{dx^2} + \frac{q_0}{kt} = 0.
\]

(b) Integrating twice, the general solution is,

\[
T(x) = -\frac{q_0}{2kt} x^2 + C_1 x + C_2
\]

and appropriate boundary conditions are \( T(0) = T_o \), and \( T(L) = T_o \). Hence, \( T_o = C_2 \), and

\[
T_o = -\frac{q_0}{2kt} L^2 + C_1 L + C_2 \quad \text{and} \quad C_1 = \frac{q_0 L}{2kt}.
\]

Hence, the temperature distribution is

\[
T(x) = -\frac{q_0}{2kt} \left( x^2 - Lx \right) + T_o.
\]

Applying Fourier’s law at \( x = 0 \), and at \( x = L \),

\[
q(0) = -k (Wt) \frac{dT}{dx} \bigg|_{x=0} = -kWt \left[ -\frac{q_0}{kt} \right] \left[ x - \frac{L}{2} \right] \bigg|_{x=0} = -\frac{q_0 W L}{2}
\]

\[
q(L) = -k (Wt) \frac{dT}{dx} \bigg|_{x=L} = -kWt \left[ -\frac{q_0}{kt} \right] \left[ x - \frac{L}{2} \right] \bigg|_{x=L} = +\frac{q_0 W L}{2}
\]

Hence the heat loss from the plates is \( q = 2 (q_0 W L/2) = q_0 W L \).

COMMENTS: (1) Note signs associated with \( q(0) \) and \( q(L) \). (2) Note symmetry about \( x = L/2 \). Alternative boundary conditions are \( T(0) = T_o \) and \( dT/dx \bigg|_{x=L/2} = 0 \).
PROBLEM 3.102

KNOWN: Dimensions and surface conditions of a plate thermally joined at its ends to heat sinks at different temperatures.

FIND: (a) Differential equation which determines temperature distribution in plate, (b) Temperature distribution and an expression for the heat rate from the plate to the sinks, and (c) Compute and plot temperature distribution and heat rates corresponding to changes in different parameters.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in x (W,L >> t), (3) Constant properties, (4) Uniform surface heat flux and convection coefficient, (5) Negligible contact resistance.

ANALYSIS: (a) Applying conservation of energy to the differential control volume
\[ q_x + dq_{\infty} = q_x + dq + dq_{\text{conv}} \]
where
\[ q_x + dq = q_x + (dq_x/dx)dx \quad dq_{\text{conv}} = h(T - T_{\infty})(W \cdot dx) \]
Hence,
\[ q_x + q_{\infty}^*(W \cdot dx) = q_x + (dq_x/dx)dx + h(T - T_{\infty})(W \cdot dx) \quad dq_x + hW(T - T_{\infty}) = q_{\infty}^*W. \]
Using Fourier’s law, \( q_x = -k(t \cdot W)dT/dx \),
\[ -ktW \frac{d^2T}{dx^2} + hW(T - T_{\infty}) = q_{\infty}^* \quad \frac{d^2T}{dx^2} - \frac{h}{kt}(T - T_{\infty}) + \frac{q_{\infty}^*}{kt} = 0. \]
(b) Introducing \( \theta = T - T_{\infty} \), the differential equation becomes
\[ \frac{d^2\theta}{dx^2} - \frac{h}{kt}\theta + \frac{q_{\infty}^*}{kt} = 0. \]
This differential equation is of second order with constant coefficients and a source term. With \( \lambda^2 = h/kt \) and \( S = q_{\infty}^*/kt \), it follows that the general solution is of the form
\[ \theta = C_1e^{\lambda x} + C_2e^{-\lambda x} + S\sqrt{\lambda^2}. \quad (1) \]
Appropriate boundary conditions are: \( \theta(0) = T_0 - T_{\infty} \equiv \theta_0 \quad \theta(L) = T_L - T_{\infty} \equiv \theta_L \) \( (2,3) \)
Substituting the boundary conditions, Eqs. (2,3) into the general solution, Eq. (1),
\[ \theta_0 = C_1e^0 + C_2e^0 + S\sqrt{\lambda^2} \quad \theta_L = C_1e^{+\lambda L} + C_2e^{-\lambda L} + S\sqrt{\lambda^2} \quad (4,5) \]
To solve for \( C_2 \), multiply Eq. (4) by \( e^{-\lambda L} \) and add the result to Eq. (5),
\[ -\theta_0e^{+\lambda L} + \theta_L = C_2\left(-e^{+\lambda L} + e^{-\lambda L}\right) + S\sqrt{\lambda^2}\left(-e^{+\lambda L} + 1\right) \]
\[ C_2 = \left[\left(\theta_L - \theta_0e^{+\lambda L}\right) - S\sqrt{\lambda^2}\left(-e^{+\lambda L} + 1\right)\right]/\left(-e^{+\lambda L} + e^{-\lambda L}\right) \quad (6) \]
Continued...
PROBLEM 3.102 (Cont.)

Substituting for $C_2$ from Eq. (6) into Eq. (4), find

$$C_1 = \theta_0 - \left[ \left( \theta_L - \theta_0 e^{+\lambda L} \right) - S/\lambda^2 \left( e^{+\lambda L} + 1 \right) \right] / \left[ \left( -e^{+\lambda L} + e^{-\lambda L} \right) \right] - S/\lambda^2 \tag{7}$$

Using $C_1$ and $C_2$ from Eqs. (6,7) and Eq. (1), the temperature distribution can be expressed as

$$\theta(x) = \left[ e^{+\lambda x} - \frac{\sinh (\lambda x)}{\sinh (\lambda L)} \right] \theta_0 + \frac{\sinh (\lambda x)}{\sinh (\lambda L)} \theta_L + \left[ -\left( 1 - e^{+\lambda L} \right) \frac{\sinh (\lambda x)}{\sinh (\lambda L)} + \left( 1 - e^{+\lambda L} \right) \right] \frac{S}{\lambda^2} \tag{8}$$

The heat rate from the plate is $q_p = -q_x (0) + q_x (L)$ and using Fourier’s law, the conduction heat rates, with $A_c = \text{W} \cdot \text{t}$, are

$$q_x (0) = -kA_c \frac{d\theta}{dx} \bigg|_{x=0} = -kA_c \left[ \lambda e^0 - \frac{e^{\lambda L}}{\sinh (\lambda L)} \right] \theta_0 + \frac{\lambda}{\sinh (\lambda L)} \theta_L \tag{c}$$

$$q_x (L) = -kA_c \frac{d\theta}{dx} \bigg|_{x=L} = -kA_c \left[ \lambda e^{\lambda L} - \frac{e^{\lambda L}}{\sinh (\lambda L) \cosh (\lambda L)} \right] \theta_0 + \frac{\lambda \cosh (\lambda L)}{\sinh (\lambda L)} \theta_L \tag{c}$$

(c) For the prescribed base-case conditions listed below, the temperature distribution (solid line) is shown in the accompanying plot. As expected, the maximum temperature does not occur at the midpoint, but slightly toward the x-origin. The sink heat rates are

$$q_x^* (0) = -17.22 \text{ W} \quad q_x^* (L) = 23.62 \text{ W} \tag{c}$$

The additional temperature distributions on the plot correspond to changes in the following parameters, with all the remaining parameters unchanged: (i) $q_0^* = 30,000 \text{ W/m}^2$, (ii) $h = 200 \text{ W/m}^2\cdot\text{K}$, (iii) the value of $q_0^*$ for which $q_x^* (0) = 0$ with $h = 200 \text{ W/m}^2\cdot\text{K}$. The condition for the last curve is $q_0^* = 4927 \text{ W/m}^2$ for which the temperature gradient at $x = 0$ is zero.

Base case conditions are: $q_0^* = 20,000 \text{ W/m}^2$, $T_o = 100^\circ\text{C}$, $T_L = 35^\circ\text{C}$, $T_\infty = 25^\circ\text{C}$, $k = 25 \text{ W/m} \cdot \text{K}$, $h = 50 \text{ W/m}^2\cdot\text{K}$, $L = 100 \text{ mm}$, $t = 5 \text{ mm}$, $W = 30 \text{ mm}$. 
PROBLEM 3.103

KNOWN: Thin plastic film being bonded to a metal strip by laser heating method; strip dimensions and thermophysical properties are prescribed as are laser heating flux and convection conditions.

FIND: (a) Expression for temperature distribution for the region with the plastic strip, -\( w_1/2 \leq x \leq w_1/2 \), (b) Temperature at the center (\( x = 0 \)) and the edge of the plastic strip (\( x = \pm w_1/2 \)) when the laser flux is 10,000 W/m\(^2\); (c) Plot the temperature distribution for the strip and point out special features.

SCHEMATIC:

![Schematic diagram]

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in x-direction only, (3) Plastic film has negligible thermal resistance, (4) Upper and lower surfaces have uniform convection coefficients, (5) Edges of metal strip are at air temperature (\( T_\infty \)), that is, strip behaves as infinite fin so that \( w_2 \to \infty \), (6) All the incident laser heating flux \( q_0' \) is absorbed by the film.

PROPERTIES: Metal strip (given): \( \rho = 7850 \) kg/m\(^3\), \( c_p = 435 \) J/kg \({} \cdot \) m\(^3\), \( k = 60 \) W/m \({} \cdot \) K.

ANALYSIS: (a) The strip-plastic film arrangement can be modeled as an infinite fin of uniform cross section a portion of which is exposed to the laser heat flux on the upper surface. The general solutions for the two regions of the strip, in terms of \( \theta \equiv T(x) - T_\infty \), are

\[
\begin{align*}
0 \leq x &\leq w_1/2 \quad \theta_1(x) = C_1 e^{+mx} + C_2 e^{-mx} + M/m^2 \\
& \quad m = (2h/kd)^{1/2} \quad \text{(1,2,3)}
\end{align*}
\]

\[
\begin{align*}
w_1/2 \leq x &\leq \infty \quad \theta_2(x) = C_3 e^{+mx} + C_4 e^{-mx}.
\end{align*}
\]

Four boundary conditions can be identified to evaluate the constants:

\[
\begin{align*}
\text{At } x = 0: & \quad \frac{d\theta_1}{dx}(0) = 0 = C_1 m e^0 - C_2 m e^{-0} + 0 \quad \Rightarrow \quad C_1 = C_2 \\
\text{At } x = w_1/2: & \quad \theta_1(w_1/2) = \theta_2(w_1/2) \\
C_1 e^{+mw_1/2} + C_2 e^{-mw_1/2} + M/m^2 = C_3 e^{+mw_1/2} + C_4 e^{-mw_1/2} \quad \text{(6)}
\end{align*}
\]

\[
\begin{align*}
\text{At } x = w_2/2: & \quad \frac{d\theta_1}{dx}(w_1/2)/dx = \frac{d\theta_2}{dx}(w_1/2)/dx \\
mC_1 e^{+mw_1/2} - mC_2 e^{-mw_1/2} + 0 = mC_3 e^{+mw_1/2} - mC_4 e^{-mw_1/2} \quad \text{(7)}
\end{align*}
\]

\[
\begin{align*}
\text{At } x \to \infty: & \quad \theta_2(\infty) = 0 = C_3 e^\infty + C_4 e^{-\infty} \quad \Rightarrow \quad C_3 = 0 \\
\text{With } C_3 = 0 \text{ and } C_1 = C_2, \text{ combine Eqs. (6 and 7) to eliminate } C_4 \text{ to find} \\
C_1 = C_2 = -\frac{M/m^2}{2 e^{mw_1/2}}.
\end{align*}
\]

and using Eq. (6) with Eq. (9) find

\[
C_4 = M/m^2 \sinh(mw_1/2)e^{-mx_1/2}
\]

Continued...
Hence, the temperature distribution in the region (1) under the plastic film, \(0 \leq x \leq w_1/2\), is
\[
\theta_1(x) = -\frac{M}{m^2} \left(\frac{m^2}{2e^{m^2 w_1/w}} \left(2e^{+mx} + e^{-mx}\right) + \frac{M}{m^2} \left(1 - e^{-m^2 w_1/2} \cosh mx\right)\right)
\]  
(11)
and for the region (2), \(x \geq w_1/2\),
\[
\theta_2(x) = \frac{M}{m^2} \sinh \left(mw_1/2\right)e^{-mx}
\]  
(12)
(b) Substituting numerical values into the temperature distribution expression above, \(\theta_1(0)\) and \(\theta_1(w_1/2)\) can be determined. First evaluate the following parameters:
\[
M = 10,000 \text{ W/m}^2/60 \text{ W/m K} \times 0.00125 \text{ m} = 133.333 \text{ K/m}^2
\]
\[
m = \left(2 \times 10 \text{ W/m}^2 \cdot \text{K}/60 \text{ W/m K} \times 0.00125 \text{ m}\right)^{1/2} = 16.33 \text{ m}^{-1}
\]
Hence, for the midpoint \(x = 0\),
\[
\theta_1(0) = \frac{133,333 \text{ K/m}^2}{(16.33 \text{ m}^{-1})^2} \left[1 - \exp \left(-16.33 \text{ m}^{-1} \times 0.020 \text{ m}\right) \times \cosh(0)\right] = 139.3 \text{ K}
\]
\[
T_1(0) = \theta_1(0) + T_\infty = 139.3 \text{ K} + 25^\circ \text{C} = 164.3^\circ \text{C}.
\]
For the position \(x = w_1/2 = 0.020 \text{ m}\),
\[
\theta_1(w_1/2) = 500.0 \left[1 - 0.721 \cosh \left(16.33 \text{ m}^{-1} \times 0.020 \text{ m}\right)\right] = 120.1 \text{ K}
\]
\[
T_1(w_1/2) = 120.1 \text{ K} + 25^\circ \text{C} = 145.1^\circ \text{C}.
\]
(c) The temperature distributions, \(\theta_1(x)\) and \(\theta_2(x)\), are shown in the plot below. Using IHT, Eqs. (11) and (12) were entered into the workspace and a graph created. The special features are noted:

1. No gradient at midpoint, \(x = 0\); symmetrical distribution.
2. No discontinuity of gradient at \(w_1/2\) (20 mm).
3. Temperature excess and gradient approach zero with increasing value of \(x\).

**COMMENTS:** How wide must the strip be in order to satisfy the infinite fin approximation such that \(\theta_2(x \to \infty) = 0\)? For \(x = 200 \text{ mm}\), find \(\theta_2(200 \text{ mm}) = 6.3^\circ \text{C}\); this would be a poor approximation. When \(x = 300 \text{ mm}\), \(\theta_2(300 \text{ mm}) = 1.2^\circ \text{C}\); hence when \(w_1/2 = 300 \text{ mm}\), the strip is a reasonable approximation to an infinite fin.
PROBLEM 3.104

KNOWN: Thermal conductivity, diameter and length of a wire which is annealed by passing an electrical current through the wire.

FIND: Steady-state temperature distribution along wire.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction along the wire, (3) Constant properties, (4) Negligible radiation, (5) Uniform convection coefficient h.

ANALYSIS: Applying conservation of energy to a differential control volume,

\[ q_x + \dot{E}_g - dq_{\text{conv}} - q_{x+dx} = 0 \]

\[ q_{x+dx} = q_x + \frac{dq_x}{dx} \quad q_x = -k \left( \pi \frac{D^2}{4} \right) \frac{dT}{dx} \]

\[ dq_{\text{conv}} = h \left( \pi D \frac{dT}{dx} \right) (T - T_\infty) \quad \dot{E}_g = \dot{q} \left( \pi \frac{D^2}{4} \right) \frac{dT}{dx} \]

Hence,

\[ k \left( \pi \frac{D^2}{4} \right) \frac{d^2T}{dx^2} + \dot{q} \left( \pi \frac{D^2}{4} \right) \frac{dT}{dx} - h \left( \pi D \frac{dT}{dx} \right) (T - T_\infty) = 0 \]

or, with \( \theta = T - T_\infty \),

\[ \frac{d^2\theta}{dx^2} - \frac{4h}{kD} \theta + \frac{\dot{q}}{k} = 0 \]

The solution (general and particular) to this nonhomogeneous equation is of the form

\[ \theta = C_1 e^{mx} + C_2 e^{-mx} + \frac{\dot{q}}{km^2} \]

where \( m^2 = (4h/kD) \). The boundary conditions are:

\[ \left. \frac{d\theta}{dx} \right|_{x=0} = 0 = m C_1 e^0 - mC_2 e^0 \rightarrow C_1 = C_2 \]

\[ \theta (L) = 0 = C_1 \left( e^{mL} + e^{-mL} \right) + \frac{\dot{q}}{km^2} \rightarrow C_1 = \frac{-\dot{q}/km^2}{e^{mL} + e^{-mL}} = C_2 \]

The temperature distribution has the form

\[ T = T_\infty - \frac{\dot{q}}{km^2} \left[ \frac{e^{mx} + e^{-mx}}{e^{mL} + e^{-mL}} - 1 \right] = T_\infty - \frac{\dot{q}}{km^2} \left[ \frac{\cosh mx}{\cosh mL} - 1 \right]. \]

COMMENTS: This process is commonly used to anneal wire and spring products. To check the result, note that \( T(L) = T(-L) = T_\infty. \)
**PROBLEM 3.105**

**KNOWN:** Electric power input and mechanical power output of a motor. Dimensions of housing, mounting pad and connecting shaft needed for heat transfer calculations. Temperature of ambient air, tip of shaft, and base of pad.

**FIND:** Housing temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional conduction in pad and shaft, (3) Constant properties, (4) Negligible radiation.

**ANALYSIS:** Conservation of energy yields

\[
P_{\text{elec}} - P_{\text{mech}} - q_h - q_p - q_s = 0
\]

\[
q_h = h_h A_h \left( T_h - T_\infty \right), \quad q_p = k_p W^2 \frac{\left( T_h - T_\infty \right)}{t}, \quad q_s = M \frac{\cosh mL - \theta_L / \theta_h}{\sinh mL}
\]

\[
\theta_L = 0, \quad mL = \left( \frac{4h_s L^2}{k_s D} \right)^{1/2}, \quad M = \left( \frac{\pi^2}{4} D^3 h_s k_s \right)^{1/2} \left( T_h - T_\infty \right).
\]

Hence

\[
q_s = \frac{\left( \frac{\pi^2}{4} D^3 h_s k_s \right)^{1/2}}{\tanh \left( \frac{4h_s L^2}{k_s D} \right)^{1/2}} \left( T_h - T_\infty \right)
\]

Substituting, and solving for \((T_h - T_\infty)\),

\[
T_h - T_\infty = \frac{P_{\text{elec}} - P_{\text{mech}}}{h_h A_h + k_p W^2 / t + \left( \frac{\pi^2}{4} D^3 h_s k_s \right)^{1/2} / \tanh \left( \frac{4h_s L^2}{k_s D} \right)^{1/2}} \left( \frac{\pi^2}{4} D^3 h_s k_s \right)^{1/2} = 6.08 \text{ W/K}, \quad \left( \frac{4h_s L^2}{k_s D} \right)^{1/2} = 3.87, \quad \tanh mL = 0.999
\]

\[
T_h - T_\infty = \frac{(25-15) \times 10^3}{10 \times 2 + 0.5 (0.7)^2 / 0.05 + 6.08 / 0.999} \text{ W/K} = \frac{10^4}{(20+4.90+6.15)} \text{ W/K}
\]

\[
T_h - T_\infty = 322.1 \text{ K} \quad T_h = 347.1^\circ \text{C}
\]

**COMMENTS:** (1) \(T_h\) is large enough to provide significant heat loss by radiation from the housing. Assuming an emissivity of 0.8 and surroundings at 25°C, \(q_{\text{rad}} = \varepsilon A_h \left( T_h^4 - T_{\text{sur}}^4 \right) = 4347\) W, which compares with \(q_{\text{conv}} = h A_h \left( T_h - T_\infty \right) = 5390\) W. Radiation has the effect of decreasing \(T_h\). (2) The infinite fin approximation, \(q_s = M\), is excellent.
PROBLEM 3.106

KNOWN: Dimensions and thermal conductivity of pipe and flange. Inner surface temperature of pipe. Ambient temperature and convection coefficient.

FIND: Heat loss through flange.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) One-dimensional radial conduction in pipe and flange, (3) Constant thermal conductivity, (4) Negligible radiation exchange with surroundings.

ANALYSIS: From the thermal circuit, the heat loss through the flanges is

\[
q = \frac{T_{s,i} - T_\infty}{R_{t,w} + R_{t,f}} = \frac{T_{s,i} - T_\infty}{\left[\ln \left(\frac{D_o}{D_i}\right)/4\pi tk + (1/hA_f \eta_f)\right]}
\]

Since convection heat transfer only occurs from one surface of a flange, the connected flanges may be modeled as a single annular fin of thickness \( t' = 2t = 30\,\text{mm} \). Hence, \( r_{2c} = (D_f / 2) + t' / 2 = 0.140\,\text{m}, \)

\[
A_f = 2\pi \left(r_{2c}^2 - \eta_i^2\right) = 2\pi \left(r_{2c}^2 - D_o /2\right) = 2\pi \left(0.140^2 - 0.06^2\right)\,\text{m}^2 = 0.101\,\text{m}^2,
\]

\[L_c = L + t' / 2 = (D_f - D_o) / 2 + t = 0.065\,\text{m}, \]

\[A_p = L_c \cdot t' = 0.00195\,\text{m}^2, \]

\[L_c^{3/2} \left(\frac{h}{kA_p}\right)^{1/2} = 0.188. \]

With \( r_{2c}/r_{1} = r_{2c}/(D_o/2) = 1.87, \) Fig. 3.19 yields \( \eta_f = 0.94. \) Hence,

\[
q = \frac{300^\circ\text{C} - 20^\circ\text{C}}{\left[\ln(1.25)/4\pi \times 0.03\,\text{m} \times 40\,\text{W}/\text{m} \cdot \text{K}\right] + \left(1/10\,\text{W}/\text{m}^2 \cdot \text{K} \times 0.101\,\text{m}^2 \times 0.94\right)}
\]

\[
q = \frac{280^\circ\text{C}}{0.0148 + 1.053} = 262\,\text{W} <
\]

COMMENTS: Without the flange, heat transfer from a section of pipe of width \( t' = 2t \) is

\[
q = \left(T_{s,i} - T_\infty\right) / \left(R_{t,w} + R_{t,cnv}\right), \text{ where } R_{t,cnv} = \left(h \times \pi D_o t'\right)^{-1} = 7.07\,\text{K/ W}. \]

Hence, \( q = 39.5\,\text{W}, \) and there is significant heat transfer enhancement associated with the extended surfaces afforded by the flanges.
PROBLEM 3.107

KNOWN: TC wire leads attached to the upper and lower surfaces of a cylindrically shaped solder bead. Base of bead attached to cylinder head operating at 350°C. Constriction resistance at base and TC wire convection conditions specified.

FIND: (a) Thermal circuit that can be used to determine the temperature difference between the two intermediate metal TC junctions, \( (T_1 - T_2) \); label temperatures, thermal resistances and heat rates; and (b) Evaluate \( (T_1 - T_2) \) for the prescribed conditions. Comment on assumptions made in building the model.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in solder bead; no losses from lateral and top surfaces; (3) TC wires behave as infinite fins, (4) Negligible thermal contact resistance between TC wire terminals and bead.

ANALYSIS: (a) The thermal circuit is shown above. Note labels for the temperatures, thermal resistances and the relevant heat fluxes. The thermal resistances are as follows:

Constriction (con) resistance, see Table 4.1, case 10

\[
R_{con} = \frac{1}{(2k_{bead}D_{sol})} = \frac{1}{(2 \times 40 \, \text{W/m} \cdot \text{K} \times 0.006 \, \text{m})} = 2.08 \, \text{K/W}
\]

TC (tc) wires, infinitely long fins; Eq. 3.80

\[
R_{tc,1} = R_{tc,2} = R_{fin} = (hP_{k_w}A_c)^{-0.5} \quad P = \pi D_w A_c = \pi D_w^2 / 4
\]

\[
R_{tc} = \left(100 \, \text{W/m}^2 \cdot \text{K} \times \pi^2 \times \left(0.003 \, \text{m}\right)^3 \times 70 \, \text{W/m} \cdot \text{K} / 4 \right)^{-0.5} = 46.31 \, \text{K/W}
\]

Solder bead (sol), cylinder \( D_{sol} \) and \( L_{sol} \)

\[
R_{sol} = L_{sol} / (k_{sol}A_{sol}) \quad A_{sol} = \pi D_{sol}^2 / 4
\]

\[
R_{sol} = 0.010 \, \text{m} \left(10 \, \text{W/m} \cdot \text{K} \times \pi \left(0.006 \, \text{m}\right)^2 \right) / 4 = 35.37 \, \text{K/W}
\]

(b) Perform energy balances on the 1- and 2-nodes, solve the equations simultaneously to find \( T_1 \) and \( T_2 \), from which \( (T_1 - T_2) \) can be determined.

Continued …..
PROBLEM 3.107 (Cont.)

Node 1
\[ \frac{T_2 - T_1}{R_{sol}} + \frac{T_{\text{head}} - T_1}{R_{\text{con}}} + \frac{T_\infty - T_1}{R_{tc,1}} = 0 \]

Node 2
\[ \frac{T_\infty - T_2}{R_{tc,2}} + \frac{T_1 - T_2}{R_{sol}} = 0 \]

Substituting numerical values with the equations in the IHT Workspace, find

\[ T_1 = 359^\circ C \quad T_2 = 199.2^\circ C \quad T_1 - T_2 = 160^\circ C \]

COMMERTS: (1) With this arrangement, the TC indicates a systematically low reading of the cylinder head. The size of the solder bead ($L_{sol}$) needs to be reduced substantially.

(2) The model neglects heat losses from the top and lateral sides of the solder bead, the effect of which would be to increase our estimate for $(T_1 - T_2)$. Constriction resistance is important; note that $T_{\text{head}} - T_1 = 26^\circ C$. 
**PROBLEM 3.108**

**KNOWN:** Rod (D, k, 2L) that is perfectly insulated over the portion of its length \(-L \leq x \leq 0\) and experiences convection \((T_\infty, h)\) over the portion \(0 \leq x \leq +L\). One end is maintained at \(T_1\) and the other is separated from a heat sink at \(T_3\) with an interfacial thermal contact resistance \(R'_{tc}\).

**FIND:** (a) Sketch the temperature distribution \(T\) vs. \(x\) and identify key features; assume \(T_1 > T_3 > T_2\); (b) Derive an expression for the mid-point temperature \(T_2\) in terms of thermal and geometric parameters of the system, (c) Using, numerical values, calculate \(T_2\) and plot the temperature distribution. Describe key features and compare to your sketch of part (a).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional conduction in rod for \(-L \leq x \leq 0\), (3) Rod behaves as one-dimensional extended surface for \(0 \leq x \leq +L\), (4) Constant properties.

**ANALYSIS:** (a) The sketch for the temperature distribution is shown below. Over the insulated portion of the rod, the temperature distribution is linear. A temperature drop occurs across the thermal contact resistance at \(x = +L\). The distribution over the exposed portion of the rod is non-linear. The minimum temperature of the system could occur in this portion of the rod.

(b) To derive an expression for \(T_2\), begin with the general solution from the conduction analysis for a fin of uniform cross-sectional area, Eq. 3.66.

\[
\theta(x) = C_1 e^{mx} + C_2 e^{-mx} \quad 0 \leq x \leq +L
\]

where \(m = (hP/kA_c)^{1/2}\) and \(\theta = T(x) - T_\infty\). The arbitrary constants are determined from the boundary conditions.

At \(x = 0\), thermal resistance of rod

\[
q_x(0) = -kA_c \frac{d\theta}{dx} \bigg|_{x=0} = kA_c \frac{\theta_1 - \theta(0)}{L} \quad \theta_1 = T_1 - T_\infty
\]

\[
mC_1e^0 - mC_2e^0 = \frac{1}{L} \left[ \theta_1 - \left(C_1e^0 + C_2e^0\right) \right]
\]

Continued …..
At \( x = L \), thermal contact resistance

\[
q_x (+L) = -kA_c \left( \frac{d\theta}{dx} \right)_{x=L} = \frac{\theta(L) - \theta_3}{R_{tc} / A_c} \quad \theta_3 = T_3 - T_\infty
\]

\[
-k \left[ mC_1e^{mL} - mC_2e^{-mL} \right] = \frac{1}{R_{tc}} \left[ C_1e^{mL} + C_2e^{-mL} - \theta_3 \right]
\]

Eqs. (2) and (3) cannot be rearranged easily to find explicit forms for \( C_1 \) and \( C_2 \). The constraints will be evaluated numerically in part (c). Knowing \( C_1 \) and \( C_2 \), Eq. (1) gives

\[
\theta_2 = \theta(0) = T_2 - T_\infty = C_1e^0 + C_2e^0
\]

(c) With Eqs. (1-4) in the IHT Workspace using numerical values shown in the schematic, find \( T_2 = 62.1^\circ C \). The temperature distribution is shown in the graph below.

**COMMENTS:**

(1) The purpose of asking you to sketch the temperature distribution in part (a) was to give you the opportunity to identify the relevant thermal processes and come to an understanding of the system behavior.

(2) Sketch the temperature distributions for the following conditions and explain their key features:

- (a) \( R_{tc} = 0 \)
- (b) \( R_{tc} \to \infty \)
- (c) The exposed portion of the rod behaves as an infinitely long fin; that is, \( k \) is very large.
**PROBLEM 3.109**

**KNOWN:** Long rod in oven with air temperature at 400°C has one end firmly pressed against surface of a billet; thermocouples imbedded in rod at locations 25 and 120 mm from the billet indicate 325 and 375°C, respectively.

**FIND:** The temperature of the billet, $T_b$.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Rod is infinitely long with uniform cross-sectional area, (3) Uniform convection coefficient along rod.

**ANALYSIS:** For an infinitely long rod of uniform cross-sectional area, the temperature distribution is

$$\theta(x) = \theta_b e^{-mx} \quad (1)$$

where

$$\theta(x) = T(x) - T_\infty \quad \theta_b = T(0) - T_\infty = T_b - T_\infty.$$  

Substituting values for $T_1$ and $T_2$ at their respective distances, $x_1$ and $x_2$, into Eq. (1), it is possible to evaluate $m$,

$$\frac{\theta(x_1)}{\theta(x_2)} = \frac{\theta_b e^{-mx_1}}{\theta_b e^{-mx_2}} = e^{-m(x_1-x_2)}$$

$$\frac{(325 - 400)° C}{(375 - 400)° C} = e^{-m(0.025-0.120)m} \quad m=11.56.$$  

Using the value for $m$ with Eq. (1) at location $x_1$, it is now possible to determine the rod base or billet temperature,

$$\theta(x_1) = T_1 - T_\infty = (T_b - T_\infty)e^{-mx}$$

$$\frac{(325 - 400)° C}{(325 - 400)° C} = (T_b - 400)° C e^{-11.56 \times 0.025}$$

$$T_b = 300° C.$$  

**COMMENTS:** Using the criteria $mL \geq 2.65$ (see Example 3.8) for the infinite fin approximation, the insertion length should be ≥ 229 mm to justify the approximation.
PROBLEM 3.110

KNOWN: Temperature sensing probe of thermal conductivity \( k \), length \( L \) and diameter \( D \) is mounted on a duct wall; portion of probe \( L_i \) is exposed to water stream at \( T_{\infty,i} \) while other end is exposed to ambient air at \( T_{\infty,o} \); convection coefficients \( h_i \) and \( h_o \) are prescribed.

FIND: (a) Expression for the measurement error, \( \Delta T_{\text{err}} = T_{\text{tip}} - T_{\infty,i} \), (b) For prescribed \( T_{\infty,i} \) and \( T_{\infty,o} \), calculate \( \Delta T_{\text{err}} \) for immersion to total length ratios of 0.225, 0.425, and 0.625, (c) Compute and plot the effects of probe thermal conductivity and water velocity \( (h_i) \) on \( \Delta T_{\text{err}} \).

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in probe, (3) Probe is thermally isolated from the duct, (4) Convection coefficients are uniform over their respective regions.

PROPERTIES: Probe material (given): \( k = 177 \text{ W/m} \cdot \text{K} \).

ANALYSIS: (a) To derive an expression for \( \Delta T_{\text{err}} = T_{\text{tip}} - T_{\infty,i} \), we need to determine the temperature distribution in the immersed length of the probe \( T_i(x) \). Consider the probe to consist of two regions: \( 0 \leq x_i \leq L_i \), the immersed portion, and \( 0 \leq x_o \leq (L - L_i) \), the ambient-air portion where the origin corresponds to the location of the duct wall. Use the results for the temperature distribution and fin heat rate of Case A, Table 3.4:

Temperature distribution in region \( i \):

\[
\frac{\theta_i}{\theta_{b,i}} = \frac{T_i(x_i) - T_{\infty,i}}{T_o - T_{\infty,i}} = \frac{\cosh(m_i(L_i - x_i)) + (h_i/m_i k) \sinh(L_i - x_i)}{\cosh(m_i L_i) + (h_i/m_i k) \sinh(m_i L_i)}
\]

and the tip temperature, \( T_{\text{tip}} = T_i(L_i) \) at \( x_i = L_i \), is

\[
\frac{T_{\text{tip}} - T_{\infty,i}}{T_o - T_{\infty,i}} = A = \frac{\cosh(0) + (h_i/m_i k) \sinh(0)}{\cosh(m_i L_i) + (h_i/m_i k) \sinh(m_i L_i)}
\]

and hence

\[
\Delta T_{\text{err}} = T_{\text{tip}} - T_{\infty,i} = A \left( T_o - T_{\infty,i} \right)
\]

where \( T_o \) is the temperature at \( x_i = x_o = 0 \) which at present is unknown, but can be found by setting the fin heat rates equal, that is,

\[
q_{f,o} = -q_{f,i}
\]

Continued...
PROBLEM 3.110 (Cont.)

\[(h_o P k A_c)^{1/2} \theta_{b,o} \cdot B = -(h_i P k A_c)^{1/2} \theta_{b,i} \cdot C\]

Solving for \(T_o\), find

\[
\frac{\theta_{b,o}}{\theta_{b,i}} = \frac{T_o - T_{\infty,o}}{T_o - T_{\infty,i}} = -(h_i P k A_c)^{1/2} \theta_{b,i} \cdot C
\]

\[
T_o = \left[ T_{\infty,o} + \left( \frac{h_i}{h_o} \right)^{1/2} \frac{C}{B} T_{\infty,i} \right] / \left[ 1 + \left( \frac{h_i}{h_o} \right)^{1/2} \frac{C}{B} \right]
\]  

(5)

where the constants \(B\) and \(C\) are,

\[
B = \frac{\sinh (m_0 L_o) + (h_o / m_0 k) \cosh (m_0 L_o)}{\cosh (m_0 L_o) + (h_o / m_0 k) \sinh (m_0 L_o)}
\]  

(6)

\[
C = \frac{\sinh (m_1 L_i) + (h_i / m_1 k) \cosh (m_1 L_i)}{\cosh (m_1 L_i) + (h_i / m_1 k) \sinh (m_1 L_i)}
\]  

(7)

(b) To calculate the immersion error for prescribed immersion lengths, \(L_i/L = 0.225, 0.425\) and \(0.625\), we use Eq. (3) as well as Eqs. (2, 6, 7 and 5) for \(A, B, C, \) and \(T_o\), respectively. Results of these calculations are summarized below.

(c) The probe behaves as a fin having ends exposed to the cool ambient air and the hot ambient water whose temperature is to be measured. If the thermal conductivity is decreased, heat transfer along the probe length is likewise decreased, the tip temperature will be closer to the water temperature. If the velocity of the water decreases, the convection coefficient will decrease, and the difference between the tip and water temperatures will increase.
PROBLEM 3.111

KNOWN: Rod protruding normally from a furnace wall covered with insulation of thickness \( L_{\text{ins}} \) with the length \( L_0 \) exposed to convection with ambient air.

FIND: (a) An expression for the exposed surface temperature \( T_0 \) as a function of the prescribed thermal and geometrical parameters. (b) Will a rod of \( L_0 = 100 \text{ mm} \) meet the specified operating limit, \( T_0 \leq 100^\circ \text{C} \)? If not, what design parameters would you change?

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in rod, (3) Negligible thermal contact resistance between the rod and hot furnace wall, (4) Insulated section of rod, \( L_{\text{ins}} \), experiences no lateral heat losses, (5) Convection coefficient uniform over the exposed portion of the rod, \( L_0 \), (6) Adiabatic tip condition for the rod and (7) Negligible radiation exchange between rod and its surroundings.

ANALYSIS: (a) The rod can be modeled as a thermal network comprised of two resistances in series: the portion of the rod, \( L_{\text{ins}} \), covered by insulation, \( R_{\text{ins}} \), and the portion of the rod, \( L_0 \), experiencing convection, and behaving as a fin with an adiabatic tip condition, \( R_{\text{fin}} \). For the insulated section:

\[
R_{\text{ins}} = \frac{L_{\text{ins}}}{kA_c} \quad (1)
\]

For the fin, Table 3.4, Case B, Eq. 3.76,

\[
R_{\text{fin}} = \frac{\theta_b}{q_f} = \frac{1}{(hP/kA_c)^{1/2} \tanh (mL_0)} \quad (2)
\]

\[
m = \left(\frac{hP}{kA_c}\right)^{1/2} \quad A_c = \frac{\pi D^2}{4} \quad P = \pi D \quad (3, 4, 5)
\]

From the thermal network, by inspection,

\[
\frac{T_D - T_{\infty}}{R_{\text{fin}}} = \frac{T_W - T_{\infty}}{R_{\text{ins}} + R_{\text{fin}}} \quad T_D = T_{\infty} + \frac{R_{\text{fin}}}{R_{\text{ins}} + R_{\text{fin}}}(T_W - T_{\infty}) \quad (6) <
\]

(b) Substituting numerical values into Eqs. (1) - (6) with \( L_0 = 200 \text{ mm} \),

\[
T_0 = 25^\circ \text{C} + \frac{6.298}{6.790 + 6.298}(200 - 25)^\circ \text{C} = 109^\circ \text{C} <
\]

\[
R_{\text{ins}} = \frac{0.200 \text{ m}}{60 \text{ W/(m} \cdot \text{K)} \times 4.909 \times 10^{-4} \text{ m}^2} = 6.790 \text{ K/W} \quad A_c = \pi \left(0.025 \text{ m}\right)^2/4 = 4.909 \times 10^{-4} \text{ m}^2
\]

\[
R_{\text{fin}} = \frac{1}{\left(0.0347 \text{ W}^2/\text{K}^2\right)^{1/2} \tanh (6.324 \times 0.200)} = 6.298 \text{ K/W}
\]

\[
(hP/kA_c) = \left(15 \text{ W/m}^2 \cdot \text{K} \times \pi \left(0.025 \text{ m}\right) \times 60 \text{ W/m} \cdot \text{K} \times 4.909 \times 10^{-4} \text{ m}^2\right) = 0.0347 \text{ W}^2/\text{K}^2
\]

Continued...
PROBLEM 3.111 (Cont.)

\[ m = \left( \frac{hP}{kA_c} \right)^{1/2} = \left( \frac{15 \text{W/m}^2 \cdot \text{K} \times (0.025 \text{m})}{60 \text{W/m} \cdot \text{K} \times 4.909 \times 10^{-4} \text{m}^2} \right)^{1/2} = 6.324 \text{m}^{-1} \]

Consider the following design changes aimed at reducing \( T_o \leq 100^\circ \text{C} \). (1) Increasing length of the fin portions: with \( L_o = 200 \text{ mm} \), the fin already behaves as an infinitely long fin. Hence, increasing \( L_o \) will not result in reducing \( T_o \). (2) Decreasing the thermal conductivity: backsolving the above equation set with \( T_o = 100^\circ \text{C} \), find the required thermal conductivity is \( k = 14 \text{ W/m-K} \). Hence, we could select a stainless steel alloy; see Table A.1. (3) Increasing the insulation thickness: find that for \( T_o = 100^\circ \text{C} \), the required insulation thickness would be \( L_{\text{ins}} = 211 \text{ mm} \). This design solution might be physically and economically unattractive. (4) A very practical solution would be to introduce thermal contact resistance between the rod base and the furnace wall by “tack welding” (rather than a continuous bead around the rod circumference) the rod in two or three places. (5) A less practical solution would be to increase the convection coefficient, since to do so, would require an air handling unit.

COMMENTS: (1) Would replacing the rod by a thick-walled tube provide a practical solution?

(2) The \textit{IHT Thermal Resistance Network Model} and the \textit{Thermal Resistance Tool} for a \textit{fin with an adiabatic tip} were used to create a model of the rod. The Workspace is shown below.

// Thermal Resistance Network Model:
// The Network:

// Heat rates into node j,qij, through thermal resistance Rij
q21 = (T2 - T1) / R21
q32 = (T3 - T2) / R32

// Nodal energy balances
q1 + q21 = 0
q2 - q21 + q32 = 0
q3 - q32 = 0

/* Assigned variables list: deselect the qi, Rij and Ti which are unknowns; set qi = 0 for embedded nodal points at which there is no external source of heat. */
T1 = Tw // Furnace wall temperature, C
q1 = // Heat rate, W
T2 = To // To, beginning of rod exposed length
q2 = 0 // Heat rate, W; node 2; no external heat source
T3 = Tinf // Ambient air temperature, C
q3 = // Heat rate, W

// Thermal Resistances:
// Rod - conduction resistance
R21 = Lins / (k * Ac) // Conduction resistance, K/W
Ac = pi * D^2 / 4 // Cross sectional area of rod, m^2

// Thermal Resistance Tools - Fin with Adiabatic Tip:
R32 = Rfin // Resistance of fin, K/W
/* Thermal resistance of a fin of uniform cross sectional area Ac, perimeter P, length L, and thermal conductivity k with an adiabatic tip condition experiencing convection with a fluid at Tinf and coefficient h, */
Rfin = 1 / (tanh (m*Lo) * (h * P * k * Ac)^(1/2)) // Case B, Table 3.4
m = sqrt(h^2 / (k*Ac))
P = pi * D // Perimeter, m

// Other Assigned Variables:
Tw = 200 // Furnace wall temperature, C
k = 60 // Rod thermal conductivity, W/m-K
Lins = 0.200 // Insulated length, m
D = 0.025 // Rod diameter, m
h = 15 // Convection coefficient, W/m^2*K
Tinf = 25 // Ambient air temperature,C
Lo = 0.200 // Exposed length, m
PROBLEM 3.112

KNOWN: Rod (D, k, 2L) inserted into a perfectly insulating wall, exposing one-half of its length to an airstream (T∞, h). An electromagnetic field induces a uniform volumetric energy generation (q) in the imbedded portion.

FIND: (a) Derive an expression for T_b at the base of the exposed half of the rod; the exposed region may be approximated as a very long fin; (b) Derive an expression for T_o at the end of the imbedded half of the rod, and (c) Using numerical values, plot the temperature distribution in the rod and describe its key features. Does the rod behave as a very long fin?

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in imbedded portion of rod, (3) Imbedded portion of rod is perfectly insulated, (4) Exposed portion of rod behaves as an infinitely long fin, and (5) Constant properties.

ANALYSIS: (a) Since the exposed portion of the rod (0 ≤ x ≤ +L) behaves as an infinite fin, the fin heat rate using Eq. 3.80 is

\[ q_x (0) = q_f = M = (hP A_c)^{1/2} (T_b - T_\infty) \]  \hspace{1cm} (1)

From an energy balance on the imbedded portion of the rod,

\[ q_f = \dot{q} A_c L \] \hspace{1cm} (2)

Combining Eqs. (1) and (2), with \( P = \pi D \) and \( A_c = \pi D^2/4 \), find

\[ T_b = T_\infty + q_f (hP A_c)^{-1/2} = T_\infty + \dot{q} A_c^{1/2} L (hP k)^{-1/2} \] \hspace{1cm} (3)

(b) The imbedded portion of the rod (-L ≤ x ≤ 0) experiences one-dimensional heat transfer with uniform \( \dot{q} \). From Eq. 3.43,

\[ T_0 = \frac{\dot{q} L^2}{2k} + T_b \] \hspace{1cm} <

(c) The temperature distribution T(x) for the rod is piecewise parabolic and exponential,

\[ T(x) - T_b = \frac{\dot{q} L^2}{2k} \left( \frac{x}{L} \right)^2 \quad -L \leq x \leq 0 \]

\[ \frac{T(x) - T_\infty}{T_b - T_\infty} = \exp(-mx) \quad 0 \leq x \leq +L \]

Continued …..
PROBLEM 3.112 (Cont.)

The gradient at $x = 0$ will be continuous since we used this condition in evaluating $T_b$. The distribution is shown below with $T_o = 105.4^\circ C$ and $T_b = 55.4^\circ C$.

![Graph of temperature distribution over embedded and exposed portions of rod]
PROBLEM 3.113

KNOWN: Very long rod (D, k) subjected to induction heating experiences uniform volumetric generation \( \dot{q} \) over the center, 30-mm long portion. The unheated portions experience convection \( (T_{\infty}, h) \).

FIND: Calculate the temperature of the rod at the mid-point of the heated portion within the coil, \( T_o \), and at the edge of the heated portion, \( T_b \).

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction with uniform \( \dot{q} \) in portion of rod within the coil; no convection from lateral surface of rod, (3) Exposed portions of rod behave as infinitely long fins, and (4) Constant properties.

ANALYSIS: The portion of the rod within the coil, \( 0 \leq x \leq L \), experiences one-dimensional conduction with uniform generation. From Eq. 3.43,

\[
T_o = \frac{\dot{q}L^2}{2k} + T_b
\]

The portion of the rod beyond the coil, \( L \leq x \leq \infty \), behaves as an infinitely long fin for which the heat rate from Eq. 3.80 is

\[
q_f = q_x \left(L\right) = \left(hP\frac{A_c}{4}\right)^{1/2} (T_b - T_{\infty})
\]

where \( P = \pi D \) and \( A_c = \pi D^2/4 \). From an overall energy balance on the imbedded portion of the rod as illustrated in the schematic above, find the heat rate as

\[
\dot{E}_{\text{in}} - \dot{E}_{\text{out}} + \dot{E}_{\text{gen}} = 0
\]

\[-q_f + \dot{q}A_cL = 0
\]

\[q_f = \dot{q}A_cL
\]

Combining Eqs. (1-3),

\[
T_b = T_{\infty} + \dot{q}A_c^{1/2}L(hPk)^{-1/2}
\]

\[
T_o = T_{\infty} + \frac{\dot{q}L^2}{2k} + \dot{q}A_c^{1/2}L(hPk)^{-1/2}
\]

and substituting numerical values find

\[T_o = 305^\circ C \quad T_b = 272^\circ C\]
PROBLEM 3.114

KNOWN: Dimensions, end temperatures and volumetric heating of wire leads. Convection coefficient and ambient temperature.

FIND: (a) Equation governing temperature distribution in the leads, (b) Form of the temperature distribution.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) One-dimensional conduction in x, (3) Uniform volumetric heating, (4) Uniform $h$ (both sides), (5) Negligible radiation.

ANALYSIS: (a) Performing an energy balance for the differential control volume,\[ \dot{E}_{\text{in}} - \dot{E}_{\text{out}} + \dot{E}_g = 0 \]
\[ q_x - q_{x+dx} - dq_{\text{conv}} + qdV = 0 \]
\[ -kA_c \frac{dT}{dx} - \left[ -kA_c \frac{dT}{dx} - d \left( kA_c \frac{dT}{dx} \right) dx \right] - hP \frac{(T - T_\infty)}{dx} + \dot{q} A_c dx = 0 \]
\[ \frac{d^2T}{dx^2} - \frac{hP}{kA_c} (T - T_\infty) + \frac{\dot{q}}{k} = 0 \]

(b) With a reduced temperature defined as $\Theta \equiv T - T_\infty - \left( \frac{\dot{q} A_c}{hP} \right)$ and $m^2 \equiv hP/kA_c$, the differential equation may be rendered homogeneous, with a general solution and boundary conditions as shown
\[ \frac{d^2\Theta}{dx^2} - m^2 \Theta = 0 \]
\[ \Theta(x) = C_1 e^{mx} + C_2 e^{-mx} \]
\[ \Theta_b = C_1 + C_2 \]
\[ \Theta_c = C_1 e^{mL} + C_2 e^{-mL} \]
it follows that
\[ C_1 = \frac{\Theta_b e^{-mL} - \Theta_c}{e^{-mL} - e^{mL}} \]
\[ C_2 = \frac{\Theta_c - \Theta_b e^{mL}}{e^{mL} - e^{-mL}} \]
\[ \Theta(x) = \left( \frac{\Theta_b e^{-mL} - \Theta_c}{e^{-mL} - e^{mL}} \right) e^{mx} + \left( \frac{\Theta_c - \Theta_b e^{mL}}{e^{mL} - e^{-mL}} \right) e^{-mx} \]

COMMENTS: If $\dot{q}$ is large and $h$ is small, temperatures within the lead may readily exceed the prescribed boundary temperatures.
**PROBLEM 3.115**

**KNOWN:** Disk-shaped electronic device \((D, L_d, k_d)\) dissipates electrical power \((P_e)\) at one of its surfaces. Device is bonded to a cooled base \((T_o)\) using a thermal pad \((L_p, k_A)\). Long fin \((D, k_f)\) is bonded to the heat-generating surface using an identical thermal pad. Fin is cooled by convection \((T_\infty, h)\).

**FIND:** (a) Construct a thermal circuit of the system, (b) Derive an expression for the temperature of the heat-generating device, \(T_d\), in terms of circuit thermal resistance, \(T_o\) and \(T_\infty\); write expressions for the thermal resistances; and (c) Calculate \(T_d\) for the prescribed conditions.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional conduction through thermal pads and device; no losses from lateral surfaces; (3) Fin is infinitely long, (4) Negligible contact resistance between components of the system, and (5) Constant properties.

**ANALYSIS:** (a) The thermal circuit is shown below with thermal resistances associated with conduction (pads, \(R_p\); device, \(R_d\)) and for the long fin, \(R_f\).

\[
q_a = T_o - T_d \\
q_b = T_\infty - T_d \\
P_e = \frac{1}{R_p} + \frac{1}{R_d} + \frac{1}{R_f}
\]

(b) To obtain an expression for \(T_d\), perform an energy balance about the d-node

\[
E_{in} - E_{out} = q_a + q_b + P_e = 0
\]

Using the conduction rate equation with the circuit

\[
q_a = \frac{T_o - T_d}{R_f + R_d} \quad q_b = \frac{T_\infty - T_d}{R_p + R_f}
\]

Combine with Eq. (1), and solve for \(T_d\),

\[
T_d = \frac{P_e + T_o / (R_p + R_d) + T_\infty / (R_p + R_f)}{1 / (R_p + R_d) + 1 / (R_p + R_f)}
\]

where the thermal resistances with \(P = \pi D\) and \(A_c = \pi D^2/4\) are

\[
R_p = L_p / k_p A_c \quad R_d = L_d / k_d A_c \quad R_f = (h P k_f A_c)^{-1/2}
\]

(c) Substituting numerical values with the foregoing relations, find

\[
R_p = 1.061 \text{ K/W} \quad R_d = 4.244 \text{ K/W} \quad R_f = 5.712 \text{ K/W}
\]

and the device temperature as

\[
T_d = 62.4^\circ C
\]

**COMMENTS:** What fraction of the power dissipated in the device is removed by the fin? Answer: \(q_b / P_e = 47\%\).
PROBLEM 3.116

**KNOWN:** Dimensions and thermal conductivity of a gas turbine blade. Temperature and convection coefficient of gas stream. Temperature of blade base and maximum allowable blade temperature.

**FIND:** (a) Whether blade operating conditions are acceptable, (b) Heat transfer to blade coolant.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional, steady-state conduction in blade, (2) Constant $k$, (3) Adiabatic blade tip, (4) Negligible radiation.

**ANALYSIS:** Conditions in the blade are determined by Case B of Table 3.4.

(a) With the maximum temperature existing at $x = L$, Eq. 3.75 yields

$$\frac{T(L) - T_\infty}{T_b - T_\infty} = \frac{1}{\cosh mL}$$

$$m = \left( \frac{hP}{kA_c} \right)^{1/2} = \left( \frac{250 \text{W/m}^2 \cdot \text{K} \times 0.11 \text{m}}{20 \text{W/m} \cdot \text{K} \times 6 \times 10^{-4} \text{m}^2} \right)^{1/2}$$

$$m = 47.87 \text{ m}^{-1} \quad \text{and} \quad mL = 47.87 \text{ m}^{-1} \times 0.05 \text{ m} = 2.39$$

From Table B.1, $\cosh mL = 5.51$. Hence,

$$T(L) = 1200 \degree C + (300 - 1200) \degree C / 5.51 = 1037 \degree C$$

and the operating conditions are acceptable.

(b) With $M = \left( \frac{hP A_c}{k} \right)^{1/2}$ $\Theta_b = \left( \frac{250 \text{W/m}^2 \cdot \text{K} \times 0.11 \text{m} \times 20 \text{W/m} \cdot \text{K} \times 6 \times 10^{-4} \text{m}^2} \right)^{1/2}$ $\left( -900 \degree C \right) = -517 \text{W}$, Eq. 3.76 and Table B.1 yield

$$q_f = M \tanh mL = -517 \text{W} \left( 0.983 \right) = -508 \text{W}$$

Hence, $q_b = -q_f = 508 \text{W}$

**COMMENTS:** Radiation losses from the blade surface and convection from the tip will contribute to reducing the blade temperatures.
PROBLEM 3.117

FIND: (a) Expression for the friction coefficient \( \mu \), (b) Radial temperature distribution in disc, (c) Value of \( \mu \) for prescribed conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional radial conduction, (3) Constant \( k \), (4) Uniform disc contact pressure \( p \), (5) All frictional heat dissipation is transferred to shaft from base of disc.

ANALYSIS: (a) The normal force acting on a differential ring extending from \( r \) to \( r + dr \) on the contact surface of the disc may be expressed as \( dF_n = p2\pi rdr \). Hence, the tangential force is \( dF_t = \mu p2\pi rdr \), in which case the torque may be expressed as

\[
d\tau = 2\pi \mu pr^2 dr
\]

For the entire disc, it follows that

\[
\tau = 2\pi \mu p \int_0^{r_2} r^2 dr = \frac{2\pi}{3} \mu pr_2^3
\]

where \( p = F/\pi r_2^2 \). Hence,

\[
\mu = \frac{3}{2} \frac{\tau}{Fr_2^2}
\]

(b) Performing an energy balance on a differential control volume in the disc, it follows that

\[ q_{\text{cond},r} + dq_{\text{fric}} - q_{\text{cond},r+dr} = 0 \]

With \( dq_{\text{fric}} = \omega d\tau = 2\mu F\omega \left(\frac{r^2}{r_2^2}\right)dr \), \( q_{\text{cond},r+dr} = q_{\text{cond},r} + \left(\frac{dq_{\text{cond},r}}{dr}\right)dr \), and \( q_{\text{cond},r} = -k \left(\frac{2\pi rt}{dr}\right)dT/dr \), it follows that

\[
2\mu F\omega \left(\frac{r^2}{r_2^2}\right)dr + 2\pi kt \frac{d(rdT/dr)}{dr}dr = 0
\]

or

\[
\frac{d(rdT/dr)}{dr} = -\frac{\mu F\omega}{\pi k tr_2^2} r^2
\]

Integrating twice,
PROBLEM 3.117 (Cont.)

\[
\frac{dT}{dr} = -\frac{\mu F\omega}{3\pi kt r^2} + \frac{C_1}{r}
\]

\[
T = -\frac{\mu F\omega}{9\pi kt r^2} r^3 + C_1 \ell n r + C_2
\]

Since the disc is well insulated at \( r = r_2 \), \( \frac{dT}{dr} \bigg|_{r_2} = 0 \) and

\[
C_1 = \frac{\mu F\omega r_2}{3\pi kt}
\]

With \( T(\eta) = T_1 \), it also follows that

\[
C_2 = T_1 + \frac{\mu F\omega}{9\pi kt r_2^2} r_1^3 - C_1 \ell n \frac{r}{\eta}
\]

Hence,

\[
T(r) = T_1 - \frac{\mu F\omega}{9\pi kt r_2^2} \left( r^3 - r_1^3 \right) + \frac{\mu F\omega r_2}{3\pi kt} \ell n \frac{r}{\eta}
\]

(c) For the prescribed conditions,

\[
\mu = \frac{3}{2} \frac{8 \text{N} \cdot \text{m}}{200 \text{N} \cdot (0.18 \text{m})} = 0.333
\]

Since the maximum temperature occurs at \( r = r_2 \),

\[
T_{\text{max}} = T(r_2) = T_1 - \frac{\mu F\omega r_2}{9\pi kt} \left[ 1 - \frac{\eta}{r_2} \right]^3 + \frac{\mu F\omega r_2}{3\pi kt} \ell n \left( \frac{r_2}{r_1} \right)
\]

With \( \left( \frac{\mu F\omega r_2}{3\pi kt} \right) = (0.333 \times 200 \text{N} \times 40 \text{rad/s} \times 0.18 \text{m} / 3\pi \times 15 \text{W/m} \cdot \text{K} \times 0.012 \text{m}) = 282.7^\circ \text{C},

\[
T_{\text{max}} = 80^\circ \text{C} - \frac{282.7^\circ \text{C}}{3} \left[ 1 - \left( \frac{0.02}{0.18} \right)^3 \right] + 282.7^\circ \text{C} \ell n \left( \frac{0.18}{0.02} \right)
\]

\[
T_{\text{max}} = 80^\circ \text{C} - 94.1^\circ \text{C} + 621.1^\circ \text{C} = 607^\circ \text{C}
\]

COMMENTS: The maximum temperature is excessive, and the disks should be actively cooled (by convection) at their outer surfaces.
PROBLEM 3.118

KNOWN: Extended surface of rectangular cross-section with heat flow in the longitudinal direction.

FIND: Determine the conditions for which the transverse (y-direction) temperature gradient is negligible compared to the longitudinal gradient, such that the 1-D analysis of Section 3.6.1 is valid by finding: (a) An expression for the conduction heat flux at the surface, \( q_y^* (t) \), in terms of \( T_s \) and \( T_o \), assuming the transverse temperature distribution is parabolic, (b) An expression for the convection heat flux at the surface for the x-location; equate the two expressions, and identify the parameter that determines the ratio \( (T_o - T_s)/(T_s - T_{\infty}) \); and (c) Developing a criterion for establishing the validity of the 1-D assumption used to model an extended surface.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform convection coefficient and (3) Constant properties.

ANALYSIS: (a) Referring to the schematics above, the conduction heat flux at the surface \( y = t \) at any x-location follows from Fourier’s law using the parabolic transverse temperature distribution.

\[
q_y^*(t) = -k \frac{\partial T}{\partial y} \bigg|_{y=t} = -k \left( [T_s(x) - T_o(x)] - \frac{2y}{t^2} \right) \bigg|_{y=t} = -\frac{2k}{t} \left( T_s(x) - T_o(x) \right)
\]

(b) The convection heat flux at the surface of any x-location follows from the rate equation

\[
q_{cv}^* = h \left( T_s(x) - T_{\infty} \right)
\]

Performing a surface energy balance as represented schematically above, equating Eqs. (1) and (2) provides

\[
q_y^*(t) = q_{cv}^*
\]

\[
-\frac{2k}{t} \left( T_s(x) - T_o(x) \right) = h \left( T_s(x) - T_{\infty} \right)
\]

\[
\frac{T_s(x) - T_o(x)}{T_{\infty}(x) - T_s(x)} = -0.5 \frac{ht}{k} = -0.5 Bi
\]

where \( Bi = \frac{ht}{k} \), the Biot number, represents the ratio of the convection to the conduction thermal resistances,

\[
Bi = \frac{R_{cd}^*}{R_{cv}^*} = \frac{t}{k} / \frac{1}{h}
\]

(c) The transverse gradient (heat flow) will be negligible compared to the longitudinal gradient when \( Bi \ll 1 \), say, 0.1, an order of magnitude smaller. This is the criterion to validate the one-dimensional assumption used to model extended surfaces.

COMMENTS: The coefficient 0.5 in Eq. (3) is a consequence of the parabolic distribution assumption. This distribution represents the simplest polynomial expression that could approximate the real distribution.
PROBLEM 3.119

KNOWN: Long, aluminum cylinder acts as an extended surface.

FIND: (a) Increase in heat transfer if diameter is tripled and (b) Increase in heat transfer if copper is used in place of aluminum.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties, (4) Uniform convection coefficient, (5) Rod is infinitely long.

PROPERTIES: Table A-1, Aluminum (pure): $k = 240 \text{ W/m-K}$; Table A-1, Copper (pure): $k = 400 \text{ W/m-K}$.

ANALYSIS: (a) For an infinitely long fin, the fin heat rate from Table 3.4 is

$$q_f = M = \left( h P k A_c \right)^{1/2} \theta_b$$

$$q_f = \left( h \pi D k \frac{\pi D^2}{4} \right)^{1/2} \theta_b = \left( \frac{\pi}{2} h k \right)^{1/2} D^{3/2} \theta_b.$$ 

where $P = \pi D$ and $A_c = \pi D^2/4$ for the circular cross-section. Note that $q_f \propto D^{3/2}$. Hence, if the diameter is tripled,

$$\frac{q_f(3D)}{q_f(D)} = 3^{3/2} = 5.2$$

and there is a 420% increase in heat transfer.

(b) In changing from aluminum to copper, since $q_f \propto k^{1/2}$, it follows that

$$\frac{q_f \text{ (Cu)}}{q_f \text{ (Al)}} = \left[ \frac{k_{Cu}}{k_{Al}} \right]^{1/2} = \left[ \frac{400}{240} \right]^{1/2} = 1.29$$

and there is a 29% increase in the heat transfer rate.

COMMENTS: (1) Because fin effectiveness is enhanced by maximizing $P/A_c = 4/D$, the use of a larger number of small diameter fins is preferred to a single large diameter fin.

(2) From the standpoint of cost and weight, aluminum is preferred over copper.
PROBLEM 3.120

KNOWN: Length, diameter, base temperature and environmental conditions associated with a brass rod.
FIND: Temperature at specified distances along the rod.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties, (4) Negligible radiation, (5) Uniform convection coefficient h.

PROPERTIES: Table A-1, Brass \((\overline{T} = 110^\circ \text{C})\): \(k = 133 \text{ W/m} \cdot \text{K}\).

ANALYSIS: Evaluate first the fin parameter

\[
m = \left[ \frac{hP}{kA_c} \right]^{1/2} = \left[ \frac{h \pi D}{k \pi D^2 / 4} \right]^{1/2} = \left[ \frac{4h}{kD} \right]^{1/2} = \left[ \frac{4 \times 30 \text{ W/m}^2 \cdot \text{K}}{133 \text{ W/m} \cdot \text{K} \times 0.005 \text{m}} \right]^{1/2}
\]

\[m = 13.43 \text{ m}^{-1}.
\]

Hence, \(mL = (13.43) \times 0.1 = 1.34\) and from the results of Example 3.8, it is advisable not to make the infinite rod approximation. Thus from Table 3.4, the temperature distribution has the form

\[\theta = \frac{\cosh mL + (h/mk) \sinh mL}{\cosh mL + (h/mk) \sinh mL} \theta_b\]

Evaluating the hyperbolic functions, \(\cosh mL = 2.04\) and \(\sinh mL = 1.78\), and the parameter

\[\frac{h}{mk} = \frac{30 \text{ W/m}^2 \cdot \text{K}}{133 \text{ W/m} \cdot \text{K}} = 0.0168,
\]

with \(\theta_b = 180^\circ \text{C}\) the temperature distribution has the form

\[\theta = \frac{\cosh mL + 0.0168 \sinh mL}{2.07} (180^\circ \text{C}).\]

The temperatures at the prescribed location are tabulated below.

<table>

COMMENTS: If the rod were approximated as infinitely long: \(T(x_1) = 148.7^\circ \text{C}, T(x_2) = 112.0^\circ \text{C},\) and \(T(L) = 67.0^\circ \text{C}\). The assumption would therefore result in significant underestimates of the rod temperature.
PROBLEM 3.121

KNOWN: Thickness, length, thermal conductivity, and base temperature of a rectangular fin. Fluid temperature and convection coefficient.

FIND: (a) Heat rate per unit width, efficiency, effectiveness, thermal resistance, and tip temperature for different tip conditions, (b) Effect of convection coefficient and thermal conductivity on the heat rate.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) One-dimensional conduction along fin, (3) Constant properties, (4) Negligible radiation, (5) Uniform convection coefficient, (6) Fin width is much longer than thickness (w >> t).

ANALYSIS: (a) The fin heat transfer rate for Cases A, B and D are given by Eqs. (3.72), (3.76) and (3.80), where 

\[ M \approx \left( \frac{2hw^2tk}{T_b - T_{\infty}} \right)^{1/2} = \left( \frac{2 \times 100 \text{ W/m}^2\cdot\text{K} \times 0.001 \text{m} \times 180 \text{ W/m-K}}{75^\circ\text{C}} \right)^{1/2} = 33.3 \text{m}^{-1} \]

\[ mL \approx 33.3 \text{m}^{-1} \times 0.010 \text{m} = 0.333 \]

\[ \left( \frac{h}{mk} \right) \approx \left( \frac{100 \text{ W/m}^2\cdot\text{K}}{33.3 \text{m}^{-1} \times 180 \text{ W/m-K}} \right) = 0.0167 \]

From Table B-1, it follows that

\[ \sinh mL \approx 0.340, \cosh mL \approx 1.057, \tanh mL \approx 0.321 \]

From knowledge of \( q_f \), Eqs. (3.86), (3.81) and (3.83) yield

\[ \eta_f = \frac{q_f}{h(2L + t)\theta_b}, \quad \varepsilon_f \approx \frac{q_f}{ht\theta_b}, \quad R_{t,f} = \frac{\theta_b}{q_f} \]

Case A: From Eq. (3.72), (3.86), (3.81), (3.83) and (3.70),

\[ q_f = M \sinh mL + \left( \frac{h}{mk} \right) \cosh mL \]

\[ \frac{w \cosh mL + \left( \frac{h}{mk} \right) \sinh mL}{150 \text{ W/m} \times 0.340 + 0.0167 \times 1.057} = 151 \text{ W/m} \]

\[ \eta_f = \frac{151 \text{ W/m}}{100 \text{ W/m}^2 \cdot \text{K}(0.021 \text{m})75^\circ\text{C}} = 0.96 \]

\[ \varepsilon_f = \frac{151 \text{ W/m}}{100 \text{ W/m}^2 \cdot \text{K}(0.001 \text{m})75^\circ\text{C}} = 20.1, \quad R_{t,f} = \frac{75^\circ\text{C}}{151 \text{ W/m}} = 0.50 \text{ m-K/W} \]

\[ T(L) = T_\infty + \frac{\theta_b}{\cosh mL + \left( \frac{h}{mk} \right) \sinh mL} = 25^\circ\text{C} + \frac{75^\circ\text{C}}{1.057 + (0.0167)0.340} = 95.6^\circ\text{C} \]

Case B: From Eqs. (3.76), (3.86), (3.81), (3.83) and (3.75)

\[ q_f = \frac{M}{w} \tanh mL = 450 \text{ W/m} \times 0.321 = 144 \text{ W/m} \]

\[ \eta_f = 0.92, \quad \varepsilon_f = 19.2, \quad R_{t,f} = 0.52 \text{ m-K/W} \]

\[ T(L) = T_\infty + \frac{\theta_b}{\cosh mL} = 25^\circ\text{C} + \frac{75^\circ\text{C}}{1.057} = 96.0^\circ\text{C} \]

Continued ….
Case D ($L \to \infty$): From Eqs. (3.80), (3.86), (3.81), (3.83) and (3.79)

\[
\dot{q}_f = \frac{M}{w} = 450 \text{ W/m} \\
\eta_f = 0, \quad \varepsilon_f = 60.0, \quad R_{t,f}' = 0.167 \text{ m} \cdot \text{K/W}, \quad T(L) = T_\infty = 25^\circ\text{C}
\]

(b) The effect of $h$ on the heat rate is shown below for the aluminum and stainless steel fins.

For both materials, there is little difference between the Case A and B results over the entire range of $h$. The difference (percentage) increases with decreasing $h$ and increasing $k$, but even for the worst case condition ($h = 10 \text{ W/m}^2\cdot\text{K}, \quad k = 180 \text{ W/m-K}$), the heat rate for Case A (15.7 W/m) is only slightly larger than that for Case B (14.9 W/m). For aluminum, the heat rate is significantly over-predicted by the infinite fin approximation over the entire range of $h$. For stainless steel, it is over-predicted for small values of $h$, but results for all three cases are within 1% for $h > 500 \text{ W/m}^2\cdot\text{K}$.

COMMENTS: From the results of Part (a), we see there is a slight reduction in performance (smaller values of $q_f$, $\eta_f$ and $\varepsilon_f$, as well as a larger value of $R_{t,f}'$) associated with insulating the tip. Although $\eta_f = 0$ for the infinite fin, $q_f'$ and $\varepsilon_f$ are substantially larger than results for $L = 10 \text{ mm}$, indicating that performance may be significantly improved by increasing $L$. 

![Graph showing variation of $q_f'$ with $h$ for $k=180 \text{ W/m.K}$](image1)

![Graph showing variation of $q_f'$ with $h$ for $k=15 \text{ W/m.K}$](image2)
PROBLEM 3.122

KNOWN: Thickness, length, thermal conductivity, and base temperature of a rectangular fin. Fluid temperature and convection coefficient.

FIND: (a) Heat rate per unit width, efficiency, effectiveness, thermal resistance, and tip temperature for different tip conditions, (b) Effect of fin length and thermal conductivity on the heat rate.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) One-dimensional conduction along fin, (3) Constant properties, (4) Negligible radiation, (5) Uniform convection coefficient, (6) Fin width is much longer than thickness (w >> t).

ANALYSIS: (a) The fin heat transfer rate for Cases A, B and D are given by Eqs. (3.72), (3.76) and (3.80), where

\[ M = \left(2hw_2t\right)^{1/2} \left(T_b - T_\infty\right) = \left(2 \times 100 \text{ W/m}^2\text{K} \times 0.001 \text{ m} \times 180 \text{ W/m-K}\right)^{1/2} = 33.3 \text{ m}^{-1} \]

and

\[ \frac{h}{mk} \approx \frac{100 \text{ W/m}^2\text{K}}{33.3 \text{ m}^{-1} \times 0.001 \text{ m}} = 0.0167. \]

From knowledge of \( q_f \), Eqs. (3.86), (3.81) and (3.83) yield

\[ \eta_f = \frac{\dot{q}_f}{h(2L+t)\theta_b}, \quad \varepsilon_f = \frac{\dot{q}_f}{ht\theta_b}, \quad R_{t,f} = \frac{\theta_b}{\dot{q}_f} \]

Case A: From Eq. (3.72), (3.86), (3.81), (3.83) and (3.70),

\[ \dot{q}_f = \frac{M \sinh mL + (h/mk) \cosh mL}{w \cosh mL + (h/mk) \sinh mL} \quad \text{where} \quad w = 450 \text{ W/m}, \quad h = 100 \text{ W/m}^2\text{K}, \quad T_b = 100 \text{°C}, \quad L = 10 \text{ mm}, \quad t = 1 \text{ mm} \]

\[ \eta_f = \frac{151 \text{ W/m}}{100 \text{ W/m}^2\text{K}(0.021 \text{ m})} = 0.96 \]

\[ \varepsilon_f = \frac{151 \text{ W/m}}{100 \text{ W/m}^2\text{K}(0.001 \text{ m})} = 20.1, \quad R_{t,f} = \frac{75 \text{°C}}{151 \text{ W/m}} = 0.50 \text{ m} \cdot \text{K/W} \]

\[ T(L) = T_\infty + \frac{\theta_b}{\cosh mL + (h/mk) \sinh mL} = 25\text{°C} + \frac{75\text{°C}}{1.057 + (0.0167)0.340} = 95.6\text{°C} \]

Case B: From Eqs. (3.76), (3.86), (3.81), (3.83) and (3.75),

\[ \dot{q}_f = \frac{M}{w} \tanh mL = 450 \text{ W/m}(0.321) = 144 \text{ W/m} \]

\[ \eta_f = 0.92, \quad \varepsilon_f = 19.2, \quad R_{t,f} = 0.52 \text{ m} \cdot \text{K/W} \]

\[ T(L) = T_\infty + \frac{\theta_b}{\cosh mL} = 25\text{°C} + \frac{75\text{°C}}{1.057} = 96.0\text{°C} \]

Continued …..
PROBLEM 3.122 (Cont.)

Case D ($L \to \infty$): From Eqs. (3.80), (3.86), (3.81), (3.83) and (3.79)

$$q'_f = \frac{M}{w} = 450 \text{ W/m}$$

$$\eta_f = 0, \varepsilon_f = 60.0, R'_{f,1} = 0.167 \text{ m} \cdot \text{K/W}, T(L) = T_\infty = 25^\circ\text{C}$$

(b) The effect of $L$ on the heat rate is shown below for the aluminum and stainless steel fins.

For both materials, differences between the Case A and B results diminish with increasing $L$ and are within 1% of each other at $L = 27 \text{ mm}$ and $L = 13 \text{ mm}$ for the aluminum and steel, respectively. At $L = 3 \text{ mm}$, results differ by 14% and 13% for the aluminum and steel, respectively. The Case A and B results approach those of the infinite fin approximation more quickly for stainless steel due to the larger temperature gradients, $|dT/dx|$, for the smaller value of $k$.

COMMENTS: From the results of Part (a), we see there is a slight reduction in performance (smaller values of $q'_f$, $\eta_f$ and $\varepsilon_f$, as well as a larger value of $R'_{f,1}$) associated with insulating the tip. Although $\eta_f = 0$ for the infinite fin, $q'_f$ and $\varepsilon_f$ are substantially larger than results for $L = 10 \text{ mm}$, indicating that performance may be significantly improved by increasing $L$. 
PROBLEM 3.123

KNOWN: Length, thickness and temperature of straight fins of rectangular, triangular and parabolic profiles. Ambient air temperature and convection coefficient.

FIND: Heat rate per unit width, efficiency and volume of each fin.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) One-dimensional conduction, (3) Constant properties, (4) Negligible radiation, (5) Uniform convection coefficient.

ANALYSIS: For each fin, 
\[ q' = q_{\text{max}} = \eta_f h A'_f \theta_b, \quad V' = A_p \]

where \( \eta_f \) depends on the value of \( m = \left( \frac{2h}{kt} \right)^{1/2} = \left( 100 \text{ W/m}^2 \cdot \text{K} / 185 \text{ W/m-K} \times 0.003 \text{ m} \right)^{1/2} = 13.4 \text{ m}^{-1} \) and the product \( mL = 13.4 \text{ m}^{-1} \times 0.015 \text{ m} = 0.201 \) or \( mL_c = 0.222 \). Expressions for \( \eta_f, A'_f \) and \( A_p \) are obtained from Table 3-5.

Rectangular Fin:
\[ \eta_f = \frac{\tanh mL_c}{mL_c} = \frac{0.218}{0.222} = 0.982, \quad A'_f = 2L_c = 0.033 \text{ m} \]
\[ q' = 0.982 \left( 50 \text{ W/m}^2 \cdot \text{K} \right) 0.033 \text{ m} (80^\circ \text{C}) = 129.6 \text{ W/m}, \quad V' = tL = 4.5 \times 10^{-5} \text{ m}^2 \]

Triangular Fin:
\[ \eta_f = \frac{1}{mL_c} \left( I_1(2mL) / I_0(2mL) \right) = \frac{0.205}{(0.201) 1.042} = 0.978, \quad A'_f = 2 \left[ L^2 + \left( \frac{t}{2} \right)^2 \right]^{1/2} = 0.030 \text{ m} \]
\[ q' = 0.978 \left( 50 \text{ W/m}^2 \cdot \text{K} \right) 0.030 \text{ m} (80^\circ \text{C}) = 117.3 \text{ W/m}, \quad V' = \left( \frac{t}{2} \right) L = 2.25 \times 10^{-5} \text{ m}^2 \]

Parabolic Fin:
\[ \eta_f = \frac{2}{\left[ 4 \left( mL_c \right)^2 + 1 \right]^{1/2} + 1} = 0.963, \quad A'_f = \left[ C_1 L + \left( \frac{L^2}{t} \right) \ln \left( \frac{t}{L + C_1} \right) \right] = 0.030 \text{ m} \]
\[ q' = 0.963 \left( 50 \text{ W/m}^2 \cdot \text{K} \right) 0.030 \text{ m} (80^\circ \text{C}) = 115.6 \text{ W/m}, \quad V' = \left( \frac{t}{3} \right) L = 1.5 \times 10^{-5} \text{ m}^2 \]

COMMENTS: Although the heat rate is slightly larger (~10%) for the rectangular fin than for the triangular or parabolic fins, the heat rate per unit volume (or mass) is larger and largest for the triangular and parabolic fins, respectively.
PROBLEM 3.124

KNOWN: Melting point of solder used to join two long copper rods.

FIND: Minimum power needed to solder the rods.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction along the rods, (3) Constant properties, (4) No internal heat generation, (5) Negligible radiation exchange with surroundings, (6) Uniform h, and (7) Infinitely long rods.

PROPERTIES: Table A-1: Copper \( T = (650 + 25) \, ^\circ \text{C} = 600\, \text{K} \); \( k = 379 \, \text{W/m} \cdot \text{K} \).

ANALYSIS: The junction must be maintained at 650°C while energy is transferred by conduction from the junction (along both rods). The minimum power is twice the fin heat rate for an infinitely long fin,

\[
q_{\text{min}} = 2q_f = 2 \left( hPA_{\text{c}} \right)^{1/2} (T_b - T_\infty).
\]

Substituting numerical values,

\[
q_{\text{min}} = 2 \left[ \frac{10 \, \text{W}}{\text{m}^2 \cdot \text{K}} \times 0.01\text{m} \right] \left[ \frac{379 \, \text{W}}{\text{m} \cdot \text{K}} \right] \frac{\pi}{4} (0.01\text{m})^2 \left( 650 - 25 \right) \, ^\circ \text{C}.
\]

Therefore,

\[
q_{\text{min}} = 120.9 \, \text{W}.
\]

COMMENTS: Radiation losses from the rods may be significant, particularly near the junction, thereby requiring a larger power input to maintain the junction at 650°C.
KNOWN: Dimensions and end temperatures of pin fins.

FIND: (a) Heat transfer by convection from a single fin and (b) Total heat transfer from a 1 m² surface with fins mounted on 4mm centers.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) One-dimensional conduction along rod, (3) Constant properties, (4) No internal heat generation, (5) Negligible radiation.

PROPERTIES: Table A-1, Copper, pure (323K): \( k \approx 400 \text{ W/m}\cdot\text{K} \).

ANALYSIS: (a) By applying conservation of energy to the fin, it follows that

\[ q_{\text{cond,i}} - q_{\text{cond,o}} = -q_{\text{conv}} \]

where the conduction rates may be evaluated from knowledge of the temperature distribution. The general solution for the temperature distribution is

\[ \theta(x) = C_1 e^{mx} + C_2 e^{-mx} \quad \theta \equiv T - T_\infty. \]

The boundary conditions are \( \theta(0) = \theta_o = 100^\circ\text{C} \) and \( \theta(L) = 0 \). Hence

\[
\begin{align*}
\theta_o &= C_1 + C_2 \\
0 &= C_1 e^{mL} + C_2 e^{-mL}
\end{align*}
\]

Therefore,

\[
C_2 = C_1 e^{2mL}
\]

\[
C_1 = \frac{\theta_o}{1 - e^{-2mL}}, \quad C_2 = -\frac{\theta_o e^{2mL}}{1 - e^{2mL}}
\]

and the temperature distribution has the form

\[ \theta = \frac{\theta_o}{1 - e^{2mL}} \left[ e^{mx} - e^{2mL-mx} \right]. \]

The conduction heat rate can be evaluated by Fourier’s law,

\[ q_{\text{cond}} = -kA_c \frac{d\theta}{dx} = -\frac{kA_c \theta_o}{1 - e^{2mL}} m \left[ e^{mx} + e^{2mL-mx} \right] \]

or, with \( m = (hP/kA_c)^{1/2} \),

\[ q_{\text{cond}} = -\frac{\theta_o (hP/kA_c)^{1/2}}{1 - e^{2mL}} \left[ e^{mx} + e^{2mL-mx} \right]. \]
PROBLEM 3.125 (Cont.)

Hence at $x = 0$,

$$q_{\text{cond},i} = -\frac{\theta_o (hP kA_c)}{1-e^{2mL}} \left( \frac{1}{1+e^{2mL}} \right)$$

at $x = L$

$$q_{\text{cond},o} = -\frac{\theta_o (hP kA_c)}{1-e^{2mL}} \left( 2e^{mL} \right)$$

Evaluating the fin parameters:

$$m = \left[ \frac{hP}{kA_c} \right]^{1/2} = \left[ \frac{4h}{kD} \right]^{1/2} = \left[ \frac{4 \times 100 \text{ W/m}^2 \cdot \text{K}}{400 \text{ W/m} \cdot \text{K} \times 0.001 \text{m}} \right]^{1/2} = 31.62 \text{ m}^{-1}$$

$$\left( hP kA_c \right)^{1/2} = \left[ \frac{\pi^2}{4} D h k \right]^{1/2} = \left[ \frac{\pi^2}{4} \times (0.001 \text{m})^3 \times 100 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} \times 400 \frac{\text{W}}{\text{m} \cdot \text{K}} \right]^{1/2} = 9.93 \times 10^{-3} \frac{\text{W}}{\text{K}}$$

$mL = 31.62 \text{ m}^{-1} \times 0.025 \text{m} = 0.791$, $e^{mL} = 2.204$, $e^{2mL} = 4.865$

The conduction heat rates are

$$q_{\text{cond},i} = -100K \left( 9.93 \times 10^{-3} \frac{\text{W}}{\text{K}} \right) \times 5.865 = 1.507 \text{ W}$$

$$q_{\text{cond},o} = -100K \left( 9.93 \times 10^{-3} \frac{\text{W}}{\text{K}} \right) \times 4.408 = 1.133 \text{ W}$$

and from the conservation relation,

$$q_{\text{conv}} = 1.507 \text{ W} - 1.133 \text{ W} = 0.374 \text{ W}.$$  

(b) The total heat transfer rate is the heat transfer from $N = 250 \times 250 = 62,500$ rods and the heat transfer from the remaining (bare) surface ($A = 1 \text{ m}^2 - NA_c$). Hence,

$$q = N q_{\text{cond},i} + hA \theta_o = 62,500 \left( 1.507 \text{ W} \right) + 100 \text{ W/m}^2 \cdot \text{K} \left( 0.951 \text{ m}^2 \right) 100K$$

$$q = 9.42 \times 10^4 \text{ W} + 0.95 \times 10^4 \text{ W} = 1.037 \times 10^5 \text{ W}.$$  

COMMENTS: (1) The fins, which cover only 5% of the surface area, provide for more than 90% of the heat transfer from the surface.

(2) The fin effectiveness, $\varepsilon = q_{\text{cond},i} / hA_c \theta_o$, is $\varepsilon = 192$, and the fin efficiency, $\eta = (q_{\text{conv}} / h\pi D L \theta_o)$, is $\eta = 0.48$.

(3) The temperature distribution, $\theta(x)/\theta_o$, and the conduction term, $q_{\text{cond},i}$, could have been obtained directly from Eqs. 3.77 and 3.78, respectively.

(4) Heat transfer by convection from a single fin could also have been obtained from Eq. 3.73.
PROBLEM 3.126

KNOWN: Pin fin of thermal conductivity k, length L and diameter D connecting two devices \( (L_g, k_g) \) experiencing volumetric generation of thermal energy \( (\dot{q}) \). Convection conditions are prescribed \( (T_\infty, h) \).

FIND: Expression for the device surface temperature \( T_b \) in terms of device, convection and fin parameters.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Pin fin is of uniform cross-section with constant h, (3) Exposed surface of device is at a uniform temperature \( T_b \), (4) Backside of device is insulated, (5) Device experiences 1-D heat conduction with uniform volumetric generation, (6) Constant properties, and (7) No contact resistance between pin and devices.

ANALYSIS: Recognizing symmetry, the pin fin is modeled as a fin of length \( L/2 \) with insulated tip. Perform a surface energy balance,

\[
\dot{E}_\text{in} - \dot{E}_\text{out} = 0
\]

\[
q_d - q_s - q_f = 0 \quad (1)
\]

The heat rate \( q_d \) can be found from an energy balance on the entire device to find

\[
\dot{E}_\text{in} - \dot{E}_\text{out} + \dot{E}_g = 0
\]

\[
-q_d + q_V = 0
\]

\[
q_d = \dot{q} A_g L_g \quad (2)
\]

The fin heat rate, \( q_f \), follows from Case B, Table 3.4

\[
q_f = M \tanh mL/2 = \left( h P A_c \right)^{1/2} \left( T_b - T_\infty \right) \tanh \left( mL/2 \right), \quad m = \left( h P / k A_c \right)^{1/2} \quad (3,4)
\]

\[
P/A_c = \pi D/\left( \pi D^2 / 4 \right) = 4/D \quad \text{and} \quad PA_c = \pi^2 D^3 / 4. \quad (5,6)
\]

Hence, the heat rate expression can be written as

\[
\dot{q} A_g L_g = h \left( A_g - A_c \right) \left( T_b - T_\infty \right) + \left( h k \left( \pi^2 D^3 / 4 \right) \right)^{1/2} \tanh \left( \frac{4h}{kD} \frac{L}{2} \right) \left( T_b - T_\infty \right) \quad (7)
\]

Solve now for \( T_b \),

\[
T_b = T_\infty + \dot{q} A_g L_g \left[ h \left( A_g - A_c \right) + \left( h k \left( \pi^2 D^3 / 4 \right) \right)^{1/2} \tanh \left( \frac{4h}{kD} \frac{L}{2} \right) \right] \quad (8)
\]
PROBLEM 3.127

KNOWN: Positions of equal temperature on two long rods of the same diameter, but different thermal conductivity, which are exposed to the same base temperature and ambient air conditions.

FIND: Thermal conductivity of rod B, k_B.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Rods are infinitely long fins of uniform cross-sectional area, (3) Uniform heat transfer coefficient, (4) Constant properties.

ANALYSIS: The temperature distribution for the infinite fin has the form

\[
\frac{\theta}{\theta_b} = \frac{T(x) - T_\infty}{T_0 - T_\infty} = e^{-mx}, \quad m = \left[ \frac{hP}{k_A c} \right]^{1/2}. \tag{1,2}
\]

For the two positions prescribed, x_A and x_B, it was observed that

\[ T_A(x_A) = T_B(x_B) \quad \text{or} \quad \theta_A(x_A) = \theta_B(x_B). \tag{3} \]

Since \( \theta_b \) is identical for both rods, Eq. (1) with the equality of Eq. (3) requires that

\[ m_A x_A = m_B x_B. \]

Substituting for m from Eq. (2) gives

\[
\left[ \frac{hP}{k_A c} \right]^{1/2} x_A = \left[ \frac{hP}{k_B c} \right]^{1/2} x_B.
\]

Recognizing that h, P and A_c are identical for each rod and rearranging,

\[
k_B = \left[ \frac{x_B}{x_A} \right]^2 k_A.
\]

Substituting for the given values,

\[
k_B = \left[ \frac{0.075 \text{m}}{0.15 \text{m}} \right]^2 \times 70 \text{ W/m} \cdot \text{K} = 17.5 \text{ W/m} \cdot \text{K}.
\]

COMMENTS: This approach has been used as a method for determining the thermal conductivity. It has the attractive feature of not requiring power or temperature measurements, assuming of course, a reference material of known thermal conductivity is available.
ProBLEM 3.128

KNOWN: Slender rod of length L with ends maintained at T₀ while exposed to convection cooling (T∞ < T₀, h).

FIND: Temperature distribution for three cases, when rod has thermal conductivity (a) kₐ, (b) k₇ < kₐ, and (c) kₐ for 0 ≤ x ≤ L/2 and k₇ for L/2 ≤ x ≤ L.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties, and (4) Negligible thermal resistance between the two materials (A, B) at the mid-span for case (c).

ANALYSIS: (a, b) The effect of thermal conductivity on the temperature distribution when all other conditions (T₀, h, L) remain the same is to reduce the minimum temperature with decreasing thermal conductivity. Hence, as shown in the sketch, the mid-span temperatures are T₇ (0.5L) < Tₐ (0.5L) for k₇ < kₐ. The temperature distribution is, of course, symmetrical about the mid-span.

(c) For the composite rod, the temperature distribution can be reasoned by considering the boundary condition at the mid-span.

\[ q_{x,A}(0.5L) = q_{x,B}(0.5L) \]
\[ -kₐ \frac{dT}{dx} \bigg |_{A,x=0.5L} = -k₇ \frac{dT}{dx} \bigg |_{B,x=0.5L} \]

Since kₐ > k₇, it follows that

\[ \left( \frac{dT}{dx} \right) \bigg |_{A,x=0.5L} < \left( \frac{dT}{dx} \right) \bigg |_{B,x=0.5L} \]

It follows that the minimum temperature in the rod must be in the k₇ region, x > 0.5L, and the temperature distribution is not symmetrical about the mid-span.

COMMENTS: (1) Recognize that the area under the curve on the T-x coordinates is proportional to the fin heat rate. What conclusions can you draw regarding the relative magnitudes of qₑ for cases (a), (b) and (c)?

(2) If L is increased substantially, how would the temperature distribution be affected?
PROBLEM 3.129

KNOWN: Base temperature, ambient fluid conditions, and temperatures at a prescribed distance from the base for two long rods, with one of known thermal conductivity.

FIND: Thermal conductivity of other rod.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) One-dimensional conduction along rods, (3) Constant properties, (4) Negligible radiation, (5) Negligible contact resistance at base, (6) Infinitely long rods, (7) Rods are identical except for their thermal conductivity.

ANALYSIS: With the assumption of infinitely long rods, the temperature distribution is

$$\frac{\theta}{\theta_b} = \frac{T - T_\infty}{T_b - T_\infty} = e^{-mx}$$

or

$$\ln \frac{T - T_\infty}{T_b - T_\infty} = -mx = \left[ \frac{hP}{kA} \right]^{1/2} x$$

Hence, for the two rods,

$$\ln \left[ \frac{T_A - T_\infty}{T_b - T_\infty} \right] = \left[ \frac{k_B}{k_A} \right]^{1/2}$$

$$k_B^{1/2} = k_A^{1/2} \left( \frac{T_A - T_\infty}{T_b - T_\infty} \right) = (200)^{1/2} \left( \frac{T_B - T_\infty}{T_b - T_\infty} \right)$$

$$k_B = 56.6 \text{ W/m} \cdot \text{K}.$$

COMMENTS: Providing conditions for the two rods may be maintained nearly identical, the above method provides a convenient means of measuring the thermal conductivity of solids.
PROBLEM 3.130

KNOWN: Arrangement of fins between parallel plates. Temperature and convection coefficient of air flow in finned passages. Maximum allowable plate temperatures.

FIND: (a) Expressions relating fin heat transfer rates to end temperatures, (b) Maximum power dissipation for each plate.

SCHEMATIC:

Plate dimensions:
D=100 mm x W=200 mm, L=12 mm, x=1 mm; N_f=50

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in fins, (3) Constant properties, (4) Negligible radiation, (5) All of the heat is dissipated to the air, (6) Uniform h, (7) Negligible variation in T_∞, (8) Negligible contact resistance.

PROPERTIES: Table A.1, Aluminum (pure), 375 K: k = 240 W/m·K.

ANALYSIS: (a) The general solution for the temperature distribution in fin is

\[ \theta(x) = T(x) - T_\infty = C_1 e^{mx} + C_2 e^{-mx} \]

Boundary conditions:
\[ \theta(0) = \theta_0 = T_0 - T_\infty, \quad \theta(L) = \theta_L = T_L - T_\infty. \]

Hence
\[ \theta_0 = C_1 + C_2 \quad \theta_L = C_1 e^{mL} + C_2 e^{-mL} \]
\[ \theta_L = C_1 e^{mL} + (\theta_0 - C_1)e^{-mL} \]
\[ C_1 = \frac{\theta_L - \theta_0 e^{-mL}}{e^{mL} - e^{-mL}} \quad C_2 = \theta_0 - \frac{\theta_L - \theta_0 e^{-mL}}{e^{mL} - e^{-mL}} = \frac{\theta_0 e^{mL} - \theta_L}{e^{mL} - e^{-mL}}. \]

Hence
\[ \theta(x) = \frac{\theta_L e^{mx} - \theta_0 e^{m(x-L)} + \theta_0 e^{m(L-x)} - \theta_L e^{-mx}}{e^{mL} - e^{-mL}}. \]
\[ \theta(x) = \frac{\theta_0 e^{m(L-x)} - e^{m(L-x)}}{e^{mL} - e^{-mL}} + \frac{\theta_L (e^{mx} - e^{-mx})}{e^{mL} - e^{-mL}}. \]
\[ \theta(x) = \frac{\theta_0 \sinh m(L-x) + \theta_L \sinh mx}{\sinh mL}. \]

The fin heat transfer rate is then
\[ q_f = -k A_c \frac{dT}{dx} = -k D T \left[ -\frac{\theta_0 m}{\sinh mL} \cosh m(L-x) + \frac{\theta_L m}{\sinh mL} \cosh mx \right]. \]

Hence
\[ q_{f,0} = k D T \left( \frac{\theta_0 m}{\tanh mL} - \frac{\theta_L m}{\sinh mL} \right) \]
\[ q_{f,L} = k D T \left( \frac{\theta_0 m}{\sinh mL} - \frac{\theta_L m}{\tanh mL} \right) \]

Continued …..
PROBLEM 3.130 (Cont.)

(b) \[ m = \left( \frac{hP}{kA_c} \right)^{1/2} = \left( \frac{50 \text{ W/m}^2 \cdot \text{K} \cdot (2 \times 0.1 \text{ m} + 2 \times 0.001 \text{ m})}{240 \text{ W/m} \cdot \text{K} \times 0.1 \text{ m} \times 0.001 \text{ m}} \right)^{1/2} = 35.5 \text{ m}^{-1} \]

\[ mL = 35.5 \text{ m}^{-1} \times 0.012 \text{ m} = 0.43 \]

\[ \sinh mL = 0.439 \quad \tanh mL = 0.401 \quad \theta_o = 100 \text{ K} \quad \theta_L = 50 \text{ K} \]

\[ q_{f,o} = 240 \text{ W/m} \cdot \text{K} \times 0.1 \text{ m} \times 0.001 \text{ m} \times \begin{pmatrix} 100 \text{ K} \times 35.5 \text{ m}^{-1} \times 0.401 \end{pmatrix} - \begin{pmatrix} 50 \text{ K} \times 35.5 \text{ m}^{-1} \times 0.439 \end{pmatrix} \]

\[ q_{f,o} = 115.4 \text{ W} \quad \text{(from the top plate)} \]

\[ q_{f,L} = 240 \text{ W/m} \cdot \text{K} \times 0.1 \text{ m} \times 0.001 \text{ m} \times \begin{pmatrix} 100 \text{ K} \times 35.5 \text{ m}^{-1} \times 0.439 \end{pmatrix} - \begin{pmatrix} 50 \text{ K} \times 35.5 \text{ m}^{-1} \times 0.401 \end{pmatrix} \]

\[ q_{f,L} = 87.8 \text{ W}. \quad \text{(into the bottom plate)} \]

Maximum power dissipations are therefore

\[ q_{o,max} = N_f q_{f,o} + (W - N_f t) Dh \theta_o \]

\[ q_{o,max} = 50 \times 115.4 \text{ W} + (0.200 - 50 \times 0.001) \text{ m} \times 0.1 \text{ m} \times 150 \text{ W/m}^2 \cdot \text{K} \times 100 \text{ K} \]

\[ q_{o,max} = 5770 \text{ W} + 225 \text{ W} = 5995 \text{ W} \]

\[ q_{L,max} = -N_f q_{f,L} + (W - N_f t) Dh \theta_o \]

\[ q_{L,max} = -50 \times 87.8 \text{ W} + (0.200 - 50 \times 0.001) \text{ m} \times 0.1 \text{ m} \times 150 \text{ W/m}^2 \cdot \text{K} \times 50 \text{ K} \]

\[ q_{L,max} = -4390 \text{ W} + 112 \text{ W} = -4278 \text{ W}. \]

**COMMENTS:**

(1) It is of interest to determine the air velocity needed to prevent excessive heating of the air as it passes between the plates. If the air temperature change is restricted to \( \Delta T_\infty = 5 \text{ K} \), its flowrate must be

\[ \dot{m}_{air} = \frac{q_{tot}}{c_p \Delta T_\infty} = \frac{1717 \text{ W}}{1007 \text{ J/kg} \cdot \text{K} \times 5 \text{ K}} = 0.34 \text{ kg/s}. \]

Its mean velocity is then

\[ V_{air} = \frac{\dot{m}_{air}}{\rho_{air} A_c} = \frac{0.34 \text{ kg/s}}{1.16 \text{ kg/m}^3 \times 0.012 \text{ m} (0.2 - 50 \times 0.001) \text{ m}} = 163 \text{ m/s}. \]

Such a velocity would be impossible to maintain. To reduce it to a reasonable value, e.g. 10 m/s, \( A_c \) would have to be increased substantially by increasing \( W \) (and hence the space between fins) and by increasing \( L \). The present configuration is impractical from the standpoint that 1717 W could not be transferred to air in such a small volume.

(2) A negative value of \( q_{L,max} \) implies that heat must be transferred from the bottom plate to the air to maintain the plate at 350 K.
PROBLEM 3.131

KNOWN: Conditions associated with an array of straight rectangular fins.

FIND: Thermal resistance of the array.

SCHEMATIC:

ASSUMPTIONS: (1) Constant properties, (2) Uniform convection coefficient, (3) Symmetry about midplane.

ANALYSIS: (a) Considering a one-half section of the array, the corresponding resistance is

\[ R_{t,o} = (\eta_t h A_t)^{-1} \]

where \( A_t = N A_f + A_b \). With \( S = 4 \text{ mm} \) and \( t = 1 \text{ mm} \), it follows that \( N = W_1 / S = 250 \), \( A_f = 2(L/2)W_2 = 0.008 \text{ m}^2 \), \( A_b = W_2(W_1 - Nt) = 0.75 \text{ m}^2 \), and \( A_t = 2.75 \text{ m}^2 \).

The overall surface efficiency is

\[ \eta_o = 1 - \frac{N A_f}{A_t} (1 - \eta_t) \]

where the fin efficiency is

\[ \eta_f = \frac{\tanh m (L/2)}{m (L/2)} \quad \text{and} \quad m = \left( \frac{hP}{k A_c} \right)^{1/2} = \left[ \frac{h(2t + 2W_2)}{ktW_2} \right]^{1/2} = \left( \frac{2h}{kt} \right)^{1/2} = 38.7 \text{ m}^{-1} \]

With \( m(L/2) = 0.155 \), it follows that \( \eta_f = 0.992 \) and \( \eta_o = 0.994 \). Hence

\[ R_{t,o} = \left( 0.994 \times 150 \frac{W}{m^2} \cdot K \times 2.75 \text{ m}^{-2} \right)^{-1} = 2.44 \times 10^{-3} \text{ K/W} \]

(b) The requirements that \( t \geq 0.5 \text{ m} \) and \( (S - t) > 2 \text{ mm} \) are based on manufacturing and flow passage restriction constraints. Repeating the foregoing calculations for representative values of \( t \) and \( (S - t) \), we obtain

COMMENTS: Clearly, the thermal performance of the fin array improves \( (R_{t,o} \) decreases) with increasing \( N \). Because \( \eta_f = 1 \) for the entire range of conditions, there is a slight degradation in performance \( (R_{t,o} \) increases) with increasing \( t \) and fixed \( N \). The reduced performance is associated with the reduction in surface area of the exposed base. Note that the overall thermal resistance for the entire fin array (top and bottom) is \( R_{t,o}/2 = 1.22 \times 10^{-2} \text{ K/W} \).
PROBLEM 3.132

KNOWN: Width and maximum allowable temperature of an electronic chip. Thermal contact resistance between chip and heat sink. Dimensions and thermal conductivity of heat sink. Temperature and convection coefficient associated with air flow through the heat sink.

FIND: (a) Maximum allowable chip power for heat sink with prescribed number of fins, fin thickness, and fin pitch, and (b) Effect of fin thickness/number and convection coefficient on performance.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) One-dimensional heat transfer, (3) Isothermal chip, (4) Negligible heat transfer from top surface of chip, (5) Negligible temperature rise for air flow, (6) Uniform convection coefficient associated with air flow through channels and over outer surfaces of heat sink, (7) Negligible radiation.

ANALYSIS: (a) From the thermal circuit,

\[
q_c = \frac{T_c - T_\infty}{R_{tot}} = \frac{T_c - T_\infty}{R_{t,c} + R_{t,b} + R_{t,o}}
\]

where \(R_{t,c} = R_{t,c}^* / W^2 = 2 \times 10^{-6} \text{m}^2 \cdot \text{K} / \text{W} \cdot (0.02 \text{m})^2 = 0.005 \text{K} / \text{W}\) and \(R_{t,b} = L_b / k \left(W^2\right) = 0.003 \text{m} / 180 \text{W} / \text{m} \cdot \text{K} (0.02 \text{m})^2 = 0.042 \text{K} / \text{W}\). From Eqs. (3.103), (3.102), and (3.99)

\[
R_{t,o} = \frac{1}{\eta_0 h A_t}
\]

\(\eta_0 = 1 - \frac{N A_f}{A_t} (1 - \eta_f)\), \(A_t = N A_f + A_b\)

where \(A_f = 2 WL_f = 2 \times 0.02 \text{m} \times 0.015 \text{m} = 6 \times 10^{-4} \text{m}^2\) and \(A_b = W^2 - N(W) = (0.02 \text{m})^2 - 11(0.182 \times 10^{-3} \text{m} \times 0.02 \text{m}) = 3.6 \times 10^{-4} \text{m}^2\). With \(mL_f = (2h/kt)^{1/2} L_f = (200 \text{W} / \text{m}^2 \cdot \text{K} / 180 \text{W} / \text{m} \cdot \text{K} \times 0.182 \times 10^{-3} \text{m})^{1/2} (0.015 \text{m}) = 1.17\), \(\tanh mL_f = 0.824\) and Eq. (3.87) yields

\[
\eta_f = \frac{\tanh mL_f}{mL_f} = \frac{0.824}{1.17} = 0.704
\]

It follows that \(A_t = 6.96 \times 10^{-3} \text{m}^2\), \(\eta_0 = 0.719\), \(R_{t,o} = 2.00 \text{K} / \text{W}\), and

\[
q_c = \frac{(85 - 20)\degree \text{C}}{(0.005 + 0.042 + 2.00) \text{K} / \text{W}} = 31.8 \text{W}
\]

(b) The following results are obtained from parametric calculations performed to explore the effect of decreasing the number of fins and increasing the fin thickness.

</table>

Although \( \eta_f \) (and \( \eta_o \)) increases with decreasing N (increasing t), there is a reduction in \( A_t \) which yields a minimum in \( R_{t,o} \), and hence a maximum value of \( q_c \), for N = 10. For N = 11, the effect of \( h \) on the performance of the heat sink is shown below.

With increasing \( h \) from 100 to 1000 W/m\(^2\)-K, \( R_{t,o} \) decreases from 2.00 to 0.47 K/W, despite a decrease in \( \eta_f \) (and \( \eta_o \)) from 0.704 (0.719) to 0.269 (0.309). The corresponding increase in \( q_c \) is significant.

**COMMENTS:** The heat sink significantly increases the allowable heat dissipation. If it were not used and heat was simply transferred by convection from the surface of the chip with \( h = 100 \) W/m\(^2\)-K, \( R_{tot} = 2.05 \) K/W from Part (a) would be replaced by \( R_{cnv} = 1/hW^2 = 25 \) K/W, yielding \( q_c = 2.60 \) W.
PROBLEM 3.133

KNOWN: Number and maximum allowable temperature of power transistors. Contact resistance between transistors and heat sink. Dimensions and thermal conductivity of heat sink. Temperature and convection coefficient associated with air flow through and along the sides of the heat sink.

FIND: (a) Maximum allowable power dissipation per transistor, (b) Effect of the convection coefficient and fin length on the transistor power.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) One-dimensional heat transfer, (3) Isothermal transistors, (4) Negligible heat transfer from top surface of heat sink (all heat transfer is through the heat sink), (5) Negligible temperature rise for the air flow, (6) Uniform convection coefficient, (7) Negligible radiation.

ANALYSIS: (a) From the thermal circuit,

\[ N_t q_t = \frac{T_t - T_\infty}{(R_{t,c})_{equiv} + R_{t,b} + R_{t,o}} \]

For the array of transistors, the corresponding contact resistance is the equivalent resistance associated with the component resistances, in which case,

\[ (R_{t,c})_{equiv} = \left[N_t \left(\frac{1}{R_{t,c}}\right)\right]^{-1} = \left(\frac{9}{0.045 \text{ K/W}}\right)^{-1} = 5 \times 10^{-3} \text{ K/W} \]

The thermal resistance associated with the base of the heat sink is

\[ R_{t,b} = \frac{L_b}{k \left(W^2\right)} = \frac{0.006 \text{ m}}{180 \text{ W/m} \cdot \text{K} \left(0.15 \text{ m}\right)^2} = 1.48 \times 10^{-3} \text{ K/W} \]

From Eqs. (3.103), (3.102) and (3.99), the thermal resistance associated with the fin array and the corresponding overall efficiency and total surface area are

\[ R_{t,o} = \frac{1}{\eta_0 h A_t}, \quad \eta_0 = 1 - \frac{N_f A_f}{A_t} (1 - \eta_f), \quad A_t = N_f A_f + A_b \]

Each fin has a surface area of \( A_f \approx 2 \text{ W/L}_f = 2 \times 0.15 \text{ m} \times 0.03 \text{ m} = 9 \times 10^{-3} \text{ m}^2 \), and the area of the exposed base is \( A_b = W^2 - N_f (tW) = (0.15 \text{ m})^2 - 25 (0.003 \text{ m} \times 0.15 \text{ m}) = 1.13 \times 10^{-2} \text{ m}^2 \). With \( mL_f = (2h/kt)^{1/2} L_f = (200 \text{ W/m}^2 \cdot \text{K}/180 \text{ W/m} \cdot \text{K} \times 0.003 \text{ m})^{1/2} (0.03 \text{ m}) = 0.577, \tan \eta_f mL_f = 0.520 \) and Eq. (3.87) yields

\[ \eta_f = \frac{\tanh mL_f}{mL_f} = \frac{0.520}{0.577} = 0.902 \]

Hence, with \( A_t = [25 (9 \times 10^{-3}) + 1.13 \times 10^{-2}] \text{m}^2 = 0.236 \text{m}^2 \)

Continued …..
\( \eta_0 = 1 - \frac{25(0.009\text{m}^2)}{0.236\text{m}^2}(1 - 0.901) = 0.907 \)

\( R_{t,o} = \left(0.907 \times 100 \text{ W/m}^2\cdot\text{K} \times 0.236\text{m}^2\right)^{-1} = 0.0467 \text{ K/W} \)

The heat rate per transistor is then
\[
q_t = \frac{1}{9} \frac{(100 - 27)\degree\text{C}}{0.0050 + 0.0015 + 0.0467} = 152 \text{ W}
\]

(b) As shown below, the transistor power dissipation may be enhanced by increasing \( h \) and/or \( L_f \).

However, in each case, the effect of the increase diminishes due to an attendant reduction in \( \eta_f \). For example, as \( h \) increases from 100 to 1000 W/m\(^2\cdot\text{K} \) for \( L_f = 30 \text{ mm} \), \( \eta_f \) decreases from 0.902 to 0.498.

**COMMENTS:** The heat sink significantly increases the allowable transistor power. If it were not used and heat was simply transferred from a surface of area \( W^2 = 0.0225 \text{ m}^2 \) with \( h = 100 \text{ W/m}^2\cdot\text{K} \), the corresponding thermal resistance would be \( R_{t,\text{cvn}} = (hW^2)^{-1} \text{ K/W} = 0.44 \) and the transistor power would be \( q_t = (T_t - T_\infty)/N_t R_{t,\text{cvn}} = 18.4 \text{ W} \).
**PROBLEM 3.134**

**KNOWN:** Geometry and cooling arrangement for a chip-circuit board arrangement. Maximum chip temperature.

**FIND:** (a) Equivalent thermal circuit, (b) Maximum chip heat rate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional heat transfer in chip-board assembly, (3) Negligible pin-chip contact resistance, (4) Constant properties, (5) Negligible chip thermal resistance, (6) Uniform chip temperature.

**PROPERTIES:** Table A.1, Copper (300 K): \( k \approx 400 \text{ W/m-K} \).

**ANALYSIS:**

(a) The thermal circuit is

\[
\begin{align*}
R_f &= \frac{\theta_b}{16 q_f} = \frac{\cosh mL + (h_o / mk) \sinh mL}{16(q_o PkA_c,f)^{1/2} \left[ \sinh mL + (h_o / mk) \cosh mL \right]} \\
\end{align*}
\]

(b) The maximum chip heat rate is

\[
q_c = 16 q_f + q_b + q_i
\]

Evaluate these parameters

\[
m = \left( \frac{h_o P}{kA_c,f} \right)^{1/2} = \left( \frac{4h_o}{kD_p} \right)^{1/2} = \left( \frac{4 	imes 1000 \text{ W/m}^2 \cdot \text{K}}{400 \text{ W/m} \cdot \text{K} \times 0.0015 \text{ m}} \right)^{1/2} = 81.7 \text{ m}^{-1}
\]

\[
mL = (81.7 \text{ m}^{-1} \times 0.015 \text{ m}) = 1.23, \quad \sinh mL = 1.57, \quad \cosh mL = 1.86
\]

\[
(h/mk) = \frac{1000 \text{ W/m}^2 \cdot \text{K}}{81.7 \text{ m}^{-1} \times 400 \text{ W/m} \cdot \text{K}} = 0.0306
\]

\[
M = \left( h_o \pi D_p k \pi D_p^2 / 4 \right)^{1/2} \theta_b
\]

\[
M = \left[ 1000 \text{ W/m}^2 \cdot \text{K} \left( \frac{\pi^2}{4} \right)(0.0015 \text{ m})^3 \times 400 \text{ W/m} \cdot \text{K} \right]^{1/2} \left( 55^\circ \text{C} \right) = 3.17 \text{ W.}
\]

Continued ….
PROBLEM 3.134 (Cont.)

The fin heat rate is

\[
q_f = M \frac{\sinh mL + (h/mk) \cosh mL}{\cosh mL + (h/mk) \sinh mL} = 3.17 \frac{W}{1.57 + 0.0306 \times 1.86}{1.86 + 0.0306 \times 1.57}
\]

\[q_f = 2.703 \text{ W}.
\]

The heat rate from the board by convection is

\[
q_b = h_o A_b \theta_b = 1000 \text{ W/m}^2 \cdot \text{K} \left[ (0.0127 \text{ m})^2 - \left( \frac{16\pi}{4} \right) (0.0015 \text{ m})^2 \right] 55^\circ \text{C}
\]

\[q_b = 7.32 \text{ W}.
\]

The convection heat rate is

\[
q_i = \frac{T_c - T_{\infty,i}}{\left( 1/h_i + R^*_t,c + L_b / k_b \right) (1/A_c)} = \frac{(0.0127 \text{ m})^2 \left( 55^\circ \text{C} \right)}{(1/40 + 10^{-4} + 0.005/1) \text{m}^2 \cdot \text{K/W}}
\]

\[q_i = 0.29 \text{ W}.
\]

Hence, the maximum chip heat rate is

\[
q_c = \left[ 16 \times (2.703) + 7.32 + 0.29 \right] \text{W} = [43.25 + 7.32 + 0.29] \text{W}
\]

\[q_c = 50.9 \text{ W}.
\]

**COMMENTS:**

(1) The fins are extremely effective in enhancing heat transfer from the chip (assuming negligible contact resistance). Their effectiveness is \(\epsilon = q_f / \left( \pi \frac{D_f^2}{4} \right) h_o \theta_b = 2.703 \text{ W/0.097 W} = 27.8\)

(2) Without the fins, \(q_c = 1000 \text{ W/m}^2 \cdot \text{K} (0.0127 \text{ m})^2 55^\circ \text{C} + 0.29 \text{ W} = 9.16 \text{ W}. \) Hence the fins provide for a \((50.9 \text{ W}/9.16 \text{ W}) \times 100\% = 555\%\) enhancement of heat transfer.

(3) With the fins, the chip heat flux is \(50.9 \text{ W}/(0.0127 \text{ m})^2 \) or \(q_c^* = 3.16 \times 10^5 \text{ W/m}^2 = 31.6 \text{ W/cm}^2\).

(4) If the infinite fin approximation is made, \(q_f = M = 3.17 \text{ W}, \) and the actual fin heat transfer is overestimated by 17\%.
**PROBLEM 3.135**

**KNOWN:** Geometry of pin fin array used as heat sink for a computer chip. Array convection and chip substrate conditions.

**FIND:** Effect of pin diameter, spacing and length on maximum allowable chip power dissipation.

**SCHEMATIC:**

Physical System:

![Diagram of physical system with relevant labels and conditions.]

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional heat transfer in chip-board assembly, (3) Negligible pin-chip contact resistance, (4) Constant properties, (5) Negligible chip thermal resistance, (6) Uniform chip temperature.

**ANALYSIS:** The total power dissipation is $q_c = q_i + q_t$, where

$$ q_i = \frac{T_c - T_{\infty,i}}{\left(1/h_i + R_{t,c} + L_b/k_b\right)/A_c} = 0.3 \text{W} $$

and

$$ q_t = \frac{T_c - T_{\infty,o}}{R_{t,o}} $$

The resistance of the pin array is

$$ R_{t,o} = \left(\eta_0 h_o A_t\right)^{-1} $$

where

$$ \eta_0 = 1 - \frac{NA_f}{A_t} (1 - \eta_f) $$

$$ A_t = NA_f + A_b $$

$$ A_f = \pi D_p L_c = \pi D_p \left(L_p + D_p/4\right) $$

Subject to the constraint that $N^{1/2}D_p \leq 9 \text{ mm}$, the foregoing expressions may be used to compute $q_i$ as a function of $D_p$ for $L_p = 15 \text{ mm}$ and values of $N = 16, 25$ and $36$. Using the IHT Performance Calculation, Extended Surface Model for the Pin Fin Array, we obtain

Continued...
Clearly, it is desirable to maximize the number of pins and the pin diameter, so long as flow passages are not constricted to the point of requiring an excessive pressure drop to maintain the prescribed convection coefficient. The maximum heat rate for the fin array ($q_t = 33.1$ W) corresponds to $N = 36$ and $D_p = 1.5$ mm. Further improvement could be obtained by using $N = 49$ pins of diameter $D_p = 1.286$ mm, which yield $q_t = 37.7$ W.

Exploring the effect of $L_p$ for $N = 36$ and $D_p = 1.5$ mm, we obtain

Clearly, there are benefits to increasing $L_p$, although the effect diminishes due to an attendant reduction in $\eta_f$ (from $\eta_f = 0.887$ for $L_p = 15$ mm to $\eta_f = 0.471$ for $L_p = 50$ mm). Although a heat dissipation rate of $q_t = 56.7$ W is obtained for $L_p = 50$ mm, package volume constraints could preclude such a large fin length.

**COMMENTS:** By increasing $N$, $D_p$ and/or $L_p$, the total surface area of the array, $A_t$, is increased, thereby reducing the array thermal resistance, $R_{t,o}$. The effects of $D_p$ and $N$ are shown for $L_p = 15$ mm.
PROBLEM 3.136

KNOWN: Copper heat sink dimensions and convection conditions.

FIND: (a) Maximum allowable heat dissipation for a prescribed chip temperature and interfacial chip/heat-sink contact resistance, (b) Effect of fin length and width on heat dissipation.

SCHEMATIC:

ANALYSIS: (a) For the prescribed system, the chip power dissipation may be expressed as

\[ q_c = \frac{T_c - T_\infty}{R_{t,c} + R_{\text{cond},b} + R_{t,o}} \]

where

\[ R_{t,c} = \frac{R_{t,c}^*}{W_c^2} = \frac{5 \times 10^{-6} \text{m}^2 \cdot \text{K/W}}{(0.016\text{m})^2} = 0.0195 \text{K/W} \]

\[ R_{\text{cond},b} = \frac{L_b}{kW_c^2} = \frac{0.003\text{m}}{400 \text{W/m} \cdot \text{K}(0.016\text{m})^2} = 0.0293 \text{K/W} \]

The thermal resistance of the fin array is

\[ R_{t,o} = (\eta_0 h A_t)^{-1} \]

where

\[ \eta_0 = 1 - \frac{N_{A_f}}{A_t} (1 - \eta_f) \]

and

\[ A_t = N_{A_f} + A_b = N (4wL_c) + \left(W_c^2 - Nw^2\right) \]

Continued...
With \( w = 0.25 \) mm, \( S = 0.50 \) mm, \( L_f = 6 \) mm, \( N = 1024 \), and \( L_c = L_f + w/4 = 6.063 \times 10^{-3} \) m, it follows that \( A_f = 6.06 \times 10^{-6} \) m\(^2\) and \( A_t = 6.40 \times 10^{-3} \) m\(^2\). The fin efficiency is

\[
\eta_f = \frac{\tanh mL_c}{mL_c}
\]

where \( m = (hP/kA_C)^{1/2} = (4h/kw)^{1/2} = 245 \) m\(^{-1}\) and \( mL_c = 1.49 \). It follows that \( \eta_f = 0.608 \) and \( \eta_o = 0.619 \), in which case

\[
R_{t,o} = \left(0.619 \times 1500 \text{ W/m}^2 \cdot \text{K} \times 6.40 \times 10^{-3} \text{ m}^2 \right) = 0.168 \text{ K/W}
\]

and the maximum allowable heat dissipation is

\[
q_c = \frac{(85 - 25)^{C}}{(0.0195 + 0.0293 + 0.168) \text{K/W}} = 276 \text{ W}
\]

(b) The IHT Performance Calculation, Extended Surface Model for the Pin Fin Array has been used to determine \( q_c \) as a function of \( L_f \) for four different cases, each of which is characterized by the closest allowable fin spacing of \((S - w) = 0.25 \) mm.

<table>

</tbody>
</table>

With increasing \( w \) and hence decreasing \( N \), there is a reduction in the total area \( A_t \) associated with heat transfer from the fin array. However, for Cases A through C, the reduction in \( A_t \) is more than balanced by an increase in \( \eta_f \) (and \( \eta_o \)), causing a reduction in \( R_{t,o} \) and hence an increase in \( q_c \).

As the fin efficiency approaches its limiting value of \( \eta_f = 1 \), reductions in \( A_t \) due to increasing \( w \) are no longer balanced by increases in \( \eta_f \), and \( q_c \) begins to decrease. Hence there is an optimum value of \( w \), which depends on \( L_f \). For the conditions of this problem, \( L_f = 10 \) mm and \( w = 0.55 \) mm provide the largest heat dissipation.
Problem 3.137

**KNOWN:** Two finned heat sinks, Designs A and B, prescribed by the number of fins in the array, \( N \), fin dimensions of square cross-section, \( w \), and length, \( L \), with different convection coefficients, \( h \).

**FIND:** Determine which fin arrangement is superior. Calculate the heat rate, \( q_f \), efficiency, \( \eta_f \), and effectiveness, \( \varepsilon_f \), of a single fin, as well as, the total heat rate, \( q_t \), and overall efficiency, \( \eta_o \), of the array. Also, compare the total heat rates per unit volume.

**SCHEMATIC:**

![Schematic diagram of finned heat sinks](image)

<table>

</tbody>
</table>

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional conduction in fins, (3) Convection coefficient is uniform over fin and prime surfaces, (4) Fin tips experience convection, and (5) Constant properties.

**ANALYSIS:** Following the treatment of Section 3.6.5, the overall efficiency of the array, Eq. (3.98), is

\[
\eta_o = \frac{\eta_f}{\eta_{\text{max}}} = \frac{q_t}{hA_t\theta_b}
\]  

(1)

where \( A_t \) is the total surface area, the sum of the exposed portion of the base (prime area) plus the fin surfaces, Eq. 3.99,

\[
A_t = N \cdot A_f + A_b
\]  

(2)

where the surface area of a single fin and the prime area are

\[
A_f = 4(L \times W) + w^2
\]  

(3)

\[
A_b = b_1 \times b_2 - N \cdot A_c
\]  

(4)

Combining Eqs. (1) and (2), the total heat rate for the array is

\[
q_t = N \eta_f hA_f\theta_b + hA_b\theta_b
\]  

(5)

where \( \eta_f \) is the efficiency of a single fin. From Table 4.3, Case A, for the tip condition with convection, the single fin efficiency based upon Eq. 3.86,

\[
\eta_f = \frac{q_f}{hA_f\theta_b}
\]  

(6)

Continued...
where
\[ q_f = M \frac{\sinh(mL) + (h/mk)\cosh(mL)}{\cosh(mL) + (h/mk)\sinh(mL)} \]  
\[ M = (hP/kA_c)^{1/2} \theta_b \quad m = (hP/kA_c)^{1/2} \quad P = 4w \quad A_c = w^2 \quad (7,8,9,10) \]
The single fin effectiveness, from Eq. 3.81,
\[ \epsilon_f = \frac{q_f}{hA_c\theta_b} \]  
Additionally, we want to compare the performance of the designs with respect to the array volume, vol
\[ q_{f}^\prime = q_f /\forall = q_f / (bl \cdot b2 \cdot L) \]  
The above analysis was organized for easy treatment with equation-solving software. Solving Eqs. (1) through (11) simultaneously with appropriate numerical values, the results are tabulated below.

</tbody>
</table>

**COMMENTS:**
(1) Both designs have good efficiencies and effectiveness. Clearly, Design B is superior because the heat rate is nearly 50% larger than Design A for the same board footprint. Further, the space requirement for Design B is four times less (\( \forall = 2.12\times10^{-5} \) vs. \( 9.06\times10^{-5} \) m^3) and the heat rate per unit volume is 6 times greater.

(2) Design A features 54 fins compared to 238 fins for Design B. Also very significant to the performance comparison is the magnitude of the convection coefficient which is 3 times larger for Design B. Estimating convection coefficients for fin arrays (and tube banks) is discussed in Chapter 7.6. Of concern is how the fins alter the flow past the fins and whether the convection coefficient is uniform over the array.

(3) The *IHT Extended Surfaces Model*, for a *Rectangular Pin Fin Array* could have been used to solve this problem.
PROBLEM 3.138

KNOWN: Geometrical characteristics of a plate with pin fin array on both surfaces. Inner and outer convection conditions.

FIND: (a) Heat transfer rate with and without pin fin arrays, (b) Effect of using silver solder to join the pins and the plate.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant k, (3) Negligible radiation.

PROPERTIES: Table A-1: Copper, $\bar{T} = 315$ K, $k = 400$ W/m·K.

ANALYSIS: (a) The heat rate may be expressed as

$$q = \frac{T_{\infty,i} - T_{\infty,o}}{R_{t,0(c),i} + R_w + R_{t,0(c),o}}$$

where

$$R_{t,0(c)} = \left( \eta_{0(c)} \frac{hA_t}{A_t} \right)^{-1},$$

$$\eta_{0(c)} = 1 - \frac{N A_f}{A_t} \left( 1 - \frac{\eta_f}{C_1} \right),$$

$$A_t = N A_f + A_b,$$

$$A_f = \pi D_p L_c = \pi D_p (L + D/4),$$

$$A_b = W^2 - N A_{c,b} = W^2 - N \left( \pi D_p^2 / 4 \right),$$

$$\eta_f = \frac{\tanh mL_c}{mL_c}, \quad m = \left( \frac{4h/kD_p}{} \right)^{1/2},$$

Continued...
PROBLEM 3.138 (Cont.)

\[ C_1 = 1 + \eta_f h A_f \left( R_{t,c}^* / A_{c,b} \right), \]

and

\[ R_w = \frac{L_w}{W^2 k}. \]

Calculations may be expedited by using the IHT Performance Calculation, Extended Surface Model for the Pin Fin Array. For \( R_{t,c}^* = 0, C_1 = 1, \) and with \( W = 0.160 \text{ m}, R_w = 0.005 \text{ m/(0.160 m)}^2 400 \text{ W/m-K} = 4.88 \times 10^{-4} \text{ K/W}. \) For the prescribed array geometry, we also obtain \( A_{c,b} = 1.26 \times 10^{-5} \text{ m}^2, A_f = 2.64 \times 10^{-4} \text{ m}^2, A_b = 2.06 \times 10^{-2} \text{ m}^2, \) and \( A_t = 0.126 \text{ m}^2. \)

On the outer surface, where \( h_o = 100 \text{ W/m}^2 \cdot \text{K}, m = 15.8 \text{ m}^{-1}, \eta_f = 0.965, \eta_o = 0.970 \) and \( R_{t,o} = 0.0817 \text{ K/W}. \) On the inner surface, where \( h_i = 5 \text{ W/m}^2 \cdot \text{K}, m = 3.54 \text{ m}^{-1}, \eta_f = 0.998, \eta_o = 0.999 \) and \( R_{t,o} = 1.588 \text{ K/W}. \)

Hence, the heat rate is

\[ q = \frac{(65 - 20) ^\circ \text{C}}{1.588 + 4.88 \times 10^{-4} + 0.0817} \text{K/W} = 26.94 \text{W} \]

Without the fins,

\[ q = \frac{T_{\text{oo},i} - T_{\text{oo},o}}{(1/h_i A_w) + R_w + (1/h_o A_w)} = \frac{(65 - 20) ^\circ \text{C}}{7.81 + 4.88 \times 10^{-4} + 0.39} = 5.49 \text{W} \]

Hence, the fin arrays provide nearly a five-fold increase in heat rate.

(b) With use of the silver solder, \( \eta_{o(c),o} = 0.962 \) and \( R_{t,o(c),o} = 0.0824 \text{ K/W}. \) Also, \( \eta_{o(c),i} = 0.998 \) and \( R_{t,o(c),i} = 1.589 \text{ K/W}. \) Hence

\[ q = \frac{(65 - 20) ^\circ \text{C}}{1.589 + 4.88 \times 10^{-4} + 0.0824} \text{K/W} = 26.92 \text{W} \]

Hence, the effect of the contact resistance is negligible.

COMMENTS: The dominant contribution to the total thermal resistance is associated with internal conditions. If the heat rate must be increased, it should be done by increasing \( h_i. \)
**PROBLEM 3.139**

**KNOWN:** Long rod with internal volumetric generation covered by an electrically insulating sleeve and supported with a ribbed spider.

**FIND:** Combination of convection coefficient, spider design, and sleeve thermal conductivity which enhances volumetric heating subject to a maximum centerline temperature of 100°C.

**SCHEMATIC:**

![Diagram of rod with internal volumetric generation, covered by an electrically insulating sleeve and supported with a ribbed spider.]

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional radial heat transfer in rod, sleeve and hub, (3) Negligible interfacial contact resistances, (4) Constant properties, (5) Adiabatic outer surface.

**ANALYSIS:** The system heat rate per unit length may be expressed as

\[
q' = \dot{q} \left( \pi r_o^2 \right) = \frac{T_1 - T_\infty}{R'_{\text{sleeve}} + R'_{\text{hub}} + R'_{t,o}}
\]

where

\[
R'_{\text{sleeve}} = \frac{\ln \left( \eta_0 / \eta_f \right)}{2\pi k_s}, \quad R'_{\text{hub}} = \frac{\ln \left( r_2 / \eta_0 \right)}{2\pi k_f} = 3.168 \times 10^{-4} \text{ m} \cdot \text{K} / \text{W}, \quad R'_{t,o} = \frac{1}{\eta_0 h A_t'},
\]

\[
\eta_0 = 1 - \frac{N A_t'}{A_t} \left( 1 - \eta_f \right), \quad A_t' = 2 \left( r_3 - r_2 \right), \quad A_t = NA_t' + (2\pi r_3 - Nt),
\]

\[
\eta_f = \frac{\tanh m \left( r_3 - r_2 \right)}{m \left( r_3 - r_2 \right)}, \quad m = (2h/k_f t)^{1/2}.
\]

The rod centerline temperature is related to \( T_1 \) through

\[
T_0 = T(0) = T_1 + \frac{\dot{q}t_o^2}{4k}
\]

Calculations may be expedited by using the IHT Performance Calculation, Extended Surface Model for the Straight Fin Array. For base case conditions of \( k_s = 0.5 \text{ W/m-K}, \ h = 20 \text{ W/m}^2 \cdot \text{K}, \ t = 4 \text{ mm} \text{ and } N = 12, \ R'_{\text{sleeve}} = 0.0580 \text{ m K/W}, \ R'_{t,o} = 0.0826 \text{ m K/W}, \ \eta_f = 0.990, \ q' = 387 \text{ W/m}, \text{ and } \dot{q} = 1.23 \times 10^6 \text{ W/m}^3. \text{ As shown below, } \dot{q} \text{ may be increased by increasing } h, \text{ where } h = 250 \text{ W/m}^2 \cdot \text{K} \text{ represents a reasonable upper limit for airflow. However, a more than 10-fold increase in } h \text{ yields only a 63% increase in } \dot{q}.\]

Continued...
The difficulty is that, by significantly increasing $h$, the thermal resistance of the fin array is reduced to 0.00727 m K/W, rendering the sleeve the dominant contributor to the total resistance.

Similar results are obtained when $N$ and $t$ are varied. For values of $t = 2, 3$ and $4$ mm, variations of $N$ in the respective ranges $12 \leq N \leq 26$, $12 \leq N \leq 21$ and $12 \leq N \leq 17$ were considered. The upper limit on $N$ was fixed by requiring that $(S - t) \geq 2$ mm to avoid an excessive resistance to airflow between the ribs. As shown below, the effect of increasing $N$ is small, and there is little difference between results for the three values of $t$.

In contrast, significant improvement is associated with changing the sleeve material, and it is only necessary to have $k_s \approx 25$ W/m-K (e.g., a boron sleeve) to approach an upper limit to the influence of $k_s$.

For $h = 250$ W/m$^2$K and $k_s = 25$ W/m-K, only a slight improvement is obtained by increasing $N$. Hence, the recommended conditions are:

$$h = 250 \text{ W/m}^2\text{K}, \quad k_s = 25 \text{ W/m} \cdot \text{K}, \quad N = 12, \quad t = 4 \text{mm}$$

**COMMENTS:** The upper limit to $\dot{q}$ is reached as the total thermal resistance approaches zero, in which case $T_1 \to T_\infty$. Hence $\dot{q}_{\text{max}} = 4k \left(T_\infty - T_1\right) / r_o^2 = 4.5 \times 10^6$ W/m$^3$. 
PROBLEM 3.140

KNOWN: Geometrical and convection conditions of internally finned, concentric tube air heater.

FIND: (a) Thermal circuit, (b) Heat rate per unit tube length, (c) Effect of changes in fin array.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat transfer in radial direction, (3) Constant k, (4) Adiabatic outer surface.

ANALYSIS: (a) For the thermal circuit shown schematically,

\[ R_{\text{conv},i} = \left( h_i 2\pi \eta \right)^{-1}, \quad R_{\text{cond}} = \ln \left( \frac{r_2}{r_1} \right)/2\pi k, \quad \text{and} \quad R'_{t,o} = \left( \eta_0 h_o A'_t \right)^{-1}, \]

where \( \eta_0 = 1 - \frac{N A'_f}{A'_t} \left( 1 - \eta_f \right), \quad A'_f = 2L = 2(r_3 - r_2), \quad A'_t = N A'_f + (2\pi r_2 - N t), \quad \text{and} \quad \eta_f = \frac{\tanh mL}{mL}. \)

(b) \[ q' = \frac{R'_{\text{conv},i} + R'_{\text{cond}} + R'_{t,o}}{R'_{\text{conv},i} + R'_{\text{cond}} + R'_{t,o}} \]

Substituting the known conditions, it follows that

\[ R_{\text{conv},i} = \left( \frac{5000 \text{ W}/\text{m}^2\cdot\text{K} \times 2\pi \times 0.013 \text{ m}}{2.45 \times 10^{-3} \text{ m} \cdot \text{K}/\text{W}} \right)^{-1} = 2.45 \times 10^{-3} \text{ m} \cdot \text{K}/\text{W} \]

\[ R'_{\text{cond}} = \ln \left( \frac{0.016 \text{ m}}{0.013 \text{ m}} \right)/2\pi \left( \frac{20 \text{ W}/\text{m} \cdot \text{K}}{2.45 \times 10^{-3} \text{ m} \cdot \text{K}/\text{W}} \right) = 1.65 \times 10^{-3} \text{ m} \cdot \text{K}/\text{W} \]

\[ R'_{t,o} = \left( \frac{0.575 \times 200 \text{ W}/\text{m}^2 \cdot \text{K} \times 0.461 \text{ m}}{2.45 \times 10^{-3} \text{ m} \cdot \text{K}/\text{W}} \right)^{-1} = 18.86 \times 10^{-3} \text{ m} \cdot \text{K}/\text{W} \]

where \( \eta_f = 0.490. \) Hence,

\[ q' = \frac{(90 - 25) \degree \text{C}}{2.45 + 1.65 + 18.86} \times 10^{-3} \text{ m} \cdot \text{K}/\text{W} = 2831 \text{ W/m} \]

(c) The small value of \( \eta_f \) suggests that some benefit may be gained by increasing \( t, \) as well as by increasing \( N. \) With the requirement that \( Nt \leq 50 \text{ mm}, \) we use the IHT Performance Calculation, Extended Surface Model for the Straight Fin Array to consider the following range of conditions: \( t = 2 \text{ mm, } 12 \leq N \leq 25; t = 3 \text{ mm, } 8 \leq N \leq 16; t = 4 \text{ mm, } 6 \leq N \leq 12; t = 5 \text{ mm, } 5 \leq N \leq 10. \) Calculations based on the foregoing model are plotted as follows.

Continued...
By increasing $t$ from 2 to 5 mm, $\eta_f$ increases from 0.410 to 0.598. Hence, for fixed $N$, $q'$ increases with increasing $t$. However, from the standpoint of maximizing $q'_f$, it is clearly preferable to use the larger number of thinner fins. Hence, subject to the prescribed constraint, we would choose $t = 2$ mm and $N = 25$, for which $q' = 4880$ W/m.

**COMMENTS:** (1) The air side resistance makes the dominant contribution to the total resistance, and efforts to increase $q'$ by reducing $R'_{t,o}$ are well directed. (2) A fin thickness any smaller than 2 mm would be difficult to manufacture.
PROBLEM 3.141

KNOWN: Dimensions and number of rectangular aluminum fins. Convection coefficient with and without fins.

FIND: Percentage increase in heat transfer resulting from use of fins.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties, (4) Negligible radiation, (5) Negligible fin contact resistance, (6) Uniform convection coefficient.

PROPERTIES: Table A-1, Aluminum, pure: \( k \approx 240 \text{ W/m} \cdot \text{K} \).

ANALYSIS: Evaluate the fin parameters

\[
L_c = L + \frac{t}{2} = 0.05025 \text{m}
\]

\[
A_p = L_c t = 0.05025 \text{m} \times 0.5 \times 10^{-3} \text{m} = 25.13 \times 10^{-6} \text{ m}^2
\]

\[
L_c^{3/2} \left( \frac{h_w}{kA_p} \right)^{1/2} = (0.05025 \text{m})^{3/2} \left[ \frac{30 \text{ W/m}^2 \cdot \text{K}}{240 \text{ W/m} \cdot \text{K} \times 25.13 \times 10^{-6} \text{ m}^2} \right]^{1/2}
\]

\[
L_c^{3/2} \left( \frac{h_w}{kA_p} \right)^{1/2} = 0.794
\]

It follows from Fig. 3.18 that \( \eta_f \approx 0.72 \). Hence,

\[
q_f = \eta_f q_{\text{max}} = 0.72 \times 30 \text{ W/m}^2 \cdot \text{K} \times 2 \times 20 \times 0.05 \times \text{m} \times (w \theta_b) = 2.16 \text{ W/m} \cdot \text{K} (w \theta_b)
\]

With the fins, the heat transfer from the walls is

\[
q_w = N q_f + (1 - Nt) w h_w \theta_b
\]

\[
q_w = 250 \times 2.16 \frac{W}{\text{m} \cdot \text{K}} (w \theta_b) + \left(1 - 250 \times 5 \times 10^{-4} \text{ m} \right) \times 30 \times 2 \text{ W/m}^2 \cdot \text{K} (w \theta_b)
\]

\[
q_w = (540 + 26.3) \frac{W}{\text{m} \cdot \text{K}} (w \theta_b) = 566 w \theta_b.
\]

Without the fins, \( q_{w_0} = h_w 1 \text{m} \times w \theta_b = 40 w \theta_b \). Hence the percentage increase in heat transfer is

\[
\frac{q_w - q_{w_0}}{q_{w_0}} = \frac{566 - 40}{40 w \theta_b} = 13.15 = 1315\%
\]

COMMENTS: If the infinite fin approximation is made, it follows that \( q_f = (hP\kappa_c)^{1/2} \theta_b \)

\[
= [h_w 2w k w t]^{1/2} \theta_b = (30 \times 2 \times 240 \times 5 \times 10^{-4})^{1/2} w \theta_b = 2.68 w \theta_b.
\]

Hence, \( q_f \) is overestimated.
**PROBLEM 3.142**

**KNOWN:** Dimensions, base temperature and environmental conditions associated with rectangular and triangular stainless steel fins.

**FIND:** Efficiency, heat loss per unit width and effectiveness associated with each fin.

**SCHEMATIC:**

![Schematic Diagram](Image)

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties, (4) Negligible radiation, (5) Uniform convection coefficient.

**PROPERTIES:** *Table A-1*, Stainless Steel 304 (T = 333 K): \( k = 15.3 \text{ W/m} \cdot \text{K} \).

**ANALYSIS:** For the rectangular fin, with \( L_c = L + t/2 \), evaluate the parameter

\[
L_c^{3/2} \left( \frac{h}{kA_p} \right)^{1/2} = (0.023 \text{ m})^{3/2} \left[ \frac{75 \text{ W/m}^2 \cdot \text{K}}{15.3 \text{ W/m} \cdot \text{K} (0.023 \text{ m})(0.006 \text{ m})} \right]^{1/2} = 0.66.
\]

Hence, from Fig. 3.18, the fin efficiency is

\( \eta_f \approx 0.79 \).

From Eq. 3.86, the fin heat rate is

\[
q_f = \eta_f hA_f \theta_b = \eta_f hP \theta_c \theta_b = \eta_f h2wL_c \theta_b \quad \text{or, per unit width,}
\]

\[
q'_f = \frac{q_f}{w} = 0.79 \left( 75 \text{ W/m}^2 \cdot \text{K} \right) 2(0.023 \text{ m})80^\circ \text{C} = 218 \text{ W/m}.
\]

From Eq. 3.81, the fin effectiveness is

\[
\epsilon_f = \frac{q_f \times w}{hA_c \theta_b} = \frac{218 \text{ W/m}}{75 \text{ W/m}^2 \cdot \text{K} (0.006 \text{ m})80^\circ \text{C}} = 6.06.
\]

For the triangular fin with

\[
L_c^{3/2} \left( \frac{h}{kA_p} \right)^{1/2} = (0.02 \text{ m})^{3/2} \left[ \frac{75 \text{ W/m}^2 \cdot \text{K}}{(15.3 \text{ W/m} \cdot \text{K})(0.020 \text{ m})(0.003 \text{ m})} \right]^{1/2} = 0.81,
\]

find from Figure 3.18,

\( \eta_f \approx 0.78 \).

From Eq. 3.86 and Table 3.5 find

\[
q'_f = \eta_f hA'_f \theta_b = \eta_f h2 \left[ L^2 + (t/2)^2 \right]^{1/2} \theta_b
\]

\[
q'_f = 0.78 \times 75 \text{ W/m}^2 \cdot \text{K} \times 2 \left[ (0.02)^2 + (0.006/2)^2 \right]^{1/2} \text{m} (80^\circ \text{C}) = 187 \text{ W/m}.
\]

and from Eq. 3.81, the fin effectiveness is

\[
\epsilon_f = \frac{q_f \times w}{h(t \times w) \theta_b} = \frac{187 \text{ W/m}}{75 \text{ W/m}^2 \cdot \text{K}(0.006 \text{ m})80^\circ \text{C}} = 5.19.
\]

**COMMENTS:** Although it is 14% less effective, the triangular fin offers a 50% weight savings.
**PROBLEM 3.143**

**KNOWN:** Dimensions, base temperature and environmental conditions associated with a triangular, aluminum fin.

**FIND:** (a) Fin efficiency and effectiveness, (b) Heat dissipation per unit width.

**SCHEMATIC:**

![Schematic](image)

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties, (4) Negligible radiation and base contact resistance, (5) Uniform convection coefficient.

**PROPERTIES:** *Table A-1*, Aluminum, pure (*T* ≈ 400 K): \( k = 240 \text{ W/m} \cdot \text{K} \).

**ANALYSIS:** (a) With \( L_c = L = 0.006 \text{ m} \), find

\[
L_c^{3/2} \left( \frac{h}{k A_p} \right)^{1/2} = 0.006 \left( \frac{40 \text{ W/m}^2 \cdot \text{K}}{240 \text{ W/m} \cdot \text{K} \times 6 \times 10^{-6} \text{ m}^2} \right)^{1/2} = 0.077
\]

and from Fig. 3.18, the fin efficiency is

\[
\eta_f \approx 0.99.
\]

From Eq. 3.86 and Table 3.5, the fin heat rate is

\[
q_f = \eta_f q_{\text{max}} = \eta_f h \Delta T \left( L^2 + (t/2)^2 \right)^{1/2} \eta_{\text{th}}.
\]

From Eq. 3.81, the fin effectiveness is

\[
\eta_f = \frac{2 \eta_f h w \left( L^2 + (t/2)^2 \right)^{1/2} \eta_{\text{th}}}{h \Delta T \left( L^2 + (t/2)^2 \right)^{1/2}} = \frac{2 \eta_f \left( L^2 + (t/2)^2 \right)^{1/2}}{t}
\]

\[
\eta_f = \frac{2 \times 0.99 \left( 0.006 \right)^2 + (0.002/2)^2 \right)^{1/2}}{0.002 \text{ m}} = 6.02
\]

(b) The heat dissipation per unit width is

\[
q'_f = \left( \frac{q_f}{w} \right) = 2 \eta_f h \left( L^2 + (t/2)^2 \right)^{1/2} \eta_{\text{th}}
\]

\[
q'_f = 2 \times 0.99 \times 40 \text{ W/m}^2 \cdot \text{K} \left( 0.006 \right)^2 + (0.002/2)^2 \right)^{1/2} m \times (250 - 20)^\circ \text{C} = 110.8 \text{ W/m}.
\]

**COMMENTS:** The triangular profile is known to provide the maximum heat dissipation per unit fin mass.
PROBLEM 3.144

KNOWN: Dimensions and base temperature of an annular, aluminum fin of rectangular profile.
Ambient air conditions.

FIND: (a) Fin heat loss, (b) Heat loss per unit length of tube with 200 fins spaced at 5 mm increments.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties,
(4) Negligible radiation and contact resistance, (5) Uniform convection coefficient.

PROPERTIES: Table A-1, Aluminum, pure (T = 400 K): k = 240 W/m·K.

ANALYSIS: (a) The fin parameters for use with Figure 3.19 are

\[ r_2 = 12.5 \text{ mm} + 10 \text{ mm} + 0.5 \text{ mm} = 23 \text{ mm} = 0.023 \text{ m} \]
\[ r_2 / \eta = 1.84 \]
\[ L_c = L + t/2 = 10.5 \text{ mm} = 0.0105 \text{ m} \]
\[ A_p = L_c t = 0.0105 \text{ m} \times 0.001 \text{ m} = 0.0105 \times 10^{-5} \text{ m}^2 \]
\[ L_c^{3/2} \left( \frac{h}{kA_p} \right)^{1/2} = (0.0105 \text{ m})^{3/2} \left( \frac{25 \text{ W/m}^2\cdot\text{K}}{240 \text{ W/m} \cdot \text{K} \times 1.05 \times 10^{-5} \text{ m}^2} \right)^{1/2} = 0.15. \]

Hence, the fin effectiveness is \( \eta_f = 0.97 \), and from Eq. 3.86 and Fig. 3.5, the fin heat rate is

\[ q_f = \eta_f q_{\text{max}} = \eta_f \left[ h A_f(\text{ann}) \theta_b \right] = 2 \pi \eta_f h \left( r_{2,c}^2 - r_1^2 \right) \theta_b \]
\[ q_f = 2 \pi \times 0.97 \times 25 \text{ W/m}^2\cdot\text{K} \times \left[ (0.023 \text{ m})^2 - (0.0125 \text{ m})^2 \right] \text{225} \text{°C} = 12.8 \text{ W}. \]

(b) Recognizing that there are \( N = 200 \) fins per meter length of the tube, the total heat rate considering contributions due to the fin and base (unfinned surfaces is

\[ q^' = N' q_f + h \left( 1 - N' t \right) 2 \pi \eta \theta_b \]
\[ q^' = 200 \text{ m}^{-1} \times 12.8 \text{ W} + 25 \text{ W/m}^2\cdot\text{K} \left( 1 - 200 \text{ m}^{-1} \times 0.001 \text{ m} \right) \times 2 \pi \times (0.0125 \text{ m}) \text{225} \text{°C} \]
\[ q^' = (2560 \text{ W} + 353 \text{ W})/\text{m} = 2.91 \text{kW/m}. \]

COMMENTS: Note that, while covering only 20% of the tube surface area, the tubes account for more than 85% of the total heat dissipation.
PROBLEM 3.145

KNOWN: Dimensions and base temperature of aluminum fins of rectangular profile. Ambient air conditions.

FIND: (a) Fin efficiency and effectiveness, (b) Rate of heat transfer per unit length of tube.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional radial conduction in fins, (3) Constant properties, (4) Negligible radiation, (5) Negligible base contact resistance, (6) Uniform convection coefficient.

PROPERTIES: Table A-1, Aluminum, pure (T ≈ 400 K): k = 240 W/m·K.

ANALYSIS: (a) The fin parameters for use with Figure 3.19 are

\[
\begin{align*}
r_2c &= r_2 + t/2 = 40 \text{ mm} + 2 \text{ mm} = 0.042 \text{ m} \\
L_c &= L + t/2 = 15 \text{ mm} + 2 \text{ mm} = 0.017 \text{ m} \\
r_2c/\eta &= 0.042 m / 0.025 m = 1.68 \\
A_p &= L_c t = 0.017 m \times 0.004 m = 6.8 \times 10^{-5} \text{ m}^2
\end{align*}
\]

\[
L_c^{3/2} \left( \frac{h}{kA_p} \right)^{1/2} = (0.017 m)^{3/2} \left[ \frac{40 \text{ W}}{\text{m}^2 \cdot \text{K}} / 240 \text{ W/m} \cdot \text{K} \times 6.8 \times 10^{-5} \text{ m}^2 \right]^{1/2} = 0.11
\]

The fin efficiency is \( \eta_f \approx 0.97 \). From Eq. 3.86 and Fig. 3.5,

\[
q_f = \eta_f q_{\text{max}} = \eta_f hA_f(\text{ann}) \theta_b = 2\pi\eta_f h \left[ \frac{r_2c}{2} - \eta \right] \theta_b
\]

\[
q_f = 2\pi \times 0.97 \times 40 \text{ W/m}^2 \cdot \text{K} \left[ (0.042)^2 - (0.025)^2 \right] \text{m}^2 \times 180^\circ \text{C} = 50 \text{ W}
\]

From Eq. 3.81, the fin effectiveness is

\[
\epsilon_f = \frac{q_f}{hA_{c,b} \theta_b} = \frac{50 \text{ W}}{40 \text{ W/m}^2 \cdot \text{K} \times \frac{2\pi (0.025 m)(0.004 m)}{180^\circ \text{C}}} = 11.05
\]

(b) The rate of heat transfer per unit length is

\[
q' = N'q_f + h(1 - N')(2\pi \eta) \theta_b
\]

\[
q' = 125 \times 50 \text{ W/m} + 40 \text{ W/m}^2 \cdot \text{K} (1 - 125 \times 0.004)(2\pi \times 0.025 m) \times 180^\circ \text{C}
\]

\[
q' = (6250 + 565) \text{ W/m} = 6.82 \text{ kW/m}
\]

COMMENTS: Note the dominant contribution made by the fins to the total heat transfer.
PROBLEM 3.146

KNOWN: Dimensions, base temperature, and contact resistance for an annular, aluminum fin. Ambient fluid conditions.

FIND: Fin heat transfer with and without base contact resistance.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties, (4) Negligible radiation, (5) Uniform convection coefficient.

PROPERTIES: Table A-1, Aluminum, pure (T = 350 K): k = 240 W/m·K.

ANALYSIS: With the contact resistance, the fin heat loss is \( q_f = \frac{T_w - T_{oo}}{R_{tc} + R_f} \) where

\[
R_{tc} = \frac{R_{tc}^2}{A_b} = 2 \times 10^{-4} \text{ m}^2 \cdot \text{K/W} / (2\pi (0.015 \text{ m})(0.002 \text{ m}) = 1.06 \text{ K/W}.
\]

From Eqs. 3.83 and 3.86, the fin resistance is

\[
R_f = \frac{\theta_b}{q_f} = \frac{\theta_b}{q_f} \eta_{f, \text{max}} = \frac{\theta_b}{\eta_f h A_f \theta_b} = \frac{1}{2\pi h \eta_f \left( \frac{r_{2,c}^2}{r_1^2} - \eta_f^2 \right)}.
\]

Evaluating parameters,

\[
r_{2,c} = r_2 + t/2 = 30 \text{ mm} + 1 \text{ mm} = 0.031 \text{ m} \quad L_c = L + t/2 = 0.016 \text{ m}
\]

\[
r_{2c}/\eta = 0.031/0.015 = 2.07 \quad A_p = L_c t = 3.2 \times 10^{-5} \text{ m}^2
\]

\[
L_c^{3/2} \left( \frac{h}{k A_p} \right)^{1/2} = (0.016 \text{ m})^{3/2} \left[ 75 \text{ W/m}^2 \cdot \text{K} / 240 \text{ W/m} \cdot \text{K} \times 3.2 \times 10^{-5} \text{ m}^2 \right]^{1/2} = 0.20
\]

find the fin efficiency from Figure 3.19 as \( \eta_f = 0.94 \). Hence,

\[
R_f = \frac{1}{2\pi \left( \frac{75 \text{ W/m}^2 \cdot \text{K}}{75 \text{ W/m} \cdot \text{K}} \right) 0.94 \left[ (0.031 \text{ m})^2 - (0.015 \text{ m})^2 \right]^1} = 3.07 \text{ K/W}
\]

\[
q_f = \frac{(100 - 25) \circ C}{(1.06 + 3.07) \text{ K/W}} = 18.2 \text{ W}.
\]

Without the contact resistance, \( T_w = T_b \) and

\[
q_f = \frac{\theta_b}{R_f} = \frac{75 \circ C}{3.07 \text{ K/W}} = 24.4 \text{ W}.
\]

COMMENTS: To maximize fin performance, every effort should be made to minimize contact resistance.
PROBLEM 3.147

KNOWN: Dimensions and materials of a finned (annular) cylinder wall. Heat flux and ambient air conditions. Contact resistance.

FIND: Surface and interface temperatures (a) without and (b) with an interface contact resistance.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, steady-state conditions, (2) Constant properties, (3) Uniform h over surfaces, (4) Negligible radiation.

ANALYSIS: The analysis may be performed per unit length of cylinder or for a 4 mm long section. The following calculations are based on a unit length. The inner surface temperature may be obtained from

$$ q' = \frac{T_i - T_\infty}{R'_\text{tot}} = q_i (2\pi \eta_t) = 10^5 \text{ W/m}^2 \times 2\pi \times 0.06 \text{ m} = 37,700 \text{ W/m} $$

where $R'_\text{tot} = R'_c + R'_t, c + R'_w + R'_\text{equiv}; \quad R'_\text{equiv} = (1/R'_f + 1/R'_b)^{-1}.$

$R'_c$, Conduction resistance of cylinder wall:

$$ R'_c = \frac{\ln (\eta_t / \eta_i)}{2\pi k} = \frac{\ln (66/60)}{2\pi (50 \text{ W/m} \cdot \text{K})} = 3.034 \times 10^{-4} \text{ m} \cdot \text{K/W} $$

$R'_{t,c}$, Contact resistance:

$$ R'_{t,c} = R'_{t,c} / 2\pi \eta_t = 10^{-4} \text{ m} \cdot \text{K/W} / 2\pi \times 0.066 \text{ m} = 2.411 \times 10^{-4} \text{ m} \cdot \text{K/W} $$

$R'_w$, Conduction resistance of aluminum base:

$$ R'_w = \frac{\ln (\eta_b / \eta_t)}{2\pi k} = \frac{\ln (70/66)}{2\pi \times 240 \text{ W/m} \cdot \text{K}} = 3.902 \times 10^{-5} \text{ m} \cdot \text{K/W} $$

$R'_b$, Resistance of prime or unfinned surface:

$$ R'_b = \frac{1}{hA'_{b}} = \frac{1}{100 \text{ W/m}^2 \cdot \text{K} \times 0.5 \times 2\pi (0.07 \text{ m})} = 454.7 \times 10^{-4} \text{ m} \cdot \text{K/W} $$

$R'_f$, Resistance of fins: The fin resistance may be determined from

$$ R'_f = \frac{T_b - T_\infty}{q'_f} = \frac{1}{\eta_f hA'_f} $$

The fin efficiency may be obtained from Fig. 3.19,

$$ r_{2c} = r_o + t/2 = 0.096 \text{ m} \quad L_c = L+t/2 = 0.026 \text{ m} $$

Continued …..
PROBLEM 3.147 (Cont.)

\[ A_p = L_c t = 5.2 \times 10^{-5} \ m^2 \quad r_2c / r_1 = 1.45 \quad L_c^{3/2} \left( h / k A_p \right)^{1/2} = 0.375 \]

Fig. 3.19 → \( \eta_f \approx 0.88 \).

The total fin surface area per meter length

\[ A'_f = 250 \left[ \pi \left( r_2^2 - r_b^2 \right) \times 2 \right] = 250 \ \text{m}^{-1} \left[ 2\pi \left( 0.096^2 - 0.07^2 \right) \right] \text{m}^2 = 6.78 \ \text{m}. \]

Hence

\[ R'_f = \left[ \frac{0.88 \times 100 \ \text{W/m}^2 \cdot \text{K} \times 6.78 \ \text{m}}{16.8 \times 10^{-4} \ \text{m} \cdot \text{K/W}} \right] = \frac{1}{16.8 \times 10^{-4} \ + 1/454.7 \times 10^{-4}} \text{W/m} \cdot \text{K} = 617.2 \ \text{W/m} \cdot \text{K} \]

\[ R'_{\text{equiv}} = 16.2 \times 10^{-4} \ \text{m} \cdot \text{K/W}. \]

Neglecting the contact resistance,

\[ R'_\text{tot} = \left( 3.034 + 0.390 + 16.2 \right) \times 10^{-4} \ \text{m} \cdot \text{K/W} = 19.6 \times 10^{-4} \ \text{m} \cdot \text{K/W} \]

\[ T_i = q'R'_\text{tot} + T_\infty = 37,700 \ \text{W/m} \times 19.6 \times 10^{-4} \ \text{m} \cdot \text{K/W} + 320 \ \text{K} = 393.9 \ \text{K} \quad \checkmark \]

\[ T_1 = T_i - q'R'_w = 393.9 \ \text{K} - 37,700 \ \text{W/m} \times 3.034 \times 10^{-4} \ \text{m} \cdot \text{K/W} = 382.5 \ \text{K} \quad \checkmark \]

\[ T_b = T_1 - q'R'_b = 382.5 \ \text{K} - 37,700 \ \text{W/m} \times 3.902 \times 10^{-5} \ \text{m} \cdot \text{K/W} = 381.0 \ \text{K}. \quad \checkmark \]

Including the contact resistance,

\[ R'_\text{tot} = \left( 19.6 \times 10^{-4} + 2.411 \times 10^{-4} \right) \ \text{m} \cdot \text{K/W} = 22.0 \times 10^{-4} \ \text{m} \cdot \text{K/W} \]

\[ T_i = 37,700 \ \text{W/m} \times 22.0 \times 10^{-4} \ \text{m} \cdot \text{K/W} + 320 \ \text{K} = 402.9 \ \text{K} \quad \checkmark \]

\[ T_{l,i} = 402.9 \ \text{K} - 37,700 \ \text{W/m} \times 3.034 \times 10^{-4} \ \text{m} \cdot \text{K/W} = 391.5 \ \text{K} \quad \checkmark \]

\[ T_{l,o} = 391.5 \ \text{K} - 37,700 \ \text{W/m} \times 2.411 \times 10^{-4} \ \text{m} \cdot \text{K/W} = 382.4 \ \text{K} \quad \checkmark \]

\[ T_b = 382.4 \ \text{K} - 37,700 \ \text{W/m} \times 3.902 \times 10^{-5} \ \text{m} \cdot \text{K/W} = 380.9 \ \text{K}. \quad \checkmark \]

COMMENTS: (1) The effect of the contact resistance is small.

(2) The effect of including the aluminum fins may be determined by computing \( T_i \) without the fins. In this case \( R'_\text{tot} = R'_c + R'_{\text{conv}} \), where

\[ R'_{\text{conv}} = \frac{1}{h \cdot 2\pi \cdot r_\eta} = \frac{1}{100 \ \text{W/m}^2 \cdot \text{K} \cdot 2\pi \left( 0.066 \ \text{m} \right)} = 241.1 \times 10^{-4} \ \text{m} \cdot \text{K/W}. \]

Hence, \( R_{\text{tot}} = 244.1 \times 10^{-4} \ \text{m} \cdot \text{K/W} \), and

\[ T_i = q'R'_\text{tot} + T_\infty = 37,700 \ \text{W/m} \times 244.1 \times 10^{-4} \ \text{m} \cdot \text{K/W} + 320 \ \text{K} = 1240 \ \text{K}. \]

Hence, the fins have a significant effect on reducing the cylinder temperature.

(3) The overall surface efficiency is

\[ \eta_o = 1 - \left( A'_f / A'_t \right) \left( 1 - \eta_f \right) = 1 - 6.78 \ \text{m/7.00 m} \left( 1 - 0.88 \right) = 0.884. \]

It follows that \( q' = \eta_o h_o A'_t \theta_b = 37,700 \ \text{W/m} \), which agrees with the prescribed value.
**PROBLEM 3.148**

**KNOWN:** Dimensions and materials of a finned (annular) cylinder wall. Combustion gas and ambient air conditions. Contact resistance.

**FIND:** (a) Heat rate per unit length and surface and interface temperatures, (b) Effect of increasing the fin thickness.

**SCHEMATIC:**

![Diagram of finned cylinder wall with dimensions and material properties]

**ASSUMPTIONS:** (1) One-dimensional, steady-state conditions, (2) Constant properties, (3) Uniform h over surfaces, (4) Negligible radiation.

**ANALYSIS:** (a) The heat rate per unit length is

\[
q' = \frac{T_g - T_\infty}{R'_\text{tot}}
\]

where \( R'_\text{tot} = R'_g + R'_w + R'_{t,c} + R'_b + R'_{t,o} \), and

\[
R'_g = \left(h_g \frac{2\pi r_1}{2\pi} \right)^{-1} = \frac{1}{150 \text{ W/m}^2\cdot\text{K} \times 2\pi \times 0.06 \text{ m}} = 0.0177 \text{ m} \cdot \text{K/W},
\]

\[
R'_w = \frac{\ln \left(\frac{\eta_w}{\eta}\right)}{2\pi k_w} = \frac{\ln (66/60)}{2\pi (50 \text{ W/m} \cdot \text{K})} = 3.03 \times 10^{-4} \text{ m} \cdot \text{K/W},
\]

\[
R'_{t,c} = \left(R_{t,c}' \frac{2\pi}{2\pi r_1} \right) = 10^{-4} \text{ m}^4 \cdot \text{K/W} / 2\pi \times 0.066 \text{ m} = 2.41 \times 10^{-4} \text{ m} \cdot \text{K/W}
\]

\[
R'_b = \frac{\ln \left(\frac{\eta_b}{\eta}\right)}{2\pi k} = \frac{\ln (70/66)}{2\pi \times 240 \text{ W/m} \cdot \text{K}} = 3.90 \times 10^{-5} \text{ m} \cdot \text{K/W},
\]

\[
R'_{t,o} = \left(\frac{\eta_o h A'_t}{A'_t} \right)
\]

\[
\eta_o = 1 - \frac{N' A_f}{A'_t} \left(1 - \eta_f \right)
\]

\[
A_f = 2\pi \left( r_{oc}^2 - r_b^2 \right)
\]

\[
A'_t = N' A_f + (1 - N') 2\pi r_b
\]

\[
\eta_f = \frac{(2\eta_b/m) K_1 (m r_b) I_1 (m r_{oc}) - I_1 (m r_b) K_1 (m r_{oc})}{\left( r_{oc}^2 - r_b^2 \right) I_0 (m\eta) K_1 (m r_{oc}) + K_0 (m r_b) I_1 (m r_{oc})}
\]

\[
r_{oc} = r_o + (t/2), \quad m = (2h/kt)^{1/2}
\]

Continued...
PROBLEM 3.148 (Cont.)

Once the heat rate is determined from the foregoing expressions, the desired interface temperatures may be obtained from

\[ T_i = T_g - q' R'_g \]
\[ T_{i,i} = T_g - q' \left( R'_g + R'_w \right) \]
\[ T_{i,o} = T_g - q' \left( R'_g + R'_w + R'_{t,c} \right) \]
\[ T_b = T_g - q' \left( R'_g + R'_w + R'_{t,c} + R'_b \right) \]

For the specified conditions we obtain
\[ t_A' = 7.00 \text{ m}, \eta_f = 0.902, \eta_o = 0.906 \text{ and } R'_{i,o} = 0.00158 \text{ m-K/W}. \]

It follows that
\[ q' = 39,300 \text{ W/m} \]
\[ T_i = 405 \text{ K}, \ T_{i,i} = 393 \text{ K}, \ T_{i,o} = 384 \text{ K}, \ T_b = 382 \text{ K} \]

(b) The Performance Calculation, Extended Surface Model for the Circular Fin Array may be used to assess the effects of fin thickness and spacing. Increasing the fin thickness to \( t = 3 \text{ mm} \), with \( \delta = 2 \text{ mm} \), reduces the number of fins per unit length to 200. Hence, although the fin efficiency increases \( (\eta_f = 0.930) \), the reduction in the total surface area \( (A'_t = 5.72 \text{ m}) \) yields an increase in the resistance of the fin array \( (R'_{i,o} = 0.00188 \text{ m-K/W}) \), and hence a reduction in the heat rate \( (q' = 38,700 \text{ W/m}) \) and an increase in the interface temperatures \( (T_i = 415 \text{ K}, \ T_{i,i} = 404 \text{ K}, \ T_{i,o} = 394 \text{ K}, \text{ and } T_b = 393 \text{ K}) \).

COMMENTS: Because the gas convection resistance exceeds all other resistances by at least an order of magnitude, incremental changes in \( R_{i,o} \) will not have a significant effect on \( q' \) or the interface temperatures.
PROBLEM 3.149

KNOWN: Dimensions of finned aluminum sleeve inserted over transistor. Contact resistance and convection conditions.

FIND: Measures for increasing heat dissipation.

SCHEMATIC: See Example 3.10.

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible heat transfer from top and bottom of transistor, (3) One-dimensional radial heat transfer, (4) Constant properties, (5) Negligible radiation.

ANALYSIS: With $2\pi r_2 = 0.0188$ m and $N_t = 0.0084$ m, the existing gap between fins is extremely small (0.87 mm). Hence, by increasing $N$ and/or $t$, it would become even more difficult to maintain satisfactory airflow between the fins, and this option is not particularly attractive.

Because the fin efficiency for the prescribed conditions is close to unity ($\eta_f = 0.998$), there is little advantage to replacing the aluminum with a material of higher thermal conductivity (e.g. Cu with $k \sim 400$ W/m·K). However, the large value of $\eta_f$ suggests that significant benefit could be gained by increasing the fin length, $L = r_3 - r_2$.

It is also evident that the thermal contact resistance is large, and from Table 3.2, it’s clear that a significant reduction could be effected by using indium foil or a conducting grease in the contact zone. Specifically, a reduction of $R_{t,c}''$ from $10^{-3}$ to $10^{-4}$ or even $10^{-5}$ m²·K/W is certainly feasible.

Table 1.1 suggests that, by increasing the velocity of air flowing over the fins, a larger convection coefficient may be achieved. A value of $h = 100$ W/m²·K would not be unreasonable.

As options for enhancing heat transfer, we therefore use the IHT Performance Calculation, Extended Surface Model for the Straight Fin Array to explore the effect of parameter variations over the ranges $10 \leq L \leq 20$ mm, $10^{-5} \leq R_{t,c}' \leq 10^{-3}$ m²·K/W and $25 \leq h \leq 100$ W/m²·K. As shown below, there is a significant enhancement in heat transfer associated with reducing $R_{t,c}'$ from $10^{-3}$ to $10^{-4}$ m²·K/W, for which $R_{t,c}$ decreases from 13.26 to 1.326 K/W. At this value of $R_{t,c}'$, the reduction in $R_{t,o}$ from 23.45 to 12.57 K/W which accompanies an increase in $L$ from 10 to 20 mm becomes significant, yielding a heat rate of $q_t = 4.30$ W for $R_{t,c}' = 10^{-4}$ m²·K/W and $L = 20$ mm. However, since $R_{t,o} >> R_{t,c}'$, little benefit is gained by further reducing $R_{t,c}'$ to $10^{-5}$ m²·K/W.

Continued...
To derive benefit from a reduction in $R_{t,c}$ to $10^{-5}$ m$^2$-K/W, an additional reduction in $R_{t,o}$ must be made. This can be achieved by increasing $h$, and for $L = 20$ mm and $h = 100$ W/m$^2$-K, $R_{t,o} = 3.56$ K/W. With $R_{t,c} = 10^{-5}$ m$^2$-K/W, a value of $q_t = 16.04$ W may be achieved.

**COMMENTS:** In assessing options for enhancing heat transfer, the limiting (largest) resistance(s) should be identified and efforts directed at their reduction.
**PROBLEM 3.150**

**KNOWN:** Diameter and internal fin configuration of copper tubes submerged in water. Tube wall temperature and temperature and convection coefficient of gas flow through the tube.

**FIND:** Rate of heat transfer per tube length.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) One-dimensional fin conduction, (3) Constant properties, (4) Negligible radiation, (5) Uniform convection coefficient, (6) Tube wall may be unfolded and represented as a plane wall with four straight, rectangular fins, each with an adiabatic tip.

**ANALYSIS:**

The rate of heat transfer per unit tube length is:

\[ q'_t = \eta_o h A'_f (T_g - T_s) \]

\[ \eta_o = 1 - \frac{N A'_f}{A'_f} (1 - \eta_f) \]

\[ N A'_f = 4 \times 2L = 8(0.025m) = 0.20m \]

\[ A'_f = N A'_f + A'_b = 0.20m + (\pi D - 4t) = 0.20m + (\pi \times 0.05m - 4 \times 0.005m) = 0.337m \]

For an adiabatic fin tip,

\[ \eta_f = \frac{q_f}{q_{max}} = \frac{M \tanh mL}{h (2L \cdot 1)(T_g - T_s)} \]

\[ M = \left[ h2(1m + t)k (1m \times t) \right]^{1/2} \left( T_g - T_s \right) = \left[ 30 \text{ W/m}^2 \cdot \text{K} (2m) 400 \text{ W/m} \cdot \text{K} \left(0.005 \text{m}^2\right) \right]^{1/2} (400 \text{K}) = 4382 \text{W} \]

\[ mL = \left[ \frac{h2(1m + t)}{k (1m \times t)} \right]^{1/2} L \approx \left[ 30 \text{ W/m}^2 \cdot \text{K} (2m) \right]^{1/2} \frac{0.025m}{400 \text{ W/m} \cdot \text{K} \left(0.005 \text{m}^2\right)} = 0.025m = 0.137 \]

Hence, \( \tanh mL = 0.136 \), and

\[ \eta_f = \frac{4382W (0.136)}{30 \text{ W/m}^2 \cdot \text{K} \left(0.005 \text{m}^2\right)(400 \text{K})} = 0.992 \]

\[ \eta_o = 1 - \frac{0.20}{0.337} (1 - 0.992) = 0.995 \]

\[ q'_t = 0.995 \left(30 \text{ W/m}^2 \cdot \text{K} 0.337m \right)(400 \text{K}) = 4025 \text{ W/m} \]

**COMMENTS:** Alternatively, \( q'_t = 4q'_f + h (A'_f - A'_b) (T_g - T_s) \). Hence, \( q'_t = 4(595 \text{ W/m}) + 30 \text{ W/m}^2 \cdot \text{K} (0.137 \text{ m})(400 \text{ K}) = (2380 + 1644) \text{ W/m} = 4024 \text{ W/m} \).
**PROBLEM 3.151**

**KNOWN:** Internal and external convection conditions for an internally finned tube. Fin/tube dimensions and contact resistance.

**FIND:** Heat rate per unit tube length and corresponding effects of the contact resistance, number of fins, and fin/tube material.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional heat transfer, (3) Constant properties, (4) Negligible radiation, (5) Uniform convection coefficient on finned surfaces, (6) Tube wall may be unfolded and approximated as a plane surface with N straight rectangular fins.

**PROPERTIES:** Copper: $k = 400 \text{ W/m} \cdot \text{K}$; St.St.: $k = 20 \text{ W/m} \cdot \text{K}$.

**ANALYSIS:** The heat rate per unit length may be expressed as

\[
q' = \frac{T_g - T_w}{R'_{t,o(c)} + R'_{\text{cond}} + R'_{\text{conv,o}}}
\]

where

\[
R'_{t,o(c)} = \left( \frac{\eta_o(c) h_g A_t'}{A_t} \right), \quad \eta_o(c) = 1 - \frac{NA_f'}{A_t} \left( 1 - \frac{\eta_f}{C_1} \right), \quad C_1 = 1 + \eta_f h_g A_f' \left( R'_{t,c} / A'_{c,b} \right),
\]

\[
A_f' = NA_f + (2\pi \eta - Nt), \quad A_t' = 2\eta, \quad \eta_f = \tanh m\eta / m\eta, \quad m = \left( 2h_g / k_t \right)^{1/2}, \quad A'_{c,b} = t,
\]

\[
R'_{\text{cond}} = \frac{\ln (r_2 / \eta)}{2\pi k}, \quad \text{and} \quad R'_{\text{conv,o}} = \left( 2\pi r_2 h_g \right)^{-1}.
\]

Using the IHT *Performance Calculation, Extended Surface Model* for the *Straight Fin Array*, the following results were obtained. For the base case, $q' = 3857 \text{ W/m}$, where $R'_{t,o(c)} = 0.101 \text{ m} \cdot \text{K/W}$, $R'_{\text{cond}} = 7.25 \times 10^{-5} \text{ m} \cdot \text{K/W}$ and $R'_{\text{conv,o}} = 0.00265 \text{ m} \cdot \text{K/W}$. If the contact resistance is eliminated ($R'_{t,c} = 0$), $q' = 3922 \text{ W/m}$, where $R'_{t,o} = 0.0993 \text{ m} \cdot \text{K/W}$. If the number of fins is increased to $N = 8$, $q' = 5799 \text{ W/m}$, with $R'_{t,o(c)} = 0.063 \text{ m} \cdot \text{K/W}$. If the material is changed to stainless steel, $q' = 3591 \text{ W/m}$, with $R'_{t,o(c)} = 0.107 \text{ m} \cdot \text{K/W}$ and $R'_{\text{cond}} = 0.00145 \text{ m} \cdot \text{K/W}$.

**COMMENTS:** The small reduction in $q'$ associated with use of stainless steel is perhaps surprising, in view of the large reduction in $k$. However, because $h_g$ is small, the reduction in $k$ does not significantly reduce the fin efficiency ($\eta_f$ changes from 0.994 to 0.891). Hence, the heat rate remains large. The influence of $k$ would become more pronounced with increasing $h_g$.
PROBLEM 3.152

KNOWN: Design and operating conditions of a tubular, air/water heater.

FIND: (a) Expressions for heat rate per unit length at inner and outer surfaces, (b) Expressions for inner and outer surface temperatures, (c) Surface heat rates and temperatures as a function of volumetric heating \( \dot{q} \) for prescribed conditions. Upper limit to \( \dot{q} \).

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Constant properties, (3) One-dimensional heat transfer.

PROPERTIES: Table A-1: Aluminum, \( T = 300 \) K, \( k_a = 237 \) W/m·K.

ANALYSIS: (a) Applying Equation C.8 to the inner and outer surfaces, it follows that

\[
q'(r_i) = \dot{q} \frac{\pi r_i^2}{2} - \frac{2\pi k_s}{\ln(r_o/r_i)} \left[ \frac{\dot{q} r_o^2}{4k_s} \left( 1 - \frac{r_i^2}{r_o^2} \right) + (T_{s,o} - T_{s,i}) \right]
\]

\[
q'(r_o) = \dot{q} \frac{\pi r_o^2}{2} - \frac{2\pi k_s}{\ln(r_o/r_i)} \left[ \frac{\dot{q} r_o^2}{4k_s} \left( 1 - \frac{r_i^2}{r_o^2} \right) + (T_{s,o} - T_{s,i}) \right]
\]

(b) From Equations C.16 and C.17, energy balances at the inner and outer surfaces are of the form

\[
h_i (T_{\infty,i} - T_{s,i}) = \frac{\dot{q} r_i^2}{2} \frac{k_s}{\ln(r_o/r_i)} \left[ \frac{\dot{q} r_o^2}{4k_s} \left( 1 - \frac{r_i^2}{r_o^2} \right) + (T_{s,o} - T_{s,i}) \right]
\]

\[
h_o (T_{s,o} - T_{\infty,o}) = \frac{\dot{q} r_o^2}{2} \frac{k_s}{\ln(r_o/r_i)} \left[ \frac{\dot{q} r_o^2}{4k_s} \left( 1 - \frac{r_i^2}{r_o^2} \right) + (T_{s,o} - T_{s,i}) \right]
\]

Accounting for the fin array and the contact resistance, Equation 3.104 may be used to cast the overall heat transfer coefficient \( U_o \) in the form

\[
U_o = \frac{\dot{q}'(r_o)}{A_w (T_{s,o} - T_{\infty,o})} = \frac{1}{A_w R_{t,o(c)}} = \frac{A'_w}{A_w} \eta_{o(c)} h_o
\]

where \( \eta_{o(c)} \) is determined from Equations 3.105a,b and \( A'_w = 2\pi r_o \).

Continued...
PROBLEM 3.152 (Cont.)

(c) For the prescribed conditions and a representative range of \(10^7 \leq \dot{q} \leq 10^8\) W/m\(^3\), use of the relations of part (b) with the capabilities of the IHT Performance Calculation Extended Surface Model for a Circular Fin Array yields the following graphical results.

![Graphical results](image)

It is in this range that the upper limit of \(T_{s,i} = 373\) K is exceeded for \(\dot{q} = 4.9 \times 10^7\) W/m\(^3\), while the corresponding value of \(T_{s,o} = 379\) K is well below the prescribed upper limit. The expressions of part (a) yield the following results for the surface heat rates, where heat transfer in the negative r direction corresponds to \(q'(r_i) < 0\).

![Graphical results](image)

For \(\dot{q} = 4.9 \times 10^7\) W/m\(^3\), \(q'(r_i) = -2.30 \times 10^4\) W/m and \(q'(r_o) = 1.93 \times 10^4\) W/m.

**COMMENTS:** The foregoing design provides for comparable heat transfer to the air and water streams. This result is a consequence of the nearly equivalent thermal resistances associated with heat transfer from the inner and outer surfaces. Specifically, \(R'_{\text{conv},i} = (h_i 2\pi r_1)^{-1} = 0.00318\) m-K/W is slightly smaller than \(R'_{\text{f,o}(c)} = 0.00411\) m-K/W, in which case |\(q'(r_i)\)| is slightly larger than \(q'(r_o)\), while \(T_{s,i}\) is slightly smaller than \(T_{s,o}\). Note that the solution must satisfy the energy conservation requirement, 

\[
\pi (r_o^2 - r_i^2) \dot{q} = |q'(r_i)| + q'(r_o).
\]
PROBLEM 4.1

KNOWN: Method of separation of variables (Section 4.2) for two-dimensional, steady-state conduction.

FIND: Show that negative or zero values of $\lambda^2$, the separation constant, result in solutions which cannot satisfy the boundary conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional, steady-state conduction, (2) Constant properties.

ANALYSIS: From Section 4.2, identification of the separation constant $\lambda^2$ leads to the two ordinary differential equations, 4.6 and 4.7, having the forms

$$\frac{d^2X}{dx^2} + \lambda^2 X = 0 \quad \frac{d^2Y}{dy^2} - \lambda^2 Y = 0 \quad (1,2)$$

and the temperature distribution is 

$$\theta (x,y) = X(x) \cdot Y(y). \quad (3)$$

Consider now the situation when $\lambda^2 = 0$. From Eqs. (1), (2), and (3), find that

$$X = C_1 + C_2 x, \quad Y = C_3 + C_4 y \quad \text{and} \quad \theta (x,y) = (C_1 + C_2 x) \cdot (C_3 + C_4 y). \quad (4)$$

Evaluate the constants - $C_1$, $C_2$, $C_3$ and $C_4$ - by substitution of the boundary conditions:

$$x = 0: \quad \theta (0,y) = (C_1 + C_2 \cdot 0) \cdot (C_3 + C_4 y) = 0 \quad C_1 = 0$$
$$y = 0: \quad \theta (x,0) = (0 + C_2 x) \cdot (C_3 + C_4 \cdot 0) = 0 \quad C_3 = 0$$
$$x = L: \quad \theta (L,0) = (0 + C_2 L) \cdot (0 + C_4 y) = 0 \quad C_2 = 0$$
$$y = W: \quad \theta (x,W) = (0 + 0 \cdot x) \cdot (0 + C_4 W) = 1 \quad 0 \neq 1$$

The last boundary condition leads to an impossibility $(0 \neq 1)$. We therefore conclude that a $\lambda^2$ value of zero will not result in a form of the temperature distribution which will satisfy the boundary conditions. Consider now the situation when $\lambda^2 < 0$. The solutions to Eqs. (1) and (2) will be

$$X = C_5 e^{-\lambda x} + C_6 e^{+\lambda x}, \quad Y = C_7 \cos \lambda y + C_8 \sin \lambda y \quad (5,6)$$

and 

$$\theta (x,y) = \left[ C_5 e^{-\lambda x} + C_6 e^{+\lambda x} \right] \cdot \left[ C_7 \cos \lambda y + C_8 \sin \lambda y \right]. \quad (7)$$

Evaluate the constants for the boundary conditions.

$$y = 0: \quad \theta (x,0) = \left[ C_5 e^{-\lambda x} + C_6 e^{+\lambda x} \right] \cdot [C_7 \cos 0 + C_8 \sin 0] = 0 \quad C_7 = 0$$
$$x = 0: \quad \theta (0,y) = \left[ C_5 e^{0} + C_6 e^{0} \right] \cdot [0 + C_8 \sin \lambda y] = 0 \quad C_8 = 0$$

If $C_8 = 0$, a trivial solution results or $C_5 = -C_6$. 

$$x = L: \quad \theta (L,y) = C_5 \left[ e^{-\lambda L} - e^{+\lambda L} \right] C_8 \sin \lambda y = 0.$$

From the last boundary condition, we require $C_5$ or $C_8$ is zero; either case leads to a trivial solution with either no $x$ or $y$ dependence.
PROBLEM 4.2

KNOWN: Two-dimensional rectangular plate subjected to prescribed uniform temperature boundary conditions.

FIND: Temperature at the mid-point using the exact solution considering the first five non-zero terms; assess error resulting from using only first three terms. Plot the temperature distributions T(x,0.5) and T(1,y).

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional, steady-state conduction, (2) Constant properties.

ANALYSIS: From Section 4.2, the temperature distribution is

\[ \theta(x, y) = \frac{T - T_1}{T_2 - T_1} = \frac{2}{\pi} \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n} \sin \left( \frac{n\pi x}{L} \right) \sinh \left( \frac{n\pi y}{L} \right) \sinh \left( \frac{n\pi W}{L} \right). \]  

(1.4.19)

Considering now the point (x,y) = (1.0,0.5) and recognizing x/L = 1/2, y/L = 1/4 and W/L = 1/2,

\[ \theta(0.5,0.5) = \frac{T - T_1}{T_2 - T_1} = \frac{2}{\pi} \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n} \sin \left( \frac{n\pi}{2} \right) \sin \left( \frac{n\pi}{4} \right) \sinh \left( \frac{n\pi}{2} \right) \sinh \left( \frac{n\pi}{4} \right). \]

When n is even (2, 4, 6 ...), the corresponding term is zero; hence we need only consider n = 1, 3, 5, 7 and 9 as the first five non-zero terms.

\[ \theta(0.5,0.5) = 0.445 \]

(2)

\[ T(1,0.5) = \theta(0.5,0.5)(T_2 - T_1) + T_1 = 0.445(150 - 50) + 50 = 94.5^\circ C. \]

If only the first three terms of the series, Eq. (2), are considered, the result will be \( \theta(1,0.5) = 0.46 \); that is, there is less than a 0.2% effect.

Using Eq. (1), and writing out the first five terms of the series, expressions for \( \theta(x,0.5) \) or \( T(x,0.5) \) and \( \theta(1,y) \) or \( T(1,y) \) were keyboarded into the IHT workspace and evaluated for sweeps over the x or y variable. Note that for \( T(1,y) \), that as \( y \to 1 \), the upper boundary, \( T(1,1) \) is greater than 150°C. Upon examination of the magnitudes of terms, it becomes evident that more than 5 terms are required to provide an accurate solution.
PROBLEM 4.3

KNOWN: Temperature distribution in the two-dimensional rectangular plate of Problem 4.2.

FIND: Expression for the heat rate per unit thickness from the lower surface \((0 \leq x \leq 2, 0)\) and result based on first five non-zero terms of the infinite series.

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional, steady-state conduction, (2) Constant properties.

ANALYSIS: The heat rate per unit thickness from the plate along the lower surface is

\[
q'_{\text{out}} = - \int_{x=0}^{x=2} dq'_{y} = - \int_{x=0}^{x=2} -k \frac{\partial T}{\partial y} \bigg|_{y=0} dx = k(T_2 - T_1) \int_{x=0}^{x=2} \frac{\partial \theta}{\partial y} \bigg|_{y=0} dx \tag{1}
\]

where from the solution to Problem 4.2,

\[
\theta = \frac{T - T_1}{T_2 - T_1} = \frac{2}{\pi} \sum_{n=1}^{\infty} \frac{(-1)^{n+1} + 1}{n} \sin \left( \frac{n\pi x}{L} \right) \frac{\sinh \left( \frac{n\pi y}{L} \right)}{\sinh \left( \frac{n\pi W}{L} \right)} \tag{2}
\]

Evaluate the gradient of \(\theta\) from Eq. (2) and substitute into Eq. (1) to obtain

\[
q'_{\text{out}} = k(T_2 - T_1) \int_{x=0}^{x=2} \frac{2}{\pi} \sum_{n=1}^{\infty} \frac{(-1)^{n+1} + 1}{n} \sin \left( \frac{n\pi x}{L} \right) \frac{\sinh \left( \frac{n\pi y}{L} \right) \cosh \left( \frac{n\pi y}{L} \right)}{\sinh \left( \frac{n\pi W}{L} \right)} \bigg|_{y=0} dx \]

\[
q'_{\text{out}} = k(T_2 - T_1) \frac{2}{\pi} \sum_{n=1}^{\infty} \frac{(-1)^{n+1} + 1}{n} \sinh \left( \frac{n\pi W}{L} \right) \left[ -\cos \left( \frac{n\pi x}{L} \right) \right]_{x=0}^{x=2} \bigg|_{x=0}^{x=1}
\]

To evaluate the first five, non-zero terms, recognize that since \(\cos(n\pi) = 1\) for \(n = 2, 4, 6 \ldots\), only the \(n\)-odd terms will be non-zero. Hence,

Continued ….
\[
q'_{\text{out}} = 50 \text{ W/m} \cdot \text{K} (150 - 50) ^\circ C \cdot \frac{2}{\pi} \left\{ (-1)^2 + 1 \cdot \frac{1}{\sinh (\pi/2)} + (\frac{-1}{3})^4 + 1 \cdot \frac{1}{\sinh (3\pi/2)} + \frac{(-1)^6 + 1}{5 \cdot \sinh (5\pi/2)} + (\frac{-1}{7})^8 + 1 \cdot \frac{1}{\sinh (7\pi/2)} + (\frac{-1}{9})^{10} + 1 \cdot \frac{1}{\sinh (9\pi/2)} \right\} \\
q'_{\text{out}} = 3.183 \text{ kW/m} \left[ 1.738 + 0.024 + 0.00062 + (...) \right] = 5.611 \text{ kW/m}
\]

**COMMENTS:** If the foregoing procedure were used to evaluate the heat rate into the upper surface, \( q'_{\text{in}} = - \int_{x=0}^{x=2} dq'_{y} (x, W) \), it would follow that

\[
q'_{\text{in}} = k (T_2 - T_1) \frac{2}{\pi} \sum_{n=1}^{\infty} \frac{(-1)^n + 1}{n} \coth (n\pi/2) \left[ 1 - \cos (n\pi) \right]
\]

However, with \( \coth(n\pi/2) \geq 1 \), irrespective of the value of \( n \), and with \( \sum_{n=1}^{\infty} \left[ (-1)^n + 1 \right]/n \) being a divergent series, the complete series does not converge and \( q'_{\text{in}} \rightarrow \infty \). This physically untenable condition results from the temperature discontinuities imposed at the upper left and right corners.
**PROBLEM 4.4**

**KNOWN:** Rectangular plate subjected to prescribed boundary conditions.

**FIND:** Steady-state temperature distribution.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, 2-D conduction, (2) Constant properties.

**ANALYSIS:** The solution follows the method of Section 4.2. The product solution is

\[
T(x,y) = X(x) \cdot Y(y) = (C_1 \cos \lambda x + C_2 \sin \lambda x) \left( C_3 e^{-\lambda y} + C_4 e^{+\lambda y} \right)
\]

and the boundary conditions are: \(T(0,y) = 0, \ T(a,y) = 0, \ T(x,0) = 0, \ T(x,b) = Ax.\) Applying BC#1, \(T(0,y) = 0,\) find \(C_1 = 0.\) Applying BC#2, \(T(a,y) = 0,\) find that \(\lambda = n\pi/a\) with \(n = 1, 2, \ldots\) Applying BC#3, \(T(x,0) = 0,\) find that \(C_3 = -C_4.\) Hence, the product solution is

\[
T(x,y) = X(x) \cdot Y(y) = C_2 C_4 \sin \left( \frac{n\pi x}{a} \right) \left( e^{\lambda y} - e^{-\lambda y} \right).
\]

Combining constants and using superposition, find

\[
T(x,y) = \sum_{n=1}^{\infty} C_n \sin \left( \frac{n\pi x}{a} \right) \sinh \left( \frac{n\pi y}{a} \right).
\]

To evaluate \(C_n,\) use orthogonal functions with Eq. 4.16 to find

\[
C_n = \int_0^a Ax \cdot \sin \left( \frac{n\pi x}{a} \right) \cdot dx / \sinh \left( \frac{n\pi b}{a} \right) \cdot \left[ \int_0^a \sin \left( \frac{n\pi x}{a} \right) \cdot dx \right],
\]

noting that \(y = b.\) The numerator, denominator and \(C_n,\) respectively, are:

\[
A \int_0^a x \cdot \sin \left( \frac{n\pi x}{a} \right) \cdot dx = A \left[ \frac{a}{n\pi} \right]^2 \sin \left( \frac{n\pi x}{a} \right) - \frac{ax}{n\pi} \cos \left( \frac{n\pi x}{a} \right) \right]_{x=0}^{x=a} = \frac{Aa^2}{n\pi} \left[ \cos (n\pi) \right] = \frac{Aa^2}{n\pi} (-1)^{n+1},
\]

\[
\sinh \left( \frac{n\pi b}{a} \right) \int_0^a \sin^2 \left( \frac{n\pi x}{a} \right) \cdot dx = \sinh \left( \frac{n\pi b}{a} \right) \left[ \frac{1}{2} x - \frac{1}{4n\pi} \sin \left( \frac{2n\pi x}{a} \right) \right]_{x=0}^{x=a} = \frac{a}{2} \sinh \left( \frac{n\pi b}{a} \right),
\]

\[
C_n = \frac{Aa^2}{n\pi} (-1)^{n+1} / \frac{a}{2} \sinh \left( \frac{n\pi b}{a} \right) = 2Aa (-1)^{n+1} / n\pi \sinh \left( \frac{n\pi b}{a} \right).
\]

Hence, the temperature distribution is

\[
T(x,y) = \frac{2Aa}{\pi} \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n} \sin \left( \frac{n\pi x}{a} \right) \sin \left( \frac{n\pi y}{a} \right) / \sinh \left( \frac{n\pi b}{a} \right).
\]
**PROBLEM 4.5**

**KNOWN:** Long furnace of refractory brick with prescribed surface temperatures and material thermal conductivity.

**FIND:** Shape factor and heat transfer rate per unit length using the flux plot method

**SCHEMATIC:**

![Furnace cross-section](image)

**ASSUMPTIONS:** (1) Furnace length normal to page, \( l \), >> cross-sectional dimensions, (2) Two-dimensional, steady-state conduction, (3) Constant properties.

**ANALYSIS:** Considering the cross-section, the cross-hatched area represents a symmetrical element. Hence, the heat rate for the entire furnace per unit length is

\[
q' = \frac{q}{l} = 4 \frac{S}{l} k (T_1 - T_2)
\]

where \( S \) is the shape factor for the symmetrical section. Selecting three temperature increments \( (N = 3) \), construct the flux plot shown below.

![Flux plot](image)

From Eq. 4.26,

\[
S = \frac{M}{N} \quad \text{or} \quad \frac{S}{l} = \frac{M}{N} = \frac{8.5}{3} = 2.83
\]

and from Eq. (1),

\[
q' = 4 \times 2.83 \times 1.2 \times \frac{W}{m \cdot K} (600 - 60)^5 C = 7.34 \text{ kW/m.}
\]

**COMMENTS:** The shape factor can also be estimated from the relations of Table 4.1. The symmetrical section consists of two plane walls (horizontal and vertical) with an adjoining edge. Using the appropriate relations, the numerical values are, in the same order,

\[
S = \frac{0.75m}{0.5m} \ell + \frac{0.5m}{0.5m} \ell + \frac{0.5m}{0.5m} \ell = 3.04 \ell
\]
Note that this result compares favorably with the flux plot result of $2.83\ell$. 
PROBLEM 4.6

KNOWN: Hot pipe embedded eccentrically in a circular system having a prescribed thermal conductivity.

FIND: The shape factor and heat transfer per unit length for the prescribed surface temperatures.

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional conduction, (2) Steady-state conditions, (3) Length \( \ell >> \) diametrical dimensions.

ANALYSIS: Considering the cross-sectional view of the pipe system, the symmetrical section shown above is readily identified. Selecting four temperature increments (\( N = 4 \)), construct the flux plot shown below.

For the pipe system, the heat rate per unit length is

\[
q' = \frac{q}{\ell} = kS(T_1 - T_2) = 0.5 \frac{W}{m \cdot K} \times 4.26 \times 150 - 35 \)°C = 245 W/m.

COMMENTS: Note that in the lower, right-hand quadrant of the flux plot, the curvilinear squares are irregular. Further work is required to obtain an improved plot and, hence, obtain a more accurate estimate of the shape factor.
PROBLEM 4.7

KNOWN: Structural member with known thermal conductivity subjected to a temperature difference.

FIND: (a) Temperature at a prescribed point P, (b) Heat transfer per unit length of the strut, (c) Sketch the 25, 50 and 75°C isotherms, and (d) Same analysis on the shape but with adiabatic-isothermal boundary conditions reversed.

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional conduction, (2) Steady-state conditions, (3) Constant properties.

ANALYSIS: (a) Using the methodology of Section 4.3.1, construct a flux plot. Note the line of symmetry which passes through the point P is an isotherm as shown above. It follows that

\[ T(P) = \frac{(T_1 + T_2)}{2} = \frac{(100 + 0)}{2} = 50°C. \]

(b) The flux plot on the symmetrical section is now constructed to obtain the shape factor from which the heat rate is determined. That is, from Eq. 4.25 and 4.26,

\[ q = kS(T_1 - T_2) \quad \text{and} \quad S = M\ell/N. \] (1,2)

From the plot of the symmetrical section,

\[ S_0 = \frac{4.2\ell}{4} = 1.05\ell. \]

For the full section of the strut,

\[ M = M_0 = 4.2 \]

but \( N = 2N_o = 8 \). Hence,

\[ S = S_o/2 = 0.53\ell \]

and with \( q' = q/\ell \), giving

\[ q'/\ell = 75 \text{ W/m} \cdot \text{K} \times 0.53(100-0)^° \text{C} = 3975 \text{ W/m}. \]

(c) The isotherms for \( T = 50, 75 \) and \( 100°C \) are shown on the flux plot. The \( T = 25°C \) isotherm is symmetric with the \( T = 75°C \) isotherm.

(d) By reversing the adiabatic and isothermal boundary conditions, the two-dimensional shape appears as shown in the sketch below. The symmetrical element to be flux plotted is the same as for the strut, except the symmetry line is now an adiabat.

Continued...
From the flux plot, find $M_o = 3.4$ and $N_o = 4$, and from Eq. (2)

$$S_o = M_o / N_o = 3.4 / 4 = 0.85\ell \quad S = 2S_o = 1.70\ell$$

and the heat rate per unit length from Eq. (1) is

$$q' = 75 \text{ W/m} \cdot \text{K} \times 1.70(100 - 0) \text{°C} = 12,750 \text{ W/m}$$

From the flux plot, estimate that

$$T(P) \approx 40^\circ C.$$ 

**COMMENTS:**
1. By inspection of the shapes for parts (a) and (b), it is obvious that the heat rate for the latter will be greater. The calculations show the heat rate is greater by more than a factor of three.
2. By comparing the flux plots for the two configurations, and corresponding roles of the adiabats and isotherms, would you expect the shape factor for parts (a) to be the reciprocal of part (b)?
PROBLEM 4.8

KNOWN: Relative dimensions and surface thermal conditions of a V-grooved channel.

FIND: Flux plot and shape factor.

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional conduction, (2) Steady-state conditions, (3) Constant properties.

ANALYSIS: With symmetry about the midplane, only one-half of the object need be considered as shown below.

Choosing 6 temperature increments (N = 6), it follows from the plot that M = 7. Hence from Eq. 4.26, the shape factor for the half section is

\[ S = \frac{M}{N} \ell = \frac{7}{6} \ell = 1.17 \ell. \]

For the complete system, the shape factor is then

\[ S = 2.34 \ell. \]
PROBLEM 4.9

KNOWN: Long conduit of inner circular cross section and outer surfaces of square cross section.

FIND: Shape factor and heat rate for the two applications when outer surfaces are insulated or maintained at a uniform temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional, steady-state conduction, (2) Constant properties and (3) Conduit is very long.

ANALYSIS: The adiabatic symmetry lines for each of the applications is shown above. Using the flux plot methodology and selecting four temperature increments (N = 4), the flux plots are as shown below.

For the symmetrical sections, \( S = 2S_o \), where \( S_o = \frac{M}{G^2} \) and the heat rate for each application is \( q = 2(S_o / G^2)k(T_1 - T_2) \).

<table>
<thead>
<tr>
<th>Application</th>
<th>M</th>
<th>N</th>
<th>( S_o / G^2 )</th>
<th>( q ) (W/m)</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>

<td>4</td>
<td>2.58</td>
<td>11,588</td>
</tr>
<tr>
<td>B</td>
<td>6.2</td>
<td>4</td>
<td>1.55</td>
<td>6,975</td>
</tr>
</tbody>
</table>

COMMENTS: (1) For application A, most of the heat lanes leave the inner surface \( (T_1) \) on the upper portion.

(2) For application B, most of the heat flow lanes leave the inner surface on the upper portion (that is, lanes 1-4). Because the lower, right-hand corner is insulated, the entire section experiences small heat flows (lane 6 + 0.2). Note the shapes of the isotherms near the right-hand, insulated boundary and that they intersect the boundary normally.
PROBLEM 4.10

KNOWN: Shape and surface conditions of a support column.

FIND: (a) Heat transfer rate per unit length. (b) Height of a rectangular bar of equivalent thermal resistance.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible three-dimensional conduction effects, (3) Constant properties, (4) Adiabatic sides.

PROPERTIES: Table A-1, Steel, AISI 1010 (323K): $k = 62.7 \text{ W/m} \cdot \text{K}.$

ANALYSIS: (a) From the flux plot for the half section, $M \approx 5$ and $N \approx 8$. Hence for the full section

\[ S = 2 \frac{M\ell}{N} \approx 1.25\ell \]

\[ q = Sk(T_1 - T_2) \]

\[ q' \approx 1.25 \times 62.7 \frac{W}{m \cdot K} \times (100 - 0) \^\circ \text{C} \]

\[ q' \approx 7.8 \text{ kW/m}. \]

(b) The rectangular bar provides for one-dimensional heat transfer. Hence,

\[ q = k A \frac{(T_1 - T_2)}{H} = k (0.3\ell) \frac{(T_1 - T_2)}{H} \]

Hence,

\[ H = \frac{0.3k(T_1 - T_2)}{q'} = \frac{0.3\text{m}(62.7 \text{ W/m} \cdot \text{K})(100 \^\circ \text{C})}{7800 \text{ W/m}} = 0.24\text{m}. \]

COMMENTS: The fact that $H < 0.3\text{m}$ is consistent with the requirement that the thermal resistance of the trapezoidal column must be less than that of a rectangular bar of the same height and top width (because the width of the trapezoidal column increases with increasing distance, $x$, from the top). Hence, if the rectangular bar is to be of equivalent resistance, it must be of smaller height.
PROBLEM 4.11

KNOWN: Hollow prismatic bars fabricated from plain carbon steel, 1m in length with prescribed temperature difference.

FIND: Shape factors and heat rate per unit length.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction, (3) Constant properties.

PROPERTIES: Table A-1, Steel, Plain Carbon (400K), $k = 57 \text{ W/m}\cdot\text{K}$.

ANALYSIS: Construct a flux plot on the symmetrical sections (shaded-regions) of each of the bars.

The shape factors for the symmetrical sections are,

$$S_{0,A} = \frac{M\ell}{N} = \frac{4}{4} \ell = 1\ell$$

$$S_{0,B} = \frac{M\ell}{N} = \frac{3.5}{4} \ell = 0.88\ell.$$ 

Since each of these sections is $\frac{1}{4}$ of the bar cross-section, it follows that

$$S_A = 4 \times 1\ell = 4\ell$$

$$S_B = 4 \times 0.88\ell = 3.5\ell.$$ 

The heat rate per unit length is $q' = q/\ell = k (S/\ell) (T_1 - T_2)$,

$$q'_{A} = 57 \frac{W}{m \cdot K} \times 4 (500 - 300) \text{ K} = 45.6 \text{ kW/m}.$$ 

$$q'_{B} = 57 \frac{W}{m \cdot K} \times 3.5 (500 - 300) \text{ K} = 39.9 \text{ kW/m}.$$
**PROBLEM 4.12**

**KNOWN:** Two-dimensional, square shapes, 1 m to a side, maintained at uniform temperatures as prescribed, perfectly insulated elsewhere.

**FIND:** Using the flux plot method, estimate the heat rate per unit length normal to the page if the thermal conductivity is 50 W/m-K

**ASSUMPTIONS:** (1) Steady-state, two-dimensional conduction, (2) Constant properties.

**ANALYSIS:** Use the methodology of Section 4.3.1 to construct the flux plots to obtain the shape factors from which the heat rates can be calculated. With Figure (a), begin at the lower-left side making the isotherms almost equally spaced, since the heat flow will only slightly spread toward the right. Start sketching the adiabats in the vicinity of the T2 surface. The dashed line represents the adiabat which separates the shape into two segments. Having recognized this feature, it was convenient to identify partial heat lanes. Figure (b) is less difficult to analyze since the isotherm intervals are nearly regular in the lower left-hand corner.

![Diagram](image)

The shape factors are calculated from Eq. 4.26 and the heat rate from Eq. 4.25.

\[
S' = \frac{M}{N} = \frac{0.5 + 3 + 0.5 + 0.5 + 0.2}{6} = 0.70
\]

\[
S' = \frac{M}{N} = \frac{4.5}{5} = 0.90
\]

\[
q' = kS'(T_1 - T_2)
\]

\[
q' = 10 \text{ W/m} \cdot \text{K} \times 0.70(100 - 0) \text{K} = 700 \text{ W/m} \]

\[
q' = 10 \text{ W/m} \cdot \text{K} \times 0.90(100 - 0) \text{K} = 900 \text{ W/m}
\]

**COMMENTS:** Using a finite-element package with a fine mesh, we determined heat rates of 956 and 915 W/m, respectively, for Figures (a) and (b). The estimate for the less difficult Figure (b) is within 2% of the numerical method result. For Figure (a), our flux plot result was 27% low.
PROBLEM 4.13

KNOWN: Uniform media of prescribed geometry.

FIND: (a) Shape factor expressions from thermal resistance relations for the plane wall, cylindrical shell and spherical shell, (b) Shape factor expression for the isothermal sphere of diameter D buried in an infinite medium.

ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform properties.

ANALYSIS: (a) The relationship between the shape factor and thermal resistance of a shape follows from their definitions in terms of heat rates and overall temperature differences.

\[ q = kS\Delta T \quad (4.25), \quad q = \frac{\Delta T}{R_t} \quad (3.19), \quad S = \frac{1}{kR_t} \quad (4.27) \]

Using the thermal resistance relations developed in Chapter 3, their corresponding shape factors are:

**Plane wall:**

\[ R_t = \frac{L}{kA}, \quad S = \frac{A}{L}. \]

**Cylindrical shell:**

\[ R_t = \frac{\ln (r_2 / \eta)}{2\pi Lk}, \quad S = \frac{2\pi L}{\ln r_2 / \eta}. \]

\((L \text{ into the page})\)

**Spherical shell:**

\[ R_t = \frac{1}{4\pi k} \left[ \frac{1}{r_1} - \frac{1}{r_2} \right], \quad S = \frac{4\pi}{l/r_1 - l/r_2}. \]

(b) The shape factor for the sphere of diameter D in an infinite medium can be derived using the alternative conduction analysis of Section 3.1. For this situation, \( q_r \) is a constant and Fourier’s law has the form

\[ q_r = -k \left( 4\pi r^2 \right) \frac{dT}{dr}. \]

Separate variables, identify limits and integrate.

\[ -\frac{q_r}{4\pi k} \left[ \frac{D}{2} \int_{r}^{T_2} \frac{dT}{T_1} \right] = -\frac{q_r}{4\pi k} \left[ -\frac{1}{r} \int_{D/2}^{\infty} \frac{dr}{D} \right] = -\frac{q_r}{4\pi k} \left[ 0 - \frac{2}{D} \right] = (T_2 - T_1) \]

\[ q_r = 4\pi k \left[ \frac{D}{2} \right] (T_1 - T_2) \quad \text{or} \quad S = 2\pi D. \]

COMMENTS: Note that the result for the buried sphere, \( S = 2\pi D \), can be obtained from the expression for the spherical shell with \( r_2 = \infty \). Also, the shape factor expression for the “isothermal sphere buried in a semi-infinite medium” presented in Table 4.1 provides the same result with \( z \to \infty \).
**PROBLEM 4.14**

**KNOWN:** Heat generation in a buried spherical container.

**FIND:** (a) Outer surface temperature of the container, (b) Representative isotherms and heat flow lines.

**SCHEMATIC:**

![Schematic Diagram](image)

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Soil is a homogeneous medium with constant properties.

**PROPERTIES:** Table A-3, Soil (300K): \( k = 0.52 \text{ W/m} \cdot \text{K} \).

**ANALYSIS:** (a) From an energy balance on the container, \( q = \dot{E}_g \) and from the first entry in Table 4.1,

\[
q = \frac{2\pi D}{1 - D/4z} k (T_1 - T_2).
\]

Hence,

\[
T_1 = T_2 + \frac{q}{k} \frac{1 - D/4z}{2\pi D} = 20^\circ C + \frac{500\text{W}}{0.52 \text{W/m} \cdot \text{K}} \frac{1 - 2\text{m}/40\text{m}}{2\pi (2\text{m})} = 92.7^\circ C
\]

(b) The isotherms may be viewed as spherical surfaces whose center moves downward with increasing radius. The surface of the soil is an isotherm for which the center is at \( z = \infty \).
**PROBLEM 4.15**

**KNOWN:** Temperature, diameter and burial depth of an insulated pipe.

**FIND:** Heat loss per unit length of pipe.

**SCHEMATIC:**

![Diagram showing the temperature difference and insulation](Image)

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional conduction through insulation, two-dimensional through soil, (3) Constant properties, (4) Negligible oil convection and pipe wall conduction resistances.

**PROPERTIES:** Table A-3, Soil (300K): \( k = 0.52 \text{ W/m} \cdot \text{K} \); Table A-3, Cellular glass (365K): \( k = 0.069 \text{ W/m} \cdot \text{K} \).

**ANALYSIS:** The heat rate can be expressed as

\[
q = \frac{T_1 - T_2}{R_{\text{tot}}},
\]

where the thermal resistance is \( R_{\text{tot}} = R_{\text{ins}} + R_{\text{soil}} \). From Eq. 3.28,

\[
R_{\text{ins}} = \frac{\ln \left( \frac{D_2}{D_1} \right)}{2\pi L k_{\text{ins}}} = \frac{\ln \left( \frac{0.7}{0.5} \right)}{2\pi L \times 0.069 \text{ W/m} \cdot \text{K}} = \frac{0.776 \text{ m} \cdot \text{K/W}}{L}.
\]

From Eq. 4.27 and Table 4.1,

\[
R_{\text{soil}} = \frac{1}{SK_{\text{soil}}} = \frac{\cosh^{-1} \left( \frac{2z}{D_2} \right)}{2\pi L k_{\text{soil}}} = \frac{\cosh^{-1} \left( \frac{3}{0.7} \right)}{2\pi \times 0.52 \text{ W/m} \cdot \text{K}}L = \frac{0.653}{L} \text{ m} \cdot \text{K/W}.
\]

Hence,

\[
q = \frac{(120 - 0) \degree \text{C}}{L} = \frac{84 \text{ W/m}}{ \frac{0.776 + 0.653}{m} \text{ m} \times L} = 84 \text{ W/m}.
\]

**COMMENTS:** (1) Contributions of the soil and insulation to the total resistance are approximately the same. The heat loss may be reduced by burying the pipe deeper or adding more insulation.

(2) The convection resistance associated with the oil flow through the pipe may be significant, in which case the foregoing result would overestimate the heat loss. A calculation of this resistance may be based on results presented in Chapter 8.

(3) Since \( z > 3D/2 \), the shape factor for the soil can also be evaluated from \( S = 2\pi L / \ell n(4z/D) \) of Table 4.1, and an equivalent result is obtained.
PROBLEM 4.16

KNOWN: Operating conditions of a buried superconducting cable.

FIND: Required cooling load.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Two-dimensional conduction in soil, (4) One-dimensional conduction in insulation.

ANALYSIS: The heat rate per unit length is

\[
q' = \frac{T_g - T_n}{R_g' + R_I'}
\]

where Tables 3.3 and 4.1 have been used to evaluate the insulation and ground resistances, respectively. Hence,

\[
q' = \frac{(300 - 77) K}{\left[\frac{1.2 W/m \cdot K}{2 \pi \ln\left(\frac{8}{0.2}\right)}\right]^{-1} + \ln\left(\frac{D_o}{D_i}\right) / 2 \pi \cdot k_i}
\]

where Tables 3.3 and 4.1 have been used to evaluate the insulation and ground resistances, respectively. Hence,

\[
q' = \frac{(300 - 77) K}{[1.2 W/m \cdot K] \left(2 \pi / \ln\left(8 / 0.2\right)\right)^{-1} + \ln\left(\frac{D_o}{D_i}\right) / 2 \pi \times 0.005 W/m \cdot K}
\]

\[
q' = \frac{223 K}{0.489 + 22.064 m \cdot K/W}
\]

\[
q' = 9.9 W/m.
\]

COMMENTS: The heat gain is small and the dominant contribution to the thermal resistance is made by the insulation.
PROBLEM 4.17

**KNOWN:** Electrical heater of cylindrical shape inserted into a hole drilled normal to the surface of a large block of material with prescribed thermal conductivity.

**FIND:** Temperature reached when heater dissipates 50 W with the block at 25°C.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Block approximates semi-infinite medium with constant properties, (3) Negligible heat loss to surroundings above block surface, (4) Heater can be approximated as isothermal at $T_1$.

**ANALYSIS:** The temperature of the heater surface follows from the rate equation written as

$$T_1 = T_2 + \frac{q}{kS}$$

where $S$ can be estimated from the conduction shape factor given in Table 4.1 for a “vertical cylinder in a semi-infinite medium,”

$$S = 2\pi L/\ell n\left(\frac{4L}{D}\right).$$

Substituting numerical values, find

$$S = 2\pi \times 0.1m/\ell n\left[\frac{4 \times 0.1m}{0.005m}\right] = 0.143m.$$

The temperature of the heater is then

$$T_1 = 25°C + 50 \frac{W}{(5 \ W/m\cdot K \times 0.143m)} = 94.9°C.$$

**COMMENTS:** (1) Note that the heater has $L >> D$, which is a requirement of the shape factor expression.

(2) Our calculation presumes there is negligible thermal contact resistance between the heater and the medium. In practice, this would not be the case unless a conducting paste were used.

(3) Since $L >> D$, assumption (3) is reasonable.

(4) This configuration has been used to determine the thermal conductivity of materials from measurement of $q$ and $T_1$. 
PROBLEM 4.18

KNOWN: Surface temperatures of two parallel pipe lines buried in soil.

FIND: Heat transfer per unit length between the pipe lines.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction, (3) Constant properties, (4) Pipe lines are buried very deeply, approximating burial in an infinite medium, (5) Pipe length >> \( D_1 \) or \( D_2 \) and \( w > D_1 \) or \( D_2 \).

ANALYSIS: The heat transfer rate per unit length from the hot pipe to the cool pipe is

\[
q' = \frac{q}{L} = \frac{S}{L} k (T_1 - T_2).
\]

The shape factor \( S \) for this configuration is given in Table 4.1 as

\[
S = \frac{2\pi L}{\cosh^{-1} \left[ \frac{4w^2 - D_1^2 - D_2^2}{2D_1D_2} \right]}.
\]

Substituting numerical values,

\[
\frac{S}{L} = 2\pi /\cosh^{-1} \left[ \frac{4 \times (0.5m)^2 - (0.1m)^2 - (0.075m)^2}{2 \times 0.1m \times 0.075m} \right] = 2\pi /\cosh^{-1}(65.63)
\]

\[
\frac{S}{L} = 2\pi /4.88 = 1.29.
\]

Hence, the heat rate per unit length is

\[
q' = 1.29 \times 0.5 W/m \cdot K (175 - 5) \circ C = 110 W/m.
\]

COMMENTS: The heat gain to the cooler pipe line will be larger than 110 W/m if the soil temperature is greater than 5°C. How would you estimate the heat gain if the soil were at 25°C?
PROBLEM 4.19

KNOWN: Tube embedded in the center plane of a concrete slab.

FIND: (a) The shape factor and heat transfer rate per unit length using the appropriate tabulated relation, (b) Shape factor using flux plot method.

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional conduction, (2) Steady-state conditions, (3) Constant properties, (4) Concrete slab infinitely long in horizontal plane, L >> z.

PROPERTIES: Table A-3, Concrete, stone mix (300K): k = 1.4 W/mK.

ANALYSIS: (a) If we relax the restriction that z >> D/2, the embedded tube-slab system corresponds to the fifth case of Table 4.1. Hence,

\[ S = \frac{2\pi L}{\ell n \left( \frac{8z}{\pi D} \right)} \]

where L is the length of the system normal to the page, z is the half-thickness of the slab and D is the diameter of the tube. Substituting numerical values, find

\[ S = \frac{2\pi L}{\ell n \left( \frac{8\times50mm}{\pi 50mm} \right)} = 6.72L. \]

Hence, the heat rate per unit length is

\[ q' = \frac{ql}{} = \frac{S}{L} k \left( T_1 - T_2 \right) = 6.72 \times 1.4 \frac{W}{m \cdot K} (85 - 20) \circ C = 612 W. \]

(b) To find the shape factor using the flux plot method, first identify the symmetrical section bounded by the symmetry adiabats formed by the horizontal and vertical center lines. Selecting four temperature increments (N = 4), the flux plot can then be constructed.

From Eq. 4.26, the shape factor of the symmetrical section is

\[ S_0 = \frac{ML}{N} = 6L/4 = 1.5L. \]

For the tube-slab system, it follows that S = 4S_0 = 6.0L, which compares favorably with the result obtained from the shape factor relation.
PROBLEM 4.20

KNOWN: Dimensions and boundary temperatures of a steam pipe embedded in a concrete casing.

FIND: Heat loss per unit length.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible steam side convection resistance, pipe wall resistance and contact resistance (T₁ = 450K), (3) Constant properties.

PROPERTIES: Table A-3, Concrete (300K): k = 1.4 W/m·K.

ANALYSIS: The heat rate can be expressed as

\[ q = S k (T_1 - T_2) \]

From Table 4.1, the shape factor is

\[ S = \frac{2\pi L}{1.08 \frac{w}{D}} \]

Hence,

\[ q' = \frac{q}{L} = \frac{2\pi k (T_1 - T_2)}{1.08 \frac{w}{D}} \]

\[ q' = \frac{2\pi \times 1.4 \text{ W/m·K} \times (450 - 300) \text{ K}}{1.08 \times 1.5m \over 0.5m} = 1122 \text{ W/m.} \]

COMMENTS: Having neglected the steam side convection resistance, the pipe wall resistance, and the contact resistance, the foregoing result overestimates the actual heat loss.
PROBLEM 4.21

KNOWN: Thin-walled copper tube enclosed by an eccentric cylindrical shell; intervening space filled with insulation.

FIND: Heat loss per unit length of tube; compare result with that of a concentric tube-shell arrangement.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Thermal resistances of copper tube wall and outer shell wall are negligible, (4) Two-dimensional conduction in insulation.

ANALYSIS: The heat loss per unit length written in terms of the shape factor $S$ is

$$q' = k \left( S/\ell \right) (T_1 - T_2)$$

and from Table 4.1 for this geometry,

$$S = 2\pi / \cosh^{-1} \left[ \frac{D^2 + d^2 - 4z^2}{2Dd} \right].$$

Substituting numerical values, all dimensions in mm,

$$S = 2\pi / \cosh^{-1} \left[ \frac{120^2 + 30^2 - 4(20)^2}{2 \times 120 \times 30} \right] = 2\pi / \cosh^{-1} (1.903) = 4.991.$$

Hence, the heat loss is

$$q' = 0.05 \text{W/m} \cdot \text{K} \times 4.991 (85 - 35) \degree \text{C} = 12.5 \text{ W/m}.$$

If the copper tube were concentric with the shell, but all other conditions were the same, the heat loss would be

$$q_c = \frac{2\pi k (T_1 - T_2)}{\ell \ln (D_2 / D_1)}$$

using Eq. 3.27. Substituting numerical values,

$$q_c = 2\pi \times 0.05 \frac{W}{m \cdot K} (85 - 35) \degree \text{C} / \ln \left( \frac{120}{30} \right)$$

$$q_c = 11.3 \text{ W/m}.$$

COMMENTS: As expected, the heat loss with the eccentric arrangement is larger than that for the concentric arrangement. The effect of the eccentricity is to increase the heat loss by $(12.5 - 11.3)/11.3 \approx 11\%$. 
**PROBLEM 4.22**

**KNOWN:** Cubical furnace, 350 mm external dimensions, with 50 mm thick walls.

**FIND:** The heat loss, \( q(W) \).

**SCHEMATIC:**

![Cross-sectional view of the furnace](image)

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Two-dimensional conduction, (3) Constant properties.

**PROPERTIES:** Table A-3, Fireclay brick \((T = (T_1 + T_2)/2 = 610K)\): \( k = 1.1 \text{ W/m} \cdot \text{K} \).

**ANALYSIS:** Using relations for the shape factor from Table 4.1,

- **Plane Walls** (6)
  \[ S_W = \frac{A}{L} = \frac{0.25 \times 0.25 \text{m}^2}{0.05 \text{m}} = 1.25 \text{m} \]

- **Edges** (12)
  \[ S_E = 0.54D = 0.54 \times 0.25 \text{m} = 0.14 \text{m} \]

- **Corners** (8)
  \[ S_C = 0.15L = 0.15 \times 0.05 \text{m} = 0.008 \text{m} \]

The heat rate in terms of the shape factors is

\[
q = kS(T_1 - T_2) = k \left( 6S_W + 12S_E + 8S_C \right) (T_1 - T_2)
\]

\[
q = 1.1 \frac{W}{\text{m} \cdot \text{K}} \left( 6 \times 1.25 \text{m} + 12 \times 0.14 \text{m} + 0.15 \times 0.008 \text{m} \right) (600 - 75) \text{°C}
\]

\[
q = 5.30 \text{ kW}.
\]

**COMMENTS:** Note that the restrictions for \( S_E \) and \( S_C \) have been met.
PROBLEM 4.23

KNOWN: Dimensions, thermal conductivity and inner surface temperature of furnace wall. Ambient conditions.

FIND: Heat loss.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Uniform convection coefficient over entire outer surface of container.

ANALYSIS: From the thermal circuit, the heat loss is

\[ q = \frac{T_{s,i} - T_\infty}{R_{\text{cond}(2D)} + R_{\text{conv}}} \]

where \( R_{\text{conv}} = 1/hA_{s,o} = 1/6(hW^2) = 1/6[5 \text{ W/m}^2 \cdot \text{K}(5 \text{ m})^2] = 0.00133 \text{ K/W}. \) From Eq. (4.27), the two-dimensional conduction resistance is

\[ R_{\text{cond}(2D)} = \frac{1}{Sk} \]

where the shape factor \( S \) must include the effects of conduction through the 8 corners, 12 edges and 6 plane walls. Hence, using the relations for Cases 8 and 9 of Table 4.1,

\[ S = 8(0.15L) + 12 \times 0.54(W - 2L) + 6 A_{s,i}/L \]

where \( A_{s,i} = (W - 2L)^2 \). Hence,

\[ S = \left[ 8(0.15 \times 0.35) + 12 \times 0.54(4.30) + 6(52.83) \right] \text{m} \]

\[ S = (0.42 + 27.86 + 316.98) \text{m} = 345.26 \text{m} \]

and \( R_{\text{cond}(2D)} = 1/(345.26 \text{ m} \times 1.4 \text{ W/m} \cdot \text{K}) = 0.00207 \text{ K/W}. \) Hence

\[ q = \frac{(1100 - 25)^\circ \text{C}}{(0.00207 + 0.00133) \text{K/W}} = 316 \text{kW} \]

COMMENTS: The heat loss is extremely large and measures should be taken to insulate the furnace.
PROBLEM 4.24

KNOWN: Platen heated by passage of hot fluid in poor thermal contact with cover plates exposed to cooler ambient air.

FIND: (a) Heat rate per unit thickness from each channel, \( q'_i \), (b) Surface temperature of cover plate, \( T_s \), (c) \( q'_i \) and \( T_s \) if lower surface is perfectly insulated, (d) Effect of changing centerline spacing on \( q'_i \) and \( T_s \)

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction in platen, but one-dimensional in coverplate, (3) Temperature of interfaces between A and B is uniform, (4) Constant properties.

ANALYSIS: (a) The heat rate per unit thickness from each channel can be determined from the following thermal circuit representing the quarter section shown.

The value for the shape factor is \( S' = 1.06 \) as determined from the flux plot shown on the next page. Hence, the heat rate is

\[
q'_i = 4 \left( T_i - T_\infty \right) / R'_\text{tot}
\]

\[
R'_\text{tot} = \left[ 1/1000 \text{ W/m}^2 \cdot \text{K} \left( \pi 0.015 \text{m}/4 \right) + 1/20 \text{ W/m} \cdot \text{K} \times 1.06 \\
+ 2.0 \times 10^{-4} \text{ m}^2 \cdot \text{K/W} \left( 0.060 \text{m}/2 \right) + 0.0075 \text{m}/75 \text{ W/m} \cdot \text{K} \left( 0.060 \text{m}/2 \right) \\
+ 1/200 \text{ W/m}^2 \cdot \text{K} \left( 0.060 \text{m}/2 \right) \right]
\]

\[
R'_\text{tot} = \left[ 0.085 + 0.047 + 0.0067 + 0.0033 + 0.1667 \right] \text{m} \cdot \text{K/W}
\]

\[
R_\text{tot} = 0.309 \text{ m} \cdot \text{K/W}
\]

\[
q'_i = 4 \left( 150 - 25 \right) \text{K} \cdot 0.309 \text{ m} \cdot \text{K/W} = 1.62 \text{ kW/m}.
\]

(b) The surface temperature of the cover plate also follows from the thermal circuit as

\[
q'_i / 4 = \frac{T_s - T_\infty}{1/\text{h}_o \left( \text{L}_o / 2 \right)}
\]
PROBLEM 4.24 (Cont.)

\[
T_s = T_\infty + \frac{q'_i}{4} \frac{1}{h_o \left( \frac{L_o}{2} \right)} = 25^\circ C + \frac{1.62 \text{ kW}}{4} \times 0.167 \text{ m} \cdot \text{K/W}
\]

\[
T_s = 25^\circ C + 67.6^\circ C \approx 93^\circ C.
\]

(c,d) The effect of the centerline spacing on \( q'_i \) and \( T_s \) can be understood by examining the relative magnitudes of the thermal resistances. The dominant resistance is that due to the ambient air convection process which is inversely related to the spacing \( L_o \). Hence, from Eq. (1), the heat rate will increase nearly linearly with an increase in \( L_o \),

\[
q'_i \sim \frac{1}{R'_{\text{tot}}} \approx \frac{1}{1/h_o \left( \frac{L_o}{2} \right)} \sim L_o.
\]

From Eq. (2), find

\[
\Delta T = T_s - T_\infty = \frac{q'_i}{4} \frac{1}{h_o \left( \frac{L_o}{2} \right)} - q'_i \cdot L_o^{-1} \sim L_o \cdot L_o^{-1} \approx 1.
\]

Hence we conclude that \( \Delta T \) will not increase with a change in \( L_o \). Does this seem reasonable?

What effect does \( L_o \) have on Assumptions (2) and (3)?

If the lower surface were insulated, the heat rate would be decreased nearly by half. This follows again from the fact that the overall resistance is dominated by the surface convection process. The temperature difference, \( T_s - T_\infty \), would only increase slightly.

Assume 1/4 lane

\[
S' = S/L = M/N = 4.25/4 = 1.06
\]
PROBLEM 4.25

KNOWN: Long constantan wire butt-welded to a large copper block forming a thermocouple junction on the surface of the block.

FIND: (a) The measurement error \(T_j - T_o\) for the thermocouple for prescribed conditions, and (b) Compute and plot \((T_j - T_o)\) for \(h = 5, 10\) and 25 W/m\(^2\)-K for block thermal conductivity \(15 \leq k \leq 400\) W/m-K. When is it advantageous to use smaller diameter wire?

SCHEMATIC:

\[
T_\infty = 25^°C \\
h = 10 \text{ W/m}^2 \cdot \text{K}
\]

\[
\text{Thermocouple wire, } D = 1 \text{ mm, } k_t
\]

\[
\text{copper block } \\
T_o = 125^°C
\]

ASSUMPTIONS: (1) Steady-state conditions, (2) Thermocouple wire behaves as a fin with constant heat transfer coefficient, (3) Copper block has uniform temperature, except in the vicinity of the junction.

PROPERTIES: Table A-1, Copper (pure, 400 K), \(k_b = 393\) W/m-K; Constantan (350 K), \(k_t \approx 25\) W/m-K.

ANALYSIS: The thermocouple wire behaves as a long fin permitting heat to flow from the surface thereby depressing the sensing junction temperature below that of the block \(T_o\). In the block, heat flows into the circular region of the wire-block interface; the thermal resistance to heat flow within the block is approximated as a disk of diameter \(D\) on a semi-infinite medium \((k_b, T_o)\). The thermocouple-block combination can be represented by a thermal circuit as shown above. The thermal resistance of the fin follows from the heat rate expression for an infinite fin, \(R_{\text{fin}} = (hP_kA_k)^{1/2}\).

From Table 4.1, the shape factor for the disk-on-a-semi-infinite medium is given as \(S = 2D\) and hence \(R_{\text{block}} = 1/k_0S = 1/2k_0D\). From the thermal circuit,

\[
T_o - T_j = \frac{R_{\text{block}}}{R_{\text{fin}} + R_{\text{block}}} (T_0 - T_\infty) = \frac{1.27}{1273 + 1.27} (125 - 25)^°C = 0.001(125 - 25)^°C = 0.1°C . \]

with \(P = \pi D\) and \(A_c = \pi D^2/4\) and the thermal resistances as

\[
R_{\text{fin}} = \left(10 \text{ W/m}^2 \cdot \text{K} \times \frac{(25 \text{ W/m} \cdot \text{K})}{4} \times \left(1 \times 10^{-3} \text{ m}\right)^3\right)^{1/2} = 1273\text{ K/W}
\]

\[
R_{\text{block}} = (1/2) \times 393\text{ W/m} \cdot \text{K} \times 10^{-3} \text{ m} = 1.27\text{ K/W} .
\]

(b) We keyed the above equations into the IHT workspace, performed a sweep on \(k_b\) for selected values of \(h\) and created the plot shown. When the block thermal conductivity is low, the error \((T_o - T_j)\) is larger, increasing with increasing convection coefficient. A smaller diameter wire will be advantageous for low values of \(k_b\) and higher values of \(h\).
PROBLEM 4.26

KNOWN: Dimensions, shape factor, and thermal conductivity of square rod with drilled interior hole. Interior and exterior convection conditions.

FIND: Heat rate and surface temperatures.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, two-dimensional conduction, (2) Constant properties, (3) Uniform convection coefficients at inner and outer surfaces.

ANALYSIS: The heat loss can be expressed as

\[ q = \frac{T_{\infty,1} - T_{\infty,2}}{R_{\text{conv,1}} + R_{\text{cond (2D)}} + R_{\text{conv,2}}} \]

where

\[ R_{\text{conv,1}} = (h_1 \pi D_1 L)^{-1} = \left( \frac{50 \text{ W/m}^2 \cdot \text{K} \times \pi \times 0.25 \text{ m} \times 2 \text{ m}}{1} \right)^{-1} = 0.01273 \text{ K/W} \]

\[ R_{\text{cond (2D)}} = (S k)^{-1} = \left( \frac{8.59 \text{ m} \times 150 \text{ W/m} \cdot \text{K}}{1} \right)^{-1} = 0.00078 \text{ K/W} \]

\[ R_{\text{conv,2}} = (h_2 \times 4wL)^{-1} = \left( \frac{4 \text{ W/m}^2 \cdot \text{K} \times 4 \text{ m} \times 1 \text{ m}}{1} \right)^{-1} = 0.0625 \text{ K/W} \]

Hence,

\[ q = \frac{(300 - 25)^\circ \text{C}}{0.076 \text{ K/W}} = 3.62 \text{ kW} \]

\[ T_1 = T_{\infty,1} - qR_{\text{conv,1}} = 300^\circ \text{C} - 46^\circ \text{C} = 254^\circ \text{C} \]

\[ T_2 = T_{\infty,2} + qR_{\text{conv,2}} = 25^\circ \text{C} + 226^\circ \text{C} = 251^\circ \text{C} \]

COMMENTS: The largest resistance is associated with convection at the outer surface, and the conduction resistance is much smaller than both convection resistances. Hence, \((T_2 - T_{\infty,2}) > (T_{\infty,1} - T_1) >> (T_1 - T_2)\).
PROBLEM 4.27

KNOWN: Long fin of aluminum alloy with prescribed convection coefficient attached to different base materials (aluminum alloy or stainless steel) with and without thermal contact resistance $R_{t,j}^{\prime\prime}$ at the junction.

FIND: (a) Heat rate $q_f$ and junction temperature $T_j$ for base materials of aluminum and stainless steel, (b) Repeat calculations considering thermal contact resistance, $R_{t,j}^{\prime\prime}$, and (c) Plot as a function of $h$ for the range $10 \leq h \leq 1000 \text{ W/m}^2\cdot\text{K}$ for each base material.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Infinite fin.

PROPERTIES: (Given) Aluminum alloy, $k = 240 \text{ W/m} \cdot \text{K}$, Stainless steel, $k = 15 \text{ W/m} \cdot \text{K}$.

ANALYSIS: (a,b) From the thermal circuits, the heat rate and junction temperature are

$$q_f = \frac{T_b - T_\infty}{R_{\text{tot}}} = \frac{T_b - T_\infty}{R_b + R_{t,j} + R_f}$$

$$T_j = T_\infty + q_f R_f$$

and, with $P = \pi D$ and $A_c = \pi D^2/4$, from Tables 4.1 and 3.4 find

$$R_b = l/Sk_b = l/(2Dk_b) = (2 \times 0.005 \text{ m} \times k_b)^{-1}$$

$$R_{t,j} = R_{t,j}/A_c = 3 \times 10^{-5} \text{ m}^2 \cdot \text{K} / \pi (0.005 \text{ m})^2 / 4 = 1.528 \text{ K/W}$$

$$R_f = (hPkA_c)^{-1/2} = \left[50 \text{ W/m}^2 \cdot \text{K} \pi^2 (0.005 \text{ m})^2 \cdot 240 \text{ W/m} \cdot \text{K}/4 \right]^{-1/2} = 16.4 \text{ K/W}$$

Without $R_{t,j}^{\prime\prime}$

With $R_{t,j}^{\prime\prime}$

(c) We used the IHT Model for Extended Surfaces, Performance Calculations, Rectangular Pin Fin to calculate $q_f$ for $10 \leq h \leq 1000 \text{ W/m}^2\cdot\text{K}$ by replacing $R_{t,c}^{\prime\prime}$ (thermal resistance at fin base) by the sum of the contact and spreading resistances, $R_{t,j}^{\prime\prime} + R_b^{\prime\prime}$.

Continued...
COMMENTS:  (1) From part (a), the aluminum alloy base material has negligible effect on the fin heat rate and depresses the base temperature by only 2°C. The effect of the stainless steel base material is substantial, reducing the heat rate by 27% and depressing the junction temperature by 25°C.

(2) The contact resistance reduces the heat rate and increases the temperature depression relatively more with the aluminum alloy base.

(3) From the plot of $q_f$ vs. $h$, note that at low values of $h$, the heat rates are nearly the same for both materials since the fin is the dominant resistance. As $h$ increases, the effect of $R_f^c$ becomes more important.
**PROBLEM 4.28**

**KNOWN:** Igloo constructed in hemispheric shape sits on ice cap; igloo wall thickness and inside/outside convection coefficients \((h_i, h_o)\) are prescribed.

**FIND:** (a) Inside air temperature \(T_{\infty,i}\) when outside air temperature is \(T_{\infty,o} = -40^\circ C\) assuming occupants provide 320 W within igloo, (b) Perform parameter sensitivity analysis to determine which variables have significant effect on \(T_i\).

**SCHEMATIC:**

![Igloo Schematic](image)

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Convection coefficient is the same on floor and ceiling of igloo, (3) Floor and ceiling are at uniform temperature, (4) Floor-ice cap resembles disk on semi-infinite medium, (5) One-dimensional conduction through igloo walls.

**PROPERTIES:** Ice and compacted snow (given): \(k = 0.15\) W/m-K.

**ANALYSIS:** (a) The thermal circuit representing the heat loss from the igloo to the outside air and through the floor to the ice cap is shown above. The heat loss is

\[
q = \frac{T_{\infty,i} - T_{\infty,o}}{R_{cv,c} + R_{wall} + R_{cv,o}} + \frac{T_{\infty,i} - T_{ic}}{R_{cv,f} + R_{cap}}.
\]

**Convection, ceiling:**

\[
R_{cv,c} = \frac{2}{h_i \left(4\pi r_i^2\right)} = \frac{2}{6\text{ W/m}^2\cdot\text{K} \times 4\pi (1.8\text{ m})^2} = 0.00819\text{ K/W}
\]

**Convection, outside:**

\[
R_{cv,o} = \frac{2}{h_o \left(4\pi r_o^2\right)} = \frac{2}{15\text{ W/m}^2\cdot\text{K} \times 4\pi (2.3\text{ m})^2} = 0.00201\text{ K/W}
\]

**Convection, floor:**

\[
R_{cv,f} = \frac{1}{h_i \left(\pi r_i^2\right)} = \frac{1}{6\text{ W/m}^2\cdot\pi (1.8\text{ m})^2} = 0.01637\text{ K/W}
\]

**Conduction, wall:**

\[
R_{wall} = 2 \left[ \frac{1}{4\pi k} \left( \frac{1}{r_i} - \frac{1}{r_o} \right) \right] = 2 \left[ \frac{1}{4\pi \times 0.15\text{ W/m} \cdot \text{K} \left( \frac{1}{1.8} - \frac{1}{2.3} \right) \text{ m}} \right] = 0.1281\text{ K/W}
\]

**Conduction, ice cap:**

\[
R_{cap} = \frac{1}{kS} = \frac{1}{4k_i \left(4 \times 0.15\text{ W/m} \cdot \text{K} \times 1.8\text{ m} \right)} = 0.9259\text{ K/W}
\]

where \(S\) was determined from the shape factor of Table 4.1. Hence,

\[
q = 320\text{ W} = \frac{T_{\infty,i} - (-40)^\circ C}{(0.00818 + 0.1281 + 0.0020)\text{ K/W}} + \frac{T_{\infty,i} - (-20)^\circ C}{(0.01637 + 0.9259)\text{ K/W}}
\]

\[
320\text{ W} = 7.232(T_{\infty,i} + 40) + 1.06(T_{\infty,i} + 20)
\]

\[
T_{\infty,i} = 1.1^\circ C.
\]

Continued...
(b) Begin the parameter sensitivity analysis to determine important variables which have a significant influence on the inside air temperature by examining the thermal resistances associated with the processes present in the system and represented by the network.

</tbody>
</table>

It follows that the convection resistances are negligible relative to the conduction resistance across the igloo wall. As such, only changes to the wall thickness will have an appreciable effect on the inside air temperature relative to the outside ambient air conditions. We don’t want to make the igloo walls thinner and thereby allow the air temperature to dip below freezing for the prescribed environmental conditions.

Using the *IHT Thermal Resistance Network Model*, we used the circuit builder to construct the network and perform the energy balances to obtain the inside air temperature as a function of the outside convection coefficient for selected increased thicknesses of the wall.

**COMMENTS:**
(1) From the plot, we can see that the influence of the outside air velocity which controls the outside convection coefficient $h_0$ is negligible.

(2) The thickness of the igloo wall is the dominant thermal resistance controlling the inside air temperature.
PROBLEM 4.29

KNOWN: Diameter and maximum allowable temperature of an electronic component. Contact resistance between component and large aluminum heat sink. Temperature of heat sink and convection conditions at exposed component surface.

FIND: (a) Thermal circuit, (b) Maximum operating power of component.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Negligible heat loss from sides of chip.

ANALYSIS: (a) The thermal circuit is:

\[
\begin{align*}
Q_{\text{air}} & \quad R_{\text{conv}} \quad Q_{\text{c}} \quad R_{t,c} \quad R_{2D,\text{cond}} \quad Q_{\text{sink}} \\
T_\infty & \quad T_c & \quad T_b
\end{align*}
\]

where \( R_{2D,\text{cond}} \) is evaluated from the shape factor \( S = 2D \) of Table 4.1.

(b) Performing an energy balance for a control surface about the component,

\[
P = Q_{\text{air}} + Q_{\text{sink}} = h \left( \frac{\pi D^2}{4} \right) (T_c - T_\infty) + \frac{T_c - T_b}{R_{t,c}/\left( \frac{\pi D^2}{4} \right) + 1/2Dk}
\]

\[
P = 25 \text{ W/m}^2 \cdot \text{K} \left( \frac{\pi}{4} \right) (0.01 \text{ m})^2 75^\circ \text{C} + \frac{75^\circ \text{C}}{\left[ 0.5 \times 10^{-4} / \left( \frac{\pi}{4} \right) (0.01)^2 \right] + (0.02 \times 237)^{-1}} \text{K/W}
\]

\[
P = 0.15 \text{ W} + \frac{75^\circ \text{C}}{(0.64+0.21) \text{ K/W}} = 0.15 \text{ W} + 88.49 \text{ W} = 88.6 \text{ W}.
\]

COMMENTS: The convection resistance is much larger than the cumulative contact and conduction resistance. Hence, virtually all of the heat dissipated in the component is transferred through the block. The two-dimensional conduction resistance is significantly underestimated by use of the shape factor \( S = 2D \). Hence, the maximum allowable power is less than 88.6 W.
PROBLEM 4.30

KNOWN: Disc-shaped electronic devices dissipating 100 W mounted to aluminum alloy block with prescribed contact resistance.

FIND: (a) Temperature device will reach when block is at 27°C assuming all the power generated by the device is transferred by conduction to the block and (b) For the operating temperature found in part (a), the permissible operating power with a 30-pin fin heat sink.

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional, steady-state conduction, (2) Device is at uniform temperature, $T_1$, (3) Block behaves as semi-infinite medium.

PROPERTIES: Table A.1, Aluminum alloy 2024 (300 K): $k = 177 \text{ W/m$\cdot$K}$.

ANALYSIS: (a) The thermal circuit for the conduction heat flow between the device and the block shown in the above Schematic where $R_e$ is the thermal contact resistance due to the epoxy-filled interface,

$$R_e = R_{t,c}^{*}/A_c = R_{t,c}^{*}/\left(\pi D^2/4\right)$$

$$R_e = 5\times10^{-5} \text{ K} \cdot \text{m}^2/\text{W}/\left(\pi (0.020 \text{ m})^2\right)/4 = 0.159 \text{ K/W}$$

The thermal resistance between the device and the block is given in terms of the conduction shape factor, Table 4.1, as

$$R_b = l/S_k = l/(2Dk)$$

$$R_b = l/(2 \times 0.020 \text{ m} \times 177 \text{ W/m$\cdot$K}) = 0.141 \text{ K/W}$$

From the thermal circuit,

$$T_1 = T_2 + q_d (R_b + R_c)$$

$$T_1 = 27\degree \text{C} + 100 \text{ W} (0.141 + 0.159) \text{ K/W}$$

$$T_1 = 27\degree \text{C} + 30\degree \text{C} = 57\degree \text{C}$$

(b) The schematic below shows the device with the 30-pin fin heat sink with fins and base material of copper ($k = 400 \text{ W/m$\cdot$K}$). The airstream temperature is 27°C and the convection coefficient is 1000 W/m$^2$-K.

Continued...
The thermal circuit for this system has two paths for the device power: to the block by conduction, \( q_{cd} \), and to the ambient air by conduction to the fin array, \( q_{cv} \).

\[
q_d = \frac{T_1 - T_2}{R_b + R_c} + \frac{T_1 - T_\infty}{R_c + R_e + R_{\text{fin}}}
\]

(3)

where the thermal resistance of the fin base material is

\[
R_c = \frac{L_c}{k_c A_c} = \frac{0.005 \text{ m}}{400 \text{ W/m} \cdot \text{K} \left(\pi 0.02^2 / 4\right) \text{m}^2} = 0.03979 \text{ K/W}
\]

(4)

and \( R_{\text{fin}} \) represents the thermal resistance of the fin array (see Section 3.6.5).

\[
R_{\text{fin}} = R_{t,o} = \frac{1}{\eta_0 h A_t}
\]

(5, 3.103)

\[
\eta_0 = 1 - \frac{N A_f}{A_t} (1 - \eta_f)
\]

(6, 3.102)

where the fin and prime surface area is

\[
A_t = N A_f + A_b
\]

(3.99)

\[
A_t = N (\pi D_f L) + \left[ \pi D_f^2 / 4 \right] - N \left( \pi D_f^2 / 4 \right)
\]

where \( A_t \) is the fin surface area, \( D_d \) is the device diameter and \( D_f \) is the fin diameter.

\[
A_t = 30 \left( \pi \times 0.0015 \text{ m} \times 0.015 \text{ m} \right) + \left[ \pi \left( 0.020 \text{ m} \right)^2 / 4 \right] - 30 \left( \pi \left( 0.0015 \text{ m} \right)^2 / 4 \right)
\]

\[
A_t = 0.06362 \text{ m}^2 + 0.0002611 \text{ m}^2 = 0.06388 \text{ m}^2
\]

Using the *IHT Model, Extended Surfaces, Performance Calculations, Rectangular Pin Fin*, find the fin efficiency as

\[
\eta_f = 0.8546
\]

(7)

Continued...
Substituting numerical values into Eq. (6), find

\[ \eta_0 = 1 - \frac{30 \times \pi \times 0.0015 \text{m} \times 0.015 \text{m}}{0.06388 \text{m}^2} (1 - 0.8546) \]

\[ \eta_0 = 0.8552 \]

and the fin array thermal resistance is

\[ R_{\text{fin}} = \frac{1}{0.8552 \times 1000 \text{W/m}^2 \cdot \text{K} \times 0.06388 \text{m}^2} = 0.01831 \text{K/W} \]

Returning to Eq. (3), with \( T_1 = 57^\circ \text{C} \) from part (a), the permissible heat rate is

\[ q_d = \frac{(57 - 27)^\circ \text{C}}{(0.141 + 0.159) \text{K/W}} + \frac{(57 - 27)^\circ \text{C}}{(0.159 + 0.03979 + 0.01831) \text{K/W}} \]

\[ q_d = 100 \text{W} + 138.2 \text{W} = 238 \text{W} \]

**COMMENTS:**

1. Recognize in the part (b) analysis, that thermal resistances of the fin base and array are much smaller than the resistance due to the epoxy contact interfaces.

2. In calculating the fin efficiency, \( \eta_f \), using the IHT Model it is not necessary to know the base temperature as \( \eta_f \) depends only upon geometric parameters, thermal conductivity and the convection coefficient.
**PROBLEM 4.31**

**KNOWN:** Dimensions and surface temperatures of a square channel. Number of chips mounted on outer surface and chip thermal contact resistance.

**FIND:** Heat dissipation per chip and chip temperature.

**SCHEMATIC:**

![Schematic Diagram](image)

**ASSUMPTIONS:** (1) Steady state, (2) Approximately uniform channel inner and outer surface temperatures, (3) Two-dimensional conduction through channel wall (negligible end-wall effects), (4) Constant thermal conductivity.

**ANALYSIS:** The total heat rate is determined by the two-dimensional conduction resistance of the channel wall, \( q = \frac{(T_2 - T_1)}{R_{t,\text{cond(2D)}}} \), with the resistance determined by using Eq. 4.27 with Case 11 of Table 4.1. For \( W/w = 1.6 > 1.4 \)

\[
R_{t,\text{cond(2D)}} = \frac{0.930 \ln \left( \frac{W}{w} \right) - 0.050}{2\pi Lk} = \frac{0.387}{2\pi (0.160m)240 \text{ W/m-K}} = 0.00160 \text{ K/W}
\]

The heat rate per chip is then

\[
q_c = \frac{T_2 - T_1}{N R_{t,\text{cond(2D)}}} = \frac{(50 - 20)\degree C}{120(0.0016 K/W)} = 156.3 \text{ W} <
\]

and, with \( q_c = \frac{T_c - T_2}{R_{t,c}} \), the chip temperature is

\[
T_c = T_2 + R_{t,c} q_c = 50\degree C + (0.2 \text{ K/W})156.3 \text{ W} = 81.3\degree C <
\]

**COMMENTS:** (1) By acting to spread heat flow lines away from a chip, the channel wall provides an excellent heat sink for dissipating heat generated by the chip. However, recognize that, in practice, there will be temperature variations on the inner and outer surfaces of the channel, and if the prescribed values of \( T_1 \) and \( T_2 \) represent minimum and maximum inner and outer surface temperatures, respectively, the rate is overestimated by the foregoing analysis. (2) The shape factor may also be determined by combining the expression for a plane wall with the result of Case 8 (Table 4.1). With \( S = \frac{4(wL)}{(W-w)/2} + 4(0.54 L) = 2.479 \text{ m, } R_{t,\text{cond(2D)}} = 1/(Sk) = 0.00168 \text{ K/W}. \)
**PROBLEM 4.32**

**KNOWN:** Dimensions and thermal conductivity of concrete duct. Convection conditions of ambient air. Inlet temperature of water flow through the duct.

**FIND:** (a) Heat loss per duct length near inlet, (b) Minimum allowable flow rate corresponding to maximum allowable temperature rise of water.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady state, (2) Negligible water-side convection resistance, pipe wall conduction resistance, and pipe/concrete contact resistance (temperature at inner surface of concrete corresponds to that of water), (3) Constant properties, (4) Negligible flow work and kinetic and potential energy changes.

**ANALYSIS:** (a) From the thermal circuit, the heat loss per unit length near the entrance is

\[
q' = \frac{T_i - T_\infty}{R'_{\text{cond}(2D)} + R'_{\text{conv}}} = \frac{T_i - T_\infty}{\ln \left( \frac{1.08 w}{D} \right)} + \frac{1}{h(4w)}
\]

where \( R'_{\text{cond}(2D)} \) is obtained by using the shape factor of Case 6 from Table 4.1 with Eq. (4.27). Hence,

\[
q' = \frac{(90 - 0)^\circ C}{\ln \left( \frac{1.08 \times 0.3 m}{0.15 m} \right)} + \frac{1}{25 \frac{W}{m^2 \cdot K}} = \frac{90^\circ C}{(0.0876 + 0.0333) \frac{K \cdot m}{W}} = 745 \frac{W}{m} <
\]

(b) From Eq. (1.11e), with \( q = q'L \) and \( T_i - T_0 = 5^\circ C \),

\[
\dot{m} = \frac{q'L}{u_i - u_o} = \frac{q'L}{c(T_i - T_0)} = \frac{745 \frac{W}{m} (100 \text{m})}{4207 \frac{J}{kg \cdot K} (5^\circ C)} = 3.54 \text{ kg/s} <
\]

**COMMENTS:** The small reduction in the temperature of the water as it flows from inlet to outlet induces a slight departure from two-dimensional conditions and a small reduction in the heat rate per unit length. A slightly conservative value (upper estimate) of \( \dot{m} \) is therefore obtained in part (b).
**PROBLEM 4.33**

**KNOWN:** Dimensions and thermal conductivities of a heater and a finned sleeve. Convection conditions on the sleeve surface.

**FIND:** (a) Heat rate per unit length, (b) Generation rate and centerline temperature of heater, (c) Effect of fin parameters on heat rate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady state, (2) Constant properties, (3) Negligible contact resistance between heater and sleeve, (4) Uniform convection coefficient at outer surfaces of sleeve, (5) Uniform heat generation, (6) Negligible radiation.

**ANALYSIS:** (a) From the thermal circuit, the desired heat rate is

\[ q' = \frac{T_S - T_\infty}{R'_{\text{cond}(2D)} + R'_{t,o}} = \frac{T_S - T_\infty}{R'_{\text{tot}}} \]

The two-dimensional conduction resistance, may be estimated from Eq. (4.27) and Case 6 of Table 4.2

\[ R'_{\text{cond}(2D)} = \frac{1}{S k_s} = \frac{\ln \left(1.08 w / D\right)}{2 \pi k_s} = \frac{\ln \left(2.16 \right)}{2 \pi \left(240 \, \text{W} / \text{m} \cdot \text{K}\right)} = 5.11 \times 10^{-4} \, \text{m} \cdot \text{K} / \text{W} \]

The thermal resistance of the fin array is given by Eq. (3.103), where \( \eta_o \) and \( A_t \) are given by Eqs. (3.102) and (3.99) and \( \eta_f \) is given by Eq. (3.89). With \( L_c = L + t/2 = 0.022 \, \text{m} \), \( m = (2h/k_st)^{1/2} = 32.3 \, \text{m}^{-1} \) and \( mL_c = 0.710 \),

\[ \eta_f = \frac{\tanh mL_c}{mL_c} = 0.61 \qquad 0.71 = 0.86 \]

\[ A_t' = NA_f' + A_b' = N \left(2L + t\right) + \left(4w - Nt\right) = 0.704m + 0.096m = 0.800m \]

\[ \eta_o = 1 - \frac{NA_f' \left(1 - \eta_f\right)}{A_t'} = 1 - \frac{0.704m}{0.800m} (0.14) = 0.88 \]

\[ R'_{t,o} = \left(\eta_o h A_t'\right)^{-1} = \left(0.88 \times 500 \, \text{W} / \text{m}^2 \cdot \text{K} \times 0.80m\right)^{-1} = 2.84 \times 10^{-3} \, \text{m} \cdot \text{K} / \text{W} \]

\[ q' = \frac{(300 - 50) \, ^\circ \text{C}}{\left(5.11 \times 10^{-4} + 2.84 \times 10^{-3}\right) \, \text{m} \cdot \text{K} / \text{W}} = 74,600 \, \text{W} / \text{m} \]

(b) Eq. (3.55) may be used to determine \( \dot{q} \), if \( h \) is replaced by an overall coefficient based on the surface area of the heater. From Eq. (3.32),
PROBLEM 4.33 (Cont.)

\[ U_s A'_s = U_s \pi D = \left( R'_{\text{tot}} \right)^{-1} = (3.35 \text{ m} \cdot \text{K} / \text{W})^{-1} = 298 \text{ W} / \text{m} \cdot \text{K} \]

\[ U_s = 298 \text{ W} / \text{m} \cdot \text{K} / (\pi \times 0.02 \text{ m}) = 4750 \text{ W} / \text{m}^2 \cdot \text{K} \]

\[ \dot{q} = 4 U_s (T_s - T_\infty) / D = 4 \left( 4750 \text{ W} / \text{m}^2 \cdot \text{K} \right) \left( 250^\circ \text{C} \right) / 0.02 \text{m} = 2.38 \times 10^8 \text{ W} / \text{m}^3 \quad < \]

From Eq. (3.53) the centerline temperature is

\[ T(0) = \frac{\dot{q} (D/2)^2}{4 k_h} + T_s = \frac{2.38 \times 10^8 \text{ W} / \text{m}^3 (0.01 \text{m})^2}{4 \left( 400 \text{ W} / \text{m} \cdot \text{K} \right)} + 300^\circ \text{C} = 315^\circ \text{C} \quad < \]

(c) Subject to the prescribed constraints, the following results have been obtained for parameter variations corresponding to \( 16 \leq N \leq 40, 2 \leq t \leq 8 \text{ mm} \) and \( 20 \leq L \leq 40 \text{ mm} \).

<table>
<thead>
<tr>
<th>N</th>
<th>t (mm)</th>
<th>L (mm)</th>
<th>( \eta_f )</th>
<th>( \dot{q}' (\text{W} / \text{m}) )</th>
</tr>
</thead>
<tbody>
<tr>
<td>16</td>
<td>4</td>
<td>20</td>

<td>151,300</td>
</tr>
</tbody>
</table>

Clearly there is little benefit to simply increasing \( t \), since there is no change in \( A'_t \) and only a marginal increase in \( \eta_f \). However, due to an attendant increase in \( A'_1 \), there is significant benefit to increasing \( N \) for fixed \( t \) (no change in \( \eta_f \)) and additional benefit in concurrently increasing \( N \) while decreasing \( t \). In this case the effect of increasing \( A'_1 \) exceeds that of decreasing \( \eta_f \). The same is true for increasing \( L \), although there is an upper limit at which diminishing returns would be reached. The upper limit to \( L \) could also be influenced by manufacturing constraints.

COMMENTS: Without the sleeve, the heat rate would be \( \dot{q}' = \pi Dh (T_s - T_\infty) = 7850 \text{ W} / \text{m} \), which is well below that achieved by using the increased surface area afforded by the sleeve.
**PROBLEM 4.34**

**FIND:** Maximum chip heat rate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Constant thermal conductivity, (3) Negligible radiation, (4) All heat transfer is by convection from the chip and the substrate surface (negligible heat transfer from bottom or sides of substrate).

**ANALYSIS:** From the thermal circuit,

\[
q = q_h + q_{sp} = \frac{T_h - T_\infty}{R_{h,\text{cnv}}} + \frac{T_h - T_\infty}{R_{t,(sp)} + R_{t,c} + R_{sp,\text{cnv}}}
\]

\[
R_{h,\text{cnv}} = \left(h A_{s,n}^{-1} \right)^{-1} \left(4 k_{\text{sub}} L_h \right)^{-1} = \left[100 \text{ W/m}^2 \cdot \text{K} (0.005 \text{m})^2 \right]^{-1} = 400 \text{ K/W}
\]

\[
R_{t,(sp)} = \frac{1 - 1.410 A_r + 0.344 A_r^3 + 0.043 A_r^5 + 0.034 A_r^7}{4 k_{\text{sub}} L_h} = \frac{1 - 0.353 + 0.005 + 0 + 0}{4 (80 \text{ W/m} \cdot \text{K})(0.005\text{m})} = 0.408 \text{ K/W}
\]

\[
R_{t,c} = \frac{R_{t,c}^*}{L_h^2} = \frac{0.5 \times 10^{-4} \text{ m}^2 \cdot \text{K/W}}{(0.005\text{m})^2} = 2.000 \text{ K/W}
\]

\[
R_{sp,\text{cnv}} = \left[ h \left(A_{\text{sub}} - A_{s,h} \right) \right]^{-1} = \left[ 100 \text{ W/m}^2 \cdot \text{K} \left(0.010 \text{m}^2 - 0.005 \text{m}^2 \right) \right]^{-1} = 133.3 \text{ K/W}
\]

\[
q = \frac{70^\circ C}{400 \text{ K/W}} + \frac{70^\circ C}{(0.408 + 2 + 133.3) \text{ K/W}} = 0.18 \text{ W} + 0.52 \text{ W} = 0.70 \text{ W}
\]

**COMMENTS:**

(1) The thermal resistances of the substrate and the chip/substrate interface are much less than the substrate convection resistance. Hence, the heat rate is increased almost in proportion to the additional surface area afforded by the substrate. An increase in the spacing between chips \((S_h)\) would increase \(q\) correspondingly.

(2) In the limit \(A_r \to 0\), \(R_{t,(sp)}\) reduces to \(2\pi^{1/2} k_{\text{sub}} D_h\) for a circular heat source and \(4k_{\text{sub}} L_h\) for a square source.
**PROBLEM 4.35**

**KNOWN:** Internal corner of a two-dimensional system with prescribed convection boundary conditions.

**FIND:** Finite-difference equations for these situations: (a) Horizontal boundary is perfectly insulated and vertical boundary is subjected to a convection process \( T_{\infty} \), \( h \), (b) Both boundaries are perfectly insulated; compare result with Eq. 4.45.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Two-dimensional conduction, (3) Constant properties, (4) No internal generation.

**ANALYSIS:** Consider the nodal network shown above and also as Case 2, Table 4.2. Having defined the control volume – the shaded area of unit thickness normal to the page – next identify the heat transfer processes. Finally, perform an energy balance wherein the processes are expressed using appropriate rate equations.

(a) With the horizontal boundary insulated and the vertical boundary subjected to a convection process, the energy balance results in the following finite-difference equation:

\[
\begin{align*}
\dot{E}_{in} - \dot{E}_{out} & = 0 \\
q_1 + q_2 + q_3 + q_4 + q_5 + q_6 & = 0 \\
 k (\Delta y \cdot 1) \frac{T_{m-1,n} - T_{m,n}}{\Delta x} + k \left[ \frac{\Delta x \cdot 1}{2} \right] \frac{T_{m,n-1} - T_{m,n}}{\Delta y} + h \left[ \frac{\Delta y \cdot 1}{2} \right] (T_{\infty} - T_{m,n}) \\
+ 0 + k \left[ \frac{\Delta y \cdot 1}{2} \right] \frac{T_{m+1,n} - T_{m,n}}{\Delta x} + k (\Delta x \cdot 1) \frac{T_{m,n+1} - T_{m,n}}{\Delta y} & = 0.
\end{align*}
\]

Letting \( \Delta x = \Delta y \), and regrouping, find

\[
2 \left( T_{m-1,n} + T_{m,n+1} \right) + \left( T_{m+1,n} + T_{m,n-1} \right) + \frac{h \Delta x}{k} T_{\infty} - \left[ 6 + \frac{h \Delta x}{k} \right] T_{m,n} = 0. \tag{<}
\]

(b) With both boundaries insulated, the energy balance would have \( q_3 = q_4 = 0 \). The same result would be obtained by letting \( h = 0 \) in the previous result. Hence,

\[
2 \left( T_{m-1,n} + T_{m,n+1} \right) + \left( T_{m+1,n} + T_{m,n-1} \right) - 6 \ T_{m,n} = 0. \tag{<}
\]

Note that this expression compares exactly with Eq. 4.45 when \( h = 0 \), which corresponds to insulated boundaries.
**PROBLEM 4.36**

**KNOWN:** Plane surface of two-dimensional system.

**FIND:** The finite-difference equation for nodal point on this boundary when (a) insulated; compare result with Eq. 4.46, and when (b) subjected to a constant heat flux.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Two-dimensional, steady-state conduction with no generation, (2) Constant properties, (3) Boundary is adiabatic.

**ANALYSIS:** (a) Performing an energy balance on the control volume, \((\Delta x/2)\Delta y\), and using the conduction rate equation, it follows that

\[
\frac{\Delta x}{2} \sum_{n} \left[ T_{m-1,n} - T_{m,n+1} - 4T_{m,n} + T_{m,n} \right] + k \frac{\Delta x}{2} \frac{\Delta y}{2} \sum_{m} \left[ T_{m,n+1} - T_{m,n} \right] = 0. \tag{3}
\]

Note that there is no heat rate across the control volume surface at the insulated boundary. Recognizing that \(\Delta x = \Delta y\), the above expression reduces to the form

\[
2T_{m-1,n} + T_{m,n-1} + T_{m,n+1} - 4T_{m,n} = 0. \tag{4}
\]

The Eq. 4.46 of Table 4.3 considers the same configuration but with the boundary subjected to a convection process. That is,

\[
(2T_{m-1,n} + T_{m,n-1} + T_{m,n+1}) + \frac{2h\Delta x}{k} \frac{T_m}{T_{\infty}} - 2 \frac{h\Delta x}{k} + 2 \frac{h\Delta y}{k} = 0. \tag{5}
\]

Note that, if the boundary is insulated, \(h = 0\) and Eq. 4.46 reduces to Eq. (4).

(b) If the surface is exposed to a constant heat flux, \(q_o\), the energy balance has the form

\[q_1 + q_2 + q_3 + q_o \cdot \Delta y = 0\]

and the finite difference equation becomes

\[
2T_{m-1,n} + T_{m,n-1} + T_{m,n+1} - 4T_{m,n} = -\frac{q_o \Delta x}{k}. \tag{6}
\]

**COMMENTS:** Equation (4) can be obtained by using the “interior node” finite-difference equation, Eq. 4.33, where the insulated boundary is treated as a symmetry plane as shown below.
PROBLEM 4.37

KNOWN: External corner of a two-dimensional system whose boundaries are subjected to prescribed conditions.

FIND: Finite-difference equations for these situations: (a) Upper boundary is perfectly insulated and side boundary is subjected to a convection process, (b) Both boundaries are perfectly insulated; compare result with Eq. 4.47.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction, (3) Constant properties, (4) No internal generation.

ANALYSIS: Consider the nodal point configuration shown in the schematic and also as Case 4, Table 4.2. The control volume about the node – shaded area above of unit thickness normal to the page – has dimensions, \((\Delta x/2)(\Delta y/2)-1\). The heat transfer processes at the surface of the CV are identified as \(q_1, q_2 \ldots\). Perform an energy balance wherein the processes are expressed using the appropriate rate equations.

(a) With the upper boundary insulated and the side boundary subjected to a convection process, the energy balance has the form

\[
\dot{E}_{in} - \dot{E}_{out} = 0 \quad q_1 + q_2 + q_3 + q_4 = 0
\]

\[
k \left[ \frac{\Delta y}{2} \right] T_{m-1,n} - T_{m,n} \Delta x + k \left[ \frac{\Delta x}{2} \right] T_{m,n-1} - T_{m,n} \Delta y + h \left[ \frac{\Delta y}{2} \right] (T_\infty - T_{m,n}) + 0 = 0.
\]

Letting \(\Delta x = \Delta y\), and regrouping, find

\[
T_{m,n-1} + T_{m-1,n} + \frac{h\Delta x}{k} T_\infty - 2 \left[ \frac{1}{2} \frac{h\Delta x}{k} + 1 \right] T_{m,n} = 0.<br>
\]

(b) With both boundaries insulated, the energy balance of Eq. (2) would have \(q_3 = q_4 = 0\). The same result would be obtained by letting \(h = 0\) in the finite-difference equation, Eq. (3). The result is

\[
T_{m,n-1} + T_{m-1,n} - 2T_{m,n} = 0.<br>
\]

Note that this expression is identical to Eq. 4.47 when \(h = 0\), in which case both boundaries are insulated.

COMMENTS: Note the convenience resulting from formulating the energy balance by assuming that all the heat flow is into the node.
PROBLEM 4.38

KNOWN: Conduction in a one-dimensional (radial) cylindrical coordinate system with volumetric generation.

FIND: Finite-difference equation for (a) Interior node, m, and (b) Surface node, n, with convection.

SCHEMATIC:

(a) Interior node, m

(b) Surface node with convection, n

ASSUMPTIONS: (1) Steady-state, one-dimensional (radial) conduction in cylindrical coordinates, (2) Constant properties.

ANALYSIS: (a) The network has nodes spaced at equal Δr increments with m = 0 at the center; hence, r = mΔr (or nΔr). The control volume is \( V = 2\pi r \cdot \Delta r \cdot \ell = 2\pi (m\Delta r) \Delta r \cdot \ell \). The energy balance is \( \dot{E}_{in} + \dot{E}_g = q_a + q_b + \dot{q} \Delta V = 0 \)

\[
\dot{E}_{in} + \dot{E}_g = q_a + q_b + \dot{q} \Delta V = 0
\]

\[
k \left[ 2\pi \left( r - \frac{\Delta r}{2} \right) \ell \right] T_{m-1} - T_m + k \left[ 2\pi \left( r + \frac{\Delta r}{2} \right) \ell \right] T_m - T_{m+1} + \dot{q} \left[ 2\pi (m\Delta r) \Delta r \ell \right] = 0.
\]

Recognizing that \( r = m\Delta r \), canceling like terms, and regrouping find

\[
\left[ m - \frac{1}{2} \right] T_{m-1} + \left[ m + \frac{1}{2} \right] T_{m+1} - 2mT_m + \frac{\dot{q} m \Delta r^2}{k} = 0.
\]

(b) The control volume for the surface node is \( V = 2\pi r \cdot (\Delta r/2) \cdot \ell \). The energy balance is

\[
\dot{E}_{in} + \dot{E}_g = q_d + q_{conv} + \dot{q} \Delta V = 0.
\]

Use Fourier’s law to express \( q_d \) and Newton’s law of cooling for \( q_{conv} \) to obtain

\[
k \left[ 2\pi \left( r - \frac{\Delta r}{2} \right) \ell \right] T_{n-1} - \left[ n - \frac{1}{2} \right] T_n + h \left[ 2\pi r \ell \right] (T_\infty - T_n) + \dot{q} \left[ 2\pi (n\Delta r) \Delta r \ell \right] = 0.
\]

Let \( r = n\Delta r \), cancel like terms and regroup to find

\[
\left[ n - \frac{1}{2} \right] T_{n-1} - \left[ n - \frac{1}{2} \right] T_n + h n \Delta r \Delta r \ell + \frac{h n \Delta r \Delta r \ell}{k} T_\infty = 0.
\]

COMMENTS: (1) Note that when \( m \) or \( n \) becomes very large compared to \( \frac{1}{2} \), the finite-difference equation becomes independent of \( m \) or \( n \). Then the cylindrical system approximates a rectangular one.

(2) The finite-difference equation for the center node (\( m = 0 \)) needs to be treated as a special case. The control volume is

\[
V = \pi \left( \Delta r / 2 \right)^2 \ell
\]

and the energy balance is

\[
\dot{E}_{in} + \dot{E}_g = q_a + \dot{q} \Delta V = k \left[ 2\pi \left( \Delta r / 2 \right) \ell \right] T_1 - T_0 + \dot{q} \left[ \pi \left( \Delta r / 2 \right) \ell \right] = 0.
\]

Regrouping, the finite-difference equation is

\[
-T_0 + T_1 + \frac{\dot{q} \Delta r^2}{4k} = 0.
\]
PROBLEM 4.39

KNOWN: Two-dimensional cylindrical configuration with prescribed radial ($\Delta r$) and angular ($\Delta \phi$) spacings of nodes.

FIND: Finite-difference equations for nodes 2, 3 and 1.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction in cylindrical coordinates (r,\(\phi\)), (3) Constant properties.

ANALYSIS: The method of solution is to define the appropriate control volume for each node, to identify relevant processes and then to perform an energy balance.

(a) Node 2. This is an interior node with control volume as shown above. The energy balance is $E_{in} = q_a' + q_b' + q_c' + q_d' = 0$. Using Fourier’s law for each process, find

\[
k\left[\frac{r_i + \frac{3}{2}\Delta r}{2}\right] \frac{(T_5 - T_2)}{\Delta r} + k \frac{(T_3 - T_2)}{(r_i + \Delta r) \Delta \phi} + \\
+ k \left[\frac{r_i + \frac{1}{2}\Delta r}{2}\right] \frac{(T_1 - T_2)}{\Delta r} + k \frac{(T_1 - T_2)}{(r_i + \Delta r) \Delta \phi} = 0.
\]

Canceling terms and regrouping yields,

\[
-2 \left[\frac{r_i + \Delta r}{(r_i + \Delta r)} + \frac{(\Delta r)^2}{(r_i + \Delta r)^2}\right] T_2 + \left[\frac{r_i + \frac{3}{2}\Delta r}{2}\right] T_5 + \frac{(\Delta r)^2}{(r_i + \Delta r)^2} \left(\frac{T_3 + T_1}{2}\right) + \left[\frac{r_i + \frac{1}{2}\Delta r}{2}\right] T_1 = 0.
\]

(b) Node 3. The adiabatic surface behaves as a symmetry surface. We can utilize the result of Part (a) to write the finite-difference equation by inspection as

\[
-2 \left[\frac{r_i + \Delta r}{(r_i + \Delta r)} + \frac{(\Delta r)^2}{(r_i + \Delta r)^2}\right] T_3 + \left[\frac{r_i + \frac{3}{2}\Delta r}{2}\right] T_6 + \frac{2(\Delta r)^2}{(r_i + \Delta r)^2} \cdot T_2 + \left[\frac{r_i + \frac{1}{2}\Delta r}{2}\right] T_1 = 0.
\]

(c) Node 1. The energy balance is $q_a' + q_b' + q_c' + q_d' = 0$. Substituting,

\[
k\left[\frac{r_i + \frac{3}{2}\Delta r}{2}\right] \frac{\Delta \phi}{2} \left[\frac{(T_4 - T_1)}{\Delta r}\right] + k \frac{(T_2 - T_1)}{(r_i + \Delta r) \Delta \phi} + \\
+ k \left[\frac{r_i + \frac{1}{2}\Delta r}{2}\right] \frac{\Delta \phi}{2} \left[\frac{(T_1 - T_1)}{\Delta r}\right] + h \frac{(\Delta r)}{(T_{\infty} - T_i)} = 0
\]

This expression could now be rearranged.
PROBLEM 4.40

FIND: Finite-difference equations for selected nodes.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction, (3) Constant properties.

ANALYSIS: (a) Performing an energy balance on the control volume, \((\Delta x/2)(\Delta y/2)\cdot1\), find the FDE for node 1,

\[
\frac{T_0 - T_1}{R_{t,c}^*/(\Delta y/2)1} + h_u \left( \frac{\Delta x}{2} \cdot 1 \right) (T_\infty - T_1) + \frac{k(\Delta y/2 \cdot 1)}{\Delta x} (T_2 - T_1) + \frac{k(\Delta x/2 \cdot 1)}{\Delta y} (T_6 - T_1) + \dot{q} \left[ \left( \Delta x/2 \right) (\Delta y/2) 1 \right] = 0
\]

\[
\left( \Delta x/kR_{t,c}^* \right) T_0 + (h_u \Delta x/k) T_\infty + T_2 + T_6 + \dot{q} (\Delta x)^2 / 2k - \left[ \left( \Delta x/kR_{t,c}^* \right) + (h_u \Delta x/k) + 2 \right] T_1 = 0.
\]

(b) Performing an energy balance on the control volume, \((\Delta x)(\Delta y/2)\cdot1\), find the FDE for node 13,

\[
h_1 (\Delta x \cdot 1) (T_\infty - T_{13}) + (k/\Delta x) (\Delta y/2 \cdot 1) (T_{12} - T_{13}) + (k/\Delta y) (\Delta x \cdot 1) (T_8 - T_{13}) + (k/\Delta x) (\Delta y/2 \cdot 1) (T_{14} - T_{13}) + \dot{q} (\Delta x \cdot \Delta y/2 \cdot 1) = 0
\]

\[
(h_1 \Delta x/k) T_\infty + 1/2 (T_{12} + 2T_8 + T_{14}) + \dot{q} (\Delta x)^2 / 2k - (h_1 \Delta x/k + 2) T_{13} = 0.
\]

COMMENTS: For fixed \(T_0\) and \(T_\infty\), the relative amounts of heat transfer to the air and heat sink are determined by the values of \(h\) and \(R_{t,c}^*\).
PROBLEM 4.41

KNOWN: Nodal point configurations corresponding to a diagonal surface boundary subjected to a convection process and to the tip of a machine tool subjected to constant heat flux and convection cooling.

FIND: Finite-difference equations for the node $m,n$ in the two situations shown.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, 2-D conduction, (2) Constant properties.

ANALYSIS: (a) The control volume about node $m,n$ has triangular shape with sides $\Delta x$ and $\Delta y$ while the diagonal (surface) length is $\sqrt{2} \Delta x$. The heat rates associated with the control volume are due to conduction, $q_1$ and $q_2$, and to convection, $q_c$. Performing an energy balance, find

$$\dot{E}_{in} - \dot{E}_{out} = 0 \quad q_1 + q_2 + q_c = 0 \quad k \left( \frac{\Delta x \cdot 1}{\Delta y} \right) \frac{T_{m,n-1} - T_{m,n}}{\Delta y} + k \left( \frac{\Delta y \cdot 1}{\Delta x} \right) \frac{T_{m+1,n} - T_{m,n}}{\Delta x} + h \left( \sqrt{2} \Delta x \cdot 1 \right) \left( T_\infty - T_{m,n} \right) = 0.$$

Note that we have considered the tool to have unit depth normal to the page. Recognizing that $\Delta x = \Delta y$, dividing each term by $k$ and regrouping, find

$$T_{m,n-1} + T_{m+1,n} + \sqrt{2} \cdot \frac{h\Delta x}{k} T_\infty - \left[ 2 + \sqrt{2} \cdot \frac{h\Delta x}{k} \right] T_{m,n} = 0.$$

(b) The control volume about node $m,n$ has triangular shape with sides $\Delta x/2$ and $\Delta y/2$ while the lower diagonal surface length is $\sqrt{2} \left( \Delta x/2 \right)$. The heat rates associated with the control volume are due to the constant heat flux, $q_a$, to conduction, $q_b$, and to the convection process, $q_c$. Perform an energy balance,

$$\dot{E}_{in} - \dot{E}_{out} = 0 \quad q_a + q_b + q_c = 0 \quad \dot{q}_o \left[ \frac{\Delta x}{2} \cdot 1 \right] + k \cdot \left[ \frac{\Delta y}{2} \cdot 1 \right] \frac{T_{m+1,n} - T_{m,n}}{\Delta x} + h \left[ \sqrt{2} \cdot \frac{\Delta x}{2} \right] \left( T_\infty - T_{m,n} \right) = 0.$$

Recognizing that $\Delta x = \Delta y$, dividing each term by $k/2$ and regrouping, find

$$T_{m+1,n} + \sqrt{2} \cdot \frac{h\Delta x}{k} \cdot T_\infty + \dot{q}_o \cdot \frac{\Delta x}{k} \left( 1 + \sqrt{2} \cdot \frac{h\Delta x}{k} \right) T_{m,n} = 0.$$

COMMENTS: Note the appearance of the term $h\Delta x/k$ in both results, which is a dimensionless parameter (the *Biot number*) characterizing the relative effects of convection and conduction.
**PROBLEM 4.42**

**KNOWN:** Nodal point on boundary between two materials.

**FIND:** Finite-difference equation for steady-state conditions.

**SCHEMATIC:**

![Diagram of nodal point on boundary between two materials, with heat fluxes and temperatures labeled.]

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Two-dimensional conduction, (3) Constant properties, (4) No internal heat generation, (5) Negligible thermal contact resistance at interface.

**ANALYSIS:** The control volume is defined about nodal point 0 as shown above. The conservation of energy requirement has the form

\[
\sum_{i=1}^{6} q_i = q_1 + q_2 + q_3 + q_4 + q_5 + q_6 = 0
\]

since all heat rates are shown as into the CV. Each heat rate can be written using Fourier’s law,

\[
k_A \frac{\Delta y}{2} \frac{T_1 - T_0}{\Delta x} + k_A \frac{\Delta x}{\Delta y} \frac{T_2 - T_0}{2} + k_A \frac{\Delta y}{\Delta x} \frac{T_3 - T_0}{2} + k_B \frac{\Delta y}{\Delta x} \frac{T_3 - T_0}{2} + k_B \frac{\Delta x}{\Delta y} \frac{T_4 - T_0}{2} + k_B \frac{\Delta y}{\Delta x} \frac{T_1 - T_0}{2} = 0.
\]

Recognizing that \(\Delta x = \Delta y\) and regrouping gives the relation,

\[
-T_0 + \frac{1}{4} T_1 + \frac{k_A}{2(k_A + k_B)} T_2 + \frac{1}{4} \frac{T_3}{2(k_A + k_B)} + \frac{k_B}{2(k_A + k_B)} T_4 = 0.
\]

**COMMENTS:** Note that when \(k_A = k_B\), the result agrees with Eq. 4.33 which is appropriate for an interior node in a medium of fixed thermal conductivity.
**PROBLEM 4.43**

**KNOWN:** Two-dimensional grid for a system with no internal volumetric generation.

**FIND:** Expression for heat rate per unit length normal to page crossing the isothermal boundary.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Two-dimensional heat transfer, (3) Constant properties.

**ANALYSIS:** Identify the surface nodes \( (T_s) \) and draw control volumes about these nodes. Since there is no heat transfer in the direction parallel to the isothermal surfaces, the heat rate out of the constant temperature surface boundary is

\[
q' = q_1' + q_2' + q_3' + q_4' + q_5' + q_6'
\]

For each \( q_i' \), use Fourier’s law and pay particular attention to the manner in which the cross-sectional area and gradients are specified.

\[
q_i' = k \left( \frac{\Delta y}{2} \right) \frac{T_1 - T_s}{\Delta x} + k \left( \frac{\Delta y}{2} \right) \frac{T_2 - T_s}{\Delta x} + k \left( \frac{\Delta y}{2} \right) \frac{T_3 - T_s}{\Delta x} + k \left( \frac{\Delta y}{2} \right) \frac{T_5 - T_s}{\Delta x} + k \left( \frac{\Delta y}{2} \right) \frac{T_6 - T_s}{\Delta x} + k \left( \frac{\Delta x}{2} \right) \frac{T_7 - T_s}{\Delta y}
\]

Regrouping with \( \Delta x = \Delta y \), find

\[
q' = k \left[ 0.5T_1 + T_2 + T_3 + T_5 + T_6 + 0.5T_7 - 5T_s \right].
\]

**COMMENTS:** Looking at the corner node, it is important to recognize the areas associated with \( q_c' \) and \( q_d' \) (\( \Delta y \) and \( \Delta x \), respectively).
PROBLEM 4.44

KNOWN: One-dimensional fin of uniform cross section insulated at one end with prescribed base temperature, convection process on surface, and thermal conductivity.

FIND: Finite-difference equation for these nodes: (a) Interior node, m and (b) Node at end of fin, n, where x = L.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction.

ANALYSIS: (a) The control volume about node m is shown in the schematic; the node spacing and control volume length in the x direction are both \( \Delta x \). The uniform cross-sectional area and fin perimeter are \( A_c \) and \( P \), respectively. The heat transfer process on the control surfaces, \( q_1 \) and \( q_2 \), represent conduction while \( q_c \) is the convection heat transfer rate between the fin and ambient fluid. Performing an energy balance, find

\[
\frac{E_{in} - E_{out}}{kA_c} = \frac{q_1 + q_2 + q_c}{\Delta x} = 0
\]

Multiply the expression by \( \Delta x/kA_c \) and regroup to obtain

\[
T_{m-1} + T_m + T_{m+1} + \frac{hP}{kA_c} \cdot \Delta x^2 T_\infty - \left[ 2 + \frac{hP}{kA_c} \Delta x^2 \right] T_m = 0 \quad 1 < m < n
\]

Considering now the special node \( m = 1 \), then the \( m-1 \) node is \( T_b \), the base temperature. The finite-difference equation would be

\[
T_b + T_2 + \frac{hP}{kA_c} \cdot \Delta x^2 T_\infty - \left[ 2 + \frac{hP}{kA_c} \Delta x^2 \right] T_1 = 0 \quad m = 1
\]

(b) The control volume of length \( \Delta x/2 \) about node \( n \) is shown in the schematic. Performing an energy balance,

\[
\frac{E_{in} - E_{out}}{kA_c} = \frac{q_3 + q_4}{\Delta x} + hP \frac{\Delta x}{2} (T_\infty - T_n) = 0.
\]

Note that \( q_4 = 0 \) since the end (\( x = L \)) is insulated. Multiplying by \( \Delta x/kA_c \) and regrouping,

\[
T_{n-1} + \frac{hP}{kA_c} \cdot \Delta x^2 T_\infty - \left[ \frac{hP}{kA_c} \cdot \Delta x^2 + 1 \right] T_n = 0.
\]

COMMENTS: The value of \( \Delta x \) will be determined by the selection of \( n \); that is, \( \Delta x = L/n \). Note that the grouping, \( hP/kA_c \), appears in the finite-difference and differential forms of the energy balance.
PROBLEM 4.45

KNOWN: Two-dimensional network with prescribed nodal temperatures and thermal conductivity of the material.

FIND: Heat rate per unit length normal to page, \( q' \).

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional heat transfer, (3) No internal volumetric generation, (4) Constant properties.

ANALYSIS: Construct control volumes around the nodes on the surface maintained at the uniform temperature \( T_s \) and indicate the heat rates. The heat rate per unit length is \( q' = q_a' + q_b' + q_c' + q_d' + q_e' \) or in terms of conduction terms between nodes,

\[
q' = q_a' + q_b' + q_c' + q_d' + q_e'.
\]

Each of these rates can be written in terms of nodal temperatures and control volume dimensions using Fourier's law,

\[
q' = k \frac{\Delta x}{2} \frac{T_1 - T_s}{\Delta y} + k \frac{\Delta x}{\Delta y} \frac{T_2 - T_s}{\Delta y} + k \frac{\Delta x}{\Delta y} \frac{T_3 - T_s}{\Delta y} + k \frac{\Delta x}{\Delta y} \frac{T_4 - T_s}{\Delta y} + k \frac{\Delta x}{\Delta y} \frac{T_5 - T_s}{\Delta y}.
\]

and since \( \Delta x = \Delta y \),

\[
q' = k \left[ \frac{1}{2} \left( \frac{T_1 - T_s}{\Delta y} \right) + \left( \frac{T_2 - T_s}{\Delta y} \right) + \left( \frac{T_3 - T_s}{\Delta y} \right) + \left( \frac{T_4 - T_s}{\Delta y} \right) + \left( \frac{T_5 - T_s}{\Delta y} \right) \right].
\]

Substituting numerical values, find

\[
q' = 50 \text{ W/m} \cdot \text{K} \left[ \frac{1}{2} \left( 120.55 - 100 \right) + \left( 120.64 - 100 \right) + \left( 121.29 - 100 \right) + \left( 123.89 - 100 \right) + \left( 134.57 - 100 \right) + \\ + \left( 147.14 - 100 \right) \right].
\]

\[
q' = 6711 \text{ W/m}. \quad <
\]

COMMENTS: For nodes a through d, there is no heat transfer into the control volumes in the x-direction. Look carefully at the energy balance for node e, \( q'_e = q'_5 + q'_7 \), and how \( q'_5 \) and \( q'_7 \) are evaluated.
PROBLEM 4.46

KNOWN: Nodal temperatures from a steady-state, finite-difference analysis for a one-eighth symmetrical section of a square channel.

FIND: (a) Beginning with properly defined control volumes, derive the finite-difference equations for nodes 2, 4 and 7, and determine $T_2$, $T_4$ and $T_7$, and (b) Heat transfer loss per unit length from the channel, $q'$.  

SCHEMATIC:

\[
T_{\infty} = 300 \text{ K, } h = 50 \text{ W/m}^2\cdot\text{K}
\]

\[
q_1' \quad q_2' \quad q_3' \quad q_4'
\]

<table>

<tr>
<td>8,9</td>
<td>600</td>
</tr>
</tbody>
</table>

ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction, (3) No internal volumetric generation, (4) Constant properties.

ANALYSIS: (a) Define control volumes about the nodes 2, 4, and 7, taking advantage of symmetry where appropriate and performing energy balances, $\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0$, with $\Delta x = \Delta y$.

Node 2: \( q'_a + q'_b + q'_c + q'_d = 0 \)

\[
h\Delta x (T_{\infty} - T_2) + k (\Delta y/2) \frac{T_3 - T_2}{\Delta x} + k\Delta x \frac{T_6 - T_2}{\Delta y} + k (\Delta y/2) \frac{T_1 - T_2}{\Delta x} = 0
\]

\[
T_2 = \left[ 0.5T_1 + 0.5T_3 + T_6 + (h\Delta x/k)T_{\infty} \right] / \left[ 2 + (h\Delta x/k) \right]
\]

\[
T_2 = \left[ 0.5 \times 430 + 0.5 \times 394 + 492 + \left( 50 \text{ W/m}^2\cdot\text{K} \times 0.01 \text{ m} \right) / 300 \text{ K} \right] / \left[ 2 + 0.50 \right]
\]

\[
T_2 = 422 \text{ K}
\]

Node 4: \( q'_a + q'_b + q'_c = 0 \)

\[
h \left( \Delta x/2 \right) (T_{\infty} - T_4) + 0 + k \left( \Delta y/2 \right) \frac{T_3 - T_4}{\Delta x} = 0
\]

\[
T_4 = \left[ T_3 + (h\Delta x/k)T_{\infty} \right] / \left[ 1 + (h\Delta x/k) \right]
\]

\[
T_4 = \left[ 394 + 0.5 \times 300 \right] / \left[ 1 + 0.5 \right] = 363 \text{ K}
\]

Continued...
Node 7: From the first schematic, recognizing that the diagonal is a symmetry adiabat, we can treat node 7 as an interior node, hence

\[ T_7 = 0.25 \left( T_3 + T_3 + T_6 + T_6 \right) = 0.25 \left( 394 + 394 + 492 + 492 \right) K = 443 K \]

(b) The heat transfer loss from the upper surface can be expressed as the sum of the convection rates from each node as illustrated in the first schematic,

\[ q'_{cv} = q'_1 + q'_2 + q'_3 + q'_4 \]

\[ q'_{cv} = h \left( \Delta x/2 \right) (T_1 - T_{\infty}) + h \Delta x (T_2 - T_{\infty}) + h \Delta x (T_3 - T_{\infty}) + h \left( \Delta x/2 \right) (T_4 - T_{\infty}) \]

\[ q'_{cv} = 50 \text{ W/m}^2 \cdot \text{K} \times 0.1 \text{ m} \left[ (430 - 300)/2 + (422 - 300) + (394 - 300) + (363 - 300)/2 \right] \text{K} \]

\[ q'_{cv} = 156 \text{ W/m} \]

COMMENTS: (1) Always look for symmetry conditions which can greatly simplify the writing of the nodal equation as was the case for Node 7.

(2) Consider using the IHT Tool, Finite-Difference Equations, for Steady-State, Two-Dimensional heat transfer to determine the nodal temperatures \( T_1 - T_7 \) when only the boundary conditions \( T_8, T_9 \) and \( (T_{\infty}, h) \) are specified.
PROBLEM 4.47

KNOWN:  Steady-state temperatures (K) at three nodes of a long rectangular bar.

FIND:  (a) Temperatures at remaining nodes and (b) heat transfer per unit length from the bar using nodal temperatures; compare with result calculated using knowledge of \( \dot{q} \).

SCHEMATIC:

ASSUMPTIONS:  (1) Steady-state, 2-D conduction, (2) Constant properties.

ANALYSIS:  (a) The finite-difference equations for the nodes (1,2,3,A,B,C) can be written by inspection using Eq. 4.39 and recognizing that the adiabatic boundary can be represented by a symmetry plane.

\[
\sum T_{\text{neighbors}} - 4T_i + \dot{q}\Delta x^2 / k = 0 \quad \text{and} \quad \frac{\dot{q}\Delta x^2}{k} = \frac{5 \times 10^7 \text{ W/m}^3 (0.005\text{m})^2}{20 \text{ W/m} \cdot \text{K}} = 62.5 \text{K}.
\]

Node A (to find \( T_2 \)):

\[
2T_2 + 2T_B - 4T_A + \dot{q}\Delta x^2 / k = 0
\]

\[T_2 = \frac{1}{2} (-2 \times 374.6 + 4 \times 398.0 - 62.5) \text{K} = 390.2 \text{K} \quad \checkmark
\]

Node 3 (to find \( T_3 \)):

\[
T_c + T_2 + T_B + 300\text{K} - 4T_3 + \dot{q}\Delta x^2 / k = 0
\]

\[T_3 = \frac{1}{4} (348.5 + 390.2 + 374.6 + 300 + 62.5) \text{K} = 369.0 \text{K} \quad \checkmark
\]

Node 1 (to find \( T_1 \)):

\[
300 + 2T_C + T_2 - 4T_I + \dot{q}\Delta x^2 / k = 0
\]

\[T_I = \frac{1}{4} (300 + 2 \times 348.5 + 390.2 + 62.5) = 362.4 \text{K} \quad \checkmark
\]

(b) The heat rate out of the bar is determined by calculating the heat rate out of each control volume around the 300K nodes. Consider the node in the upper left-hand corner; from an energy balance

\[\dot{E}_{\text{in}} - \dot{E}_{\text{out}} + \dot{E}_g = 0 \quad \text{or} \quad \dot{q}' = \dot{q}'_{\text{in}} + \dot{E}_g \quad \text{where} \quad \dot{E}_g = \dot{q}V.
\]

Hence, for the entire bar \( \dot{q}'_{\text{bar}} = \dot{q}'_{\text{A}} + \dot{q}'_{\text{B}} + \dot{q}'_{\text{C}} + \dot{q}'_{\text{D}} + \dot{q}'_{\text{E}} + \dot{q}'_{\text{F}} \), or

\[
\dot{q}'_{\text{bar}} = \left[ \frac{k}{2} \frac{T_1 - 300}{\Delta x} + \frac{\Delta x}{2} \right]_a + \left[ \frac{k}{2} \frac{T_C - 300}{\Delta x} + \frac{\Delta x}{2} \right]_d + \left[ \frac{k}{2} \frac{T_3 - 300}{\Delta y} + \frac{\Delta y}{2} \right]_e + \left[ \frac{k}{2} \frac{T_B - 300}{\Delta y} + \frac{\Delta y}{2} \right]_f.
\]

Substituting numerical values, find \( \dot{q}'_{\text{bar}} = 7,502.5 \text{ W/m} \). From an overall energy balance on the bar,

\[
\dot{q}'_{\text{bar}} = \dot{E}_g = \dot{q}V/\ell = \dot{q} (3\Delta x \cdot 2\Delta y) = 5 \times 10^7 \text{ W/m}^3 \times 6(0.005\text{m})^2 = 7,500 \text{ W/m}.
\]

As expected, the results of the two methods agree. Why must that be?
**PROBLEM 4.48**

**KNOWN:** Steady-state temperatures at selected nodal points of the symmetrical section of a flow channel with uniform internal volumetric generation of heat. Inner and outer surfaces of channel experience convection.

**FIND:** (a) Temperatures at nodes 1, 4, 7, and 9, (b) Heat rate per unit length (W/m) from the outer surface A to the adjacent fluid, (c) Heat rate per unit length (W/m) from the inner fluid to surface B, and (d) Verify that results are consistent with an overall energy balance.

**SCHEMATIC:**

![Schematic](image)

**ASSUMPTIONS:** (1) Steady-state, two-dimensional conduction, (2) Constant properties.

**ANALYSIS:** (a) The nodal finite-difference equations are obtained from energy balances on control volumes about the nodes shown in the schematics below.

**Node 1**

\[ q_a' + q_b' + q_c' + q_d' + \dot{E}_g' = 0 \]

\[ 0 + k \left( \frac{\Delta y}{2} \right) \frac{T_2 - T_1}{\Delta x} + k \left( \frac{\Delta x}{2} \right) \frac{T_3 - T_1}{\Delta y} + 0 + q \left( \Delta x \cdot \Delta y / 4 \right) = 0 \]

\[ T_1 = \frac{T_2 + T_3}{2} + q \Delta x^2 / 2k \]

\[ T_1 = (95.47 + 117.3) \times 10^6 \, \text{W/m}^3 \left( 25 \times 25 \right) \times 10^{-6} \, \text{m}^2 / (2 \times 10 \, \text{W/mK}) = 122.0 \, \text{C} \]

**Node 4**

\[ q_a' + q_b' + q_c' + q_d' + \dot{E}_g' = 0 \]

\[ k \left( \frac{\Delta x}{2} \right) \frac{T_2 - T_4}{\Delta y} + h_i \left( \frac{\Delta y}{2} \right) \left( T_{\infty,i} - T_4 \right) + h_i \left( \frac{\Delta x}{2} \right) \left( T_{\infty} - T_4 \right) + \]

Continued .....
PROBLEM 4.48 (Cont.)

\[
\frac{k}{\Delta x} \frac{T_5 - T_4}{\Delta x} + \frac{k}{\Delta y} \frac{T_8 - T_4}{\Delta y} + \frac{k}{\Delta x} \frac{T_3 - T_4}{\Delta x} + \dot{q} \left( 3 \Delta x \cdot \Delta y / 4 \right) = 0
\]

\[
T_4 = \left[ T_2 + 2T_3 + T_5 + 2T_8 + 2 \left( h_x \Delta x / k \right) T_{\infty,1} + \left( 3 \dot{q} \Delta x^2 / 2k \right) \right] / \left[ 6 + 2 \left( h_x \Delta x / k \right) \right]
\]

\[
T_4 = 94.50^\circ C
\]

**Node 7**

\[
q_a' + q_b' + q_c' + q_d' + \dot{E}_g' = 0
\]

\[
k \left( \frac{\Delta x}{2} \right) \frac{T_3 - T_7}{\Delta y} + k \left( \frac{\Delta y}{2} \right) \frac{T_8 - T_7}{\Delta x} + h_o \left( \Delta x / 2 \right) \left( T_{\infty,0} - T_7 \right) + \dot{q} \left( \Delta x \cdot \Delta y / 4 \right) = 0
\]

\[
T_7 = \left[ T_3 + T_8 + \left( h_o \Delta x / k \right) T_{\infty,0} + \dot{q} \Delta x^2 / 2k \right] / \left( 2 + h_o \Delta x / k \right)
\]

\[
T_7 = 95.80^\circ C
\]

**Node 9**

\[
q_a' + q_b' + q_c' + q_d' + \dot{E}_g' = 0
\]

\[
k \left( \frac{\Delta x}{2} \right) \frac{T_5 - T_9}{\Delta y} + k \left( \frac{\Delta y}{2} \right) \frac{T_{10} - T_9}{\Delta y} + h_o \left( \Delta x \right) \left( T_{\infty,0} - T_9 \right)
\]

\[
+ k \left( \frac{\Delta y}{2} \right) \frac{T_8 - T_9}{\Delta x} + \dot{q} \left( \Delta x \cdot \Delta y / 2 \right) = 0
\]

\[
T_9 = \left[ T_5 + 0.5T_8 + 0.5T_{10} + \left( h_o \Delta x / k \right) T_{\infty,0} + \dot{q} \Delta x^2 / 2k \right] / \left( 2 + h_o \Delta x / k \right)
\]

\[
T_9 = 79.67^\circ C
\]

(b) The heat rate per unit length from the outer surface A to the adjacent fluid, \( q'_A \), is the sum of the convection heat rates from the outer surfaces of nodes 7, 8, 9 and 10.

\[
q'_A = h_o \left[ \left( \Delta x / 2 \right) \left( T_7 - T_{\infty,0} \right) + \Delta x \left( T_8 - T_{\infty,0} \right) + \Delta x \left( T_9 - T_{\infty,0} \right) + \left( \Delta x / 2 \right) \left( T_{10} - T_{\infty,0} \right) \right]
\]

\[
q'_A = 250 \text{ W/m}^2 \cdot \text{K} \left[ \left( 25 / 2 \right) (95.80 - 25) + 25(87.28 - 25) 
\]

\[
+ 25(79.67 - 25) + (25 / 2)(77.65 - 25) \right] \times 10^{-3} \text{ m} \cdot \text{K}
\]

**Continued …..**
PROBLEM 4.48 (Cont.)

\[ q_A' = 1117 \text{ W/m} \]  

(c) The heat rate per unit length from the inner fluid to the surface \( B \), \( q_B' \), is the sum of the convection heat rates from the inner surfaces of nodes 2, 4, 5 and 6.

\[
q_B' = h_1 \left[ \left( \frac{\Delta y}{2} \right) \left( T_{\infty,1} - T_2 \right) + \left( \frac{\Delta y}{2} + \frac{\Delta x}{2} \right) \left( T_{\infty,i} - T_4 \right) + \frac{\Delta x}{2} \left( T_{\infty,i} - T_5 \right) + \left( \frac{\Delta x}{2} \right) \left( T_{\infty,i} - T_6 \right) \right]
\]

\[
q_B' = 500 \text{ W/m}^2 \cdot K \left[ \left( \frac{25}{2} \right) \left( 50 - 95.47 \right) + \left( \frac{25}{2} + 25 \right) \left( 50 - 94.50 \right) + 25 \left( 50 - 79.79 \right) + \left( \frac{25}{2} \right) \left( 50 - 77.29 \right) \right] \times 10^{-3} \text{ m} \cdot \text{K}
\]

\[ q_B' = -1383 \text{ W/m} < 

(d) From an overall energy balance on the section, we see that our results are consistent since the conservation of energy requirement is satisfied.

\[
\dot{E}_\text{in} - \dot{E}_\text{out} + \dot{E}_\text{gen} = -q_A' + q_B' + \dot{E}_\text{gen} = (-1117 - 1383 + 2500) \text{ W/m} = 0
\]

where

\[
\dot{E}_\text{gen} = \dot{q} \nu' = 10^6 \text{ W/m}^3 \left[ 25 \times 50 + 25 \times 50 \right] \times 10^{-6} \text{ m}^2 = 2500 \text{ W/m}
\]

COMMENTS:

The nodal finite-difference equations for the four nodes can be obtained by using IHT Tool *Finite-Difference Equations | Two-Dimensional | Steady-state*. Options are provided to build the FDEs for interior, corner and surface nodal arrangements including convection and internal generation. The IHT code lines for the FDEs are shown below.

/* Node 1: interior node; e, w, n, s labeled 2, 2, 3, 3. */
0.0 = fd_2d_int(T1,T2,T2,T3,T3,k,qdot,deltax,deltay)

/* Node 4: internal corner node, e-n orientation; e, w, n, s labeled 5, 3, 2, 8. */
0.0 = fd_2d_ic_en(T4,T5,T3,T2,T8,k,qdot,deltax,deltay,Tinfx,hi,q a4
q a4 = 0 // Applied heat flux, W/m^2; zero flux shown

/* Node 7: plane surface node, s-orientation; e, w, n labeled 8, 8, 3. */
0.0 = fd_2d_psur_s(T7,T8,T8,T3,k,qdot,deltax,deltay,Tinfo,ho,q a7
q a7 = 0 // Applied heat flux, W/m^2; zero flux shown

/* Node 9: plane surface node, s-orientation; e, w, n labeled 10, 8, 5. */
0.0 = fd_2d_psur_s(T9, T10, T8, T5,k,qdot,deltax,deltay,Tinfo,ho,q a9
q a9 = 0 // Applied heat flux, W/m^2; zero flux shown
**PROBLEM 4.49**

**KNOWN:** Outer surface temperature, inner convection conditions, dimensions and thermal conductivity of a heat sink.

**FIND:** Nodal temperatures and heat rate per unit length.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Two-dimensional conduction, (3) Uniform outer surface temperature, (4) Constant thermal conductivity.

**ANALYSIS:** (a) To determine the heat rate, the nodal temperatures must first be computed from the corresponding finite-difference equations. From an energy balance for node 1,

\[
 h \left( \Delta x / 2 \cdot 1 \right) \left( T_\infty - T_1 \right) + k \left( \Delta y / 2 \cdot 1 \right) \frac{T_2 - T_1}{\Delta x} + k \left( \Delta x \cdot 1 \right) \frac{T_5 - T_1}{\Delta y} = 0
\]

\[
 - \left( 3 + \frac{h \Delta x}{k} \right) T_1 + T_2 + 2T_5 + \frac{h \Delta x}{k} T_\infty = 0 \tag{1}
\]

With nodes 2 and 3 corresponding to Case 3 of Table 4.2,

\[
 T_1 - 2 \left( \frac{h \Delta x}{k} + 2 \right) T_2 + T_3 + 2T_6 + \frac{2h \Delta x}{k} T_\infty = 0 \tag{2}
\]

\[
 T_2 - \left( \frac{h \Delta x}{k} + 2 \right) T_3 + T_7 + \frac{h \Delta x}{k} T_\infty = 0 \tag{3}
\]

where the symmetry condition is invoked for node 3. Applying an energy balance to node 4, we obtain

\[
 -2T_4 + T_5 + T_s = 0 \tag{4}
\]

The interior nodes 5, 6 and 7 correspond to Case 1 of Table 4.2. Hence,

\[
 T_1 + T_4 - 4T_5 + T_6 + T_s = 0 \tag{5}
\]

\[
 T_2 + T_5 - 4T_6 + T_7 + T_s = 0 \tag{6}
\]

\[
 T_3 + 2T_6 - 4T_7 + T_s = 0 \tag{7}
\]

where the symmetry condition is invoked for node 7. With \( T_s = 50^\circ C, T_\infty = 20^\circ C \), and

\[
 h \Delta x / k = 5000 \text{ W} / \text{m}^2 \cdot \text{K} \left( 0.005 \text{m} \right) / 240 \text{ W} / \text{m} \cdot \text{K} = 0.1042 \text{, the solution to Eqs. (1) \ldots (7) yields}
\]

\[
 T_1 = 46.61^\circ C, T_2 = 45.67^\circ C, T_3 = 45.44^\circ C, T_4 = 49.23^\circ C
\]

\[
 T_5 = 48.46^\circ C, T_6 = 48.00^\circ C, T_7 = 47.86^\circ C
\]

Continued …..
PROBLEM 4.49 (Cont.)

The heat rate per unit length of channel may be evaluated by computing convection heat transfer from
the inner surface. That is,

\[ q' = 8h \left[ \Delta x / 2(T_1 - T_\infty) + \Delta x (T_2 - T_\infty) + \Delta x / 2(T_3 - T_\infty) \right] \]

\[ q' = 8 \times 5000 \text{ W/m} \cdot \text{K} \left[ 0.0025 \times (46.61 - 20)°\text{C} + 0.005 \times (45.67 - 20)°\text{C} \right] \]

\[ + 0.0025 \times (45.44 - 20)°\text{C} = 10,340 \text{ W/m} \]

(b) Since \( h = 5000 \text{ W/m}^2 \cdot \text{K} \) is at the high end of what can be achieved through forced convection, we consider the effect of reducing \( h \). Representative results are as follows

<table>
<thead>
<tr>
<th>( h ) (W/m^2·K)</th>
<th>( T_1 ) (°C)</th>
<th>( T_2 ) (°C)</th>
<th>( T_3 ) (°C)</th>

</tr>
</tbody>
</table>

There are two resistances to heat transfer between the outer surface of the heat sink and the fluid, that
due to conduction in the heat sink, \( R_{\text{cond}}(2D) \), and that due to convection from its inner surface to the
fluid, \( R_{\text{conv}} \). With decreasing \( h \), the corresponding increase in \( R_{\text{conv}} \) reduces heat flow and
increases the uniformity of the temperature field in the heat sink. The nearly 5-fold reduction in \( q' \)
corresponding to the 5-fold reduction in \( h \) from 1000 to 200 W/m^2·K indicates that the convection
resistance is dominant \((R_{\text{conv}} \gg R_{\text{cond}}(2D))\).

COMMENTS: To check our finite-difference solution, we could assess its consistency with
conservation of energy requirements. For example, an energy balance performed at the inner surface
requires a balance between convection from the surface and conduction to the surface, which may be
expressed as

\[ q' = k \frac{(\Delta x \cdot 1)(T_5 - T_1)}{\Delta y} + k \frac{(\Delta x \cdot 1)(T_6 - T_2)}{\Delta y} + k \frac{(\Delta x / 2 \cdot 1)(T_7 - T_3)}{\Delta y} \]

Substituting the temperatures corresponding to \( h = 5000 \text{ W/m}^2 \cdot \text{K} \), the expression yields
\( q' = 10,340 \text{ W/m} \), and, as it must be, conservation of energy is precisely satisfied. Results of the
analysis may also be checked by using the expression \( q' = (T_s - T_\infty)/(R_{\text{cond}}(2D) + R_{\text{conv}}') \), where, for
\( h = 5000 \text{ W/m}^2 \cdot \text{K} \), \( R_{\text{conv}}' = (1/4hw) = 2.5 \times 10^{-3} \text{ m·K}/\text{W} \), and from Eq. (4.27) and Case 11 of
Table 4.1, \( R_{\text{cond}}' = [0.930 \ln (W/w) - 0.05]/2\pi k = 3.94 \times 10^{-4} \text{ m·K}/\text{W} \). Hence,
\( q' = (50 - 20)°\text{C}/\left(2.5 \times 10^{-3} + 3.94 \times 10^{-4}\right) \text{m·K}/\text{W} = 10,370 \text{ W/m} \), and the agreement with the
finite-difference solution is excellent. Note that, even for \( h = 5000 \text{ W/m}^2 \cdot \text{K} \), \( R_{\text{conv}}' \gg R_{\text{cond}}'(2D) \).
PROBLEM 4.50

KNOWN: Steady-state temperatures (°C) associated with selected nodal points in a two-dimensional system.

FIND: (a) Temperatures at nodes 1, 2 and 3, (b) Heat transfer rate per unit thickness from the system surface to the fluid.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, two-dimensional conduction, (2) Constant properties.

ANALYSIS: (a) Using the finite-difference equations for Nodes 1, 2 and 3:

Node 1, Interior node, Eq. 4.33: \( T_1 = \frac{1}{4} \sum T_{\text{neighbors}} \)

\[
T_1 = \frac{1}{4} (172.9 + 137.0 + 132.8 + 200.0) \degree C = 160.7 \degree C
\]

Node 2, Insulated boundary, Eq. 4.46 with \( h = 0, T_{m,n} = T_2 \)

\[
T_2 = \frac{1}{4} (T_{m-1,n} + T_{m+1,n} + T_{m,n-1})
\]

\[
T_2 = \frac{1}{4} (129.4 + 45.8 + 2 \times 103.5) \degree C = 95.6 \degree C
\]

Node 3, Plane surface with convection, Eq. 4.46, \( T_{m,n} = T_3 \)

\[
2 \left[ \frac{h\Delta x}{k} + 2 \right] T_3 = \frac{2h\Delta x}{k} T_\infty + \frac{2h\Delta x}{k} T_\infty
\]

\[
h\Delta x/k = 50 \text{W/m}^2 \cdot \text{K} \times 0.1 \text{m} / 1.5 \text{W/m} \cdot \text{K} = 3.33
\]

\[
2(3.33 + 2) T_3 = (2 \times 103.5 + 45.8 + 67.0) \degree C + 2 \times 3.33 \times 30 \degree C
\]

\[
T_3 = \frac{1}{10.66} (319.80 + 199.80) \degree C = 48.7 \degree C
\]

(b) The heat rate per unit thickness from the surface to the fluid is determined from the sum of the convection rates from each control volume surface.

\[
q_{\text{conv}} = q_a + q_b + q_c + q_d
\]

\[
q_i = h\Delta y_i (T_i - T_\infty)
\]

\[
q_{\text{conv}} = 50 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} \left[ 0.1m \left(45.8 - 30.0 \right) \degree C + 0.1m \left(48.7 - 30.0 \right) \degree C + 0.1m \left(67.0 - 30.0 \right) \degree C + 0.1m \left(200.0 - 30.0 \right) \degree C \right]
\]

\[
q_{\text{conv}} = (39.5 + 93.5 + 185.0 + 425) \text{ W/m} = 743 \text{ W/m}
\]
PROBLEM 4.51

**KNOWN:** Nodal temperatures from a steady-state finite-difference analysis for a cylindrical fin of prescribed diameter, thermal conductivity and convection conditions \((T_\infty, h)\).

**FIND:** (a) The fin heat rate, \(q_f\), and (b) Temperature at node 3, \(T_3\).

**SCHEMATIC:**

\[
T_0 = 100.0^\circ C \\
T_1 = 93.4^\circ C \\
T_2 = 89.5^\circ C
\]

**ASSUMPTIONS:** (a) The fin heat rate, \(q_f\), is that of conduction at the base plane, \(x = 0\), and can be found from an energy balance on the control volume about node 0, \(\dot{E}_{in} - \dot{E}_{out} = 0\).

\[
q_f + q_1 + q_{conv} = 0 \quad \text{or} \quad q_f = -q_1 - q_{conv}.
\]

Writing the appropriate rate equation for \(q_1\) and \(q_{conv}\), with \(A_c = \pi D^2/4\) and \(P = \pi D\),

\[
q_f = -kA_c \frac{T_1 - T_0}{\Delta x} - hP(\Delta x/2)(T_\infty - T_0) = -\frac{\pi kD^2}{4\Delta x} (T_1 - T_0) - \frac{\pi}{2} D h \Delta x (T_\infty - T_0)
\]

Substituting numerical values, with \(\Delta x = 0.010\ m\), find

\[
q_f = (1.120 + 0.353)W = 1.473W.
\]

(b) To determine \(T_3\), derive the finite-difference equation for node 2, perform an energy balance on the control volume shown above, \(\dot{E}_{in} - \dot{E}_{out} = 0\),

\[
q_{cv} + q_3 + q_1 = 0 \\
hP\Delta x (T_\infty - T_2) + kA_c \frac{T_3 - T_2}{\Delta x} + kA_c \frac{T_1 - T_2}{\Delta x} = 0
\]

\[
T_3 = -T_1 + 2T_2 - \frac{hP\Delta x^2}{kA_c} \Delta x^2 [T_\infty - T_2]
\]

Substituting numerical values, find

\[
T_2 = 89.2^\circ C
\]

**COMMENTS:** Note that in part (a), the convection heat rate from the outer surface of the control volume is significant (25%). It would have been poor approximation to ignore this term.
PROBLEM 4.52

KNOWN: Long rectangular bar having one boundary exposed to a convection process \( T_{\infty}, h \) while the other boundaries are maintained at a constant temperature \( T_s \).

FIND: (a) Using a grid spacing of 30 mm and the Gauss-Seidel method, determine the nodal temperatures and the heat rate per unit length into the bar from the fluid, (b) Effect of grid spacing and convection coefficient on the temperature field.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, two-dimensional conduction, (2) Constant properties.

ANALYSIS: (a) With the grid spacing \( \Delta x = \Delta y = 30 \text{ mm} \), three nodes are created. Using the finite-difference equations as shown in Table 4.2, but written in the form required of the Gauss-Seidel method (see Section 4.5.2), and with \( \text{Bi} = h \Delta x/k = 100 \text{ W/m}^2 \cdot \text{K} \times 0.030 \text{ m} / 1 \text{ W/m} \cdot \text{K} = 3 \), we obtain:

\[
\text{Node 1: } T_1 = \frac{1}{(\text{Bi} + 2)} (T_2 + T_s + \text{Bi}T_{\infty}) = \frac{1}{5} (T_2 + 50 + 3 \times 100) = \frac{1}{5} (T_2 + 350) \quad (1)
\]

\[
\text{Node 2: } T_2 = \frac{1}{4} (T_1 + 2T_s + T_3) = \frac{1}{4} (T_1 + T_3 + 2 \times 50) = \frac{1}{4} (T_1 + T_3 + 100) \quad (2)
\]

\[
\text{Node 3: } T_3 = \frac{1}{4} (T_2 + 3T_s) = \frac{1}{4} (T_2 + 3 \times 50) = \frac{1}{4} (T_2 + 150) \quad (3)
\]

Denoting each nodal temperature with a superscript to indicate iteration step, e.g. \( T_1^k \), calculate values as shown below.

<table>
<thead>
<tr>
<th>( k )</th>
<th>( T_1 )</th>
<th>( T_2 )</th>
<th>( T_3 ) (°C)</th>

</tbody>
</table>

By the 4th iteration, changes are of order 0.02°C, suggesting that further calculations may not be necessary.

Continued...
In finite-difference form, the heat rate from the fluid to the bar is

\[ q'_{\text{conv}} = h \left( \frac{\Delta x}{2} \right) (T_\infty - T_s) + h\Delta x (T_\infty - T_j) + h \left( \frac{\Delta x}{2} \right) (T_\infty - T_s) \]

\[ q'_{\text{conv}} = h\Delta x (T_\infty - T_s) + h\Delta x (T_\infty - T_j) = h\Delta x \left[ (T_\infty - T_s) + (T_\infty - T_j) \right] \]

\[ q'_{\text{conv}} = 100 \text{ W/m}^2 \cdot \text{K} \times 0.030 \text{ m} \left[ (100 - 50) + (100 - 81.7) \right] \degree C = 205 \text{ W/m} \ . \]

(b) Using the \textit{Finite-Difference Equations} option from the \textit{Tools} portion of the IHT menu, the following two-dimensional temperature field was computed for the grid shown in schematic (b), where x and y are in mm and the temperatures are in °C.

<table>

</tr>
</tbody>
</table>

The improved prediction of the temperature field has a significant influence on the heat rate, where, accounting for the symmetrical conditions,

\[ q' = 2h \left( \frac{\Delta x}{2} \right) (T_\infty - T_s) + 2h (\Delta x)(T_\infty - T_j) + h (\Delta x)(T_\infty - T_2) \]

\[ q' = h (\Delta x) \left[ (T_\infty - T_s) + 2 (T_\infty - T_j) + (T_\infty - T_2) \right] \]

\[ q' = 100 \text{ W/m}^2 \cdot \text{K} \times 0.015 \text{ m} \left[ 50 + 2 (19.67) + 14.84 \right] \degree C = 156.3 \text{ W/m} \]

Additional improvements in accuracy could be obtained by reducing the grid spacing to 5 mm, although the requisite number of finite-difference equations would increase from 12 to 108, significantly increasing problem \textit{set-up} time.

An increase in h would increase temperatures everywhere within the bar, particularly at the heated surface, as well as the rate of heat transfer by convection to the surface.

**COMMENTS:** (1) Using the matrix-inversion method, the exact solution to the system of equations (1, 2, 3) of part (a) is \( T_1 = 81.70°C, T_2 = 58.44°C, \) and \( T_3 = 52.12°C. \) The fact that only 4 iterations were required to obtain agreement within 0.01°C is due to the close initial guesses.

(2) Note that the rate of heat transfer by convection to the top surface of the rod must balance the rate of heat transfer by conduction to the sides and bottom of the rod.

**NOTE TO INSTRUCTOR:** Although the problem statement calls for calculations with \( \Delta x = \Delta y = 5 \) mm and for plotting associated isotherms, the instructional value and benefit-to-effort ratio are small. Hence, it is recommended that this portion of the problem not be assigned.
PROBLEM 4.53

KNOWN: Square shape subjected to uniform surface temperature conditions.

FIND: (a) Temperature at the four specified nodes; estimate the midpoint temperature $T_o$, (b) Reducing the mesh size by a factor of 2, determine the corresponding nodal temperatures and compare results, and (c) For the finer grid, plot the 75, 150, and 250°C isotherms.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, two-dimensional conduction, (2) Constant properties.

ANALYSIS: (a) The finite-difference equation for each node follows from Eq. 4.33 for an interior point written in the form, $T_i = 1/4 \sum T_{neighbors}$. Using the Gauss-Seidel iteration method, Section 4.5.2, the finite-difference equations for the four nodes are:

$$T_1^k = 0.25 \left( 100 + T_2^{k-1} + T_3^{k-1} + 50 \right) = 0.25T_2^{k-1} + 0.25T_3^{k-1} + 37.5$$

$$T_2^k = 0.25 \left( 100 + 200 + T_4^{k-1} + T_1^{k-1} \right) = 0.25T_4^{k-1} + 0.25T_1^{k-1} + 75.0$$

$$T_3^k = 0.25 \left( T_1^{k-1} + T_4^{k-1} + 300 + 50 \right) = 0.25T_1^{k-1} + 0.25T_4^{k-1} + 87.5$$

$$T_4^k = 0.25 \left( T_2^{k-1} + 200 + 300 + T_3^{k-1} \right) = 0.25T_2^{k-1} + 0.25T_3^{k-1} + 125.0$$

The iteration procedure using a hand calculator is implemented in the table below. Initial estimates are entered on the $k = 0$ row.

<table>

</table>

Continued...
PROBLEM 4.53 (Cont.)

By the seventh iteration, the convergence is approximately 0.01°C. The midpoint temperature can be estimated as

\[ T_0 = \frac{1}{4} (T_1 + T_2 + T_3 + T_4) = \frac{1}{4} (118.76 + 156.25 + 168.76 + 206.25) \degree C = 162.5 \degree C \]

(b) Because all the nodes are interior ones, the nodal equations can be written by inspection directly into the IHT workspace and the set of equations solved for the nodal temperatures (°C).

<table>
<thead>
<tr>
<th>Mesh</th>
<th>T₀</th>
<th>T₁</th>
<th>T₂</th>
<th>T₃</th>
<th>T₄</th>
</tr>
</thead>
<tbody>
<tr>
<td>Coarse</td>
<td>162.5</td>
<td>118.76</td>
<td>156.25</td>
<td>168.76</td>
<td>206.25</td>
</tr>
<tr>
<td>Fine</td>
<td>162.5</td>
<td>117.4</td>
<td>156.1</td>
<td>168.9</td>
<td>207.6</td>
</tr>
</tbody>
</table>

The maximum difference for the interior points is 1.5°C (node 4), but the estimate at the center, T₀, is the same, independently of the mesh size. In terms of the boundary surface temperatures,

\[ T_0 = \frac{1}{4} (50 + 100 + 200 + 300) \degree C = 162.5 \degree C \]

Why must this be so?

(c) To generate the isotherms, it would be necessary to employ a contour-drawing routine using the tabulated temperature distribution (°C) obtained from the finite-difference solution. Using these values as a guide, try sketching a few isotherms.

</tbody>
</table>

COMMENTS: Recognize that this finite-difference solution is only an approximation to the temperature distribution, since the heat conduction equation has been solved for only four (or 25) discrete points rather than for all points if an analytical solution had been obtained.
**PROBLEM 4.54**

**KNOWN:** Long bar of square cross section, three sides of which are maintained at a constant temperature while the fourth side is subjected to a convection process.

**FIND:** (a) The mid-point temperature and heat transfer rate between the bar and fluid; a numerical technique with grid spacing of 0.2 m is suggested, and (b) Reducing the grid spacing by a factor of 2, find the midpoint temperature and the heat transfer rate. Also, plot temperature distribution across the surface exposed to the fluid.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, two-dimensional conduction, (2) Constant properties.

**ANALYSIS:** (a) Considering symmetry, the nodal network is shown above. The matrix inversion method of solution will be employed. The finite-difference equations are:

- **Nodes 1, 3, 5** - Interior nodes, Eq. 4.33; written by inspection.
- **Nodes 2, 4, 6** - Also can be treated as interior points, considering symmetry.
- **Nodes 7, 8** - On a plane with convection, Eq. 4.46; noting that \( h \Delta x/k = 10 \text{ W/m}^2\cdot\text{K} \times 0.2 \text{ m}/2\text{W/m}\cdot\text{K} = 1 \), find
  
  Node 7: \((2T_5 + 300 + T_8) + 20 \times 100 - 2(1+2)T_7 = 0\)
  Node 8: \((2T_3 + T_7 + T_7) + 20 \times 100 - 2(1+2)T_8 = 0\)

The solution matrix \([T]\) can be found using a stock matrix program using the \([A]\) and \([C]\) matrices shown below to obtain the solution matrix \([T]\) (Eq. 4.52). Alternatively, the set of equations could be entered into the IHT workspace and solved for the nodal temperatures.

\[
A = \begin{bmatrix} -4 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 2 & -4 & 0 & 1 & 0 & 0 & 0 & 0 \\ 1 & 0 & -4 & 1 & 1 & 0 & 0 & 0 \\ 0 & 1 & 2 & -4 & 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 & -4 & 1 & 1 & 0 \\ 0 & 0 & 0 & 1 & 2 & -4 & 0 & 1 \\ 0 & 0 & 0 & 0 & 2 & 0 & -6 & 1 \\ 0 & 0 & 0 & 0 & 0 & 2 & 2 & -6 \end{bmatrix}, \quad C = \begin{bmatrix} 0 & -600 & 292.2 \\ 0 & -300 & 289.2 \\ 0 & -300 & 279.7 \\ 0 & 0 & 272.2 \\ 0 & 0 & 254.5 \\ 0 & -500 & 198.1 \\ 0 & -200 & 179.4 \end{bmatrix}, \quad T = \begin{bmatrix} 272.2 \end{bmatrix}
\]

From the solution matrix \([T]\), find the mid-point temperature as

\[T_4 = 272.2°C\]
PROBLEM 4.54 (Cont.)

The heat rate by convection between the bar and fluid is given as,

\[ q'_{\text{conv}} = 2(q'_a + q'_b + q'_c) \]

\[ q'_{\text{conv}} = 2x \left[ h \left( \Delta x/2 \right) (T_8 - T_\infty) + h \left( \Delta x \right) (T_7 - T_\infty) + h \left( \Delta x/2 \right) (300 - T_\infty) \right] \]

\[ q'_{\text{conv}} = 2x \left[ 10 \, \text{W/m}^2 \cdot \text{K} \times (0.2 \, \text{m}/2) \left[ (179.4 - 100) + 2(198.1 - 100) + (300 - 100) \right] \right] \text{K} \]

\[ q'_{\text{conv}} = 952 \, \text{W/m} \, . \]

(b) Reducing the grid spacing by a factor of 2, the nodal arrangement will appear as shown. The finite-difference equation for the interior and centerline nodes were written by inspection and entered into the IHT workspace. The IHT Finite-Difference Equations Tool for 2-D, SS conditions, was used to obtain the FDE for the nodes on the exposed surface.

The midpoint temperature \( T_{13} \) and heat rate for the finer mesh are

\[ T_{13} = 271.0 ^\circ \text{C} \quad q' = 834 \, \text{W/m} \, . \]

COMMENTS: The midpoint temperatures for the coarse and finer meshes agree closely, \( T_4 = 272^\circ \text{C} \) vs. \( T_{13} = 271.0^\circ \text{C} \), respectively. However, the estimate for the heat rate is substantially influenced by the mesh size; \( q' = 952 \) vs. 834 W/m for the coarse and finer meshes, respectively.
**PROBLEM 4.55**

**KNOWN:** Volumetric heat generation in a rectangular rod of uniform surface temperature.

**FIND:** (a) Temperature distribution in the rod, and (b) With boundary conditions unchanged, heat generation rate causing the midpoint temperature to reach 600 K.

**SCHEMATIC:**

![Schematic Diagram]

**ASSUMPTIONS:** (1) Steady-state, two-dimensional conduction, (2) Constant properties, (3) Uniform volumetric heat generation.

**ANALYSIS:** (a) From symmetry it follows that six unknown temperatures must be determined. Since all nodes are interior ones, the finite-difference equations may be obtained from Eq. 4.39 written in the form

\[
T_i = \frac{1}{2} \sum T_{\text{neighbors}} + \frac{1}{4} \left( \dot{q} \left( \Delta x \Delta y \right) / k \right).
\]

With \( \dot{q} \left( \Delta x \Delta y \right) / 4k = 62.5 \text{ K} \), the system of finite-difference equations is

\[
\begin{align*}
T_1 &= 0.25 (T_S + T_2 + T_4 + T_S) + 15.625 \\
T_2 &= 0.25 (T_S + T_3 + T_5 + T_1) + 15.625 \\
T_3 &= 0.25 (T_S + T_2 + T_6 + T_2) + 15.625 \\
T_4 &= 0.25 (T_1 + T_5 + T_1 + T_3) + 15.625 \\
T_5 &= 0.25 (T_2 + T_6 + T_2 + T_4) + 15.625 \\
T_6 &= 0.25 (T_3 + T_5 + T_3 + T_5) + 15.625
\end{align*}
\]

With \( T_S = 300 \text{ K} \), the set of equations was written directly into the IHT workspace and solved for the nodal temperatures,

<table>
<thead>
<tr>
<th>( T_1 )</th>
<th>( T_2 )</th>
<th>( T_3 )</th>
<th>( T_4 )</th>
<th>( T_5 )</th>
<th>( T_6 ) (K)</th>
</tr>
</thead>
<tbody>
<tr>
<td>348.6</td>
<td>368.9</td>
<td>374.6</td>
<td>362.4</td>
<td>390.2</td>
<td>398.0</td>
</tr>
</tbody>
</table>

(b) With the boundary conditions unchanged, the \( \dot{q} \) required for \( T_6 = 600 \text{ K} \) can be found using the same set of equations in the IHT workspace, but with these changes: (1) replace the last term on the RHS (15.625) of Eqs. (1-6) by \( \dot{q} \left( \Delta x \Delta y \right) / 4k = (0.005 \text{ m})^2 \dot{q} / 4 \times 20 \text{ W/m-K} = 3.125 \times 10^{-7} \dot{q} \) and (2) set \( T_S = 600 \text{ K} \). The set of equations has 6 unknown, five nodal temperatures plus \( \dot{q} \). Solving find

\[
\dot{q} = 1.53 \times 10^8 \text{ W/m}^3
\]
PROBLEM 4.56

KNOWN: Flue of square cross section with prescribed geometry, thermal conductivity and inner and outer surface temperatures.

FIND: Heat loss per unit length from the flue, \( q' \).

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, two-dimensional conduction, (2) Constant properties, (3) No internal generation.

ANALYSIS: Taking advantage of symmetry, the nodal network using the suggested 75mm grid spacing is shown above. To obtain the heat rate, we first need to determine the unknown temperatures \( T_1, T_2, T_3 \) and \( T_4 \). Recognizing that these nodes may be treated as interior nodes, the nodal equations from Eq. 4.33 are

\[
(T_2 + 25 + T_2 + 350) - 4T_1 = 0 \\
(T_1 + 25 + T_3 + 350) - 4T_2 = 0 \\
(T_2 + 25 + T_4 + 350) - 4T_3 = 0 \\
(T_3 + 25 + 25 + T_3) - 4T_4 = 0.
\]

The Gauss-Seidel iteration method is convenient for this system of equations and following the procedures of Section 4.5.2, they are rewritten as,

\[
T_1^k = 0.50 T_1^{k-1} + 93.75 \\
T_2^k = 0.25 T_1^k + 0.25 T_3^{k-1} + 93.75 \\
T_3^k = 0.25 T_2^k + 0.25 T_4^{k-1} + 93.75 \\
T_4^k = 0.50 T_3^k + 12.5.
\]

The iteration procedure is implemented in the table on the following page, one row for each iteration \( k \). The initial estimates, for \( k = 0 \), are all chosen as \( (350 + 25)/2 \approx 185 \degree C \). Iteration is continued until the maximum temperature difference is less than \( 0.2 \degree C \), i.e., \( \varepsilon < 0.2 \degree C \).

Note that if the system of equations were organized in matrix form, Eq. 4.52, diagonal dominance would exist. Hence there is no need to reorder the equations since the magnitude of the diagonal element is greater than that of other elements in the same row.

</tbody>
</table>

From knowledge of the temperature distribution, the heat rate may be obtained by summing the heat rates across the nodal control volume surfaces, as shown in the sketch.

The heat rate leaving the outer surface of this flue section is,

$$q' = q_a' + q_b' + q_c' + q_d' + q_e'$$

$$q' = k \frac{\Delta x}{\Delta y} \left[ \frac{1}{2} (T_1 - 25) + (T_2 - 25) + (T_3 - 25) + (T_4 - 25) + 0 \right]$$

$$q' = 0.85 \frac{W}{m \cdot K} \left[ \frac{1}{2} (183.9 - 25) + (180.3 - 25) + (162.2 - 26) + (93.6 - 25) \right]$$

$$q' = 374.5 \text{ W/m.}$$

Since this flue section is 1/8 the total cross section, the total heat loss from the flue is

$$q' = 8 \times 374.5 \text{ W/m} = 3.00 \text{ kW/m.}$$

**COMMENTS:** The heat rate could have been calculated at the inner surface, and from the above sketch has the form

$$q' = k \frac{\Delta x}{\Delta y} \left[ \frac{1}{2} (350 - T_1) + (350 - T_2) + (350 - T_3) \right] = 374.5 \text{ W/m.}$$

This result should compare very closely with that found for the outer surface since the conservation of energy requirement must be satisfied in obtaining the nodal temperatures.
PROBLEM 4.57

KNOWN: Flue of square cross section with prescribed geometry, thermal conductivity and inner and outer surface convective conditions.

FIND: (a) Heat loss per unit length, \( q' \), by convection to the air, (b) Effect of grid spacing and convection coefficients on temperature field; show isotherms.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, two-dimensional conduction, (2) Constant properties.

ANALYSIS: (a) Taking advantage of symmetry, the nodal network for a 75 mm grid spacing is shown in schematic (a). To obtain the heat rate, we need first to determine the temperatures \( T_i \). Recognize that there are four types of nodes: interior (4-7), plane surface with convection (1, 2, 8-11), internal corner with convection (3), and external corner with convection (12). Using the appropriate relations from Table 4.2, the finite-difference equations are

</table>

Continued...
PROBLEM 4.57 (Cont.)

The Gauss-Seidel iteration is convenient for this system of equations. Following procedures of Section 4.5.2, the system of equations is rewritten in the proper form. Note that diagonal dominance is present; hence, no re-ordering is necessary.

\[
\begin{align*}
T_k^1 &= 0.09239T_{k-1}^2 + 0.09239T_{k-1}^4 + 285.3 \\
T_k^2 &= 0.04620T_{k-1}^1 + 0.04620T_{k-1}^3 + 0.09239T_{k-1}^5 + 285.3 \\
T_k^3 &= 0.08457T_{k-1}^2 + 0.1692T_{k-1}^6 + 261.2 \\
T_k^4 &= 0.25T_{k-1}^1 + 0.50T_{k-1}^5 + 0.25T_{k-1}^8 \\
T_k^5 &= 0.25T_{k-1}^2 + 0.25T_{k-1}^4 + 0.25T_{k-1}^6 + 0.25T_{k-1}^9 \\
T_k^6 &= 0.25T_{k-1}^3 + 0.25T_{k-1}^5 + 0.25T_{k-1}^7 + 0.25T_{k-1}^9 \\
T_k^7 &= 0.50T_{k-1}^6 + 0.50T_{k-1}^{11} \\
T_k^8 &= 0.4096T_{k-1}^7 + 0.4096T_{k-1}^{10} + 4.52 \\
T_k^9 &= 0.4096T_{k-1}^8 + 0.2048T_{k-1}^9 + 0.2048T_{k-1}^{10} + 4.52 \\
T_k^{10} &= 0.4096T_{k-1}^9 + 0.2048T_{k-1}^{10} + 0.2048T_{k-1}^{11} + 4.52 \\
T_k^{11} &= 0.4096T_{k-1}^{10} + 0.2048T_{k-1}^{11} + 4.52 \\
T_k^{12} &= 0.6939T_{k-1}^{11} + 7.65
\end{align*}
\]

The initial estimates (\(k = 0\)) are carefully chosen to minimize calculation labor; let \(\varepsilon < 1.0\).

\[
\begin{array}{cccccccccccc}
k & T_1 & T_2 & T_3 & T_4 & T_5 & T_6 & T_7 & T_8 & T_9 & T_{10} & T_{11} & T_{12} \\
0 & 340 & 330 & 315 & 250 & 225 & 205 & 195 & 160 & 150 & 140 & 125 & 110 \\
1 & 338.9 & 336.3 & 324.3 & 237.2 & 232.1 & 225.4 & 175.2 & 163.1 & 161.7 & 155.6 & 130.7 & 98.3 \\
2 & 338.3 & 337.4 & 328.0 & 241.4 & 241.5 & 226.6 & 178.6 & 169.6 & 170.0 & 158.9 & 130.4 & 98.1 \\
3 & 338.8 & 338.4 & 328.2 & 247.7 & 245.7 & 230.6 & 180.5 & 175.6 & 173.7 & 161.2 & 131.6 & 98.9 \\
4 & 339.4 & 338.8 & 328.9 & 251.6 & 248.7 & 232.9 & 182.3 & 178.7 & 176.0 & 162.9 & 132.8 & 99.8 \\
5 & 339.8 & 339.2 & 329.3 & 254.0 & 250.5 & 234.5 & 183.7 & 180.6 & 177.5 & 164.1 & 133.8 & 100.5 \\
6 & 340.1 & 339.4 & 329.7 & 255.4 & 251.7 & 235.7 & 184.7 & 181.8 & 178.5 & 164.7 & 134.5 & 101.0 \\
7 & 340.3 & 339.5 & 329.9 & 256.4 & 252.5 & 236.4 & 185.5 & 182.7 & 179.1 & 165.6 & 135.1 & 101.4 \\
\end{array}
\]

The heat loss to the outside air for the upper surface (Nodes 8 through 12) is of the form

\[
q' = h_o \Delta x \left[ \frac{1}{2} (T_8 - T_{\infty,0}) + (T_9 - T_{\infty,0}) + (T_{10} - T_{\infty,0}) + (T_{11} - T_{\infty,0}) + \frac{1}{2} (T_{12} - T_{\infty,0}) \right]
\]

\[
q' = 5 \text{ W/m}^2 \cdot K \times 0.075 \text{ m} \times \frac{1}{2} (182.7 - 25) + (179.1 - 25) + (165.6 - 25) + (135.1 - 25) + \frac{1}{2} (101.4 - 25) \degree C = 195 \text{ W/m}
\]

Hence, for the entire flue cross-section, considering symmetry,

\[
q'_\text{tot} = 8 \times q' = 8 \times 195 \text{ W/m} = 1.57 \text{ kW/m}
\]

The convection heat rate at the inner surface is

\[
q'_\text{tot} = 8 \times h_i \Delta x \left[ \frac{1}{2} (T_{\infty,i} - T_1) + (T_{\infty,i} - T_2) + \frac{1}{2} (T_{\infty,i} - T_3) \right] = 8 \times 190.5 \text{ W/m} = 1.52 \text{ kW/m}
\]

which is within 2.5% of the foregoing result. The calculation would be identical if \(\varepsilon = 0\).

Continued...
PROBLEM 4.57 (Cont.)

(b) Using the *Finite-Difference Equations* option from the *Tools* portion of the IHT menu, the following two-dimensional temperature field was computed for the grid shown in the schematic below, where \( x \) and \( y \) are in mm and the temperatures are in °C.

Agreement between the temperature fields for the (a) and (b) grids is good, with the largest differences occurring at the interior and exterior corners. Ten isotherms generated using *FEHT* are shown on the symmetric section below. Note how the heat flow is nearly normal to the flue wall around the mid-section. In the corner regions, the isotherms are curved and we’d expect that grid size might influence the accuracy of the results. Convection heat transfer to the inner surface is

\[
q' = 8h_i \Delta x \left[ \left( T_{\infty,i} - T_1 \right)/2 + \left( T_{\infty,i} - T_2 \right) + \left( T_{\infty,i} - T_3 \right) + \left( T_{\infty,i} - T_4 \right) + \left( T_{\infty,i} - T_5 \right) + \left( T_{\infty,i} - T_6 \right) + \left( T_{\infty,i} - T_7 \right)/2 \right] = 1.52 \text{ kW/m}
\]

and the agreement with results of the coarse grid is excellent.

The heat rate increases with increasing \( h_i \) and \( h_o \), while temperatures in the wall increase and decrease, respectively, with increasing \( h_i \) and \( h_o \).
**PROBLEM 4.58**

**KNOWN:** Rectangular air ducts having surfaces at 80°C in a concrete slab with an insulated bottom and upper surface maintained at 30°C.

**FIND:** Heat rate from each duct per unit length of duct, \( q' \).

**SCHEMATIC:**

![Schematic diagram of air ducts](image)

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Two-dimensional conduction, (3) No internal volumetric generation, (4) Constant properties.

**PROPERTIES:** Concrete (given): \( k = 1.4 \text{ W/mK} \).

**ANALYSIS:** Taking advantage of symmetry, the nodal network, using the suggested grid spacing
\[
\Delta x = 2\Delta y = 37.50 \text{ mm}
\]
\[
\Delta y = 0.125L = 18.75 \text{ mm}
\]
where \( L = 150 \text{ mm} \), is shown in the sketch. To evaluate the heat rate, we need the temperatures \( T_1, T_2, T_3, T_4, \) and \( T_5 \). All the nodes may be treated as interior nodes (considering symmetry for those nodes on insulated boundaries), Eq. 4.33. Use matrix notation, Eq. 4.52, \([A][T] = [C]\), and perform the inversion.

The heat rate per unit length from the prescribed section of the duct follows from an energy balance on the nodes at the top isothermal surface.

\[
q' = q_1' + q_2' + q_3' + q_4' + q_5'
\]
\[
q_1' = k \left( \frac{\Delta x}{2} \right) \frac{T_1 - T_s}{\Delta y} + k \cdot \Delta x \frac{T_2 - T_s}{\Delta y} + k \cdot \Delta x \frac{T_3 - T_s}{\Delta y} + k \cdot \Delta x \frac{T_4 - T_s}{\Delta y} + k \left( \frac{\Delta x}{2} \right) \frac{T_5 - T_s}{\Delta y}
\]
\[
q_2' = k \left[ (T_1 - T_s) + 2(T_2 - T_s) + 2(T_3 - T_s) + 2(T_4 - T_s) + (T_5 - T_s) \right]
\]
\[
q_3' = 1.4 \text{ W/m-K} \left[ (41.70 - 30) + 2(44.26 - 30) + 2(53.92 - 30) + 2(54.89 - 30) + (54.98 - 30) \right]
\]
\[
q_4' = 228 \text{ W/m}.
\]

Since the section analyzed represents one-half of the region about an air duct, the heat loss per unit length for each duct is,

\[
q'_\text{duct} = 2xq' = 456 \text{ W/m}.
\]

Solution Vector
PROBLEM 4.59

KNOWN: Dimensions and operating conditions for a gas turbine blade with embedded channels.

FIND: Effect of applying a zirconia, thermal barrier coating.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, two-dimensional conduction, (2) Constant properties, (3) Negligible radiation.

ANALYSIS: Preserving the nodal network of Example 4.4 and adding surface nodes for the TBC, finite-difference equations previously developed for nodes 7 through 21 are still appropriate, while new equations must be developed for nodes 1c-6c, 1o-6o, and 1i-6i. Considering node 3c as an example, an energy balance yields

\[ h_{o} \Delta x \left( T_{\infty, o} - T_{3c} \right) + \frac{k_{c} \left( \Delta y_{c} / 2 \right)}{\Delta x} (T_{2c} - T_{3c}) + \frac{k_{c} \left( \Delta y_{c} / 2 \right)}{\Delta x} (T_{4c} - T_{3c}) + \frac{k_{c} \Delta x}{\Delta y_{c}} (T_{3o} - T_{3c}) = 0 \]

or, with \( \Delta x = 1 \) mm and \( \Delta y_{c} = 0.5 \) mm,

\[ 0.25(T_{2c} + T_{4c}) + 2T_{3o} - \left( 2.5 + \frac{h_{o} \Delta x}{k_{c}} \right) T_{3c} = - \frac{h_{o} \Delta x}{k_{c}} T_{\infty, o} \]

Similar expressions may be obtained for the other 5 nodal points on the outer surface of the TBC.

Applying an energy balance to node 3o at the inner surface of the TBC, we obtain

\[ \frac{k_{c} \Delta x}{\Delta y_{c}} (T_{3c} - T_{3o}) + \frac{k_{c} \left( \Delta y_{c} / 2 \right)}{\Delta x} (T_{2o} - T_{3o}) + \frac{k_{c} \left( \Delta y_{c} / 2 \right)}{\Delta x} (T_{4o} - T_{3o}) + \frac{\Delta x}{R_{t,c}^{*}} (T_{3i} - T_{3o}) = 0 \]

or,

\[ 2T_{3c} + 0.25(T_{2o} + T_{4o}) + \frac{\Delta x}{k_{c} R_{t,c}^{*}} T_{3i} - \left( 2.5 + \frac{\Delta x}{k_{c} R_{t,c}^{*}} \right) T_{3o} = 0 \]

Similar expressions may be obtained for the remaining nodal points on the inner surface of the TBC (outer region of the contact resistance).

Continued...
Applying an energy balance to node 3i at the outer surface of the turbine blade, we obtain
\[
\frac{\Delta x}{R_{t,c}'} \left(T_{3o} - T_{3i}\right) + \frac{k \left(\Delta y/2\right)}{\Delta x} \left(T_{2i} - T_{3i}\right) + \frac{k \left(\Delta y/2\right)}{\Delta x} \left(T_{4i} - T_{3i}\right) + \frac{k \Delta x}{\Delta y} \left(T_9 - T_{3i}\right) = 0
\]
or,
\[
\frac{\Delta x}{k R_{t,c}'} T_{3o} + 0.5 \left(T_{2,i} + T_{4,i}\right) + T_9 - \left(2 + \frac{\Delta x}{k R_{t,c}'}\right) T_{3i} = 0
\]
Similar expressions may be obtained for the remaining nodal points on the inner region of the contact resistance.

The 33 finite-difference equations were entered into the workspace of IHT from the keyboard (model equations are appended), and for \(h_o = 1000 \text{ W/m}^2\cdot\text{K}\), \(T_{\infty,o} = 1700 \text{ K}\), \(h_i = 200 \text{ W/m}^2\cdot\text{K}\) and \(T_{\infty,i} = 400 \text{ K}\), the following temperature field was obtained, where coordinate (x,y) locations are in mm and temperatures are in °C.

</table>

Note the significant reduction in the turbine blade temperature, as, for example, from a surface temperature of \(T_1 = 1526 \text{ K}\) without the TBC to \(T_{1i} = 1456 \text{ K}\) with the coating. Hence, the coating is serving its intended purpose.

**COMMENTS:** (1) Significant additional benefits may still be realized by increasing \(h_i\). (2) The foregoing solution may be used to determine the temperature field without the TBC by setting \(k_c \to \infty\) and \(R_{t,c}' \to 0\).
**PROBLEM 4.60**

**KNOWN:** Bar of rectangular cross-section subjected to prescribed boundary conditions.

**FIND:** Using a numerical technique with a grid spacing of 0.1m, determine the temperature distribution and the heat transfer rate from the bar to the fluid.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Two-dimensional conduction, (3) Constant properties.

**ANALYSIS:** The nodal network has $\Delta x = \Delta y = 0.1$m. Note the adiabat corresponding to system symmetry. The finite-difference equations for each node can be written using either Eq. 4.33, for interior nodes, or Eq. 4.46, for a plane surface with convection. In the case of adiabatic surfaces, Eq. 4.46 is used with $h = 0$. Note that

$$\frac{h \Delta x}{k} = \frac{50 \text{W/m}^2 \cdot \text{K} \times 0.1\text{m}}{1.5 \text{ W/m} \cdot \text{K}} = 3.333.$$

Considering symmetry, the heat transfer rate to the fluid is twice the convection rate from the surfaces of the control volumes exposed to the fluid. Using Newton’s law of cooling, considering a unit thickness of the bar, find

\[
q_{\text{conv}} = 2 \left[ h \cdot \frac{\Delta y}{2} \cdot (T_{13} - T_{\infty}) + h \cdot \Delta y \cdot (T_{14} - T_{\infty}) + h \cdot \Delta y \cdot (T_{15} - T_{\infty}) + h \cdot \frac{\Delta y}{2} \cdot (200 - T_{\infty}) \right]
\]

\[
q_{\text{conv}} = 2h \cdot \Delta y \left[ \frac{1}{2} (T_{13} - T_{\infty}) + (T_{14} - T_{\infty}) + (T_{15} - T_{\infty}) + \frac{1}{2} (200 - T_{\infty}) \right]
\]

\[
q_{\text{conv}} = 2 \times 50 \times \frac{W}{m^2 \cdot K} \times 0.1m \left[ \frac{1}{2} (45.8 - 30) + (48.7 - 30) + (67.0 - 30) + \frac{1}{2} (200 - 30) \right]
\]

\[
q_{\text{conv}} = 1487 \text{ W/m.}
\]
PROBLEM 4.61

KNOWN: Upper surface and grooves of a plate are maintained at a uniform temperature $T_1$, while the lower surface is maintained at $T_2$ or is exposed to a fluid at $T_{\infty}$.

FIND: (a) Heat rate per width of groove spacing ($w$) for isothermal top and bottom surfaces using a finite-difference method with $\Delta x = 40$ mm, (b) Effect of grid spacing and convection at bottom surface.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, two-dimensional conduction, (2) Constant properties.

ANALYSIS: (a) Using a space increment of $\Delta x = 40$ mm, the symmetrical section shown in schematic (a) corresponds to one-half the groove spacing. There exist only two interior nodes for which finite-difference equations must be written.

Node $a$: 
$$4T_a - (T_1 + T_b + T_2 + T_1) = 0$$
$$4T_a - (200 + T_b + 20 + 200) = 0$$
$$4T_a - T_b = 420$$

Node $b$: 
$$4T_b - (T_1 + T_a + T_2 + T_a) = 0$$
$$4T_b - (200 + 2T_a + 20) = 0$$
$$-2T_a + 4T_b = 220$$

Multiply Eq. (2) by 2 and subtract from Eq. (1) to obtain 
$$7T_b = 860$$
$$T_b = 122.9^\circ C$$

From Eq. (1),
$$4T_a - 122.9 = 420$$
$$T_a = (420 + 122.9)/4 = 135.7^\circ C.$$

The heat transfer through the symmetrical section is equal to the sum of heat flows through control volumes adjacent to the lower surface. From the schematic,
$$q' = q_1 + q_2 + q_3 = k \left( \frac{\Delta x}{2} \right) \frac{T_1 - T_2}{\Delta y} + k \left( \frac{\Delta x}{2} \right) \frac{T_a - T_2}{\Delta y} + k \left( \frac{\Delta x}{2} \right) \frac{T_b - T_2}{\Delta y}.$$

Continued...
PROBLEM 4.61 (Cont.)

Noting that $\Delta x = \Delta y$, regrouping and substituting numerical values, find

\[
q' = k \left[ \frac{1}{2} (T_1 - T_2) + (T_a - T_2) + \frac{1}{2} (T_b - T_2) \right]
\]

\[
q' = 15 \text{ W/m} \cdot \text{K} \left[ \frac{1}{2} (200 - 20) + (135.7 - 20) + \frac{1}{2} (122.9 - 20) \right] = 3.86 \text{ kW/m}.
\]

For the full groove spacing, $q_{\text{total}} = 2 \times 3.86 \text{ kW/m} = 7.72 \text{ kW/m}$. <

(b) Using the Finite-Difference Equations option from the Tools portion of the IHT menu, the following two-dimensional temperature field was computed for the grid shown in schematic (b), where $x$ and $y$ are in mm and the nodal temperatures are in °C. Nodes 2-54 are interior nodes, with those along the symmetry adiabats characterized by $T_{m-1,n} = T_{m+1,n}$, while nodes 55-63 lie on a plane surface.

\[
\begin{array}{ccccccccccccc}
y/x & 0 & 10 & 20 & 30 & 40 & 50 & 60 & 70 & 80 \\
0 & 200 & 200 & 200 & 200 & 200 & 200 & 200 & 200 & 200 \\
10 & 200 & 191 & 186.6 & 184.3 & 183.1 & 182.8 & 182.5 & 182.2 & 182.0 \\
20 & 200 & 186.7 & 177.2 & 171.2 & 167.5 & 165.5 & 164.8 & 164.2 & 163.7 \\
30 & 200 & 182.4 & 169.5 & 160.1 & 153.4 & 149.0 & 146.4 & 145.5 & 144.6 \\
40 & 200 & 175.4 & 160.3 & 148.9 & 140.1 & 133.5 & 128.7 & 125.7 & 124.4 \\
50 & 141.4 & 134.3 & 125.7 & 118.0 & 111.6 & 106.7 & 103.1 & 100.9 & 101.0 \\
60 & 97.09 & 94.62 & 90.27 & 85.73 & 81.73 & 78.51 & 76.17 & 74.73 & 74.24 \\
70 & 57.69 & 56.83 & 55.01 & 52.95 & 51.04 & 49.46 & 48.31 & 47.60 & 47.36 \\
80 & 20 & 20 & 20 & 20 & 20 & 20 & 20 & 20 & 20 \\
\end{array}
\]

The foregoing results were computed for $h = 10^7$ W/m²·K ($h \to \infty$) and $T_\infty = 20^\circ$C, which is tantamount to prescribing an isothermal bottom surface at 20°C. Agreement between corresponding results for the coarse and fine grids is surprisingly good ($T_a = 135.7^\circ$C $\leftrightarrow$ $T_{23} = 140.1^\circ$C; $T_b = 122.9^\circ$C $\leftrightarrow$ $T_{27} = 124.4^\circ$C). The heat rate is

\[
q' = 2 \times k \left[ \frac{(T_{46} - T_{55})}{2} + (T_{47} - T_{56}) + (T_{48} - T_{57}) + (T_{49} - T_{58}) + (T_{50} - T_{59}) + (T_{51} - T_{60}) + (T_{52} - T_{61}) + (T_{53} - T_{62}) + (T_{54} - T_{63}) \right] / 2
\]

\[
q' = 2 \times 15 \text{ W/m} \cdot \text{K} \left[ 18.84 + 36.82 + 35.00 + 32.95 + 31.04 + 29.46 + 28.31 + 27.6 + 13.68 \right] \text{ C} = 7.61 \text{ kW/m}
\]

The agreement with $q' = 7.72$ kW/m from the coarse grid of part (a) is excellent and a fortuitous consequence of compensating errors. With reductions in the convection coefficient from $h \to \infty$ to $h = 1000, 200$ and $5$ W/m²·K, the corresponding increase in the thermal resistance reduces the heat rate to values of 6.03, 3.28 and 0.14 kW/m, respectively. With decreasing $h$, there is an overall increase in nodal temperatures, as, for example, from 191°C to 199.8°C for $T_2$ and from 20°C to 196.9°C for $T_{55}$.

NOTE TO INSTRUCTOR: To reduce computational effort, while achieving the same educational objectives, the problem statement has been changed to allow for convection at the bottom, rather than the top, surface.
PROBLEM 4.62

KNOWN: Rectangular plate subjected to uniform temperature boundaries.

FIND: Temperature at the midpoint using a finite-difference method with space increment of 0.25m

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction, (3) Constant properties.

ANALYSIS: For the nodal network above, 12 finite-difference equations must be written. It follows that node 8 represents the midpoint of the rectangle. Since all nodes are interior nodes, Eq. 4.33 is appropriate and is written in the form

\[ 4T_m - \sum T_{\text{neighbors}} = 0. \]

For nodes on the symmetry adiabat, the neighboring nodes include two symmetrical nodes. Hence, for Node 4, the neighbors are \( T_b, T_8 \) and \( 2T_3 \). Because of the simplicity of the finite-difference equations, we may proceed directly to the matrices \([A]\) and \([C]\) – see Eq. 4.52 – and matrix inversion can be used to find the nodal temperatures \( T_m \).

\[
A = \begin{bmatrix}
-4 & 1 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
1 & -4 & 1 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 1 & -4 & 1 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 2 & -4 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\
1 & 0 & 0 & 0 & -4 & 1 & 0 & 0 & 1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 1 & -4 & 1 & 0 & 0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & 1 & -4 & 1 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1 & 0 & 0 & 2 & -4 & 0 & 0 & 0 & 1 \\
0 & 0 & 0 & 0 & 1 & 0 & 0 & 2 & -4 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 1 & -4 & 1 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 2 & -4 & 0 \\
\end{bmatrix},
\]

\[
C = \begin{bmatrix}
-200 \\
-150 \\
-150 \\
-150 \\
-50 \\
0 \\
0 \\
0 \\
0 \\
-100 \\
-50 \\
-50 \\
\end{bmatrix},
\]

\[
T = \begin{bmatrix}
96.5 \\
112.9 \\
118.9 \\
120.4 \\
73.2 \\
86.2 \\
92.3 \\
94.0 \\
59.9 \\
65.5 \\
69.9 \\
71.0 \\
\end{bmatrix}.
\]

The temperature at the midpoint (Node 8) is

\[ T(1,0.5) = T_8 = 94.0 \, ^\circ \text{C}. \]

COMMENTS: Using the exact analytical solution – see Eq. 4.19 and Problem 4.2 – the midpoint temperature is found to be 94.5\(^\circ\)C. To improve the accuracy of the finite-difference method, it would be necessary to decrease the nodal mesh size.
PROBLEM 4.63

KNOWN: Long bar with trapezoidal shape, uniform temperatures on two surfaces, and two insulated surfaces.

FIND: Heat transfer rate per unit length using finite-difference method with space increment of 10mm.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction, (3) Constant properties.

ANALYSIS: The heat rate can be found after the temperature distribution has been determined. Using the nodal network shown above with \( \Delta x = 10mm \), nine finite-difference equations must be written. Nodes 1-4 and 6-8 are interior nodes and their finite-difference equations can be written directly from Eq. 4.33. For these nodes

\[
T_{m,n+1} + T_{m,n-1} + T_{m+1,n} + T_{m-1,n} - 4T_{m,n} = 0 \quad m = 1-4, 6-8. \tag{1}
\]

For nodes 5 and 9 located on the diagonal, insulated boundary, the appropriate finite-difference equation follows from an energy balance on the control volume shown above (upper-right corner of schematic),

\[
\dot{E}_{in} - \dot{E}_{out} = q_a + q_b = 0
\]

\[
k (\Delta y \cdot 1) \frac{T_{m-1,n} - T_{m,n}}{\Delta x} + k (\Delta x \cdot 1) \frac{T_{m,n-1} - T_{m,n}}{\Delta y} = 0.
\]

Since \( \Delta x = \Delta y \), the finite-difference equation for nodes 5 and 9 is of the form

\[
T_{m-1,n} + T_{m,n-1} - 2T_{m,n} = 0 \quad m = 5,9. \tag{2}
\]

The system of 9 finite-difference equations is first written in the form of Eqs. (1) or (2) and then written in explicit form for use with the Gauss-Seidel iteration method of solution; see Section 4.5.2.

</tbody>
</table>

Note that by the sixth iteration the change is less than 0.3°; hence, we assume the temperature distribution is approximated by the last row of the table.

The heat rate per unit length can be determined by evaluating the heat rates in the \(x\)-direction for the control volumes about nodes 6, 7, and 8. From the schematic, find that

\[
q' = q_1' + q_2' + q_3'
\]

\[
q' = k\Delta y \frac{T_8 - 25}{\Delta x} + k\Delta y \frac{T_7 - 25}{\Delta x} + k \frac{\Delta y}{2} \frac{T_6 - 25}{\Delta x}
\]

Recognizing that \(\Delta x = \Delta y\) and substituting numerical values, find

\[
q' = 20 \frac{W}{m \cdot K} \left[(57.5 - 25) + (52.9 - 25) + \frac{1}{2} (51.9 - 25)\right] K
\]

\[
q' = 1477 \text{ W/m.}
\]

**COMMENTS:**

1. Recognize that, while the temperature distribution may have been determined to a reasonable approximation, the uncertainty in the heat rate could be substantial. This follows since the heat rate is based upon a gradient and hence on temperature differences.

2. Note that the initial guesses \((k = 0)\) for the iteration are within 5° of the final distribution. The geometry is simple enough that the guess can be very close. In some instances, a flux plot may be helpful and save labor in the calculation.

3. In writing the FDEs, the iteration index (superscript \(k\)) was not included to simplify expression of the equations. However, the most recent value of \(T_{m,n}\) is always used in the computations. Note that this system of FDEs is diagonally dominant and no rearrangement is required.
PROBLEM 4.64

KNOWN:  Edge of adjoining walls (k = 1 W/m-K) represented by symmetrical element bounded by the diagonal symmetry adiabat and a section of the wall thickness over which the temperature distribution is assumed to be linear.

FIND:  (a) Temperature distribution, heat rate and shape factor for the edge using the nodal network with \( \Delta x = \Delta y = 10 \text{ mm} \); compare shape factor result with that from Table 4.1;  (b) Assess the validity of assuming linear temperature distributions across sections at various distances from the edge.

SCHEMATIC:

ASSUMPTIONS:  (1) Two-dimensional, steady-state conduction, (2) Constant properties, and (3) Linear temperature distribution at specified locations across the section.

ANALYSIS:  (a) Taking advantage of symmetry along the adiabat diagonal, all the nodes may be treated as interior nodes.  Across the left-hand boundary, the temperature distribution is specified as linear.  The finite-difference equations required to determine the temperature distribution, and hence the heat rate, can be written by inspection.

\[
T_3 = 0.25(T_2 + T_4 + T_6 + T_c)
\]
\[
T_4 = 0.25(T_2 + T_5 + T_7 + T_3)
\]
\[
T_5 = 0.25(T_2 + T_2 + T_4 + T_4)
\]
\[
T_6 = 0.25(T_3 + T_7 + T_8 + T_b)
\]
\[
T_7 = 0.25(T_4 + T_4 + T_6 + T_6)
\]
\[
T_8 = 0.25(T_6 + T_6 + T_a + T_a)
\]

The heat rate for both surfaces of the edge is

\[
q'_{\text{tot}} = 2[q'_a + q'_b + q'_c + q'_d]
\]

\[
q'_{\text{tot}} = 2[k(\Delta x/2)(T_c - T_2)/\Delta y + k\Delta x(T_3 - T_2)/\Delta y + k\Delta x(T_4 - T_2)/\Delta y + k\Delta x(T_5 - T_2)/\Delta x]
\]

The shape factor for the full edge is defined as

\[
q'_{\text{tot}} = kS'(T_1 - T_2)
\]

Solving the above equation set in IHT, the temperature (°C) distribution is

Continued...
and the heat rate and shape factor are

\[ q'_{\text{tot}} = 100 \text{ W/m} \quad S = 1 \]

From Table 4.1, the edge shape factor is 0.54, considerably below our estimate from this coarse grid analysis.

(b) The effect of the linear temperature distribution on the shape factor estimate can be explored using a more extensive grid as shown below. The FDE analysis was performed with the linear distribution imposed as the different sections a, b, c, d, e. Following the same approach as above, find

<table>
<thead>
<tr>
<th>Location of linear distribution</th>
<th>(a)</th>
<th>(b)</th>
<th>(c)</th>
<th>(d)</th>
<th>(e)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Shape factor, S</td>
<td>0.797</td>
<td>0.799</td>
<td>0.809</td>
<td>0.857</td>
<td>1.00</td>
</tr>
</tbody>
</table>

The shape factor estimate decreases as the imposed linear temperature distribution section is located further from the edge. We conclude that assuming the temperature distribution across the section directly at the edge is a poor-one.

**COMMENTS:** The grid spacing for this analysis is quite coarse making the estimates in poor agreement with the Table 4.1 result. However, the analysis does show the effect of positioning the linear temperature distribution condition.
**PROBLEM 4.65**

**KNOWN:** Long triangular bar insulated on the diagonal while sides are maintained at uniform temperatures $T_a$ and $T_b$.

**FIND:** (a) Using a nodal network with five nodes to the side, and beginning with properly defined control volumes, derive the finite-difference equations for the interior and diagonal nodes and obtain the temperature distribution; sketch the 25, 50 and 75°C isotherms and (b) Recognizing that the insulated diagonal surface can be treated as a symmetry line, show that the diagonal nodes can be treated as interior nodes, and write the finite-difference equations by inspection.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Two-dimensional heat transfer, and (3) Constant properties.

**ANALYSIS:** (a) For the nodal network shown above, nodes 2, 4, 5, 7, 8 and 9 are interior nodes and, since $\Delta x = \Delta y$, the corresponding finite-difference equations are of the form, Eq. 4.33,

$$T_j = \frac{1}{4} \sum T_{\text{neighbors}}$$  \hspace{1cm} (1)

For a node on the adiabatic, diagonal surface, an energy balance, $\dot{E}_{in} - \dot{E}_{out} = 0$, yields

$$q_a + q_b + q_c = 0$$  

$$0 + k\Delta x \frac{T_5 - T_3}{\Delta y} + k\Delta y \frac{T_2 - T_3}{\Delta x} = 0$$  

$$T_3 = \frac{1}{2} (T_2 + T_5)$$  \hspace{1cm} (2)

That is, for the diagonal nodes, $m$,

$$T_m = \frac{1}{2} \sum T_{\text{neighbors}}$$  \hspace{1cm} (3)

To obtain the temperature distributions, enter Eqs. (1, 2, 3) into the IHT workspace and solve for the nodal temperatures (°C), tabulated according to the nodal arrangement:

Continued...
The 25, 50 and 75°C isotherms are sketched below, using an interpolation scheme to scale the isotherms on the triangular bar.

(b) If we consider the insulated surface as a symmetry plane, the nodal network appears as shown. As such, the diagonal nodes can be treated as interior nodes, as Eq. (1) above applies. Recognize the form is the same as that of Eq. (2) or (3).

COMMENTS: Always look for symmetry conditions which can greatly simplify the writing of nodal equations. In this situation, the adiabatic surface can be treated as a symmetry plane such that the nodes can be treated as interior nodes, and the finite-difference equations can be written by inspection.
PROBLEM 4.66

KNOWN: Straight fin of uniform cross section with prescribed thermal conditions and geometry; tip condition allows for convection.

FIND: (a) Calculate the fin heat rate, \( q_f' \), and tip temperature, \( T_L \), assuming one-dimensional heat transfer in the fin; calculate the Biot number to determine whether the one-dimensional assumption is valid, (b) Using the finite-element software FEHT, perform a two-dimensional analysis to determine the fin heat rate and the tip temperature; display the isotherms; describe the temperature field and the heat flow pattern inferred from the display, and (c) Validate your FEHT code against the 1-D analytical solution for a fin using a thermal conductivity of 50 and 500 W/m·K.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conduction with constant properties, (2) Negligible radiation exchange, (3) Uniform convection coefficient.

ANALYSIS: (a) Assuming one-dimensional conduction, \( q_f' \) and \( T_L \) can be determined using Eqs. 3.72 and 3.70, respectively, from Table 3.4, Case A. Alternatively, use the IHT Model | Extended Surfaces | Temperature Distribution and Heat Rate | Straight Fin | Rectangular. These results are tabulated below and labeled as “1-D.” The Biot number for the fin is

\[
Bi = \frac{h(t/2)}{k} = \frac{500 \text{ W/m}^2 \cdot \text{K} \times 0.020 \text{ m}/2}{5 \text{ W/m} \cdot \text{K}} = 1
\]

(b, c) The fin can be drawn as a two-dimensional outline in FEHT with convection boundary conditions on the exposed surfaces, and with a uniform temperature on the base. Using a fine mesh (at least 1280 elements), solve for the temperature distribution and use the View | Temperature Contours command to view the isotherms and the Heat Flow command to determine the heat rate into the fin base. The results of the analysis are summarized in the table below.

<table>
<thead>
<tr>
<th>( k ) (W/m·K)</th>
<th>Bi</th>
<th>Tip temperature, ( T_L ) (°C)</th>
<th>Fin heat rate, ( q_f' ) (W/m)</th>

</tbody>
</table>

* Difference = \( (q_f',1D - q_f',2D) \times 100 / q_f',1D \)

COMMENTS: (1) From part (a), since \( Bi = 1 > 0.1 \), the internal conduction resistance is not negligible. Therefore significant transverse temperature gradients exist, and the one-dimensional conduction assumption in the fin is a poor one.

Continued ….
PROBLEM 4.66 (Cont.)

(2) From the table, with $k = 5 \text{ W/m-K (Bi = 1)}$, the 2-D fin heat rate obtained from the FEA analysis is 20% lower than that for the 1-D analytical analysis. This is as expected since the 2-D model accounts for transverse thermal resistance to heat flow. Note, however, that analyses predict the same tip temperature, a consequence of the fin approximating an infinitely long fin ($mL = 20.2 >> 2.56$; see Ex. 3.8 Comments).

(3) For the $k = 5 \text{ W/m-K}$ case, the FEHT isotherms show considerable curvature in the region near the fin base. For example, at $x = 10$ and $20 \text{ mm}$, the difference between the centerline and surface temperatures are 15 and $7^\circ \text{C}$.

(4) From the table, with increasing thermal conductivity, note that $\text{Bi}$ decreases, and the one-dimensional heat transfer assumption becomes more appropriate. The difference for the case when $k = 500 \text{ W/m-K}$ is mostly due to the approximate manner in which the heat rate is calculated in the FEA software.
**PROBLEM 4.67**

**KNOWN:** Long rectangular bar having one boundary exposed to a convection process \( (T_\infty, h) \) while the other boundaries are maintained at constant temperature \( T_s \).

**FIND:** Using the finite-element method of FEHT, (a) Determine the temperature distribution, plot the isotherms, and identify significant features of the distribution, (b) Calculate the heat rate per unit length \((W/m)\) into the bar from the air stream, and (c) Explore the effect on the heat rate of increasing the convection coefficient by factors of two and three; explain why the change in the heat rate is not proportional to the change in the convection coefficient.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, two dimensional conduction, (2) Constant properties.

**ANALYSIS:** (a) The symmetrical section shown in the schematic is drawn in FEHT with the specified boundary conditions and material property. The View \( \mid \) Temperature Contours command is used to represent ten isotherms (isopotentials) that have minimum and maximum values of 53.9\(^\circ\)C and 85.9\(^\circ\)C, respectively.

Because of the symmetry boundary condition, the isotherms are normal to the center-plane indicating an adiabatic surface. Note that the temperature change along the upper surface of the bar is substantial (= 40\(^\circ\)C), whereas the lower half of the bar has less than a 3\(^\circ\)C change. That is, the lower half of the bar is largely unaffected by the heat transfer conditions at the upper surface.

(b, c) Using the View \( \mid \) Heat Flows command considering the upper surface boundary with selected convection coefficients, the heat rates into the bar from the air stream were calculated.

\[
\begin{align*}
  h \left( \text{W/m}^2 \cdot \text{K} \right) & \quad 100 & 200 & 300 \\
  q' \left( \text{W/m} \right) & \quad 128 & 175 & 206
\end{align*}
\]

Increasing the convection coefficient by factors of 2 and 3, increases the heat rate by 37\% and 61\%, respectively. The heat rate from the bar to the air stream is controlled by the thermal resistances of the bar (conduction) and the convection process. Since the conduction resistance is significant, we should not expect the heat rate to change proportionally to the change in convection resistance.
PROBLEM 4.68

KNOWN: Log rod of rectangular cross-section of Problem 4.55 that experiences uniform heat generation while its surfaces are maintained at a fixed temperature. Use the finite-element software FEHT as your analysis tool.

FIND: (a) Represent the temperature distribution with representative isotherms; identify significant features; and (b) Determine what heat generation rate will cause the midpoint to reach 600 K with unchanged boundary conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, and (2) Two-dimensional conduction with constant properties.

ANALYSIS: (a) Using FEHT, do the following: in Setup, enter an appropriate scale; Draw the outline of the symmetrical section shown in the above schematic; Specify the Boundary Conditions (zero heat flux or adiabatic along the symmetrical lines, and isothermal on the edges). Also Specify the Material Properties and Generation rate. Draw three Element Lines as shown on the annotated version of the FEHT screen below. To reduce the mesh, hit Draw/Reduce Mesh until the desired fineness is achieved (256 elements is a good choice).

Continued …
PROBLEM 4.68 (Cont.)

After hitting Run, Check and then Calculate, use the View/Temperature Contours and select the 10-isopotential option to display the isotherms as shown in an annotated copy of the FEHT screen below.

The isotherms are normal to the symmetrical lines as expected since those surfaces are adiabatic. The isotherms, especially near the center, have an elliptical shape. Along the \( x = 0 \) axis and the \( y = 10 \) mm axis, the temperature gradient is nearly linear. The hottest point is of course the center for which the temperature is

\[
(T(0, 10 \text{ mm})) = 401.3 \, \text{K}.
\]

The temperature of this point can be read using the View/Temperatures or View|Tabular Output command.

(b) To determine the required generation rate so that \( T(0, 10 \text{ mm}) = 600 \, \text{K} \), it is necessary to re-run the model with several guessed values of \( \dot{q} \). After a few trials, find

\[
\dot{q} = 1.48 \times 10^8 \, \text{W/m}^3
\]
**PROBLEM 4.69**

**KNOWN:** Symmetrical section of a flow channel with prescribed values of \( \dot{q} \) and \( k \), as well as the surface convection conditions. See Problem 4.5(S).

**FIND:** Using the finite-element method of FEHT, (a) Determine the temperature distribution and plot the isotherms; identify the coolest and hottest regions, and the region with steepest gradients; describe the heat flow field, (b) Calculate the heat rate per unit length (W/m) from the outer surface A to the adjacent fluid, (c) Calculate the heat rate per unit length (W/m) to surface B from the inner fluid, and (d) Verify that the results are consistent with an overall energy balance on the section.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, two-dimensional conduction, (2) Constant properties.

**ANALYSIS:** (a) The symmetrical section shown in the schematic is drawn in FEHT with the specified boundary conditions, material property and generation. The View Temperature Contours command is used to represent ten isotherms (isopotentials) that have minimum and maximum values of 82.1°C and 125.2°C.

The hottest region of the section is the upper vertical leg (left-hand corner). The coolest region is in the lower horizontal leg at the far right-hand boundary. The maximum and minimum section temperatures (125°C and 77°C), respectively, are higher than either adjoining fluid. Remembering that heat flow lines are normal to the isotherms, heat flows from the hottest corner directly to the inner fluid and downward into the lower leg and then flows out surface A and the lower portion of surface B.

Continued ….
PROBLEM 4.69 (Cont.)

(b, c) Using the View | Heat Flows command considering the boundaries for surfaces A and B, the heat rates are:
\[ q_A' = 1135 \text{ W/m} \quad q_B' = -1365 \text{ W/m}. \]

From an energy balance on the section, we note that the results are consistent since conservation of energy is satisfied.
\[
\dot{E}_{\text{in}}' - \dot{E}_{\text{out}}' + \dot{E}_g = 0 \\
-q_A' + q_B' + q_\text{\forall}' = 0 \\
-1135 \text{ W/m} + (-1365 \text{ W/m}) + 2500 \text{ W/m} = 0 \]

where \( q_\text{\forall}' = 1 \times 10^6 \text{ W/m}^3 \times [25 \times 50 + 25 \times 50] \times 10^{-6} \text{ m}^2 = 2500 \text{ W/m} \).

COMMENTS: (1) For background on setting up this problem in FEHT, see the tutorial example of the User’s Manual. While the boundary conditions are different, and the internal generation term is to be included, the procedure for performing the analysis is the same.

(2) The heat flow distribution can be visualized using the View | Temperature Gradients command. The direction and magnitude of the heat flow is represented by the directions and lengths of arrows. Compare the heat flow distribution to the isotherms shown above.
PROBLEM 4.70

KNOWN: Hot-film flux gage for determining the convection coefficient of an adjoining fluid stream by measuring the dissipated electric power, $P_e$, and the average surface temperature, $T_{s,f}$.

FIND: Using the finite-element method of FEHT, determine the fraction of the power dissipation that is conducted into the quartz substrate considering three cases corresponding to convection coefficients of 500, 1000 and 2000 $W/m^2 \cdot K$.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, two-dimensional conduction, (2) Constant substrate properties, (3) Uniform convection coefficient over the hot-film and substrate surfaces, (4) Uniform power dissipation over hot film.

ANALYSIS: The symmetrical section shown in the schematic above (right) is drawn into FEHT specifying the substrate material property. On the upper surface, a convection boundary condition ($T_{\infty}, h$) is specified over the full width $W/2$. Additionally, an applied uniform flux $\left( P_e', W/m^2 \right)$ boundary condition is specified for the hot-film region ($w/2$). The remaining surfaces of the two-dimensional system are specified as adiabatic. In the schematic below, the electrical power dissipation $P_e'$ (W/m) in the hot film is transferred by convection from the film surface, $q_{cv,f}'$, and from the adjacent substrate surface, $q_{cv,s}'$.

The analysis evaluates the fraction, $F$, of the dissipated electrical power that is conducted into the substrate and convected to the fluid stream,

$$ F = \frac{q_{cv,s}'}{P_e'} = 1 - \frac{q_{cv,f}'}{P_e'} $$

where $P_e' = P_e' (w/2) = 5000 \ W/m^2 \times (0.002 \ m) = 10 \ W/m$.

After solving for the temperature distribution, the View|Heat Flow command is used to evaluate $q_{cv,f}'$ for the three values of the convection coefficient.

Continued ….

COMMENTS: (1) For the ideal hot-film flux gage, there is negligible heat transfer to the substrate, and the convection coefficient of the air stream is calculated from the measured electrical power, $P'_e$, the average film temperature (by a thin-film thermocouple), $T_{s,f}$, and the fluid stream temperature, $T_\infty$, as $h = P'_e / (T_{s,f} - T_\infty)$. The purpose in performing the present analysis is to estimate a correction factor to account for heat transfer to the substrate.

(2) As anticipated, the fraction of the dissipated electrical power conducted into the substrate, F, decreases with increasing convection coefficient. For the case of the largest convection coefficient, F amounts to 25%, making it necessary to develop a reliable, accurate heat transfer model to estimate the applied correction. Further, this condition limits the usefulness of this gage design to flows with high convection coefficients.

(3) A reduction in F, and hence the effect of an applied correction, could be achieved with a substrate material having a lower thermal conductivity than quartz. However, quartz is a common substrate material for fabrication of thin-film heat-flux gages and thermocouples. By what other means could you reduce F?

(4) In addition to the tutorial example in the FEHT User’s Manual, the solved models for Examples 4.3 and 4.4 are useful for developing skills helpful in solving this problem.
PROBLEM 4.71

KNOWN: Hot-plate tool for micro-lithography processing of 300-mm silicon wafer consisting of an aluminum alloy equalizing block (EB) heated by ring-shaped main and trim electrical heaters (MH and TH) providing two-zone control.

FIND: The assignment is to size the heaters, MH and TH, by specifying their applied heat fluxes, \( q_{\text{mh}} \) and \( q_{\text{th}} \), and their radial extents, \( \Delta r_{\text{mh}} \) and \( \Delta r_{\text{th}} \), to maintain an operating temperature of 140°C with a uniformity of 0.1°C. Consider these steps in the analysis: (a) Perform an energy balance on the EB to obtain an initial estimate for the heater fluxes with \( q_{\text{mh}} = q_{\text{th}} \) extending over the full radial limits; using FEHT, determine the upper surface temperature distribution and comment on whether the desired uniformity has been achieved; (b) Re-run your FEHT code with different values of the heater fluxes to obtain the best uniformity possible and plot the surface temperature distribution; (c) Re-run your FEHT code for the best arrangement found in part (b) using the representative distribution of the convection coefficient (see schematic for \( h(r) \) for downward flowing gas across the upper surface of the EB; adjust the heat flux of TH to improve uniformity; and (d) Suggest changes to the design for improving temperature uniformity.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction with uniform and constant properties in EB, (3) Lower surface of EB perfectly insulated, (4) Uniform convection coefficient over upper EB surface, unless otherwise specified and (5) negligible radiation exchange between the EB surfaces and the surroundings.

ANALYSIS: (a) To obtain initial estimates for the MH and TH fluxes, perform an overall energy balance on the EB as illustrated in the schematic below.

\[
\dot{E}_\text{in} - \dot{E}_\text{out} = 0
\]
\[
q_{\text{mh}} \pi \left( r_2^2 - r_1^2 \right) + q_{\text{th}} \pi \left( r_4^2 - r_3^2 \right) - h \left[ \pi r_0^2 + 2\pi r_0 w \right] (T_s - T_\infty) = 0
\]

Continued …..
PROBLEM 4.71 (Cont.)

Substituting numerical values and letting \( q_{mh} = q_{th} \), find

\[
q_{mh} = q_{th} = 2939 \, \text{W/m}^2
\]

Using FEHT, the analysis is performed on an axisymmetric section of the EB with the nodal arrangement as shown below.

The Temperature Contour view command is used to create the temperature distribution shown below. The temperatures at the center \( (T_1) \) and the outer edge of the wafer \( (r = 150 \, \text{mm}, T_{14}) \) are read from the Tabular Output page. The Temperature Gradients view command is used to obtain the heat flow distribution when the line length is proportional to the magnitude of the heat rate.

From the analysis results, for this base case design \( (q_{mh} = q_{th}) \), the temperature difference across the radius of the wafer is 1.7°C, much larger than the design goal of 0.1°C. The upper surface temperature distribution is shown in the graph below.

Continued …..
(b) From examination of the results above, we conclude that if \( q_{mh} \) is reduced and \( q_{th} \) increased, the EB surface temperature uniformity could improve. The results of three trials compared to the base case are tabulated below.

</tbody>
</table>

The strategy of changing the heater fluxes (trials 1-3) has not resulted in significant improvements in the EB surface temperature uniformity.
(c) Using the same \textit{FEHT} code as with part (b), base case, the boundary conditions on the upper surface of the EB were specified by the function $h(r)$ shown in the schematic. The value of $h(r)$ ranged from 5.4 to 13.5 \text{ W/m}^2\text{K} between the centerline and EB edge. The result of the analysis is tabulated above, labeled as part (c). Note that the temperature uniformity has become significantly poorer.

(d) There are at least two options that should be considered in the re-design to improve temperature uniformity. \textit{Higher thermal conductivity material for the EB.} Aluminum alloy is the material most widely used in practice for reasons of low cost, ease of machining, and durability of the heated surface. The results of analyses for thermal conductivity values of 150 and 300 \text{ W/m} \cdot \text{K} are tabulated above, labeled as part (d). Using pure or oxygen-free copper could improve the temperature uniformity to better than 0.5°C.

\textit{Distributed heater elements.} The initial option might be to determine whether temperature uniformity could be improved using two elements, but located differently. Another option is a single element heater spirally embedded in the lower portion of the EB. By appropriately positioning the element as a function of the EB radius, improved uniformity can be achieved. This practice is widely used where precise and uniform temperature control is needed.
PROBLEM 4.72

KNOWN: Straight fin of uniform cross section with insulated end.

FIND: (a) Temperature distribution using finite-difference method and validity of assuming one-dimensional heat transfer, (b) Fin heat transfer rate and comparison with analytical solution, Eq. 3.76, (c) Effect of convection coefficient on fin temperature distribution and heat rate.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in fin, (3) Constant properties, (4) Uniform film coefficient.

ANALYSIS: (a) From the analysis of Problem 4.45, the finite-difference conduction in fin can be directly written. For the nodal spacing \( \Delta x = 4 \text{ mm} \), there will be 12 nodes. With \( \ell \gg w \) representing the distance normal to the page,

\[
\frac{h P}{k A_c} \Delta x^2 = \frac{h \cdot 2 \ell}{k \cdot w} \Delta x^2 = \frac{500 \text{ W/m}^2 \cdot \text{K} \cdot 2}{50 \text{ W/m} \cdot \text{K} \cdot 6 \cdot 10^{-3} \text{ m}} \left(4 \times 10^{-3} \text{ mm}\right) = 0.0533
\]

Node 1: \( 100 + T_2 + 0.0533 \times 30 - (2 + 0.0533) T_1 = 0 \) or \(-2.053 T_1 + T_2 = -101.6 \)

Node \( n \): \( T_{n+1} + T_{n-1} + 1.60 - 2.0533 T_n = 0 \) or \( T_{n-1} - 2.053 T_n + T_{n+1} = -1.60 \)

Node 12: \( T_{11} + (0.0533/2) 30 - (0.0533/2 + 1) T_{12} = 0 \) or \( T_{11} - 1.0267 T_{12} = -0.800 \)

Using matrix notation, Eq. 4.52, where \([A][T] = [C]\), the A-matrix is tridiagonal and only the non-zero terms are shown below. A matrix inversion routine was used to obtain \([T]\).

</tbody>
</table>

The assumption of one-dimensional heat conduction is justified when \( \text{Bi} = h(w/2)/k < 0.1 \). Hence, with \( \text{Bi} = 500 \text{ W/m}^2 \cdot \text{K}(3 \times 10^{-3} \text{ m})/50 \text{ W/m} \cdot \text{K} = 0.03 \), the assumption is reasonable.

Continued...
(b) The fin heat rate can be most easily found from an energy balance on the control volume about Node \(0,\)

\[
q'_f = q'_f + q'_{\text{conv}} = k \cdot w \frac{T_0 - T_1}{\Delta x} + h \left( 2 \frac{\Delta x}{2} \right) \left( T_0 - T_\infty \right)
\]

\[
q'_f = 50 \text{ W/m} \cdot \text{K} \left( 6 \times 10^{-3} \text{ m} \right) \left( \frac{100 - 85.8}{4 \times 10^{-3} \text{ m}} \right) + 500 \text{ W/m}^2 \cdot \text{K} \left( 2 \frac{4 \times 10^{-3} \text{ m}}{2} \right) \left( 100 - 30 \right) \text{ C}
\]

\[
q'_f = (1065 + 140) \text{ W/m} = 1205 \text{ W/m}.
\]

From Eq. 3.76, the fin heat rate is

\[
q = \left( hP_kA_c \right)^{1/2} \cdot \theta_b \cdot \tanh mL.
\]

Substituting numerical values with \(P = 2(w + \ell) = 2 \ell\) and \(A_c = w \cdot \ell, m = (hP_kA_c)^{1/2} = 57.74 \text{ m}^{-1}\) and \(M = (hP_kA_c)^{1/2} = 17.32 \text{ W/K}\). Hence, with \(\theta_b = 70^\circ\text{C},\)

\[
q'_f = 17.32 \text{ W/K} \times 70 \text{ K} \times \tanh \left( 57.44 \times 0.048 \right) = 1203 \text{ W/m}
\]

and the finite-difference result agrees very well with the exact (analytical) solution.

(c) Using the IHT Finite-Difference Equations Tool Pad for 1D, SS conditions, the fin temperature distribution and heat rate were computed for \(h = 10, 100, 500\) and 1000 W/m²-K. Results are plotted as follows.

The temperature distributions were obtained by first creating a Lookup Table consisting of 4 rows of nodal temperatures corresponding to the 4 values of \(h\) and then using the LOOKUPVAL2 interpolating function with the Explore feature of the IHT menu. Specifically, the function \(T_{\text{EVAL}} = \text{LOOKUPVAL2}(t0467, h, x)\) was entered into the workspace, where \(t0467\) is the file name given to the Lookup Table. For each value of \(h,\) Explore was used to compute \(T(x),\) thereby generating 4 data sets which were placed in the Browser and used to generate the plots. The variation of \(q'\) with \(h\) was simply generated by using the Explore feature to solve the finite-difference model equations for values of \(h\) incremented by 10 from 10 to 1000 W/m²-K.

Although \(q'_f\) increases with increasing \(h,\) the effect of changes in \(h\) becomes less pronounced. This trend is a consequence of the reduction in fin temperatures, and hence the fin efficiency, with increasing \(h.\) For \(10 \leq h \leq 1000 \text{ W/m}^2\cdot\text{K}, \) \(0.95 \geq \eta_f \geq 0.24.\) Note the nearly isothermal fin for \(h = 10 \text{ W/m}^2\cdot\text{K}\) and the pronounced temperature decay for \(h = 1000 \text{ W/m}^2\cdot\text{K}.\)
PROBLEM 4.73

KNOWN: Pin fin of 10 mm diameter and length 250 mm with base temperature of 100°C experiencing radiation exchange with the surroundings and free convection with ambient air.

FIND: Temperature distribution using finite-difference method with five nodes. Fin heat rate and relative contributions by convection and radiation.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in fin, (3) Constant properties, (4) Fin approximates small object in large enclosure, (5) Fin tip experiences convection and radiation, (6) $h_{fc} = 2.89[0.6 + 0.624(T - T_\infty)]^{1/6}$. 

ANALYSIS: To apply the finite-difference method, define the 5-node system shown above where $\Delta x = L/5$. Perform energy balances on the nodes to obtain the finite-difference equations for the nodal temperatures.

Interior node, $n = 1, 2, 3$ or 4

\[
\dot{E}_{in} - \dot{E}_{out} = 0
\]
\[
q_a + q_b + q_c + q_d = 0 \quad (1)
\]
\[
h_{r,n}P\Delta x \left( T_{\text{sur}} - T_n \right) + kA_c \frac{T_{n+1} - T_n}{\Delta x} + h_{fc,n}P\Delta x \left( T_\infty - T_n \right) + kA_c \frac{T_{n-1} - T_n}{\Delta x} = 0 \quad (2)
\]

where the free convection coefficient is
\[
h_{fc,n} = 2.89 \left[ 0.6 + 0.624(T_n - T_\infty) \right]^{1/6} \quad (3)
\]

and the linearized radiation coefficient is
\[
h_{r,n} = \varepsilon\sigma \left( T_n + T_{\text{sur}} \right) \left( T_n^2 + T_{\text{sur}}^2 \right) \quad (4)
\]
with $P = \pi D$ and $A_c = \pi D^2/4$. 

Tip node, $n = 5$

\[
\dot{E}_{in} - \dot{E}_{out} = 0
\]
\[
q_a + q_b + q_c + q_d + q_e = 0
\]
\[
h_{r,5} \left( P\Delta x/2 \right) \left( T_{\text{sur}} - T_5 \right) + h_{r,5} A_c \left( T_{\text{sur}} - T_5 \right) + h_{fc,5} A_c \left( T_\infty - T_5 \right) + h_{fc,5} \left( P\Delta x/2 \right) \left( T_\infty - T_5 \right) + kA_c \frac{T_4 - T_5}{\Delta x} = 0 \quad (7)
\]

Continued...
Knowing the nodal temperatures, the heat rates are evaluated as:

**Fin Heat Rate:** Perform an energy balance around Node b.

\[ \dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0 \]

\[ q_a + q_b + q_c + q_{\text{fin}} = 0 \]

\[ h_{r,b} \left( P\Delta x/2 \right) \left( T_{\text{sur}} - T_b \right) + h_{fc,b} \left( P\Delta x/2 \right) \left( T_{\infty} - T_b \right) + kA c \frac{\left( T_1 - T_b \right)}{\Delta x} + q_{\text{fin}} = 0 \] (8)

where \( h_{r,b} \) and \( h_{fc,b} \) are evaluated at \( T_b \).

**Convection Heat Rate:** To determine the portion of the heat rate by convection from the fin surface, we need to sum contributions from each node. Using the convection heat rate terms from the foregoing energy balances, for, respectively, node b, nodes 1, 2, 3, 4 and node 5.

\[ q_{cv} = -q_b \right)_b - \sum q_{c\text{,}1-4} - \left( q_c + q_d \right)_5 \] (9)

**Radiation Heat Rate:** In the same manner,

\[ q_{\text{rad}} = -q_a \right)_b - \sum q_{b\text{,}1-4} - \left( q_a + q_b \right)_5 \]

The above equations were entered into the IHT workspace and the set of equations solved for the nodal temperatures and the heat rates. Summary of key results including the temperature distribution and heat rates is shown below.

**COMMENTS:** From the tabulated results, it is evident that free convection is the dominant node. Note that the free convection coefficient varies almost by a factor of two over the length of the fin.
PROBLEM 4.74

KNOWN: Thin metallic foil of thickness, \( t \), whose edges are thermally coupled to a sink at temperature \( T_{\text{sink}} \) is exposed on the top surface to an ion beam heat flux, \( q''_s \), and experiences radiation exchange with the vacuum enclosure walls at \( T_{\text{sur}} \).

FIND: Temperature distribution across the foil.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, steady-state conduction in the foil, (2) Constant properties, (3) Upper and lower surfaces of foil experience radiation exchange, (4) Foil is of unit length normal to the page.

ANALYSIS: The 10-node network representing the foil is shown below.

From an energy balance on node \( n \), \( \dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0 \), for a unit depth,

\[
q'_{a} + q'_{b} + q'_{c} + q'_{d} + q'_{e} = 0
\]

\[
q''_s \Delta x + h_{r,n} \Delta x (T_{\text{sur}} - T_{n}) + k (1)(T_{n+1} - T_{n})/\Delta x + h_{r,n} \Delta x (T_{\text{sur}} - T_{n}) + k (1)(T_{n-1} - T_{n})/\Delta x = 0 \quad (1)
\]

where the linearized radiation coefficient for node \( n \) is

\[
h_{r,n} = \varepsilon \sigma \left( T_{\text{sur}} + T_{n} \right) \left( T_{\text{sur}}^2 + T_{n}^2 \right)
\]

Solving Eq. (1) for \( T_{n} \) find,

\[
T_{n} = \left[ (T_{n+1} + T_{n-1}) + (2h_{r,n} \Delta x^2 / kt)T_{\text{sur}} + (\Delta x^2 / kt)q''_s \right] / \left[ (h_{r,n} \Delta x^2 / kt) + 2 \right] \quad (3)
\]

which, considering symmetry, applies also to node 1. Using IHT for Eqs. (3) and (2), the set of finite-difference equations was solved for the temperature distribution (K):

\[
\begin{align*}
T_1 & = 374.1 \\
T_2 & = 374.0 \\
T_3 & = 373.5 \\
T_4 & = 372.5 \\
T_5 & = 370.9 \\
T_6 & = 368.2 \\
T_7 & = 363.7 \\
T_8 & = 356.6 \\
T_9 & = 345.3 \\
T_{10} & = 327.4
\end{align*}
\]

Continued...
COMMENTS: (1) If the temperature gradients were excessive across the foil, it would wrinkle; most likely since its edges are constrained, the foil will bow.

(2) The IHT workspace for the finite-difference analysis follows:

// The nodal equations:
T1 = ( (T2 + T2) + A1 * Tsur + B *q's ) / ( A1 + 2)
A1= 2 * hr1 * deltax^2 / (k * t)
hr1 = eps * sigma * (Tsur + T1) * (Tsur^2 + T1^2)
sigma = 5.67e-8
B = deltax^2 / (k * t)

T2 = ( (T1 + T3) + A2 * Tsur + B *q's ) / ( A2 + 2)
A2= 2 * hr2 * deltax^2 / (k * t)
hr2 = eps * sigma * (Tsur + T2) * (Tsur^2 + T2^2)

T3 = ( (T2 + T4) + A3 * Tsur + B *q's ) / ( A3 + 2)
A3= 2 * hr3 * deltax^2 / (k * t)
hr3 = eps * sigma * (Tsur + T3) * (Tsur^2 + T3^2)

T4 = ( (T3 + T5) + A4 * Tsur + B *q's ) / ( A4 + 2)
A4= 2 * hr4 * deltax^2 / (k * t)
hr4 = eps * sigma * (Tsur + T4) * (Tsur^2 + T4^2)

T5 = ( (T4 + T6) + A5 * Tsur + B *q's ) / ( A5 + 2)
A5= 2 * hr5 * deltax^2 / (k * t)
hr5 = eps * sigma * (Tsur + T5) * (Tsur^2 + T5^2)

T6 = ( (T5 + T7) + A6 * Tsur + B *q's ) / ( A6 + 2)
A6= 2 * hr6 * deltax^2 / (k * t)
hr6 = eps * sigma * (Tsur + T6) * (Tsur^2 + T6^2)

T7 = ( (T6 + T8) + A7 * Tsur + B *q's ) / ( A7 + 2)
A7= 2 * hr7 * deltax^2 / (k * t)
hr7 = eps * sigma * (Tsur + T7) * (Tsur^2 + T7^2)

T8 = ( (T7 + T9) + A8 * Tsur + B *q's ) / ( A8 + 2)
A8= 2 * hr8 * deltax^2 / (k * t)
hr8 = eps * sigma * (Tsur + T8) * (Tsur^2 + T8^2)

T9 = ( (T8 + T10) + A9 * Tsur + B *q's ) / ( A9 + 2)
A9= 2 * hr9 * deltax^2 / (k * t)
hr9 = eps * sigma * (Tsur + T9) * (Tsur^2 + T9^2)

T10 = ( (T9 + Tsink) + A10 * Tsur + B *q's ) / ( A10 + 2)
A10= 2 * hr10 * deltax^2 / (k * t)
hr10 = eps * sigma * (Tsur + T10) * (Tsur^2 + T10^2)

// Assigned variables

**PROBLEM 4.75**

**KNOWN:** Electrical heating elements with known dissipation rate embedded in a ceramic plate of known thermal conductivity; lower surface is insulated, while upper surface is exposed to a convection process.

**FIND:** (a) Temperature distribution within the plate using prescribed grid spacing, (b) Sketch isotherms to illustrate temperature distribution, (c) Heat loss by convection from exposed surface (compare with element dissipation rate), (d) Advantage, if any, in not setting $\Delta x = \Delta y$, (e) Effect of grid size and convection coefficient on the temperature field.

**SCHEMATIC:**

![Schematic Image]

**ASSUMPTIONS:** (1) Steady-state, two-dimensional conduction in ceramic plate, (2) Constant properties, (3) No internal generation, except for Node 7 (or Node 15 for part (e)), (4) Heating element approximates a line source of negligible wire diameter.

**ANALYSIS:** (a) The prescribed grid for the symmetry element shown above consists of 12 nodal points. Nodes 1-3 are points on a surface experiencing convection; nodes 4-6 and 8-12 are interior nodes. Node 7 is a special case of the interior node having a generation term; because of symmetry, $q'_{ht} = 25 \text{ W/m}$. The finite-difference equations are derived as follows:

Continued...
**PROBLEM 4.75 (Cont.)**

*Surface Node 2.* From an energy balance on the prescribed control volume with $\Delta x/\Delta y = 3$, \[ E_{\text{in}} - E_{\text{out}} = q_a + q_b + q_c + q_d = 0; \]
\[
 k \frac{\Delta y}{2} T_1 - T_2 + h\Delta x \left( T_{\infty} - T_2 \right) + k \frac{\Delta y}{2} T_3 - T_2 + k\Delta x \frac{T_5 - T_2}{\Delta y} = 0.
\]

Regrouping, find
\[
 T_2 \left( 1 + 2N \frac{\Delta x}{\Delta y} + \left( \frac{\Delta x}{\Delta y} \right)^2 \right) = T_1 + T_3 + 2 \left( \frac{\Delta x}{\Delta y} \right)^2 T_5 + 2N \frac{\Delta x}{\Delta y} T_{\infty}
\]
where $N = h\Delta x/k = 100 \text{ W/m}^2\cdot\text{K} \times 0.006 \text{ m/2 W/m-K} = 0.30 \text{ K}$. Hence, with $T_{\infty} = 30^\circ\text{C}$,
\[
 T_2 = 0.04587T_1 + 0.04587T_3 + 0.82569T_5 + 2.4771
\]
From this FDE, the forms for nodes 1 and 3 can also be deduced.

*Interior Node 7.* From an energy balance on the prescribed control volume, with $\Delta x/\Delta y = 3$,
\[ E_{\text{in}} - E_{\text{out}} = 0, \]
where $E_g$ is the conduction terms. Hence,
\[
 q_a + q_b + q_c + q_d + 2q_{ht} = 0,
\]
Regrouping,
\[
 T_7 \left[ 1 + \left( \frac{\Delta x}{\Delta y} \right)^2 \right] = T_8 \left( \frac{\Delta x}{\Delta y} \right)^2 + T_4 + T_8 + \left( \frac{\Delta x}{\Delta y} \right)^2 T_{10} + 2q_{ht} \frac{\Delta x}{k}
\]
Recognizing that $\Delta x/\Delta y = 3$, $q_{ht} = 25 \text{ W/m}$ and $k = 2 \text{ W/m-K}$, the FDE is
\[
 T_7 = 0.0500T_8 + 0.4500T_4 + 0.0500T_8 + 0.4500T_{10} + 3.7500
\]
The FDEs for the remaining nodes may be deduced from this form. Following the procedure described in Section 4.5.2 for the Gauss-Seidel method, the system of FDEs has the form:

\[
 T_1^k = 0.09174T_2^{k-1} + 0.8257T_4^{k-1} + 2.4771
\]
\[
 T_2^k = 0.4500T_1^k + 0.4500T_3^{k-1} + 0.8257T_5^{k-1} + 2.4771
\]
\[
 T_3^k = 0.09174T_2^k + 0.8257T_6^{k-1} + 2.4771
\]
\[
 T_4^k = 0.4500T_1^k + 0.1000T_5^{k-1} + 0.4500T_7^{k-1}
\]
\[
 T_5^k = 0.4500T_2^k + 0.0500T_4^k + 0.0500T_6^{k-1} + 0.4500T_8^{k-1}
\]
\[
 T_6^k = 0.4500T_3^k + 0.1000T_5^k + 0.4500T_9^{k-1}
\]
\[
 T_7^k = 0.4500T_4^k + 0.1000T_8^{k-1} + 0.4500T_{10}^{k-1} + 3.7500
\]
\[
 T_8^k = 0.4500T_5^k + 0.0500T_4^k + 0.0500T_6^{k-1} + 0.4500T_1^{k-1}
\]
\[
 T_9^k = 0.4500T_6^k + 0.1000T_5^k + 0.4500T_{12}^{k-1}
\]
\[
 T_{10}^k = 0.9000T_7^k + 0.1000T_1^{k-1}
\]
\[
 T_{11}^k = 0.9000T_8^k + 0.0500T_{10}^{k-1} + 0.0500T_{12}^{k-1}
\]
\[
 T_{12}^k = 0.9000T_9^k + 0.1000T_{11}^k
\]
Continued …..
**PROBLEM 4.75 (Cont.)**

Note the use of the superscript $k$ to denote the level of iteration. Begin the iteration procedure with rational estimates for $T_i (k = 0)$ and prescribe the convergence criterion as $\varepsilon \leq 0.1$.

</tbody>
</table>

The last row with $k = \infty$ corresponds to the solution obtained by matrix inversion. It appears that at least 20 iterations would be required to satisfy the convergence criterion using the Gauss-Seidel method.

(b) Selected isotherms are shown in the sketch of the nodal network.

![Sketch of isotherms](image)

Note that the isotherms are normal to the adiabatic surfaces.

(c) The heat loss by convection can be expressed as

\[
q_{\text{conv}}' = |h| \left[ \frac{1}{2} \Delta x (T_1 - T_{\infty}) + \Delta x (T_2 - T_{\infty}) + \frac{1}{2} \Delta x (T_3 - T_{\infty}) \right]
\]

\[
q_{\text{conv}}' = 100 \text{ W/m}^2 \cdot \text{K} \times 0.006 \text{ m} \left[ \frac{1}{2} (55.80 - 30) + (49.93 - 30) + \frac{1}{2} (47.67 - 30) \right] = 25.00 \text{ W/m} .
\]

As expected, the heat loss by convection is equal to the heater element dissipation. This follows from the conservation of energy requirement.

(d) For this situation, choosing $\Delta x = 3 \Delta y$ was advantageous from the standpoint of precision and effort. If we had chosen $\Delta x = \Delta y = 2$ mm, there would have been 28 nodes, doubling the amount of work, but with improved precision.

(e) Examining the effect of grid size by using the *Finite-Difference Equations* option from the *Tools* portion of the IHT Menu, the following temperature field was computed for $\Delta x = \Delta y = 2$ mm, where $x$ and $y$ are in mm and the temperatures are in °C.

Continued ….
Agreement with the results of part (a) is excellent, except in proximity to the heating element, where $T_{15} = 66.6^\circ C$ for the fine grid exceeds $T_7 = 63.9^\circ C$ for the coarse grid by 2.7$^\circ C$.

For $h = 10\text{ W/m}^2\cdot\text{K}$, the maximum temperature in the ceramic corresponds to $T_{15} = 254^\circ C$, and the heater could still be operated at the prescribed power. With $h = 10\text{ W/m}^2\cdot\text{K}$, the critical temperature of $T_{15} = 400^\circ C$ would be reached with a heater power of approximately 82 W/m.

**COMMENTS:** (1) The method used to obtain the rational estimates for $T_i (k = 0)$ in part (a) is as follows. Assume 25 W/m is transferred by convection uniformly over the surface; find $T_{\text{surf}} \approx 50^\circ C$. Set $T_2 = 50^\circ C$ and recognize that $T_1$ and $T_3$ will be higher and lower, respectively. Assume 25 W/m is conducted uniformly to the outer nodes; find $T_5 - T_2 \approx 4^\circ C$. For the remaining nodes, use intuition to guess reasonable values. (2) In selecting grid size (and whether $\Delta x = \Delta y$), one should consider the region of largest temperature gradients.

**NOTE TO INSTRUCTOR:** Although the problem statement calls for calculations with $\Delta x = \Delta y = 1$ mm, the instructional value and benefit-to-effort ratio are small. Hence, consideration of this grid size is not recommended.
PROBLEM 4.76

KNOWN: Silicon chip mounted in a dielectric substrate. One surface of system is convectively cooled while the remaining surfaces are well insulated.

FIND: Whether maximum temperature in chip will exceed 85°C.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction, (3) Negligible contact resistance between chip and substrate, (4) Upper surface experiences uniform convection coefficient, (5) Other surfaces are perfectly insulated.

ANALYSIS: Performing an energy balance on the chip assuming it is perfectly insulated from the substrate, the maximum temperature occurring at the interface with the dielectric substrate will be, according to Eqs. 3.43 and 3.46,

\[ T_{\text{max}} = \frac{\dot{q}(H/4)^2}{2k_c} + \frac{\dot{q}(H/4)}{h} + T_\infty = \frac{10^7 \text{ W/m}^3 (0.003 \text{ m})^2}{2 \times 50 \text{ W/m} \cdot \text{K}} + \frac{10^7 \text{ W/m}^3 (0.003 \text{ m})}{500 \text{ W/m}^2 \cdot \text{K}} + 20^\circ \text{C} = 80.9^\circ \text{C}. \]

Since \( T_{\text{max}} < 85^\circ \text{C} \) for the assumed situation, for the actual two-dimensional situation with the conducting dielectric substrate, the maximum temperature should be less than 80°C.

Using the suggested grid spacing of 3 mm, construct the nodal network and write the finite-difference equation for each of the nodes taking advantage of symmetry of the system. Note that we have chosen to not locate nodes on the system surfaces for two reasons: (1) fewer total number of nodes, 20 vs. 25, and (2) Node 5 corresponds to center of chip which is likely the point of maximum temperature. Using these numerical values,

\[ h \Delta x = \frac{500 \text{ W/m}^2 \cdot \text{K} \times 0.003 \text{ m}}{5 \text{ W/m} \cdot \text{K}} = 0.30 \quad \alpha = \frac{2}{(k_s / k_c) + 1} = \frac{2}{5/50 + 1} = 1.818 \]

\[ h \Delta x = \frac{500 \text{ W/m}^2 \cdot \text{K} \times 0.003 \text{ m}}{5 \text{ W/m} \cdot \text{K}} = 0.030 \quad \beta = \frac{2}{(k_c / k_s) + 1} = \frac{2}{50/5 + 1} = 0.182 \]

\[ \dot{q} \Delta x \Delta y = 1.800 \quad \gamma = \frac{1}{k_c / k_s + 1} = 0.0910 \]

find the nodal equations:

Node 1 \[ k_s \Delta x \frac{T_6 - T_1}{\Delta y} + k_s \Delta y \frac{T_2 - T_1}{\Delta x} + h \Delta x (T_\infty - T_1) = 0 \]

Continued …..
PROBLEM 4.76 (Cont.)

\[- \left( 2 + \frac{hAx}{k_s} \right) T_1 + T_2 + T_6 = - \frac{hAx}{k_s} T_\infty - 2.30T_1 + T_2 + T_6 = -6.00 \]  \hspace{1cm} (1)

**Node 2**

\[ T_1 - 3.3T_2 + T_3 + T_7 = -6.00 \]  \hspace{1cm} (2)

**Node 3**

\[ k_s \Delta y \frac{T_2 - T_3}{\Delta x} + \frac{T_4 - T_3}{(\Delta x/2)/k_c \Delta y + (\Delta x/2)/k_s \Delta y} + k_s \Delta x \frac{T_8 - T_3}{\Delta y} + hAx (T_\infty - T_2) = 0 \]

\[ T_2 - (2 + \alpha + (hAx/k_s) T_3) + \alpha T_4 + T_8 = -(hAx/k) T_\infty \]

\[ T_2 - 4.12T_3 + 1.82T_4 + T_8 = -6.00 \]  \hspace{1cm} (3)

**Node 4**

\[ \frac{T_3 - T_4}{(\Delta x/2)/k_s \Delta y + (\Delta x/2)/k_c \Delta y} + \frac{T_5 - T_4}{\Delta x} + \frac{T_9 - T_4}{(\Delta y/2)/k_s \Delta x + (\Delta y/2) k_c \Delta x} \]

\[ + q \left( \Delta x \Delta y \right) + hAx (T_\infty - T_4) = 0 \]

\[ \beta T_3 - (1 + 2\beta + \left[ hAx/k_c \right]) T_4 + T_5 + \beta T_9 = -(hAx/k_c) T_\infty - q \Delta x \Delta y/k_c \]

\[ 0.182T_3 - 1.39T_4 + T_5 + 0.182T_9 = -2.40 \]  \hspace{1cm} (4)

**Node 5**

\[ k_c \Delta y \frac{T_4 - T_5}{\Delta x} + \frac{T_10 - T_3}{(\Delta y/2)/k_s (\Delta x/2) + (\Delta y/2)/k_c (\Delta x/2)} \]

\[ + h (\Delta x/2) (T_\infty - T_5) + q \Delta y (\Delta x/2) = 0 \]

\[ 2T_4 - 2.21T_5 + 0.182T_10 = -2.40 \]  \hspace{1cm} (5)

**Nodes 6 and 11**

\[ k_s \Delta x (T_1 - T_6)/\Delta y + k_s \Delta y (T_7 - T_6)/\Delta x + k_s \Delta x (T_{11} - T_6)/\Delta y = 0 \]

\[ T_1 - 3T_6 + T_7 + T_{11} = 0 \]

\[ T_6 - 3T_{11} + T_{12} + T_6 = 0 \]  \hspace{1cm} (6,11)

**Nodes 7, 8, 12, 13, 14**  Treat as interior points,

\[ T_2 + T_6 - 4T_7 + T_8 + T_{12} = 0 \]

\[ T_3 + T_7 - 4T_8 + T_9 + T_{13} = 0 \]

\[ T_7 + T_{11} - 4T_{12} + T_{13} + T_{17} = 0 \]

\[ T_8 + T_{12} - 4T_{13} + T_{14} + T_{18} = 0 \]

\[ T_9 + T_{13} - 4T_{14} + T_{15} + T_{19} = 0 \]  \hspace{1cm} (7,8,12,13,14)

**Node 9**

\[ k_s \Delta y \frac{T_8 - T_9}{\Delta x} + \frac{T_4 - T_9}{(\Delta y/2)/k_c \Delta x + (\Delta y/2)/k_s \Delta x} + k_s \Delta y \frac{T_{10} - T_9}{\Delta x} + k_s \Delta x \frac{T_{14} - T_9}{\Delta y} = 0 \]

\[ 1.82T_4 + T_8 - 4.82T_9 + T_{10} + T_{14} = 0 \]  \hspace{1cm} (9)

**Node 10** Using the result of Node 9 and considering symmetry,

\[ 1.82T_5 + 2T_9 - 4.82T_{10} + T_{15} = 0 \]  \hspace{1cm} (10)

**Node 15**  Interior point considering symmetry

\[ T_{10} + 2T_{14} - 4T_{15} + T_{20} = 0 \]  \hspace{1cm} (15)

**Node 16**  By inspection,

\[ T_{11} - 2T_{16} + T_{17} = 0 \]  \hspace{1cm} (16)

Continued …..
Nodes 17, 18, 19, 20

\[
\begin{align*}
T_{12} + T_{16} - 3T_{17} + T_{18} &= 0 \\
T_{14} + T_{18} - 3T_{19} + T_{20} &= 0
\end{align*}
\]  (17,18)

\[
\begin{align*}
T_{13} + T_{17} - 3T_{18} + T_{19} &= 0 \\
T_{15} + 2T_{19} - 3T_{20} &= 0
\end{align*}
\]  (19,20)

Using the matrix inversion method, the above system of finite-difference equations is written in matrix notation, Eq. 4.52, \([A][T] = [C]\) where

\[
[A] = \begin{bmatrix}
-2.3 & 1 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -6 \\

<td>40.76</td>
<td>41.70</td>
<td>42.06</td>
</tr>
</tbody>
</table>

The maximum temperature is \(T_5 = 46.23°C\) which is indeed less than 85°C.

**COMMENTS:** (1) The convection process for the energy balances of Nodes 1 through 5 were simplified by assuming the node temperature is also that of the surface. Considering Node 2, the energy balance processes for \(q_a, q_b\) and \(q_c\) are identical (see Eq. (2)); however,

\[
q_{\text{conv}} = \frac{T_\infty - T_2}{1/h + \Delta y/2k} \approx h \left( T_\infty - T_2 \right)
\]

where \(h\Delta y/2k = 5 \text{ W/m}^2\text{-K} \times 0.003 \text{ m/2x50 W/mK} = 1.5\times10^{-4} \ll 1\). Hence, for this situation, the simplification is justified.
**PROBLEM 4.77**

**KNOWN:** Electronic device cooled by conduction to a heat sink.

**FIND:** (a) Beginning with a symmetrical element, find the thermal resistance per unit depth between the device and lower surface of the sink, $R_{t,d-s}^{'}$ (m·K/W) using the flux plot method; compare result with thermal resistance based upon assumption of one-dimensional conduction in rectangular domains of (i) width $w_d$ and length $L$ and (ii) width $w_s$ and length $L$; (b) Using a coarse (5x5) nodal network, determine $R_{t,d-s}^{'}$; (c) Using nodal networks with finer grid spacings, determine the effect of grid size on the precision of the thermal resistance calculation; (d) Using a fine nodal network, determine the effect of device width on $R_{t,d-s}^{'}$ with $w_d/w_s = 0.175, 0.275, 0.375$ and $0.475$ keeping $w_s$ and $L$ fixed.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, two-dimensional conduction, (2) Constant properties, and (3) No internal generation, (4) Top surface not covered by device is insulated.

**ANALYSIS:** (a) Begin the flux plot for the symmetrical element noting that the temperature drop along the left-hand symmetry line will be almost linear. Choosing to sketch five isotherms and drawing the adiabats, find

$$N = 5 \quad M = 2.75$$

so that the shape factor for the device to the sink considering two symmetrical elements per unit depth is

$$S' = 2S_0' = 2 \frac{M}{N} = 1.10$$

and the thermal resistance per unit depth is

$$R_{t,d-s,fp} = \frac{1}{kS'} = \frac{1}{300 \text{ W/m·K} \times 1.10} = 3.03 \times 10^{-3} \text{ m·K/W}$$

The thermal resistances for the two rectangular domains are represented schematically below.
We expect the flux plot result to be bounded by the results for the rectangular domains. The spreading effect can be seen by comparing \( R'_{t,d-s,fp} \) with \( R'_{t,d-s,i} \).

(b) The coarse 5x5 nodal network is shown in the sketch including the nodes adjacent to the symmetry lines and the adiabatic surface. As such, all the finite-difference equations are interior nodes and can be written by inspection directly onto the IHT workspace. Alternatively, one could use the IHT Finite-Difference Equations Tool. The temperature distribution (°C) is tabulated in the same arrangement as the nodal network.

</tbody>
</table>

The thermal resistance between the device and sink per unit depth is

\[ R'_{t,s-d} = \frac{T_d - T_s}{2q'_{tot}} \]

Performing an energy balance on the device nodes, find

\[ q'_{tot} = q'_{a} + q'_{b} + q'_{c} \]

\[ q'_{tot} = k \left( \frac{\Delta y}{2} \right) \frac{T_d - T_1}{\Delta x} + k \Delta x \frac{T_d - T_5}{\Delta y} + k \left( \frac{\Delta x}{2} \right) \frac{T_d - T_4}{\Delta y} \]

\[ q'_{tot} = 300 \text{ W/m·K} \left[ \frac{(85 - 62.31)}{2} + \frac{(85 - 63.85)}{2} + \frac{(85 - 65.76)}{2} \right] \text{K} = 1.263 \times 10^4 \text{ W/m} \]

\[ R'_{t,s-d} = \frac{(85 - 25)}{2 \times 1.263 \times 10^4 \text{ W/m}} = 2.38 \times 10^{-3} \text{ m·K/W} \]

(c) The effect of grid size on the precision of the thermal resistance estimate should be tested by systematically reducing the nodal spacing \( \Delta x \) and \( \Delta y \). This is a considerable amount of work even with IHT since the equations need to be individually entered. A more generalized, powerful code would be
required which allows for automatically selecting the grid size. Using FEHT, a finite-element package, with eight elements across the device, representing a much finer mesh, we found

\[ R'_{t,s-d} = 3.64 \times 10^{-3} \text{ m} \cdot \text{K/W} \]

(d) Using the same tool, with the finest mesh, the thermal resistance was found as a function of \( \frac{w_d}{w_s} \) with fixed \( w_s \) and \( L \).

As expected, as \( w_d \) increases, \( R'_{t,d-s} \) decreases, and eventually will approach the value for the rectangular domain (ii). The spreading effect is shown for the base case, \( \frac{w_d}{w_s} = 0.375 \), where the thermal resistance of the sink is less than that for the rectangular domain (i).

**COMMENTS:** It is useful to compare the results for estimating the thermal resistance in terms of precision requirements and level of effort,

\[ R'_{t,d-s} \times 10^3 \text{ (m-K/W)} \]

**PROBLEM 4.78**

**KNOWN:** Nodal network and boundary conditions for a water-cooled cold plate.

**FIND:** (a) Steady-state temperature distribution for prescribed conditions, (b) Means by which operation may be extended to larger heat fluxes.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Two-dimensional conduction, (3) Constant properties.

**ANALYSIS:** Finite-difference equations must be obtained for each of the 28 nodes. Applying the energy balance method to regions 1 and 5, which are similar, it follows that

Node 1: \[ (\Delta y/\Delta x)T_2 + (\Delta x/\Delta y)T_6 - \left[ (\Delta y/\Delta x) + (\Delta x/\Delta y) \right]T_1 = 0 \]

Node 5: \[ (\Delta y/\Delta x)T_4 + (\Delta x/\Delta y)T_{10} - \left[ (\Delta y/\Delta x) + (\Delta x/\Delta y) \right]T_5 = 0 \]

Nodal regions 2, 3 and 4 are similar, and the energy balance method yields a finite-difference equation of the form

Nodes 2, 3, 4:

\[ (\Delta y/\Delta x)(T_{m-1,n} + T_{m+1,n}) + 2(\Delta x/\Delta y)T_{m,n-1} - 2\left[ (\Delta y/\Delta x) + (\Delta x/\Delta y) \right]T_{m,n} = 0 \]

Energy balances applied to the remaining combinations of similar nodes yield the following finite-difference equations.

Continued...
PROBLEM 4.78 (Cont.)

Nodes 6, 14:
\[(\Delta x/\Delta y)T_1 + (\Delta y/\Delta x)T_7 - [(\Delta x/\Delta y) + (\Delta y/\Delta x) + (h\Delta x/k)]T_6 = - (h\Delta x/k)T_\infty\]
\[(\Delta x/\Delta y)T_{19} + (\Delta y/\Delta x)T_{15} - [(\Delta x/\Delta y) + (\Delta y/\Delta x) + (h\Delta x/k)]T_{14} = - (h\Delta x/k)T_\infty\]

Nodes 7, 15:
\[(\Delta y/\Delta x)(T_6 + T_8) + 2(\Delta y/\Delta x)T_9 - 2[(\Delta x/\Delta y) + (\Delta y/\Delta x) + (h\Delta y/k)]T_7 = - (2h\Delta y/k)T_\infty\]
\[(\Delta y/\Delta x)(T_{14} + T_{16}) + 2(\Delta y/\Delta x)T_{20} - 2[(\Delta x/\Delta y) + (\Delta y/\Delta x) + (h\Delta y/k)]T_{15} = - (2h\Delta y/k)T_\infty\]

Nodes 8, 16:
\[(\Delta y/\Delta x)T_7 + 2(\Delta y/\Delta x)T_9 + (\Delta x/\Delta y)T_{11} + 2(\Delta x/\Delta y)T_3 - 3[(\Delta y/\Delta x) + 3(\Delta x/\Delta y)]
+ (h/k)(\Delta x + \Delta y)]T_8 = -(h/k)(\Delta x + \Delta y)T_\infty\]
\[(\Delta y/\Delta x)T_{15} + 2(\Delta y/\Delta x)T_{17} + (\Delta x/\Delta y)T_{11} + 2(\Delta x/\Delta y)T_{21} - 3[(\Delta y/\Delta x) + 3(\Delta x/\Delta y)]
+ (h/k)(\Delta x + \Delta y)]T_{16} = -(h/k)(\Delta x + \Delta y)T_\infty\]

Node 11:
\[(\Delta x/\Delta y)T_8 + (\Delta y/\Delta x)T_{16} + 2(\Delta y/\Delta x)T_{12} - 2[(\Delta x/\Delta y) + (\Delta y/\Delta x) + (h\Delta y/k)]T_{11} = - (2h\Delta y/k)T_\infty\]

Nodes 9, 12, 17, 20, 21, 22:
\[(\Delta y/\Delta x)T_{m-1,n} + (\Delta y/\Delta x)T_{m+1,n} + (\Delta x/\Delta y)T_{m,n+1} + (\Delta x/\Delta y)T_{m,n-1} - 2[(\Delta x/\Delta y) + (\Delta y/\Delta x)]T_{m,n} = 0\]

Nodes 10, 13, 18, 23:
\[(\Delta x/\Delta y)T_{n+1,m} + (\Delta y/\Delta x)T_{n-1,m} + 2(\Delta y/\Delta x)T_{m,n-1} - 2[(\Delta x/\Delta y) + (\Delta y/\Delta x)]T_{m,n} = 0\]

Node 19:
\[(\Delta y/\Delta x)T_{14} + (\Delta x/\Delta y)T_{24} + 2(\Delta y/\Delta x)T_{20} - 2[(\Delta x/\Delta y) + (\Delta y/\Delta x)]T_{19} = 0\]

Nodes 24, 28:
\[(\Delta x/\Delta y)T_{19} + (\Delta y/\Delta x)T_{25} - [(\Delta x/\Delta y) + (\Delta y/\Delta x)]T_{24} = - (q_0^*\Delta x/k)\]
\[(\Delta x/\Delta y)T_{23} + (\Delta y/\Delta x)T_{27} - [(\Delta x/\Delta y) + (\Delta y/\Delta x)]T_{28} = - (q_0^*\Delta x/k)\]

Nodes 25, 26, 27:
\[(\Delta y/\Delta x)T_{m-1,n} + (\Delta y/\Delta x)T_{m+1,n} + 2(\Delta y/\Delta x)T_{m,n+1} - 2[(\Delta x/\Delta y) + (\Delta y/\Delta x)]T_{m,n} = -(2q_0^*\Delta x/k)\]

Evaluating the coefficients and solving the equations simultaneously, the steady-state temperature distribution (°C), tabulated according to the node locations, is:

```
23.77  23.91  24.27  24.61  24.74
23.41  23.62  24.31  24.89  25.07
      25.70  26.18  26.33
30.72  30.67  30.57  30.53  30.52
32.77  32.69  32.64  32.65
```

Alternatively, the foregoing results may readily be obtained by accessing the IHT Tools pat and using the 2-D, SS, Finite-Difference Equations options (model equations are appended). Maximum and minimum cold plate temperatures are at the bottom (T_{24}) and top center (T_1) locations respectively.

(b) For the prescribed conditions, the maximum allowable temperature (T_{24} = 40°C) is reached when \(q_0^* = 1.407 \times 10^5 \text{ W/m}^2 \) (14.07 W/cm²). Options for extending this limit could include use of a copper cold plate \((k \approx 400 \text{ W/m} \cdot \text{K})\) and/or increasing the convection coefficient associated with the coolant. With \(k = 400 \text{ W/m-K}\), a value of \(q_0^* = 17.37 \text{ W/cm}^2\) may be maintained. With \(k = 400 \text{ W/m-K}\) and \(h = 10,000 \text{ W/m}^2\cdot\text{K}\) (a practical upper limit), \(q_0^* = 28.65 \text{ W/cm}^2\). Additional, albeit small, improvements may be realized by relocating the coolant channels closer to the base of the cold plate.

COMMENTS: The accuracy of the solution may be confirmed by verifying that the results satisfy the overall energy balance

\[
q_o^* (4\Delta x) = h\left(\frac{(\Delta x)}{2}(T_6 \, T_\infty) + \Delta x (T_7 \, T_\infty) + (\Delta x + \Delta y)(T_8 \, T_\infty)/2 \right.
+ \Delta y (T_{11} \, T_\infty) + (\Delta x + \Delta y)(T_{16} \, T_\infty)/2 + \Delta x (T_{15} \, T_\infty) + (\Delta x/2)(T_{14} \, T_\infty)\right).
\]
**PROBLEM 4.79**

**KNOWN:** Heat sink for cooling computer chips fabricated from copper with microchannels passing fluid with prescribed temperature and convection coefficient.

**FIND:** (a) Using a square nodal network with 100 µm spatial increment, determine the temperature distribution and the heat rate to the coolant per unit channel length for maximum allowable chip temperature $T_{c,max} = 75^\circ C$; estimate the thermal resistance between the chip surface and the fluid, $R'_{t,c-f}$ (m-K/W); maximum allowable heat dissipation for a chip that measures 10 x 10 mm on a side; (b) The effect of grid spacing by considering spatial increments of 50 and 25 µm; and (c) Consistent with the requirement that $a + b = 400$ µm, explore altering the sink dimensions to decrease the thermal resistance.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, two-dimensional conduction, (2) Constant properties, and (3) Convection coefficient is uniform over the microchannel surface and independent of the channel dimensions and shape.

**ANALYSIS:** (a) The square nodal network with $\Delta x = \Delta y = 100$ µm is shown below. Considering symmetry, the nodes 1, 2, 3, 4, 7, and 9 can be treated as interior nodes and their finite-difference equations representing nodal energy balances can be written by inspection. Using the, IHT Finite-Difference Equations Tool, appropriate FDEs for the nodes experiencing surface convection can be obtained. The IHT code including results is included in the Comments. Having the temperature distribution, the heat rate to the coolant per unit channel length for two symmetrical elements can be obtained by applying Newton’s law of cooling to the surface nodes,

$$ q'_{cv} = 2\left[h\left(\Delta y/2 + \Delta x/2\right)\left(T_5 - T_\infty\right) + h\left(\Delta x/2\right)\left(T_6 - T_\infty\right) + h\left(\Delta y\right)\left(T_8 - T_\infty\right)h\left(\Delta y/2\right)\left(T_10 - T_\infty\right)\right] $$

$$ q'_{cv} = 2\times30,000 \text{ W/m}^2 \times 100\times10^{-6} \text{ m}\left[(74.02 - 25) + (74.09 - 25)/2 + (73.60 - 25) + (73.37 - 25)/2\right] \text{ K} $$

$$ q'_{cv} = 878 \text{ W/m} $$

The thermal resistance between the chip and fluid per unit length for each microchannel is

$$ R'_{t,c-f} = \frac{T_c - T_\infty}{q'_{cv}} = \frac{\left(75 - 25\right)^\circ C}{878 \text{ W/m}} = 5.69\times10^{-2} \text{ m} \cdot \text{K/W} $$

The maximum allowable heat dissipation for a 10 mm x 10 mm chip is

$$ P_{chip,max} = q''_{c} \times A_{chip} = 2.20\times10^6 \text{ W/m}^2 \times (0.01\times0.01) \text{ m}^2 = 220 \text{ W} $$

where $A_{chip} = 10 \text{ mm} \times 10 \text{ mm}$ and the heat flux on the chip surface ($w_f + w_s$) is

$$ q''_c = q'_{cv}/(w_f + w_s) = 878 \text{ W/m}^2/(200 + 200)\times10^{-6} \text{ m} = 2.20\times10^6 \text{ W/m}^2 $$

Continued...
(b) To investigate the effect of grid spacing, the analysis was repeated with a spatial increment of 50 µm (32 nodes as shown above) with the following results

\[ q_{cv} = 881 \text{ W/m} \quad R'_{t,c-f} = 5.67 \times 10^{-2} \text{ m} \cdot \text{K/W} \]

Using a finite-element package with a mesh around 25 µm, we found \( R'_{t,c-f} = 5.70 \times 10^{-2} \text{ m} \cdot \text{K/W} \) which suggests the grid spacing effect is not very significant.

(c) Requiring that the overall dimensions of the symmetrical element remain unchanged, we explored what effect changes in the microchannel cross-section would have on the overall thermal resistance, \( R'_{t,c-f} \). It is important to recognize that the sink conduction path represents the dominant resistance, since for the convection process

\[ R'_{t,cv} = l/A'_{s} = 1/\left(30,000 \text{ W/m}^2 \cdot \text{K} \times 600 \times 10^{-6} \text{ m}\right) = 5.55 \times 10^{-2} \text{ m} \cdot \text{K/W} \]

where \( A'_{s} = (w_f + 2b) = 600 \mu \text{m} \).

Using a finite-element package, the thermal resistances per unit length for three additional channel cross-sections were determined and results summarized below.

COMMENTS: (1) The IHT Workspace for the 5x5 coarse node analysis with results follows.
PROBLEM 4.80

KNOWN: Longitudinal rib (k = 10 W/m·K) with rectangular cross-section with length L = 8 mm and width w = 4 mm. Base temperature $T_b$ and convection conditions, $T_\infty$ and h, are prescribed.

FIND: (a) Temperature distribution and fin base heat rate using a finite-difference method with $\Delta x = \Delta y = 2$ mm for a total of $5 \times 3 = 15$ nodal points and regions; compare results with those obtained assuming one-dimensional heat transfer in rib; and (b) The effect of grid spacing by reducing nodal spacing to $\Delta x = \Delta y = 1$ mm for a total of $9 \times 3 = 27$ nodal points and regions considering symmetry of the centerline; and (c) A criterion for which the one-dimensional approximation is reasonable; compare the heat rate for the range $1.5 \leq L/w \leq 10$, keeping L constant, as predicted by the two-dimensional, finite-difference method and the one-dimensional fin analysis.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, and (3) Convection coefficient uniform over rib surfaces, including tip.

ANALYSIS: (a) The rib is represented by a $5 \times 3$ nodal grid as shown above where the symmetry plane is an adiabatic surface. The IHT Tool, Finite-Difference Equations, for Two-Dimensional, Steady-State conditions is used to formulate the nodal equations (see Comment 2 below) which yields the following nodal temperatures ($^\circ$C)

<table>
<thead>
<tr>
<th></th>
<th>45</th>
<th>39.3</th>
<th>35.7</th>
<th>33.5</th>
<th>32.2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>45</td>
<td>40.0</td>
<td>36.4</td>
<td>34.0</td>
<td>32.6</td>
</tr>
<tr>
<td>2</td>
<td>45</td>
<td>39.3</td>
<td>35.7</td>
<td>33.5</td>
<td>32.2</td>
</tr>
</tbody>
</table>

Note that the fin tip temperature is

$T_{\text{tip}} = T_{12} = 32.6^\circ$C

The fin heat rate per unit width normal to the page, $q_{\text{fin}}'$, can be determined from energy balances on the three base nodes as shown in the schematic below.

$q_{\text{fin}}' = q_a' + q_b' + q_c' + q_d' + q_e'$
$q_a' = h(\Delta x/2)(T_b - T_\infty)$
$q_b' = k(\Delta y/2)(T_b - T_1)/\Delta x$
$q_c' = k(\Delta y/2)(T_b - T_5)/\Delta x$
$q_d' = k(\Delta y/2)(T_b - T_9)/\Delta x$
$q_3' = h(\Delta x/2)(T_b - T_\infty)$

Continued...
PROBLEM 4.80 (Cont.)

Substituting numerical values, find

\[ q'_{\text{fin}} = (12.0 + 28.4 + 50.0 + 28.4 + 12.0) \text{ W/m} = 130.8 \text{ W/m} \]

Using the IHT Model, Extended Surfaces, Heat Rate and Temperature Distributions for Rectangular, Straight Fins, with convection tip condition, the one-dimensional fin analysis yields

\[ q'_{\text{f}} = 131 \text{ W/m} \quad \text{and} \quad T_{\text{tip}} = 32.2^\circ \text{C} \]

(b) With \( \Delta x = L/8 = 1 \text{ mm} \) and \( \Delta x = 1 \text{ mm} \), for a total of \( 9 \times 3 = 27 \) nodal points and regions, the grid appears as shown below. Note the rib centerline is a plane of symmetry.

Using the same IHT FDE Tool as above with an appropriate expression for the fin heat rate, Eq. (1), the fin heat rate and tip temperature were determined.

<table>
<thead>
<tr>
<th>1-D analysis</th>
<th>2-D analysis (nodes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>( T_{\text{tip}} ) (^{\circ} \text{C})</td>
<td>( 32.2 )</td>
</tr>
<tr>
<td>( q'_{\text{fin}} ) ( \text{W/m} )</td>
<td>( 131 )</td>
</tr>
</tbody>
</table>

(c) To determine when the one-dimensional approximation is reasonable, consider a rib of constant length, \( L = 8 \text{ mm} \), and vary the thickness \( w \) for the range \( 1.5 \leq L/w \leq 10 \). Using the above IHT model for the 27 node grid, the fin heat rates for 1-D, \( q'_{1d} \), and 2-D, \( q'_{2d} \), analysis were determined as a function of \( w \) with the error in the approximation evaluated as

\[ \text{Error} \% = \left( \frac{q'_{2d} - q'_{1d}}{q'_{1d}} \right) \times 100 \]

Note that for small \( L/w \), a thick rib, the 1-D approximation is poor. For large \( L/w \), a thin rib which approximates a fin, we would expect the 1-D approximation to become increasingly more satisfactory. The discrepancy at large \( L/w \) must be due to discretization error; that is, the grid is too coarse to accurately represent the slender rib.
**PROBLEM 4.81**

**KNOWN**: Bottom half of an I-beam exposed to hot furnace gases.

**FIND**: (a) The heat transfer rate per unit length into the beam using a coarse nodal network (5 × 4) considering the temperature distribution across the web is uniform and (b) Assess the reasonableness of the uniform web-flange interface temperature assumption.

**SCHEMATIC**:

**ASSUMPTIONS**: (1) Steady-state, two-dimensional conduction, and (2) Constant properties.

**ANALYSIS**: (a) The symmetrical section of the I-beam is shown in the Schematic above indicating the web-flange interface temperature is uniform, $T_w = 100^\circ C$. The nodal arrangement to represent this system is shown below. The nodes on the line of symmetry have been shown for convenience in deriving the nodal finite-difference equations.

Using the **IHT Finite-Difference Equations Tool**, the set of nodal equations can be readily formulated. The temperature distribution (°C) is tabulated in the same arrangement as the nodal network.

The heat rate to the beam can be determined from energy balances about the web-flange interface nodes as shown in the sketch below.

Continued...
PROBLEM 4.81 (Cont.)

\[ q'_w = q'_a + q'_b + q'_c \]

\[ q'_w = k \left( \frac{\Delta y}{2} \right) \frac{T_1 - T_w}{\Delta x} + k \left( \frac{\Delta x}{\Delta y} \right) \frac{T_5 - T_w}{\Delta y} + k \left( \frac{\Delta x}{2} \right) \frac{T_4 - T_w}{\Delta y} \]

\[ q'_w = 10 \text{ W/m} \cdot \text{K} \left[ \frac{(215.8 - 100)}{2} + (177.1 - 100) + (166.6 - 100) / 2 \right] = 1683 \text{ W/m} \]

(b) The schematic below poses the question concerning the reasonableness of the uniform temperature assumption at the web-flange interface. From the analysis above, note that \( T_1 = 215.8^\circ \text{C} \) vs. \( T_w = 100^\circ \text{C} \) indicating that this assumption is a poor one. This L-shaped section has strong two-dimensional behavior. To illustrate the effect, we performed an analysis with \( T_w = 100^\circ \text{C} \) located nearly 2 times further up the web than it is wide. For this situation, the temperature difference at the web-flange interface across the width of the web was nearly 40°C. The steel beam with its low thermal conductivity has substantial internal thermal resistance and given the L-shape, the uniform temperature assumption \( (T_w) \) across the web-flange interface is inappropriate.
PROBLEM 4.82

KNOWN: Plane composite wall with exposed surfaces maintained at fixed temperatures. Material A has temperature-dependent thermal conductivity.

FIND: Heat flux through the wall (a) assuming a uniform thermal conductivity in material A evaluated at the average temperature of the section, and considering the temperature-dependent thermal conductivity of material A using (b) a finite-difference method of solution in IHT with a space increment of 1 mm and (c) the finite-element method of FEHT.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, one-dimensional conduction, (2) No thermal contact resistance between the materials, and (3) No internal generation.

ANALYSIS: (a) From the thermal circuit in the above schematic, the heat flux is

\[ q_x = \frac{T_1 - T_2}{R_A^* + R_B^*} = \frac{T_{AB} - T_2}{R_B^*} \]

and the thermal resistances of the two sections are

\[ R_A^* = \frac{L_A}{k_A} \quad R_B^* = \frac{L_B}{k_B} \]

The thermal conductivity of material A is evaluated at the average temperature of the section

\[ k_A = k_o \left[ 1 + \alpha (T - T_o) \right] \]

Substituting numerical values and solving the system of equations simultaneously in IHT, find

\[ T_{AB} = 563.2 \, \text{K} \quad q_x^* = 52.64 \, \text{kW/m}^2 \]

(b) The nodal arrangement for the finite-difference method of solution is shown in the schematic below. FDEs must be written for the internal nodes (02 – 10, 12 – 15) and the A-B interface node (11) considering in section A, the temperature-dependent thermal conductivity.

Continued …..
PROBLEM 4.82 (Cont.)

\[
q^*_{c} = k_a \left( m, m+1 \right) \frac{T_{m+1} - T_m}{\Delta x} 
\]

(1)

\[
q^*_{d} = k_a \left( m-1, m \right) \frac{T_{m-1} - T_m}{\Delta x} 
\]

(2)

and the FDEs are obtained from the energy balance written as

\[
q^*_{c} + q^*_{d} = 0 
\]

(3)

\[
k_a \left( m, m+1 \right) \frac{T_{m+1} - T_m}{\Delta x} + k_a \left( m-1, m \right) \frac{T_{m-1} - T_m}{\Delta x} = 0 
\]

(4)

where the thermal conductivities averaged over the path between the nodes are expressed as

\[
k_a \left( m-1, m \right) = k_o \left\{ 1 + \alpha \left[ \frac{(T_{m-1} + T_m)}{2} - T_o \right] \right\} 
\]

(5)

\[
k_a \left( m, m+1 \right) = k_o \left\{ 1 + \alpha \left[ \frac{(T_m + T_{m+1})}{2} - T_o \right] \right\} 
\]

(6)

**A-B Interface Node 11**

Referring to the above schematic, the energy balance on the interface node, \( q^*_{c} + q^*_{d} = 0 \), has the form

\[
k_b \frac{T_{12} - T_{11}}{\Delta x} + k_a \left( 10, 11 \right) \frac{T_{10} - T_{11}}{\Delta x} = 0 
\]

(7)

where the thermal conductivity in the section A path is

\[
k \left( 10, 11 \right) = k_o \left\{ 1 + \alpha \left[ \frac{(T_{10} + T_{11})}{2} - T_o \right] \right\} 
\]

(8)

**Interior Nodes, Section B (n = 12 …15)**

Since the thermal conductivity in Section B is uniform, the FDEs have the form

\[
T_n = \frac{(T_{n-1} + T_{n+1})}{2} 
\]

(9)

And the heat flux in the x-direction is

\[
q^*_{x} = k_b \frac{T_n - T_{n+1}}{\Delta x} 
\]

(10)

**Finite-Difference Method of Solution**

The foregoing FDE equations for section A nodes (m = 02 to 10), the AB interface node and their respective expressions for the thermal conductivity, \( k \left( m, m+1 \right) \), and for section B nodes are entered into the IHT workspace and solved for the temperature distribution. The heat flux can be evaluated using Eq. (2) or (10). A portion of the IHT code is contained in the Comments, and the results of the analysis are tabulated below.

\[
T_{11} = T_{AB} = 563.2 \, \text{K} \quad q^*_{x} = 52.64 \, \text{kW/m}^2 
\]

Continued ......
(c) The finite-element method of FEHT can be used readily to obtain the heat flux considering the temperature-dependent thermal conductivity of section A. Draw the composite wall outline with properly scaled section thicknesses in the x-direction with an arbitrary y-direction dimension. In the Specify | Materials Properties box for the thermal conductivity, specify \( k_a \) as \( 4.4 \ast [1 + 0.008 \ast (T - 300)] \) having earlier selected Set | Temperatures in K. The results of the analysis are

\[
T_{AB} = 563 \text{ K} \quad q_x^* = 5.26 \text{ kW/m}^2
\]

**COMMENTS:**

(1) The results from the three methods of analysis compare very well. Because the thermal conductivity in section A is linear, and moderately dependent on temperature, the simplest method of using an overall section average, part (a), is recommended. This same method is recommended when using tabular data for temperature-dependent properties.

(2) For the finite-difference method of solution, part (b), the heat flux was evaluated at several nodes within section A and in section B with identical results. This is a consequence of the technique for averaging \( k_a \) over the path between nodes in computing the heat flux into a node.

(3) To illustrate the use of IHT in solving the finite-difference method of solution, lines of code for representative nodes are shown below.

```plaintext
// FDEs – Section A
k01_02 * (T01-T02)/deltax + k02_03 * (T03-T02)/deltax = 0
k01_02 = ko * (1 + alpha * ((T01 + T02)/2 – To))
k02_03 = ko * (1 + alpha * ((T02 + T03)/2 – To))

k02_03 * (T02 – T03)/deltax + k03_04 * (T04 – T03)/deltax = 0
k03_04 = ko * (1 + alpha * ((T03 + T04)/2 – To))

// Interface, node 11
k11 * (T10 –T11)/deltax + kb * (T12 –T11)/deltax =0
k11 = ko * (1 + alpha * ((T10 + T11)/2 – To))

// Section B (using Tools/FDE/One-dimensional/Steady-state)
/* Node 12: interior node; */
0.0 = fd_1d_int(T12, T13, T11, kb, qdot, deltax)
```

(4) The solved models for Text Examples 4.3 and 4.4, plus the tutorial of the User’s Manual, provide background for developing skills in using FEHT.
**PROBLEM 4.83**

**KNOWN:** Upper surface of a platen heated by hot fluid through the flow channels is used to heat a process fluid.

**FIND:** (a) The maximum allowable spacing, W, between channel centerlines that will provide a uniform temperature requirement of 5°C on the upper surface of the platen, and (b) Heat rate per unit length from the flow channel for this condition.

**SCHEMATIC:**

![Schematic](image)

**ASSUMPTIONS:** (1) Steady-state, two-dimensional conduction with constant properties, and (2) Lower surface of platen is adiabatic.

**ANALYSIS:** As shown in the schematic above for a symmetrical section of the platen-flow channel arrangement, the temperature uniformity requirement will be met when $T_1 - T_2 = 5^\circ C$. The maximum temperature, $T_1$, will occur directly over the flow channel centerline, while the minimum surface temperature, $T_2$, will occur at the mid-span between channel centerlines.

We chose to use FEHT to obtain the temperature distribution and heat rate for guessed values of the channel centerline spacing, W. The following method of solution was used: (1) Make an initial guess value for W; try $W = 100$ mm, (2) Draw an outline of the symmetrical section, and assign properties and boundary conditions, (3) Make a copy of this file so that in your second trial, you can use the Draw | Move Node option to modify the section width, W/2, larger or smaller, (4) Draw element lines within the outline to create triangular elements, (5) Use the Draw | Reduce Mesh command to generate a suitably fine mesh, then solve for the temperature distribution, (6) Use the View | Temperatures command to determine the temperatures $T_1$ and $T_2$, (7) If, $T_1 - T_2 = 5^\circ C$, use the View | Heat Flows command to find the heat rate, otherwise, change the width of the section outline and repeat the analysis. The results of our three trials are tabulated below.

<table>

**COMMENTS:** (1) In addition to the tutorial example in the FEHT User’s Manual, the solved models for Examples 4.3 and 4.4 of the Text are useful for developing skills in using this problem-solving tool.

(2) An alternative numerical method of solution would be to create a nodal network, generate the finite-difference equations and solve for the temperature distribution and the heat rate. The FDEs should allow for a non-square grid, $\Delta x \neq \Delta y$, so that different values for W/2 can be accommodated by changing the value of $\Delta x$. Even using the IHT tool for building FDEs (Tools | Finite-Difference Equations | Steady-State) this method of solution is very labor intensive because of the large number of nodes required for obtaining good estimates.
**PROBLEM 4.84**

**KNOWN:** Silicon chip mounted in a dielectric substrate. One surface of system is convectively cooled, while the remaining surfaces are well insulated. See Problem 4.77. Use the finite-element software FEHT as your analysis tool.

**FIND:** (a) The temperature distribution in the substrate-chip system; does the maximum temperature exceed 85°C?; (b) Volumetric heating rate that will result in a maximum temperature of 85°C; and (c) Effect of reducing thickness of substrate from 12 to 6 mm, keeping all other dimensions unchanged with \( \dot{q} = 1 \times 10^7 \text{ W/m}^3 \); maximum temperature in the system for these conditions, and fraction of the power generated within the chip removed by convection directly from the chip surface.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Two-dimensional conduction in system, and (3) Uniform convection coefficient over upper surface.

**ANALYSIS:** Using FEHT, the symmetrical section is represented in the workspace as two connected regions, chip and substrate. **Draw** first the chip outline; **Specify** the material and generation parameters. Now, **Draw** the outline of the substrate, connecting the nodes of the interfacing surfaces; **Specify** the material parameters for this region. Finally, **Assign** the **Boundary Conditions:** zero heat flux for the symmetry and insulated surfaces, and convection for the upper surface. **Draw** **Element Lines**, making the triangular elements near the chip and surface smaller than near the lower insulated boundary as shown in a copy of the FEHT screen on the next page. Use the **Draw|Reduce Mesh** command and **Run** the model.

(a) Use the **View|Temperature** command to see the nodal temperatures throughout the system. As expected, the hottest location is on the centerline of the chip at the bottom surface. At this location, the temperature is

\[
T(0, 9 \text{ mm}) = 46.7^\circ\text{C}
\]

(b) Run the model again, with different values of the generation rate until the temperature at this location is \( T(0, 9 \text{ mm}) = 85^\circ\text{C} \), finding

\[
\dot{q} = 2.43 \times 10^7 \text{ W/m}^3
\]

Continued .....
PROBLEM 4.84 (Cont.)

(c) Returning to the model code with the conditions of part (a), reposition the nodes on the lower boundary, as well as the intermediate ones, to represent a substrate that is of 6-mm, rather than 12-mm thickness. Find the maximum temperature as

\[ T(0, 3 \text{ mm}) = 47.5 ^\circ \text{C} \]

Using the View Heat Flow command, click on the adjacent line segments forming the chip surface exposed to the convection process. The heat rate per unit width (normal to the page) is

\[ q_{\text{chip,cv}}' = 60.26 \text{ W/m} \]

The total heat generated within the chip is

\[ q_{\text{tot}}' = q'\left( \frac{L}{6 \times H/4} \right) = 1 \times 10^7 \text{ W/m}^3 \times (0.0045 \times 0.003) m^2 = 135 \text{ W/m} \]

so that the fraction of the power dissipated by the chip that is convected directly to the coolant stream is

\[ F = \frac{q_{\text{chip,cv}}'}{q_{\text{tot}}'} = \frac{60.26}{135} = 45\% \]

COMMENTS: (1) Comparing the maximum temperatures for the system with the 12-mm and 6-mm thickness substrates, note that the effect of halving the substrate thickness is to raise the maximum temperature by less than 1\(^\circ\)C. The thicker substrate does not provide significantly improved heat removal capability.

(2) Without running the code for part (b), estimate the magnitude of \( q' \) that would make \( T(0, 9 \text{ mm}) = 85\% \). Did you get \( q' = 2.43 \times 10^7 \text{ W/m}^3 \)? Why?
PROBLEM 5.1

KNOWN: Electrical heater attached to backside of plate while front surface is exposed to convection process \( (T_\infty, h) \); initially plate is at a uniform temperature of the ambient air and suddenly heater power is switched on providing a constant \( q^o \).

FIND: (a) Sketch temperature distribution, \( T(x,t) \), (b) Sketch the heat flux at the outer surface, \( q^o_x (L,t) \) as a function of time.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, (3) Negligible heat loss from heater through insulation.

ANALYSIS: (a) The temperature distributions for four time conditions including the initial distribution, \( T(x,0) \), and the steady-state distribution, \( T(x,\infty) \), are as shown above.

Note that the temperature gradient at \( x = 0 \), \(-dT/dx)_{x=0} \), for \( t > 0 \) will be a constant since the flux, \( q^o_x (0) \), is a constant. Noting that \( T_0 = T(0,\infty) \), the steady-state temperature distribution will be linear such that

\[
q^o = k \frac{T_0 - T(L,\infty)}{L} = h \left[ T(L,\infty) - T_\infty \right].
\]

(b) The heat flux at the front surface, \( x = L \), is given by \( q^o_x (L,t) = -k (dT/dx)_{x=L} \). From the temperature distribution, we can construct the heat flux-time plot.

COMMENTS: At early times, the temperature and heat flux at \( x = L \) will not change from their initial values. Hence, we show a zero slope for \( q^o_x (L,t) \) at early times. Eventually, the value of \( q^o_x (L,t) \) will reach the steady-state value which is \( q^o \).
**PROBLEM 5.2**

**KNOWN:** Plane wall whose inner surface is insulated and outer surface is exposed to an airstream at $T_\infty$. Initially, the wall is at a uniform temperature equal to that of the airstream. Suddenly, a radiant source is switched on applying a uniform flux, $q_o''$, to the outer surface.

**FIND:** (a) Sketch temperature distribution on $T$-x coordinates for initial, steady-state, and two intermediate times, (b) Sketch heat flux at the outer surface, $q_x''(L,t)$, as a function of time.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional conduction, (2) Constant properties, (3) No internal generation, $\dot{E}_g = 0$, (4) Surface at $x = 0$ is perfectly insulated, (5) All incident radiant power is absorbed and negligible radiation exchange with surroundings.

**ANALYSIS:** (a) The temperature distributions are shown on the $T$-x coordinates and labeled accordingly. Note these special features: (1) Gradient at $x = 0$ is always zero, (2) gradient is more steep at early times and (3) for steady-state conditions, the radiant flux is equal to the convective heat flux (this follows from an energy balance on the CS at $x = L$),

$$q_o'' = q_{\text{conv}}'' = h [T(L,\infty) - T_\infty].$$

(b) The heat flux at the outer surface, $q_x''(L,t)$, as a function of time appears as shown above.

**COMMENTS:** The sketches must reflect the initial and boundary conditions:

$$T(x,0) = T_\infty$$

uniform initial temperature.

$$-k \frac{\partial T}{\partial x} |_{x=0} = 0$$

insulated at $x = 0$.

$$-k \frac{\partial T}{\partial x} |_{x=L} = h [T(L,t) - T_\infty] - q_o''$$

surface energy balance at $x = L$. 
PROBLEM 5.3

KNOWN: Microwave and radiant heating conditions for a slab of beef.

FIND: Sketch temperature distributions at specific times during heating and cooling.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in x, (2) Uniform internal heat generation for microwave, (3) Uniform surface heating for radiant oven, (4) Heat loss from surface of meat to surroundings is negligible during the heating process, (5) Symmetry about midplane.

ANALYSIS:

COMMENTS: (1) With uniform generation and negligible surface heat loss, the temperature distribution remains nearly uniform during microwave heating. During the subsequent surface cooling, the maximum temperature is at the midplane.

(2) The interior of the meat is heated by conduction from the hotter surfaces during radiant heating, and the lowest temperature is at the midplane. The situation is reversed shortly after cooling begins, and the maximum temperature is at the midplane.
PROBLEM 5.4

KNOWN: Plate initially at a uniform temperature $T_i$ is suddenly subjected to convection process ($T_\infty,h$) on both surfaces. After elapsed time $t_o$, plate is insulated on both surfaces.

FIND: (a) Assuming $Bi >> 1$, sketch on $T - x$ coordinates: initial and steady-state ($t \to \infty$) temperature distributions, $T(x,t_o)$ and distributions for two intermediate times $t_o < t < \infty$. (b) Sketch on $T - t$ coordinates midplane and surface temperature histories, (c) Repeat parts (a) and (b) assuming $Bi << 1$, and (d) Obtain expression for $T(x,\infty) = T_f$ in terms of plate parameters $(M,c_p)$, thermal conditions $(T_i, T_\infty, h)$, surface temperature $T(L,t)$ and heating time $t_o$.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, (3) No internal generation, (4) Plate is perfectly insulated for $t > t_o$, (5) $T(0, t < t_o) < T_\infty$.

ANALYSIS: (a,b) With $Bi >> 1$, appreciable temperature gradients exist in the plate following exposure to the heating process.

On $T-x$ coordinates: (1) initial, uniform temperature, (2) steady-state conditions when $t \to \infty$, (3) distribution at $t_o$ just before plate is covered with insulation, (4) gradients are always zero (symmetry), and (5) when $t > t_o$ (dashed lines) gradients approach zero everywhere.

(c) If $Bi << 1$, plate is space-wise isothermal (no gradients). On $T-x$ coordinates, the temperature distributions are flat; on $T-t$ coordinates, $T(L,t) = T(0,t)$.

(d) The conservation of energy requirement for the interval of time $\Delta t = t_o$ is

$$E_{in} - E_{out} = \Delta E = E_{final} - E_{initial} = 2 \int_0^{t_o} hA_s \left[T_\infty - T(L,t) \right] dt - 0 = Mc_p (T_f - T_i)$$

where $E_{in}$ is due to convection heating over the period of time $t = 0 \to t_o$. With knowledge of $T(L,t)$, this expression can be integrated and a value for $T_f$ determined.
PROBLEM 5.5

KNOWN: Diameter and initial temperature of steel balls cooling in air.

FIND: Time required to cool to a prescribed temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible radiation effects, (2) Constant properties.

ANALYSIS: Applying Eq. 5.10 to a sphere \( L_c = r_o/3 \),

\[
\text{Bi} = \frac{hL_c}{k} = \frac{h(\frac{r_o}{3})}{k} = \frac{20 \text{ W/m}^2 \cdot \text{K}}{40 \text{ W/m} \cdot \text{K}} \left( \frac{0.002 \text{m}}{0.001} \right) = 0.001.
\]

Hence, the temperature of the steel remains approximately uniform during the cooling process, and the lumped capacitance method may be used. From Eqs. 5.4 and 5.5,

\[
t = \frac{\rho V c_p}{hA_s} \ln \frac{T_i - T_\infty}{T - T_\infty} = \frac{\rho \left( \frac{\pi D^3}{6} \right) c_p}{h \pi D^2} \ln \frac{T_i - T_\infty}{T - T_\infty}.
\]

\[
t = \frac{7800 \text{ kg/m}^3 \left( 0.012 \text{m} \right) 600 \text{ J/kg} \cdot \text{K}}{6 \times 20 \text{ W/m}^2 \cdot \text{K}} \ln \frac{1150 - 325}{400 - 325}
\]

\[
t = 1122 \text{ s} = 0.312 \text{h}
\]

COMMENTS: Due to the large value of \( T_i \), radiation effects are likely to be significant during the early portion of the transient. The effect is to shorten the cooling time.
PROBLEM 5.6

KNOWN: The temperature-time history of a pure copper sphere in an air stream.

FIND: The heat transfer coefficient between the sphere and the air stream.

SCHEMATIC:

\[ T(0) = 66^\circ C \]
\[ T(69s) = 55^\circ C \]
\[ D = 12.7 \text{ mm} \]

\[ T_\infty = 27^\circ C \]

ASSUMPTIONS: (1) Temperature of sphere is spatially uniform, (2) Negligible radiation exchange, (3) Constant properties.

PROPERTIES: Table A-1, Pure copper (333K): \( \rho = 8933 \text{ kg/m}^3 \), \( c_p = 389 \text{ J/kg} \cdot \text{K} \), \( k = 398 \text{ W/m} \cdot \text{K} \).

ANALYSIS: The time-temperature history is given by Eq. 5.6 with Eq. 5.7.

\[
\frac{\theta(t)}{\theta_i} = \exp \left( -\frac{t}{R_t C_t} \right) \quad \text{where} \quad R_t = \frac{1}{hA_s} \quad A_s = \pi D^2
\]

\[
C_t = \rho V c_p \quad V = \frac{\pi D^3}{6}
\]

\[
\theta = T - T_\infty.
\]

Recognize that when \( t = 69s \),

\[
\frac{\theta(t)}{\theta_i} = \frac{(55 - 27)^{\circ} C}{(66 - 27)^{\circ} C} = 0.718 = \exp \left( -\frac{t}{\tau_t} \right) = \exp \left( -\frac{69s}{\tau_t} \right)
\]

and noting that \( \tau_t = R_t C_t \) find \( \tau_t = 208s \).

Hence,

\[
h = \frac{\rho V c_p}{A_s \tau_t} = \frac{8933 \text{ kg/m}^3 \left( \pi 0.0127^3 \text{ m}^3 / 6 \right) 389 \text{ J/kg} \cdot \text{K}}{\pi 0.0127^2 \text{ m}^2 \times 208s}
\]

\[
h = 35.3 \text{ W/m}^2 \cdot \text{K}.
\]

COMMENTs: Note that with \( L_c = D_o / 6 \),

\[
Bi = \frac{hL_c}{k} = 35.3 \text{ W/m}^2 \cdot \text{K} \times \frac{0.0127}{6} \text{ m} / 398 \text{ W/m} \cdot \text{K} = 1.88 \times 10^{-4}.
\]

Hence, \( Bi < 0.1 \) and the spatially isothermal assumption is reasonable.
PROBLEM 5.7

KNOWN: Solid steel sphere (AISI 1010), coated with dielectric layer of prescribed thickness and thermal conductivity. Coated sphere, initially at uniform temperature, is suddenly quenched in an oil bath.

FIND: Time required for sphere to reach 140°C.

SCHEMATIC:

PROPERTIES: Table A-1, AISI 1010 Steel \( \bar{T} = \frac{[500 + 140]}{2} = 320°C \approx 600K \):

\[ \rho = 7832 \text{ kg/m}^3, \quad c = 559 \text{ J/kg}\cdot\text{K}, \quad k = 48.8 \text{ W/m}\cdot\text{K}. \]

ASSUMPTIONS: (1) Steel sphere is space-wise isothermal, (2) Dielectric layer has negligible thermal capacitance compared to steel sphere, (3) Layer is thin compared to radius of sphere, (4) Constant properties.

ANALYSIS: The thermal resistance to heat transfer from the sphere is due to the dielectric layer and the convection coefficient. That is,

\[ R'' = \frac{\ell}{k} + \frac{1}{h} = \frac{0.002}{0.04} + \frac{1}{3300} = 0.050 + 0.0003 = 0.0503 \text{ m}^2\cdot\text{K/W}, \]

or in terms of an overall coefficient, \( U = 1/R'' = 19.88 \text{ W/m}^2\cdot\text{K}. \) The effective Biot number is

\[ \text{Bi}_c = \frac{U L_c}{k} = \frac{19.88 \times 0.300/6}{48.8} = 0.0204 \]

where the characteristic length is \( L_c = r_o/3 \) for the sphere. Since \( \text{Bi}_c < 0.1 \), the lumped capacitance approach is applicable. Hence, Eq. 5.5 is appropriate with \( h \) replaced by \( U \),

\[ t = \frac{\rho c}{U} \left[ \frac{V}{A_s} \right] \ln \left( \frac{\theta_i}{\theta_o} \right) = \frac{\rho c}{U} \left[ \frac{V}{A_s} \right] \ln \left( \frac{T(0) - T_\infty}{T(t) - T_\infty} \right). \]

Substituting numerical values with \( (V/A_s) = r_o/3 = D/6 \),

\[ t = \frac{7832 \times 559}{19.88} \left[ \frac{0.300}{6} \right] \ln \left( \frac{500 - 100}{140 - 100} \right) \approx 25,358 \text{ s} = 7.04 \text{h}. \]

COMMENTS: (1) Note from calculation of \( R'' \) that the resistance of the dielectric layer dominates and therefore nearly all the temperature drop occurs across the layer.
PROBLEM 5.8

KNOWN: Thickness, surface area, and properties of iron base plate. Heat flux at inner surface. Temperature of surroundings. Temperature and convection coefficient of air at outer surface.

FIND: Time required for plate to reach a temperature of 135°C. Operating efficiency of iron.

SCHEMATIC:

ASSUMPTIONS: (1) Radiation exchange is between a small surface and large surroundings, (2) Convection coefficient is independent of time, (3) Constant properties, (4) Iron is initially at room temperature ($T_i = T_{\infty}$).

ANALYSIS: Biot numbers may be based on convection heat transfer and/or the maximum heat transfer by radiation, which would occur when the plate reaches the desired temperature ($T = 135$°C).

From Eq. (1.9) the corresponding radiation transfer coefficient is $h_r = \varepsilon\sigma(T + T_{\text{sur}})\left(\frac{22}{T^2 + T_{\text{sur}}^2}\right) = 0.8 \times 5.67 \times 10^{-8} \text{ W/m}^2\text{K}^4 (408 + 298) \text{ K} (408^2 + 298^2) \text{ K}^2 = 8.2 \text{ W/m}^2\text{K}$. Hence,

$$\text{Bi} = \frac{hL}{k} = \frac{10 \text{ W/m}^2\text{K}(0.007 \text{m})}{180 \text{ W/m} \cdot \text{K}} = 3.9 \times 10^{-4}$$

$$\text{Bi}_r = \frac{h_rL}{k} = \frac{8.2 \text{ W/m}^2\text{K}(0.007 \text{m})}{180 \text{ W/m} \cdot \text{K}} = 3.2 \times 10^{-4}$$

With convection and radiation considered independently or collectively, $\text{Bi}$, $\text{Bi}_r$, $\text{Bi} + \text{Bi}_r << 1$ and the lumped capacitance analysis may be used.

The energy balance, Eq. (5.15), associated with Figure 5.5 may be applied to this problem. With $\dot{E}_g = 0$, the integral form of the equation is

$$T - T_i = \frac{A_s}{\rho V c} \left[ t \int_0^t q_h^* - h(T - T_{\infty}) - \varepsilon\sigma(T^4 - T_{\text{sur}}^4) \right] dt$$

Integrating numerically, we obtain, for $T = 135$°C,

$$t = 168 \text{s}$$

COMMENTS: Note that, if heat transfer is by natural convection, $h$, like $h_r$, will vary during the process from a value of 0 at $t = 0$ to a maximum at $t = 168$ s.
PROBLEM 5.9

KNOWN: Diameter and radial temperature of AISI 1010 carbon steel shaft. Convection coefficient and temperature of furnace gases.

FIND: Time required for shaft centerline to reach a prescribed temperature.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, radial conduction, (2) Constant properties.

PROPERTIES: AISI 1010 carbon steel, Table A.1 \( (T = 550 \text{ K}) \): \( \rho = 7832 \text{ kg/ m}^3 \), \( k = 51.2 \) W/mK, \( c = 541 \text{ J/kg\cdot K} \), \( \alpha = 1.21 \times 10^{-5} \text{ m}^2/\text{s} \).

ANALYSIS: The Biot number is

\[
\text{Bi} = \frac{hr_o/2}{k} = \frac{100 \text{ W/m}^2\cdot\text{K}(0.05 \text{ m}/2)}{51.2 \text{ W/m}\cdot\text{K}} = 0.0488.
\]

Hence, the lumped capacitance method can be applied. From Equation 5.6,

\[
\frac{T - T_{\infty}}{T_i - T_{\infty}} = \exp \left[ -\frac{hA}{\rho cD} t \right] = \exp \left[ -\frac{4h}{\rho cD} t \right]
\]

\[
\ln \left( \frac{800 - 1200}{300 - 1200} \right) = -0.811 = -\frac{4 \times 100 \text{ W/m}^2\cdot\text{K}}{7832 \text{ kg/m}^3 \cdot (541 \text{ J/kg\cdot K}) \cdot 0.1 \text{ m}} t
\]

\[
t = 859 \text{ s}.
\]

COMMENTS: To check the validity of the foregoing result, use the one-term approximation to the series solution. From Equation 5.49c,

\[
\frac{T_o - T_{\infty}}{T_i - T_{\infty}} = \frac{-400}{-900} = 0.444 = C_1 \exp \left( -\frac{\zeta_1^2 F_0}{1} \right)
\]

For Bi = hr_o/k = 0.0976, Table 5.1 yields \( \zeta_1 = 0.436 \) and \( C_1 = 1.024 \). Hence

\[
-\left(0.436\right)^2 \left(1.2 \times 10^{-5} \text{ m}^2/\text{s}\right) \left(0.05 \text{ m}\right)^2 t = \ln \left(0.434\right) = -0.835
\]

\[
t = 915 \text{ s}.
\]

The results agree to within 6%. The lumped capacitance method underestimates the actual time, since the response at the centerline lags that at any other location in the shaft.
**PROBLEM 5.10**

**KNOWN:** Configuration, initial temperature and charging conditions of a thermal energy storage unit.

**FIND:** Time required to achieve 75% of maximum possible energy storage. Temperature of storage medium at this time.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional conduction, (2) Constant properties, (3) Negligible radiation exchange with surroundings.

**PROPERTIES:** Table A-1, Aluminum, pure \( T \approx 600K = 327^\circ C \):

\[
\begin{align*}
    k &= 231 \text{ W/m} \cdot \text{K} \\
    c &= 1033 \text{ J/kg} \cdot \text{K} \\
    \rho &= 2702 \text{ kg/m}^3
\end{align*}
\]

**ANALYSIS:** Recognizing the characteristic length is the half thickness, find

\[
\frac{hL}{2} = \frac{100 \text{ W/m}^2 \cdot \text{K} \times 0.025 \text{ m}}{231 \text{ W/m} \cdot \text{K}} = 0.011. 
\]

Hence, the lumped capacitance method may be used. From Eq. 5.8,

\[
Q = (\rho \nu c)\theta_i \left[ 1 - \exp\left(-t/\tau_t\right) \right] = -\Delta E_{st} 
\]

\[
-\Delta E_{st,max} = (\rho \nu c)\theta_i. 
\]

Dividing Eq. (1) by (2),

\[
\frac{\Delta E_{st}}{\Delta E_{st,max}} = 1 - \exp\left(-t/\tau_{th}\right) = 0.75. 
\]

Solving for \( \tau_{th} = \frac{\rho \nu c}{hA_s} = \frac{\rho Lc}{h} = \frac{2702 \text{ kg/m}^3 \times 0.025 \text{ m} \times 1033 \text{ J/kg} \cdot \text{K}}{100 \text{ W/m}^2 \cdot \text{K}} = 698 \text{ s} \)

Hence, the required time is

\[
-\exp\left(-t/698 \text{ s}\right) = -0.25 \quad \text{or} \quad t = 968 \text{ s}. 
\]

From Eq. 5.6,

\[
\frac{T - T_\infty}{T_i - T_\infty} = \exp\left(-t/\tau_{th}\right) \\
T_i - T_\infty = \exp\left(-t/\tau_{th}\right) \\
T = T_\infty + (T_i - T_\infty) \exp\left(-t/\tau_{th}\right) = 600^\circ C - \left(575^\circ C\right) \exp\left(-968/698\right)
\]

\[T = 456^\circ C.\]

**COMMENTS:** For the prescribed temperatures, the property temperature dependence is significant and some error is incurred by assuming constant properties. However, selecting properties at 600K was reasonable for this estimate.
**PROBLEM 5.11**

**KNOWN:** Diameter, density, specific heat and thermal conductivity of aluminum spheres used in packed bed thermal energy storage system. Convection coefficient and inlet gas temperature.

**FIND:** Time required for sphere to acquire 90% of maximum possible thermal energy and the corresponding center temperature. Potential advantage of using copper in lieu of aluminum.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat transfer to or from a sphere by radiation or conduction due to contact with other spheres, (2) Constant properties.

**ANALYSIS:** To determine whether a lumped capacitance analysis can be used, first compute $\frac{B_i = h\left(\rho \rho / 3\right) / k = 75 \text{ W/m}^2\cdot\text{K} / 2700 \text{ kg/m}^3 \times 0.075 \text{ m}}{150 \text{ W/m} \cdot \text{K} = 0.013 < 0.1}$. Hence, the lumped capacitance approximation may be made, and a uniform temperature may be assumed to exist in the sphere at any time. From Eq. 5.8a, achievement of 90% of the maximum possible thermal energy storage corresponds to

$$Q_{\text{max}} = \frac{\rho cV}{\theta_i} = 0.90 = 1 - \exp\left(-t / \tau_t\right)$$

where $\tau_t = \rho Vc / hA_s = \rho Dc / 6h = 2700 \text{ kg/m}^3 \times 0.075 \text{ m} \times 950 \text{ J/kg} \cdot \text{K} / 6 \times 75 \text{ W/m} \cdot \text{K} = 427 \text{s}$. Hence,

$$t = -\tau_t \ln (0.1) = 427 \times 2.30 = 984 \text{s}$$

From Eq. (5.6), the corresponding temperature at any location in the sphere is

$$T(984 \text{s}) = T_{g,i} + \left(T_i - T_{g,i}\right) \exp\left(-6ht / \rho Dc\right)$$

$$T(984 \text{s}) = 300\text{°C} - 275\text{°C} \exp\left(-6 \times 75 \text{ W/m}^2 \cdot \text{K} \times 984 \text{s} / 2700 \text{ kg/m}^3 \times 0.075 \text{ m} \times 950 \text{ J/kg} \cdot \text{K}\right)$$

$$T(984 \text{s}) = 272.5\text{°C}$$

Obtaining the density and specific heat of copper from Table A-1, we see that $(\rho c)_{\text{Cu}} = 8900 \text{ kg/m}^3 \times 400 \text{ J/kg} \cdot \text{K} = 3.56 \times 10^6 \text{ J/m}^3 \cdot \text{K} > (\rho c)_{\text{Al}} = 2.57 \times 10^6 \text{ J/m}^3 \cdot \text{K}$. Hence, for an equivalent sphere diameter, the copper can store approximately 38% more thermal energy than the aluminum.

**COMMENTS:** Before the packed bed becomes fully charged, the temperature of the gas decreases as it passes through the bed. Hence, the time required for a sphere to reach a prescribed state of thermal energy storage increases with increasing distance from the bed inlet.
PROBLEM 5.12

KNOWN: Wafer, initially at 100°C, is suddenly placed on a chuck with uniform and constant temperature, 23°C. Wafer temperature after 15 seconds is observed as 33°C.

FIND: (a) Contact resistance, $R_{tc}''$, between interface of wafer and chuck through which helium slowly flows, and (b) Whether $R_{tc}''$ will change if air, rather than helium, is the purge gas.

SCHEMATIC:

PROPERTIES: Wafer (silicon, typical values): $\rho = 2700$ kg/m$^3$, $c = 875$ J/kg-K, $k = 177$ W/m-K.

ASSUMPTIONS: (1) Wafer behaves as a space-wise isothermal object, (2) Negligible heat transfer from wafer top surface, (3) Chuck remains at uniform temperature, (4) Thermal resistance across the interface is due to conduction effects, not convective, (5) Constant properties.

ANALYSIS: (a) Perform an energy balance on the wafer as shown in the Schematic.

\[
\dot{E}_{in}'' - \dot{E}_{out}'' + \dot{E}_g = \dot{E}_{st}'' \tag{1}
\]

\[-q_{\text{cond}}'' = \dot{E}_{st}'' \tag{2}
\]

\[-\frac{T_w(t) - T_c}{R_{tc}''} = \rho_{wc} \frac{dT_w}{dt} \tag{3}
\]

Separate and integrate Eq. (3)

\[
-\int_0^t dt = \int_{T_w(0)}^{T_w(t)} \frac{dT_w}{T_w - T_c} \tag{4}
\]

\[
\frac{T_w(t) - T_c}{T_w(0) - T_c} = \exp \left[-\frac{t}{\rho_{wc}R_{tc}''} \right] \tag{5}
\]

Substituting numerical values for $T_w(15s) = 33°C$,

\[
\frac{(33 - 23)°C}{(100 - 23)°C} = \exp \left[\frac{15s}{2700\text{kg}/\text{m}^3 \times 0.758 \times 10^{-3} \text{m} \times 875\text{ J/kg-K} \times \text{X} \times R_{tc}''} \right] \tag{6}
\]

\[
R_{tc}'' = 0.0041\text{m}^2 \cdot \text{K/W} <\]

(b) $R_{tc}''$ will increase since $k_{\text{air}} < k_{\text{helium}}$. See Table A.4.

COMMENTS: Note that $\text{Bi} = R_{in}/R_{ext} = (w/k)/R_{tc}'' = 0.001$. Hence the spacewise isothermal assumption is reasonable.
PROBLEM 5.13

KNOWN: Inner diameter and wall thickness of a spherical, stainless steel vessel. Initial temperature, density, specific heat and heat generation rate of reactants in vessel. Convection conditions at outer surface of vessel.

FIND: (a) Temperature of reactants after one hour of reaction time, (b) Effect of convection coefficient on thermal response of reactants.

SCHEMATIC:

ASSUMPTIONS: (1) Temperature of well stirred reactants is uniform at any time and is equal to inner surface temperature of vessel \((T = T_{s,i})\), (2) Thermal capacitance of vessel may be neglected, (3) Negligible radiation exchange with surroundings, (4) Constant properties.

ANALYSIS: (a) Transient thermal conditions within the reactor may be determined from Eq. (5.25), which reduces to the following form for \(T_i - T_{\infty} = 0\).

\[
T = T_{\infty} + \left(\frac{b}{a}\right) \left[1 - \exp\left(-\frac{at}{a}\right)\right]
\]

where \(a = \frac{U\alpha}{\rho Vc}\) and \(b = \frac{\dot{q}}{\rho V c} = \frac{\dot{q}}{\rho c}\). From Eq. (3.19) the product of the overall heat transfer coefficient and the surface area is \(U\alpha = (R_{cond} + R_{conv})^{-1}\), where from Eqs. (3.36) and (3.9),

\[
R_{t,cond} = \frac{1}{2\pi k} \left(\frac{1}{D_i} - \frac{1}{D_o}\right) = \frac{1}{2\pi (17 \text{ W/m} \cdot \text{K})} \left(\frac{1}{1.0\text{ m}} - \frac{1}{1.1\text{ m}}\right) = 8.51 \times 10^{-4} \text{ K/W}
\]

\[
R_{t,conv} = \frac{1}{h\alpha_o} = \frac{1}{\left(\frac{6 \text{ W/m}^2 \cdot \text{K}}{\pi (1.1\text{ m})^2}\right)} = 0.0438 \text{ K/W}
\]

Hence, \(U\alpha = 24.4 \text{ W/K}\). It follows that, with \(V = \pi D_i^3 / 6\),

\[
a = \frac{U\alpha}{\rho V c} = \frac{6 (22.4 \text{ W/K})}{1100 \text{ kg/m}^3 \times \pi (1\text{ m})^3 2400 \text{ J/kg} \cdot \text{K}} = 1.620 \times 10^{-5} \text{ s}^{-1}
\]

\[
b = \frac{\dot{q}}{\rho c} = \frac{10^4 \text{ W/m}^3}{1100 \text{ kg/m}^3 \times 2400 \text{ J/kg} \cdot \text{K}} = 3.788 \times 10^{-3} \text{ K/s}
\]

With \((b/a) = 233.8^\circ\text{C and } t = 18,000\text{s},

\[
T = 25^\circ C + 233.8^\circ C \left[1 - \exp\left(-1.62 \times 10^{-5} \text{s}^{-1} \times 18,000\text{s}\right)\right] = 84.1^\circ C <
\]

Neglecting the thermal capacitance of the vessel wall, the heat rate by conduction through the wall is equal to the heat transfer by convection from the outer surface, and from the thermal circuit, we know that

Continued ….
PROBLEM 5.13 (Cont.)

\[
\frac{T - T_{s_0}}{T_{s_0} - T_\infty} = \frac{R_{t,\text{cond}}}{R_{t,\text{conv}}} = \frac{8.51 \times 10^{-4} \text{K/W}}{0.0438 \text{K/W}} = 0.0194
\]

\[
T_{s_0} = \frac{T + 0.0194T_\infty}{1.0194} = \frac{84.1^\circ \text{C} + 0.0194(25^\circ \text{C})}{1.0194} = 83.0^\circ \text{C}
\]

(b) Representative low and high values of \( h \) could correspond to 2 W/m\(^2\)-K and 100 W/m\(^2\)-K for free and forced convection, respectively. Calculations based on Eq. (5.25) yield the following temperature histories.

Forced convection is clearly an effective means of reducing the temperature of the reactants and accelerating the approach to steady-state conditions.

**COMMENTS:** The validity of neglecting thermal energy storage effects for the vessel may be assessed by contrasting its thermal capacitance with that of the reactants. Selecting values of \( \rho = 8000 \text{ kg/m}^3 \) and \( c = 475 \text{ J/kg K} \) for stainless steel from Table A-1, the thermal capacitance of the vessel is \( C_{t,v} = (\rho V)c_{sl} = 6.57 \times 10^5 \text{ J/K} \), where \( V = \left( \frac{\pi}{6} \right) \left( D_0^3 - D_1^3 \right) \). With \( C_{t,r} = (\rho Vc)_r = 2.64 \times 10^6 \text{ J/K} \) for the reactants, \( C_{t,r}/C_{t,v} = 4 \). Hence, the capacitance of the vessel is not negligible and should be considered in a more refined analysis of the problem.
PROBLEM 5.14

KNOWN: Volume, density and specific heat of chemical in a stirred reactor. Temperature and convection coefficient associated with saturated steam flowing through submerged coil. Tube diameter and outer convection coefficient of coil. Initial and final temperatures of chemical and time span of heating process.

FIND: Required length of submerged tubing. Minimum allowable steam flowrate.

SCHEMATIC:

ASSUMPTIONS: (1) Constant properties, (2) Negligible heat loss from vessel to surroundings, (3) Chemical is isothermal, (4) Negligible work due to stirring, (5) Negligible thermal energy generation (or absorption) due to chemical reactions associated with the batch process, (6) Negligible tube wall conduction resistance, (7) Negligible kinetic energy, potential energy, and flow work changes for steam.

ANALYSIS: Heating of the chemical can be treated as a transient, lumped capacitance problem, wherein heat transfer from the coil is balanced by the increase in thermal energy of the chemical. Hence, conservation of energy yields

\[
\frac{dU}{dt} = \rho V c \frac{dT}{dt} = UA_s (T_h - T)
\]

Integrating,

\[
\int_{T_i}^{T_s} \frac{dT}{T_h - T} = \frac{UA_s}{\rho V c} t
\]

\[
\ln \left( \frac{T_h - T}{T_h - T_i} \right) = \frac{UA_s t}{\rho V c}
\]

\[
A_s = -\frac{\rho V c \ln \left( \frac{T_h - T}{T_h - T_i} \right)}{Ut}
\]

\[
U = \left( h_i^{-1} + h_o^{-1} \right)^{-1} = \left[ (1/10,000) + (1/2000) \right]^{-1} \text{ W/m}^2 \cdot \text{K}
\]

\[
U = 1670 \text{ W/m}^2 \cdot \text{K}
\]

\[
A_s = -\frac{\left( 1200 \text{ kg/m}^3 \right) \left( 2.25 \text{ m}^3 \right) \left( 2200 \text{ J/kg} \cdot \text{K} \right)}{\left( 1670 \text{ W/m}^2 \cdot \text{K} \right) \left( 3600 \text{ s} \right)} \ln \frac{500 - 450}{500 - 300} = 1.37 \text{ m}^2
\]

\[
L = \frac{A_s}{\pi D} = \frac{1.37 \text{ m}^2}{\pi \left( 0.02 \text{ m} \right)} = 21.8 \text{ m}
\]

COMMENTS: Eq. (1) could also have been obtained by adapting Eq. (5.5) to the conditions of this problem, with \( T_\infty \) and \( h \) replaced by \( T_h \) and \( U \), respectively.
**PROBLEM 5.15**

**KNOWN:** Thickness and properties of furnace wall. Thermal resistance of film on surface of wall exposed to furnace gases. Initial wall temperature.

**FIND:** (a) Time required for surface of wall to reach a prescribed temperature, (b) Corresponding value of film surface temperature.

**SCHEMATIC:**

![Schematic](image)

**ASSUMPTIONS:** (1) Constant properties, (2) Negligible film thermal capacitance, (3) Negligible radiation.

**PROPERTIES:** Carbon steel (given): \( \rho = 7850 \text{ kg/m}^3 \), \( c = 430 \text{ J/kg} \cdot \text{K} \), \( k = 60 \text{ W/m} \cdot \text{K} \).

**ANALYSIS:** The overall coefficient for heat transfer from the surface of the steel to the gas is

\[
U = (R_{tot}^{-1})^{-1} = \left( \frac{1}{h} + R_f^{-1} \right)^{-1} = \left( \frac{1}{25 \text{ W/m}^2 \cdot \text{K}} + 10^{-2} \text{ m}^2 \cdot \text{K/W} \right)^{-1} = 20 \text{ W/m}^2 \cdot \text{K}.
\]

Hence,

\[
Bi = \frac{UL}{k} = \frac{20 \text{ W/m}^2 \cdot \text{K} \times 0.01 \text{ m}}{60 \text{ W/m} \cdot \text{K}} = 0.0033
\]

and the lumped capacitance method can be used.

(a) It follows that

\[
\frac{T - T_\infty}{T_i - T_\infty} = \exp \left( -t/\tau_t \right) = \exp \left( -t/RC \right) = \exp \left( -Ut/\rho Lc \right)
\]

\[
t = \frac{\rho Lc}{U} \ln \frac{T - T_\infty}{T_i - T_\infty} = -\frac{7850 \text{ kg/m}^3 \times 0.01 \text{ m} \times 430 \text{ J/kg} \cdot \text{K}}{20 \text{ W/m}^2 \cdot \text{K}} \ln \frac{1200 - 1300}{300 - 1300}
\]

\[
t = 3886 \text{s} = 1.08 \text{h}.
\]

(b) Performing an energy balance at the outer surface \((s,o)\),

\[
h \left( T_\infty - T_{s,o} \right) = \left( T_{s,o} - T_{s,i} \right) / R_f
\]

\[
T_{s,o} = \frac{hT_\infty + T_{s,i}}{h + \left( 1 / R_f \right)} = \frac{25 \text{ W/m}^2 \cdot \text{K} \times 1300 \text{ K} + 1200 \text{ K} / 10^{-2} \text{ m}^2 \cdot \text{K/W}}{(25 + 100) \text{ W/m}^2 \cdot \text{K}}
\]

\[
T_{s,o} = 1220 \text{ K}.
\]

**COMMENTS:** The film increases \( \tau_t \) by increasing \( R_t \) but not \( C_t \).
**PROBLEM 5.16**

**KNOWN:** Thickness and properties of strip steel heated in an annealing process. Furnace operating conditions.

**FIND:** (a) Time required to heat the strip from 300 to 600°C. Required furnace length for prescribed strip velocity \( V = 0.5 \text{ m/s} \), (b) Effect of wall temperature on strip speed, temperature history, and radiation coefficient.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties, (2) Negligible temperature gradients in transverse direction across strip, (c) Negligible effect of strip conduction in longitudinal direction.

**PROPERTIES:** Steel: \( \rho = 7900 \text{ kg/m}^3 \), \( c_p = 640 \text{ J/kg} \cdot \text{K} \), \( k = 30 \text{ W/m} \cdot \text{K} \), \( \varepsilon = 0.7 \).

**ANALYSIS:** (a) Considering a fixed (control) mass of the moving strip, its temperature variation with time may be obtained from an energy balance which equates the change in energy storage to heat transfer by convection and radiation. If the surface area associated with one side of the control mass is designated as \( A_s \), \( A_{s,c} = A_{s,r} = 2A_s \) and \( V = \delta A_s \) in Equation 5.15, which reduces to

\[
\frac{dT}{dt} = -2 \left[ h(T - T_\infty) + \varepsilon \sigma \left( T^4 - T_{\text{sur}}^4 \right) \right]
\]

or, introducing the radiation coefficient from Equations 1.8 and 1.9 and integrating,

\[
T_f - T_i = -\frac{1}{\rho c \delta/2} \int_0^t \left[ h(T - T_\infty) + h_r(T - T_{\text{sur}}) \right] dt
\]

Using the IHT *Lumped Capacitance Model* to integrate numerically with \( T_i = 573 \text{ K} \), we find that \( T_f = 873 \text{ K} \) corresponds to

\( t_f \approx 209s \)

in which case, the required furnace length is

\( L = Vt_f = 0.5 \text{ m/s} \times 209s \approx 105 \text{ m} \)

(b) For \( T_w = 1123 \text{ K} \) and 1273 K, the numerical integration yields \( t_f \approx 102s \) and 62s respectively. Hence, for \( L = 105 \text{ m} \), \( V = L/t_f \) yields

\( V(T_w = 1123 \text{ K}) = 1.03 \text{ m/s} \)

\( V(T_w = 1273 \text{ K}) = 1.69 \text{ m/s} \)

Continued...
which correspond to increased process rates of 106% and 238%, respectively. Clearly, productivity can be enhanced by increasing the furnace environmental temperature, albeit at the expense of increasing energy utilization and operating costs.

If the annealing process extends from 25°C (298 K) to 600°C (873 K), numerical integration yields the following results for the prescribed furnace temperatures.

As expected, the heating rate and time, respectively, increase and decrease significantly with increasing \( T_w \). Although the radiation heat transfer rate decreases with increasing time, the coefficient \( h_r \) increases with \( t \) as the strip temperature approaches \( T_w \).

**COMMENTS:** To check the validity of the lumped capacitance approach, we calculate the Biot number based on a maximum cumulative coefficient of \((h + h_r) = 300 \text{ W/m}^{2}\cdot\text{K}\). It follows that \( \text{Bi} = (h + h_r)\delta/k = 0.06 \) and the assumption is valid.
**PROBLEM 5.17**

**KNOWN:** Diameter, resistance and current flow for a wire. Convection coefficient and temperature of surrounding oil.

**FIND:** Steady-state temperature of the wire. Time for the wire temperature to come within 1°C of its steady-state value.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Constant properties, (2) Wire temperature is independent of x.

**PROPERTIES:** Wire (given): \( \rho = 8000 \text{ kg/m}^3 \), \( c_p = 500 \text{ J/kg} \cdot \text{K} \), \( k = 20 \text{ W/m} \cdot \text{K} \), \( R'_e = 0.01 \Omega / \text{m} \).

**ANALYSIS:** Since

\[
\text{Bi} = \frac{h \left( \frac{r_0}{2} \right)}{k} = \frac{500 \text{ W/m}^2 \cdot \text{K}}{20 \text{ W/m} \cdot \text{K}} \left( 2.5 \times 10^{-4} \text{ m} \right) = 0.006 < 0.1
\]

the lumped capacitance method can be used. The problem has been analyzed in Example 1.3, and without radiation the steady-state temperature is given by

\[
\pi \frac{Dh}{\rho} (T - T_\infty) = I^2 R'_e.
\]

Hence

\[
T = T_\infty + \frac{I^2 R'_e}{\pi Dh} = 25°C + \frac{(100A)^2 0.01\Omega / \text{m}}{\pi (0.001 \text{ m}) 500 \text{ W/m}^2 \cdot \text{K}} = 88.7°C.
\]

With no radiation, the transient thermal response of the wire is governed by the expression (Example 1.3)

\[
\frac{dT}{dt} = \frac{I^2 R'_e}{\rho c_p \left( \pi D^2 / 4 \right)} - \frac{4h}{\rho c_p D} (T - T_\infty).
\]

With \( T = T_i = 25°C \) at \( t = 0 \), the solution is

\[
\frac{T - T_\infty - \left( \frac{I^2 R'_e}{\pi Dh} / \right)}{T_1 - T_\infty - \left( \frac{I^2 R'_e}{\pi Dh} \right)} = \exp \left\{ -\frac{4h}{\rho c_p D} t \right\}.
\]

Substituting numerical values, find

\[
\frac{87.7 - 25 - 63.7}{25 - 25 - 63.7} = \exp \left\{ -\frac{4 \times 500 \text{ W/m}^2 \cdot \text{K}}{8000 \text{ kg/m}^3 \times 500 \text{ J/kg} \cdot \text{K} \times 0.001 \text{ m}} t \right\}
\]

\( t = 8.31 \text{s}. \)

**COMMENTS:** The time to reach steady state increases with increasing \( \rho \), \( c_p \) and D and with decreasing h.
PROBLEM 5.18

KNOWN: Electrical heater attached to backside of plate while front is exposed to a convection process \( (T_\infty, h) \); initially plate is at uniform temperature \( T_\infty \) before heater power is switched on.

FIND: (a) Expression for temperature of plate as a function of time assuming plate is spacewise isothermal, (b) Approximate time to reach steady-state and \( T(\infty) \) for prescribed \( T_\infty \), \( h \) and \( q_0^\prime \) when wall material is pure copper, (c) Effect of \( h \) on thermal response.

SCHEMATIC:

\[ q_0^\prime = 5000 \text{ W/m}^2 \]

Heater

\[ T_\infty = 27 \degree \text{C} \]

\[ h = 50, 100, 200 \text{ W/m}^2\cdot\text{K} \]

Copper, pure

\[ T_i = 27 \degree \text{C} \]

\[ L = 12 \text{ mm} \]

\[ q_0^\prime \rightarrow q_0^\prime_{\text{conv}} = h(T-T_\infty) \]

ASSUMPTIONS: (1) Plate behaves as lumped capacitance, (2) Negligible loss out backside of heater, (3) Negligible radiation, (4) Constant properties.

PROPERTIES: Table A-1, Copper, pure (350 K): \( k = 397 \text{ W/m}\cdot\text{K}, c_p = 385 \text{ J/kg}\cdot\text{K}, \rho = 8933 \text{ kg/m}^3 \).

ANALYSIS: (a) Following the analysis of Section 5.3, the energy conservation requirement for the system is \( \dot{E}_\text{in} - \dot{E}_\text{out} = \dot{E}_\text{st} \) or \( q_0^\prime - h(T-T_\infty) = \rho L c_p \text{ d}T/\text{d}t \). Rearranging, and with \( R_t^\prime = 1/h \) and \( C_t^\prime = \rho L c_p \),

\[
T - T_\infty - q_0^\prime/h = -R_t^\prime \cdot C_t^\prime \text{ d}T/\text{d}t \tag{1}
\]

Defining \( \theta(t) = T - T_\infty - q_0^\prime/h \) with \( d\theta = dT \), the differential equation is

\[
\theta = -R_t^\prime C_t^\prime \frac{d\theta}{dt}. \tag{2}
\]

Separating variables and integrating,

\[
\int_{\theta_i}^{\theta} \frac{d\theta}{\theta} = -\int_{0}^{t} \frac{dt}{R_t^\prime C_t^\prime}
\]

it follows that

\[
\frac{\theta}{\theta_i} = \exp\left(-\frac{t}{R_t^\prime C_t^\prime}\right) \tag{3}\]

where \( \theta_i = \theta(0) = T_i - T_\infty - (q_0^\prime/h) \tag{4} \)

(b) For \( h = 50 \text{ W/m}^2\cdot\text{K} \), the steady-state temperature can be determined from Eq. (3) with \( t \to \infty \); that is,

\[ \theta(\infty) = 0 = T(\infty) - T_\infty - q_0^\prime/h \quad \text{or} \quad T(\infty) = T_\infty + q_0^\prime/h, \]

giving \( T(\infty) = 27\degree \text{C} + 5000 \text{ W/m}^2 \div 50 \text{ W/m}^2\cdot\text{K} = 127\degree \text{C} \). To estimate the time to reach steady-state, first determine the thermal constant of the system,

\[
\tau_t = R_t^\prime C_t^\prime = \left(\frac{1}{h}\right)(\rho c_p L) = \left(\frac{1}{50 \text{ W/m}^2\cdot\text{K}}\right)(8933 \text{ kg/m}^3 \times 385 \text{ J/kg}\cdot\text{K} \times 12 \times 10^{-3} \text{ m}) = 825 \text{s}
\]

Continued...
PROBLEM 5.18 (Cont.)

When \( t = 3\tau = 3 \times 25s = 2475s \), Eqs. (3) and (4) yield

\[
\theta (3\tau) = T(3\tau) - 27^\circ C - \frac{5000 \text{ W/m}^2}{50 \text{ W/m}^2 \cdot \text{K}} = e^{-3} \left[ 27^\circ C - 27^\circ C - \frac{5000 \text{ W/m}^2}{50 \text{ W/m}^2 \cdot \text{K}} \right]
\]

\[\frac{T(3\tau)}{G} = 122^\circ C\]

(c) As shown by the following graphical results, which were generated using the IHT Lumped Capacitance Model, the steady-state temperature and the time to reach steady-state both decrease with increasing \( h \).

![Graph showing temperature vs. time for different values of h](image)

**COMMENTS:** Note that, even for \( h = 200 \text{ W/m}^2 \cdot \text{K} \), \( Bi = hL/k \ll 0.1 \) and assumption (1) is reasonable.
PROBLEM 5.19

KNOWN: Electronic device on aluminum, finned heat sink modeled as spatially isothermal object with internal generation and convection from its surface.

FIND: (a) Temperature response after device is energized, (b) Temperature rise for prescribed conditions after 5 min.

SCHEMATIC:

ASSUMPTIONS: (1) Spatially isothermal object, (2) Object is primarily aluminum, (3) Initially, object is in equilibrium with surroundings at $T_\infty$.

PROPERTIES: Table A-1, Aluminum, pure $\left(T = (20 + 100)^\circ C/2 = 333 K\right)$: $c = 918 \text{ J/kg} \cdot \text{K}$.

ANALYSIS: (a) Following the general analysis of Section 5.3, apply the conservation of energy requirement to the object,

$$\dot{E}_{\text{in}} + \dot{E}_g - \dot{E}_{\text{out}} = \dot{E}_{\text{st}} \quad \dot{E}_g - \hbar A_s (T - T_\infty) = Mc \frac{dT}{dt} \quad (1)$$

where $T = T(t)$. Consider now steady-state conditions, in which case the storage term of Eq. (1) is zero. The temperature of the object will be $T(\infty)$ such that

$$\dot{E}_g = \hbar A_s (T(\infty) - T_\infty) \quad (2)$$

Substituting for $\dot{E}_g$ using Eq. (2) into Eq. (1), the differential equation is

$$\left[T(\infty) - T_\infty\right] - \left[T - T_\infty\right] = \frac{Mc}{\hbar A_s} \frac{dT}{dt} \quad \text{or} \quad \theta = -\frac{Mc}{\hbar A_s} \frac{d\theta}{dt} \quad (3,4)$$

with $\theta = T - T(\infty)$ and noting that $d\theta = dT$. Identifying $R_t = 1/\hbar A_s$ and $C_t = Mc$, the differential equation is integrated with proper limits,

$$\frac{1}{R_tC_t} \int_0^t dt = -\int_{\theta_i}^{\theta} \frac{d\theta}{\theta} \quad \text{or} \quad \frac{\theta}{\theta_i} = \exp\left[-\frac{t}{R_tC_t}\right] \quad (5)$$

where $\theta_i = \theta(0) = T_i - T(\infty)$ and $T_i$ is the initial temperature of the object.

(b) Using the information about steady-state conditions and Eq. (2), find first the thermal resistance and capacitance of the system,

$$R_t = \frac{1}{\hbar A_s} = \frac{T(\infty) - T_\infty}{\dot{E}_g} = \frac{(100 - 20)}{60 \text{ W}} = 1.33 \text{ K/W} \quad C_t = Mc = 0.31 \text{ kg} \times 918 \text{ J/kg} \cdot \text{K} = 285 \text{ J/K}.$$

Using Eq. (5), the temperature of the system after 5 minutes is

$$\theta(5 \text{ min}) = \frac{T(5 \text{ min}) - T(\infty)}{T_i - T(\infty)} = \frac{T(5 \text{ min}) - 100^\circ C}{(20 - 100)^\circ C} = \exp\left[-\frac{5 \times 60s}{1.33 \text{ K/W} \times 285 \text{ J/K}}\right] = 0.453$$

$$T(5 \text{ min}) = 100^\circ C + (20 - 100)^\circ C \times 0.453 = 63.8^\circ C$$

COMMENTS: Eq. 5.24 may be used directly for Part (b) with $a = \hbar A_s/Mc$ and $b = \dot{E}_g / Mc$. 

<
PROBLEM 5.20

KNOWN:  Spherical coal pellet at 25°C is heated by radiation while flowing through a furnace maintained at 1000°C.

FIND:  Length of tube required to heat pellet to 600°C.

SCHEMATIC:

ASSUMPTIONS:  (1) Pellet is suspended in air flow and subjected to only radiative exchange with furnace, (2) Pellet is small compared to furnace surface area, (3) Coal pellet has emissivity, $\varepsilon = 1$.

PROPERTIES:  Table A-3, Coal \( T = (600 + 25) \frac{°C}{2} = 585K \), however, only 300K data available: \( \rho = 1350 \frac{kg}{m^3}, c_p = 1260 \frac{J}{kg \cdot K}, k = 0.26 \frac{W}{m \cdot K} \).

ANALYSIS:  Considering the pellet as spatially isothermal, use the lumped capacitance method of Section 5.3 to find the time required to heat the pellet from \( T_o = 25°C \) to \( T_L = 600°C \). From an energy balance on the pellet \( \dot{E}_{in} = \dot{E}_{st} \) where

\[
\dot{E}_{in} = q_{rad} = \sigma A_s \left( T_{sur}^4 - T_s^4 \right) \quad \dot{E}_{st} = \rho \frac{d}{dt} \frac{c}{T}\frac{dT}{dt}
\]

giving

\[
A_s \sigma \left( T_{sur}^4 - T_s^4 \right) = \rho \frac{d}{dt} \frac{c}{T}\frac{dT}{dt}.
\]

Separating variables and integrating with limits shown, the temperature-time relation becomes

\[
\frac{A_s \sigma}{\rho \frac{d}{dt} \frac{c}{T}} \int_0^t dt = \int_{T_o}^{T_L} \frac{dT}{T_{sur}^4 - T^4}.
\]

The integrals are evaluated in Eq. 5.18 giving

\[
t = \frac{\rho \frac{c}{T}}{4 A_s \sigma T_{sur}^3} \left\{ \ln \left[ \frac{T_{sur} + T}{T_{sur} - T} \right] - \ln \left[ \frac{T_{sur} + T_i}{T_{sur} - T_i} \right] + 2 \left\{ \tan^{-1} \left[ \frac{T}{T_{sur}} \right] - \tan^{-1} \left[ \frac{T_i}{T_{sur}} \right] \right\} \right\}.
\]

Recognizing that \( A_s = \pi D^2 \) and \( \frac{d}{A_s} = \pi D^3 / 6 \) or \( A_s / \frac{d}{A_s} = 6/D \) and substituting values,

\[
t = \frac{1350 \frac{kg}{m^3} (0.001 m) 1260 \frac{J}{kg \cdot K}}{24 \times 5.67 \times 10^{-8} \frac{W}{m^2 \cdot K} D^4 (1273 K)^3} \left\{ \ln \left[ \frac{1273 + 873}{1273 - 873} \right] - \ln \left[ \frac{1273 + 298}{1273 - 298} \right] + 2 \left\{ \tan^{-1} \left( \frac{873}{1273} \right) - \tan^{-1} \left( \frac{298}{1273} \right) \right\} \right\} = 1.18s.
\]

Hence, \( L = V \cdot t = 3 m/s \times 1.18s = 3.54m. \)

The validity of the lumped capacitance method requires \( Bi = h (\frac{d}{A_s}) k < 0.1 \). Using Eq. (1.9) for \( h = h_f \) and \( \frac{d}{A_s} = D/6 \), find that when \( T = 600°C \), \( Bi = 0.19 \); but when \( T = 25°C \), \( Bi = 0.10 \). At early times, when the pellet is cooler, the assumption is reasonable but becomes less appropriate as the pellet heats.
PROBLEM 5.21

KNOWN: Metal sphere, initially at a uniform temperature $T_i$, is suddenly removed from a furnace and suspended in a large room and subjected to a convection process ($T_\infty$, $h$) and to radiation exchange with surroundings, $T_{sur}$.

FIND: (a) Time it takes for sphere to cool to some temperature $T$, neglecting radiation exchange, (b) Time it takes for sphere to cool to some temperature $t$, neglecting convection, (c) Procedure to obtain time required if both convection and radiation are considered, (d) Time to cool an anodized aluminum sphere to 400 K using results of Parts (a), (b) and (c).

SCHEMATIC:

ASSUMPTIONS: (1) Sphere is spacewise isothermal, (2) Constant properties, (3) Constant heat transfer convection coefficient, (4) Sphere is small compared to surroundings.

PROPERTIES: Table A-1, Aluminum, pure ($\bar{T} = [800 + 400]/2 = 600$ K): $\rho = 2702$ kg/m$^3$, $c = 1033$ J/kg·K, $k = 231$ W/m·K, $\alpha = k/\rho c = 8.276 \times 10^{-5}$ m$^2$/s; Aluminum, anodized finish: $\varepsilon = 0.75$, polished surface: $\varepsilon = 0.1$.

ANALYSIS: (a) Neglecting radiation, the time to cool is predicted by Eq. 5.5,

$$t = \frac{\rho Vc}{hA_s} \ln \frac{\theta_i}{\theta} = \frac{\rho Dc}{6h} \ln \frac{T_i - T_\infty}{T - T_\infty}$$  \hspace{1cm} (1) <

where $V/A_s = (\pi D^3)/((\pi D^2)) = D/6$ for the sphere.

(b) Neglecting convection, the time to cool is predicted by Eq. 5.18,

$$t = \frac{\rho Dc}{24\varepsilon\sigma T_{sur}^3} \left\{ \ln \frac{T_{sur} + T}{|T_{sur} + T|} - \ln \frac{T_{sur} + T_i}{|T_{sur} + T_i|} + 2 \left[ \tan^{-1} \left( \frac{T}{T_{sur}} \right) - \tan^{-1} \left( \frac{T_i}{T_{sur}} \right) \right] \right\}$$  \hspace{1cm} (2) <

where $V/A_{s,r} = D/6$ for the sphere.

(c) If convection and radiation exchange are considered, the energy balance requirement results in Eq. 5.15 (with $q_{s}^* = \dot{E}_g = 0$). Hence

$$\frac{dT}{dt} = \frac{6}{\rho Dc} \left[ h(T - T_\infty) + \varepsilon\sigma \left( T^4 - T_{sur}^4 \right) \right]$$  \hspace{1cm} (3) <

where $A_{s(c,r)} = \pi D^2$ and $V/A_{s(c,r)} = D/6$. This relation must be solved numerically in order to evaluate the time-to-cool.

(d) For the aluminum (pure) sphere with an anodized finish and the prescribed conditions, the times to cool from $T_i = 800$ K to $T = 400$ K are:

Continued...
PROBLEM 5.21 (Cont.)

**Convection only, Eq. (1)**

\[ t = \frac{2702 \text{ kg/m}^3 \times 0.050 \text{ m} \times 1033 \text{ J/kg} \cdot \text{K}}{6 \times 10 \text{ W/m}^2 \cdot \text{K}} \ln \frac{800 - 300}{400 - 300} = 3743 \text{s} = 1.04 \text{h} \]

**Radiation only, Eq. (2)**

\[
\begin{align*}
t &= \frac{2702 \text{ kg/m}^3 \times 0.050 \text{ m} \times 1033 \text{ J/kg} \cdot \text{K}}{24 \times 0.75 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (300 \text{ K})^3} \times \left[ \ln \frac{400 + 300}{400 - 300} - \ln \frac{800 + 300}{800 - 300} \right] + \\
&\quad 2 \left[ \tan \left( \frac{400}{300} \right) - \tan \left( \frac{800}{300} \right) \right] \\
&= 5.065 \times 10^3 \left\{ 1.946 - 0.789 + 2 \left( 0.927 - 1.212 \right) \right\} = 2973 \text{s} = 0.826 \text{h}
\end{align*}
\]

**Radiation and convection, Eq. (3)**

Using the IHT **Lumped Capacitance Model**, numerical integration yields

\[ t = 1600 \text{s} = 0.444 \text{h} \]

In this case, heat loss by radiation exerts the stronger influence, although the effects of convection are by no means negligible. However, if the surface is polished (\( \varepsilon = 0.1 \)), convection clearly dominates. For each surface finish and the three cases, the temperature histories are as follows.

**COMMENTS:**

1. A summary of the analyses shows the relative importance of the various modes of heat loss:

<table>
<thead>
<tr>
<th>Active Modes</th>
<th>Time required to cool to 400 K (h)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>( \varepsilon = 0.75 )</td>
</tr>
<tr>
<td>Convection only</td>
<td>1.040</td>
</tr>
<tr>
<td>Radiation only</td>
<td>0.827</td>
</tr>
<tr>
<td>Both modes</td>
<td>0.444</td>
</tr>
</tbody>
</table>

2. Note that the spacewise isothermal assumption is justified since Be << 0.1. For the convection-only process,

\[ \text{Bi} = \frac{h(t_o/3)/k = 10 \text{ W/m}^2 \cdot \text{K} (0.025 \text{ m/3})/231 \text{ W/m-K} = 3.6 \times 10^{-4}} \]
PROBLEM 5.22

KNOWN: Droplet properties, diameter, velocity and initial and final temperatures.

FIND: Travel distance and rejected thermal energy.

SCHEMATIC:

ASSUMPTIONS: (1) Constant properties, (2) Negligible radiation from space.

PROPERTIES: Droplet (given): \( \rho = 885 \text{ kg/m}^3 \), \( c = 1900 \text{ J/kg} \cdot \text{K} \), \( k = 0.145 \text{ W/m} \cdot \text{K} \), \( \varepsilon = 0.95 \).

ANALYSIS: To assess the suitability of applying the lumped capacitance method, use Equation 1.9 to obtain the maximum radiation coefficient, which corresponds to \( T = T_i \).

\[ h_r = \varepsilon \sigma T_i^3 = 0.95 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K} \cdot K^4 (500 \text{ K})^3 = 6.73 \text{ W/m}^2 \cdot \text{K}. \]

Hence

\[ \text{Bi}_r = \frac{h_r \left( \frac{r_o}{3} \right)}{k} = \frac{(6.73 \text{ W/m}^2 \cdot \text{K}) \left(0.25 \times 10^{-3} \text{ m/3} \right)}{0.145 \text{ W/m} \cdot \text{K}} = 0.0039 \]

and the lumped capacitance method can be used. From Equation 5.19,

\[ t = \frac{L}{V} = \frac{\rho c \left( \pi D^3 / 6 \right)}{3 \varepsilon \left( \pi D^2 \right) \sigma} \left( \frac{1}{T_f^3} - \frac{1}{T_i^3} \right) \]

\[ L = \frac{(0.1 \text{ m/s})885 \text{ kg/m}^3 \left(1900 \text{ J/kg} \cdot \text{K} \right)0.5 \times 10^{-3} \text{ m}}{18 \times 0.95 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4} \left( \frac{1}{300^3} - \frac{1}{500^3} \right) \frac{1}{K^3} \]

\[ L = 2.52 \text{ m}. \]

The amount of energy rejected by each droplet is equal to the change in its internal energy.

\[ E_i - E_f = \rho V c (T_i - T_f) = 885 \text{ kg/m}^3 \pi \left( \frac{5 \times 10^{-4} \text{ m}}{6} \right)^3 1900 \text{ J/kg} \cdot \text{K} (200 \text{ K}) \]

\[ E_i - E_f = 0.022 \text{ J}. \]

COMMENTS: Because some of the radiation emitted by a droplet will be intercepted by other droplets in the stream, the foregoing analysis overestimates the amount of heat dissipated by radiation to space.
PROBLEM 5.23

KNOWN: Initial and final temperatures of a niobium sphere. Diameter and properties of the sphere. Temperature of surroundings and/or gas flow, and convection coefficient associated with the flow.

FIND: (a) Time required to cool the sphere exclusively by radiation, (b) Time required to cool the sphere exclusively by convection, (c) Combined effects of radiation and convection.

SCHEMATIC:

ASSUMPTIONS: (1) Uniform temperature at any time, (2) Negligible effect of holding mechanism on heat transfer, (3) Constant properties, (4) Radiation exchange is between a small surface and large surroundings.

ANALYSIS: (a) If cooling is exclusively by radiation, the required time is determined from Eq. (5.18). With $V = \pi D^3/6$, $A_{s,r} = \pi D^2$, and $\varepsilon = 0.1$,

$$t = \frac{8600 \text{ kg/m}^3 (290 \text{ J/kg} \cdot \text{K}) 0.01 \text{m}}{24(0.1)5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (298 \text{K})^3} \left\{ \ln \left[ \frac{298+573}{298-573} \right] - \ln \left[ \frac{298+1173}{298-1173} \right] \right\}$$

$$+ 2 \left[ \tan^{-1} \left( \frac{573}{298} \right) - \tan^{-1} \left( \frac{1173}{298} \right) \right]$$

$$t = 6926 \text{s} \left\{ 1.153 - 0.519 + 2(1.091 - 1.322) \right\} = 1190 \text{s} \quad (\varepsilon = 0.1)$$

If $\varepsilon = 0.6$, cooling is six times faster, in which case,

$$t = 199 \text{s} \quad (\varepsilon = 0.6)$$

(b) If cooling is exclusively by convection, Eq. (5.5) yields

$$t = \rho c D \left\{ \ln \left( \frac{T_i - T_\infty}{T_f - T_\infty} \right) \right\} = \frac{8600 \text{ kg/m}^3 (290 \text{ J/kg} \cdot \text{K}) 0.01 \text{m}}{1200 \text{ W/m}^2 \cdot \text{K}} \left\{ \ln \left( \frac{875}{275} \right) \right\}$$

$$t = 24.1 \text{s}$$

(c) With both radiation and convection, the temperature history may be obtained from Eq. (5.15).

$$\rho \left( \pi D^3 / 6 \right) c \frac{dT}{dt} = -\pi D^2 \left[ h \left( T - T_\infty \right) + \varepsilon \sigma \left( T^4 - T_{\text{sur}}^4 \right) \right]$$

Integrating numerically from $T_i = 1173 \text{K}$ at $t = 0$ to $T = 573 \text{K}$, we obtain

$$t = 21.0 \text{s}$$

Continued …..
PROBLEM 5.23 (Cont.)

Cooling times corresponding to representative changes in $\varepsilon$ and h are tabulated as follows

<table>
<thead>
<tr>
<th>h (W/m$^2$ K)</th>
<th>200</th>
<th>200</th>
<th>20</th>
<th>500</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\varepsilon$</td>
<td>0.6</td>
<td>1.0</td>
<td>0.6</td>
<td>0.6</td>
</tr>
<tr>
<td>t (s)</td>
<td>21.0</td>
<td>19.4</td>
<td>102.8</td>
<td>9.1</td>
</tr>
</tbody>
</table>

For values of h representative of forced convection, the influence of radiation is secondary, even for a maximum possible emissivity of 1.0. Hence, to accelerate cooling, it is necessary to increase h. However, if cooling is by natural convection, radiation is significant. For a representative natural convection coefficient of $h = 20 \text{ W/m}^2 \cdot \text{K}$, the radiation flux exceeds the convection flux at the surface of the sphere during early to intermediate stages of the transient.

**COMMENTS:**
1. Even for $h$ as large as 500 W/m$^2$-K, $Bi = h (D/6)/k = 500 \text{ W/m}^2 \cdot \text{K} (0.01\text{m}/6)/63 \text{ W/m-K} = 0.013 < 0.1$ and the lumped capacitance model is appropriate.
2. The largest value of $h_f$ corresponds to $T_i = 1173 \text{ K}$, and for $\varepsilon = 0.6$ Eq. (1.9) yields $h_f = 0.6 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (1173 + 298)\text{K} (1173^2 + 298^2)\text{K}^2 = 73.3 \text{ W/m}^2 \cdot \text{K}$. 
PROBLEM 5.24

KNOWN: Diameter and thermophysical properties of alumina particles. Convection conditions associated with a two-step heating process.

FIND: (a) Time-in-flight \((t_{i-f})\) required for complete melting, (b) Validity of assuming negligible radiation.

SCHEMATIC: 

ASSUMPTIONS: (1) Particle behaves as a lumped capacitance, (2) Negligible radiation, (3) Constant properties.

ANALYSIS: (a) The two-step process involves (i) the time \(t_1\) to heat the particle to its melting point and (ii) the time \(t_2\) required to achieve complete melting. Hence, \(t_{i-f} = t_1 + t_2\), where from Eq. (5.5),

\[
t_1 = \frac{\rho_p V_c p}{h A_s} \ln \left( \frac{\theta_i}{\theta} \right) = \frac{\rho_p D_p c_p}{6 h} \ln \left( \frac{T_i - T_\infty}{T_{mp} - T_\infty} \right)
\]

\[
t_1 = \frac{3970 \text{ kg/m}^3 \left( 50 \times 10^{-6} \text{ m} \right) 1560 \text{ J/kg} \cdot \text{K}}{6 \left( 30,000 \text{ W/m}^2 \cdot \text{K} \right)} \ln \left( \frac{300 - 10,000}{2318 - 10,000} \right) = 4 \times 10^{-4} \text{s}
\]

Performing an energy balance for the second step, we obtain

\[
\int_{t_1}^{t_1 + t_2} q_{\text{conv}} dt = \Delta E_{st}
\]

where \(q_{\text{conv}} = h A_s (T_\infty - T_{mp})\) and \(\Delta E_{st} = \rho_p V_h s_f\). Hence,

\[
t_2 = \frac{\rho_p D_p}{6 h} \frac{h s_f}{\left( T_\infty - T_{mp} \right)} = \frac{3970 \text{ kg/m}^3 \left( 50 \times 10^{-6} \text{ m} \right)}{6 \left( 30,000 \text{ W/m}^2 \cdot \text{K} \right)} \times \frac{3.577 \times 10^6 \text{ J/kg}}{\left( 10,000 - 2318 \right) \text{K}} = 5 \times 10^{-4} \text{s}
\]

Hence  \(t_{i-f} = 9 \times 10^{-4} \text{s} \approx 1 \text{ ms}\)

(b) Contrasting the smallest value of the convection heat flux, \(q_{\text{conv,min}} = h \left( T_\infty - T_{mp} \right) = 2.3 \times 10^8 \text{ W/m}^2\) to the largest radiation flux, \(q_{\text{rad,max}} = \varepsilon \sigma \left( T_{mp}^4 - T_{\text{sur}}^4 \right) = 6.5 \times 10^5 \text{ W/m}^2\), we conclude that radiation is, in fact, negligible.

COMMENTS: (1) Since \(Bi = (hr_p/3)/k = 0.05\), the lumped capacitance assumption is good. (2) In an actual application, the droplet should impact the substrate in a superheated condition \((T > T_{mp})\), which would require a slightly larger \(t_{i-f}\).
PROBLEM 5.25

KNOWN: Diameters, initial temperature and thermophysical properties of WC and Co in composite particle. Convection coefficient and freestream temperature of plasma gas. Melting point and latent heat of fusion of Co.

FIND: Times required to reach melting and to achieve complete melting of Co.

SCHEMATIC:

ASSUMPTIONS: (1) Particle is isothermal at any instant, (2) Radiation exchange with surroundings is negligible, (3) Negligible contact resistance at interface between WC and Co, (4) Constant properties.

ANALYSIS: From Eq. (5.5), the time required to reach the melting point is

\[
t_1 = \frac{(\rho V_c)_{\text{tot}}}{\frac{h}{\pi D_0^2}} \ln \frac{T_i - T_\infty}{T_{mp} - T_\infty}
\]

where the total heat capacity of the composite particle is

\[
(\rho V_c)_{\text{tot}} = (\rho V_c)_c + (\rho V_c)_s = 16,000 \text{ kg/m}^3 \left[ \pi \left( 1.6 \times 10^{-5} \text{ m} \right)^3 / 6 \right] 300 \text{ J/kg} \cdot \text{K} + 8900 \text{ kg/m}^3 \left[ \pi / 6 \left( 2.0 \times 10^{-5} \text{ m} \right)^3 - \left( 1.6 \times 10^{-5} \text{ m} \right)^3 \right] 750 \text{ J/kg} \cdot \text{K}
\]

\[
= (1.03 \times 10^{-8} + 1.36 \times 10^{-8}) \text{ J/K} = 2.39 \times 10^{-8} \text{ J/K}
\]

\[
t_1 = \frac{2.39 \times 10^{-8} \text{ J/K}}{20,000 \text{ W/m}^2 \cdot \text{K} \pi \left( 2.0 \times 10^{-5} \text{ m} \right)^2} \ln \left( \frac{300 - 10,000}{1770 - 10,000} \right) = 1.56 \times 10^{-4} \text{ s} \quad <
\]

The time required to melt the Co may be obtained by applying the first law, Eq. (1.11b) to a control surface about the particle. It follows that

\[
E_{\text{in}} = h\pi D_0^2 \left( T_\infty - T_{mp} \right) t_2 = \Delta E_{\text{st}} = \rho_s \left( \pi / 6 \right) \left( D_0^3 - D_i^3 \right) h_{sf}
\]

\[
= 8900 \text{ kg/m}^3 \left( \pi / 6 \right) \left[ 2 \times 10^{-5} \text{ m}^3 - 1.6 \times 10^{-5} \text{ m}^3 \right] 2.59 \times 10^5 \text{ J/kg}
\]

\[
t_2 = \frac{8900 \text{ kg/m}^3 \left( \pi / 6 \right) \left( 2 \times 10^{-5} \text{ m} \right)^2 \left( 10,000 - 1770 \right) \text{ K}}{20,000 \text{ W/m}^2 \cdot \text{K} \pi \left( 2 \times 10^{-5} \text{ m} \right)^2} = 2.28 \times 10^{-5} \text{ s} \quad <
\]

COMMENTS: (1) The largest value of the radiation coefficient corresponds to \( h_r = 6 \sigma \left( T_{mp} + T_{sur} \right) \left( T_{mp}^2 + T_{sur}^2 \right) \). For the maximum possible value of \( \varepsilon = 1 \) and \( T_{sur} = 300 \text{K} \), \( h_r = 378 \text{ W/m}^2 \cdot \text{K} \ll h = 20,000 \text{ W/m}^2 \cdot \text{K} \). Hence, the assumption of negligible radiation exchange is excellent. (2) Despite the large value of \( h \), the small values of \( D_0 \) and \( D_i \) and the large thermal conductivities (~ 40 W/m·K and 70 W/m·K for WC and Co, respectively) render the lumped capacitance approximation a good one. (3) A detailed treatment of plasma heating of a composite powder particle is provided by Demetriou, Lavine and Ghoniem (Proc. 5th ASME/JSME Joint Thermal Engineering Conf., March, 1999).
PROBLEM 5.26

KNOWN: Dimensions and operating conditions of an integrated circuit.

FIND: Steady-state temperature and time to come within 1°C of steady-state.

SCHEMATIC:

ASSUMPTIONS: (1) Constant properties, (2) Negligible heat transfer from chip to substrate.

PROPERTIES: Chip material (given): \( \rho = 2000 \text{ kg/m}^3, c = 700 \text{ J/kg} \cdot \text{K} \).

ANALYSIS: At steady-state, conservation of energy yields

\[
-\dot{E}_{\text{out}} + \dot{E}_g = 0 \\
-h(L^2)(T_f - T_\infty) + \dot{q}(L^2 \cdot t) = 0
\]

\[
T_f = T_\infty + \frac{\dot{q}}{h}
\]

\[
T_f = 20^\circ \text{C} + \frac{9 \times 10^6 \text{ W/m}^3 \times 0.001 \text{ m}}{150 \text{ W/m}^2 \cdot \text{K}} = 80^\circ \text{C}.
\]

From the general lumped capacitance analysis, Equation 5.15 reduces to

\[
\rho c \frac{dT}{dt} = \dot{q}(L^2 \cdot t) - h(T - T_\infty)L^2.
\]

With

\[
a \equiv \frac{h}{\rho c} = \frac{150 \text{ W/m}^2 \cdot \text{K}}{(2000 \text{ kg/m}^3)(0.001 \text{ m})(700 \text{ J/kg} \cdot \text{K})} = 0.107 \text{ s}^{-1}
\]

\[
b \equiv \frac{\dot{q}}{\rho c} = \frac{9 \times 10^6 \text{ W/m}^3}{(2000 \text{ kg/m}^3)(700 \text{ J/kg} \cdot \text{K})} = 6.429 \text{ K/s}.
\]

From Equation 5.24,

\[
\exp(-at) = \frac{T - T_\infty - b/a}{T_i - T_\infty - b/a} = \frac{(79 - 20 - 60) \text{ K}}{(20 - 20 - 60) \text{ K}} = 0.01667
\]

\[
t = -\frac{\ln (0.01667)}{0.107 \text{ s}^{-1}} = 38.3 \text{ s}.
\]

COMMENTS: Due to additional heat transfer from the chip to the substrate, the actual values of \( T_f \) and \( t \) are less than those which have been computed.
PROBLEM 5.27

KNOWN: Dimensions and operating conditions of an integrated circuit.

FIND: Steady-state temperature and time to come within 1°C of steady-state.

SCHEMATIC:

ASSUMPTIONS: (1) Constant properties.

PROPERTIES: Chip material (given): \( \rho = 2000 \text{ kg/m}^3 \), \( c_p = 700 \text{ J/kg} \cdot \text{K} \).

ANALYSIS: The direct and indirect paths for heat transfer from the chip to the coolant are in parallel, and the equivalent resistance is

\[
R_{\text{equiv}} = \left[ hL^2 + R_t^{-1} \right]^{-1} = \left[ (3.75 \times 10^{-3} + 5 \times 10^{-3}) \text{W/K} \right]^{-1} = 114.3 \text{ K/W}.
\]

The corresponding overall heat transfer coefficient is

\[
U = \frac{(R_{\text{equiv}})^{-1}}{L^2} = \frac{0.00875 \text{ W/K}}{(0.005 \text{ m})^2} = 350 \text{ W/m}^2 \cdot \text{K}.
\]

To obtain the steady-state temperature, apply conservation of energy to a control surface about the chip.

\[
-E_{\text{out}} + E_{\text{g}} = 0 \quad \Rightarrow \quad -UL^2 (T_f - T_\infty) + \dot{q}(L^2 \cdot t) = 0
\]

\[
T_f = T_\infty + \frac{\dot{q}t}{U} = 20^\circ \text{C} + \frac{9 \times 10^6 \text{ W/m}^3 \times 0.001 \text{ m}}{350 \text{ W/m}^2 \cdot \text{K}} = 45.7^\circ \text{C}.
\]

From the general lumped capacitance analysis, Equation 5.15 yields

\[
\rho \left( L^2 \cdot t \right) \frac{dT}{dt} = \dot{q} \left( L^2 \cdot t \right) - U (T - T_\infty)L^2.
\]

With

\[
a = \frac{U}{\rho \cdot c_t} = \frac{350 \text{ W/m}^2 \cdot \text{K}}{(2000 \text{ kg/m}^3)(0.001 \text{ m})(700 \text{ J/kg} \cdot \text{K})} = 0.250 \text{ s}^{-1}
\]

\[
b = \frac{\dot{q}}{\rho \cdot c} = \frac{9 \times 10^6 \text{ W/m}^3}{(2000 \text{ kg/m}^3)(700 \text{ J/kg} \cdot \text{K})} = 6.429 \text{ K/s}
\]

Equation 5.24 yields

\[
\exp \left( -at \right) = \frac{T-T_\infty - b/a}{T_i - T_\infty - b/a} = \frac{(44.7 - 20 - 25.7) \text{ K}}{(20 - 20 - 25.7) \text{ K}} = 0.0389
\]

\[
t = -\ln \left( 0.0389 \right) / 0.250 \text{ s}^{-1} = 13.0 \text{ s}.
\]

COMMENTS: Heat transfer through the substrate is comparable to that associated with direct convection to the coolant.
PROBLEM 5.28

KNOWN: Dimensions, initial temperature and thermophysical properties of chip, solder and substrate. Temperature and convection coefficient of heating agent.

FIND: (a) Time constants and temperature histories of chip, solder and substrate when heated by an air stream. Time corresponding to maximum stress on a solder ball. (b) Reduction in time associated with using a dielectric liquid to heat the components.

SCHEMATIC:

ASSUMPTIONS: (1) Lumped capacitance analysis is valid for each component, (2) Negligible heat transfer between components, (3) Negligible reduction in surface area due to contact between components, (4) Negligible radiation for heating by air stream, (5) Uniform convection coefficient among components, (6) Constant properties.

ANALYSIS: (a) From Eq. (5.7), $\tau_t = (\rho Vc) / hA$

**Chip:**
$$V = \left( \frac{L_{\text{ch}}^2}{t_{\text{ch}}} \right) = \left( 0.015m \right)^2 \left( 0.002m \right) = 4.50 \times 10^{-7} \, m^3$$
$$A_s = \left( 2L_{\text{ch}} + 4L_{\text{ch}}t_{\text{ch}} \right)$$
$$\tau_t = \frac{2300 \, kg/m^3 \times 4.50 \times 10^{-7} \, m^3 \times 710 \, J/kg \cdot K}{50 \, W/m^2 \cdot K \times 5.70 \times 10^{-4} \, m^2} = 25.8s$$

**Solder:**
$$V = \pi D^3 / 6 = \pi \left( 0.002m \right)^3 / 6 = 4.19 \times 10^{-9} \, m^3$$
$$A_s = \pi D^2 = \pi \left( 0.002m \right)^2 = 1.26 \times 10^{-5} \, m^2$$
$$\tau_t = \frac{11,000 \, kg/m^3 \times 4.19 \times 10^{-9} \, m^3 \times 130 \, J/kg \cdot K}{50 \, W/m^2 \cdot K \times 1.26 \times 10^{-5} \, m^2} = 9.5s$$

**Substrate:**
$$V = \left( \frac{L_{sb}^2}{t_{sb}} \right) = \left( 0.025m \right)^2 \left( 0.01m \right) = 6.25 \times 10^{-6} \, m^3$$
$$A_s = L_{sb}^2 = \left( 0.025m \right)^2 = 6.25 \times 10^{-4} \, m^2$$
$$\tau_t = \frac{4000 \, kg/m^3 \times 6.25 \times 10^{-6} \, m^3 \times 770 \, J/kg \cdot K}{50 \, W/m^2 \cdot K \times 6.25 \times 10^{-4} \, m^2} = 616.0s$$

Substituting Eq. (5.7) into (5.5) and recognizing that $(T - T_i)/(T_{\infty} - T_i) = 1 - (\theta / \theta_i)$, in which case $(T - T_i)/(T_{\infty} - T_i) = 0.99$ yields $\theta / \theta_i = 0.01$, it follows that the time required for a component to experience 99% of its maximum possible temperature rise is
$$t_{0.99} = \tau \ln \left( \theta_i / \theta \right) = \tau \ln (100) = 4.61 \tau$$

Hence,

**Chip:** $t = 118.9s$, \hspace{1cm} **Solder:** $t = 43.8s$, \hspace{1cm} **Substrate:** $t = 2840$

Continued …..
Histories of the three components and temperature differences between a solder ball and its adjoining components are shown below.

Commensurate with their time constants, the fastest and slowest responses to heating are associated with the solder and substrate, respectively. Accordingly, the largest temperature difference is between these two components, and it achieves a maximum value of 55°C at

\[ t_{\text{maximum stress}} \approx 40s \]

(b) With the 4-fold increase in \( h \) associated with use of a dielectric liquid to heat the components, the time constants are each reduced by a factor of 4, and the times required to achieve 99% of the maximum temperature rise are

*Chip*: \( t = 29.5s, \)  \quad *Solder*: \( t = 11.0s, \)  \quad *Substrate*: \( t = 708s \)

The time savings is approximately 75%.

**COMMENTS:** The foregoing analysis provides only a first, albeit useful, approximation to the heating problem. Several of the assumptions are highly approximate, particularly that of a uniform convection coefficient. The coefficient will vary between components, as well as on the surfaces of the components. Also, because the solder balls are flattened, there will be a reduction in surface area exposed to the fluid for each component, as well as heat transfer between components, which reduces differences between time constants for the components.
**PROBLEM 5.29**

**KNOWN:** Electrical transformer of approximate cubical shape, 32 mm to a side, dissipates 4.0 W when operating in ambient air at 20°C with a convection coefficient of 10 W/m²·K.

**FIND:** (a) Develop a model for estimating the steady-state temperature of the transformer, \( T(\infty) \), and evaluate \( T(\infty) \), for the operating conditions, and (b) Develop a model for estimating the temperature-time history of the transformer if initially the temperature is \( T_i = T_{\infty} \) and suddenly power is applied. Determine the time required to reach within 5°C of its steady-state operating temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Transformer is spatially isothermal object, (2) Initially object is in equilibrium with its surroundings, (3) Bottom surface is adiabatic.

**ANALYSIS:**

(a) Under steady-state conditions, for the control volume shown in the schematic above, the energy balance is

\[
\dot{E}_{in} - \dot{E}_{out} + \dot{E}_{gen} = 0 \quad \Rightarrow \quad 0 - q_{CV} + P_e = -h A_s \left[ T(\infty) - T_{\infty} \right] + P_e = 0
\]

where \( A_s = 5 \times 0.032^2 = 5 \times 0.032 \times 0.032 = 5.12 \times 10^{-3} \, \text{m}^2 \), find

\[
T(\infty) = T_{\infty} + P_e / h A_s = 20^\circ C + 4 \, \text{W} / \left( 10 \, \text{W} / \text{m}^2 \cdot \text{K} \times 5.12 \times 10^{-3} \, \text{m}^2 \right) = 98.1^\circ C <
\]

(b) Under transient conditions, for the control volume shown above, the energy balance is

\[
\dot{E}_{in} - \dot{E}_{out} + \dot{E}_{gen} = \dot{E}_{st} \quad \Rightarrow \quad 0 - q_{CV} + P_e = Mc \frac{dT}{dt}
\]

Substitute from Eq. (1) for \( P_e \), separate variables, and define the limits of integration.

\[
-h \left[ T(t) - T_{\infty} \right] + h \left[ T(\infty) - T_{\infty} \right] = Mc \frac{dT}{dt}
\]

where \( \theta = T(t) - T(\infty); \theta_i = T_i - T(\infty) = T_{\infty} - T(\infty); \) and \( \theta_o = T(t_o) - T(\infty) \) with \( t_o \) as the time when \( \theta_o = -5^\circ C \). Integrating and rearranging find (see Eq. 5.5),

\[
t_o = \frac{Mc}{h A_s} \ln \frac{\theta_i}{\theta_o}
\]

\[
t_o = \frac{0.28 \, \text{kg} \times 400 \, \text{J/kg} \cdot \text{K}}{10 \, \text{W/m}^2 \cdot \text{K} \times 5.12 \times 10^{-3} \, \text{m}^2} \ln \frac{(20 - 98.1)^\circ C}{-5^\circ C} = 1.67 \, \text{hour}
\]

**COMMENTS:** The spacewise isothermal assumption may not be a gross over simplification since most of the material is copper and iron, and the external resistance by free convection is high. However, by ignoring internal resistance, our estimate for \( t_o \) is optimistic.
PROBLEM 5.30

KNOWN: Series solution, Eq. 5.39, for transient conduction in a plane wall with convection.

FIND: Midplane ($x^*=0$) and surface ($x^*=1$) temperatures $\theta^*$ for $\text{Fo}=0.1$ and 1, using $\text{Bi}=0.1, 1$ and 10 with only the first four eigenvalues. Based upon these results, discuss the validity of the approximate solutions, Eqs. 5.40 and 5.41.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional transient conduction, (2) Constant properties.

ANALYSIS: The series solution, Eq. 5.39a, is of the form,

$$\theta^* = \sum_{n=1}^{\infty} C_n \exp\left(\zeta_n^2 \text{Fo}\right) \cos\left(\zeta_n x^*\right)$$

where the eigenvalues, $\zeta_n$, and the constants, $C_n$, are from Eqs. 5.39b and 5.39c.

$$\zeta_n \tan \zeta_n = \text{Bi} \quad C_n = 4 \sin \zeta_n / \left(2 \zeta_n + \sin \left(2 \zeta_n\right)\right).$$

The eigenvalues are tabulated in Appendix B.3; note, however, that $\zeta_1$ and $C_1$ are available from Table 5.1. The values of $\zeta_n$ and $C_n$ used to evaluate $\theta^*$ are as follows:

<table>
<thead>
<tr>
<th>Bi</th>
<th>$\zeta_1$</th>
<th>$C_1$</th>
<th>$\zeta_2$</th>
<th>$C_2$</th>
<th>$\zeta_3$</th>
<th>$C_3$</th>
<th>$\zeta_4$</th>
<th>$C_4$</th>

The tabulated results for $\theta^* = \theta^* (x^*, Bi, Fo)$ demonstrate that for $Fo=1$, the first eigenvalue is sufficient to accurately represent the series. However, for $Fo=0.1$, three eigenvalues are required for accurate representation.

A more detailed analysis would show that a practical criterion for representation of the series solution by one eigenvalue is $Fo>0.2$. For these situations the approximate solutions, Eqs. 5.40 and 5.41, are appropriate.

For the midplane, $x^*=0$, the first two eigenvalues for $Fo=0.2$ are:

<table>
<thead>
<tr>
<th>Bi</th>
<th>Fo=0.2</th>
<th>x*=0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>0.1</td>
<td>1.0</td>
</tr>
<tr>
<td>$\theta_1^*$</td>
<td>0.9965</td>
<td>0.9651</td>
</tr>
<tr>
<td>$\theta_2^*$</td>
<td>-0.00226</td>
<td>-0.0145</td>
</tr>
<tr>
<td>$\theta^*$</td>
<td>0.9939</td>
<td>0.9506</td>
</tr>
</tbody>
</table>

The percentage error shown in the last row of the above table is due to the effect of the second term. For $Bi=0.1$, neglecting the second term provides an error of 0.26%. For $Bi=1$, the error is 1.53%.

Hence we conclude that the approximate series solutions (with only one eigenvalue) provides systematically high results, but by less than 1.5%, for the Biot number range from 0.1 to 10.
**PROBLEM 5.31**

**KNOWN:** One-dimensional wall, initially at a uniform temperature, $T_i$, is suddenly exposed to a convection process ($T_{\infty}$, $h$). For wall #1, the time ($t_1 = 100s$) required to reach a specified temperature at $x = L$ is prescribed, $T(L_1, t_1) = 315^\circ C$.

**FIND:** For wall #2 of different thickness and thermal conditions, the time, $t_2$, required for $T(L_2, t_2) = 28^\circ C$.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional conduction, (2) Constant properties.

**ANALYSIS:** The properties, thickness and thermal conditions for the two walls are:

<table>
<thead>
<tr>
<th>Wall</th>
<th>$L$(m)</th>
<th>$\alpha$(m$^2$/s)</th>
<th>$k$(W/m$\cdot$K)</th>
<th>$T_i$(°C)</th>
<th>$T_{\infty}$(°C)</th>
<th>$h$(W/m$^2\cdot$K)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0.10</td>
<td>$15\times10^{-6}$</td>

<td>$25\times10^{-6}$</td>
<td>100</td>
<td>30</td>
<td>20</td>
<td>100</td>
</tr>
</tbody>
</table>

The dimensionless functional dependence for the one-dimensional, transient temperature distribution, Eq. 5.38, is

$$\theta^* = \frac{T(x,t) - T_{\infty}}{T_i - T_{\infty}} = f\left(x^*, Bi, Fo\right)$$

where

$$x^* = \frac{x}{L} \quad Bi = \frac{hL}{k} \quad Fo = \frac{\alpha t}{L^2}.$$ 

If the parameters $x^*$, Bi, and Fo are the same for both walls, then $\theta_1^* = \theta_2^*$. Evaluate these parameters:

<table>
<thead>
<tr>
<th>Wall</th>
<th>$x^*$</th>
<th>Bi</th>
<th>Fo</th>
<th>$\theta^*$</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>0.40</td>
<td>0.150</td>
<td>0.85</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>0.40</td>
<td>$1.563\times10^{-4}t_2$</td>
<td>0.85</td>
</tr>
</tbody>
</table>

where

$$\theta_1^* = \frac{315 - 400}{300 - 400} = 0.85 \quad \theta_2^* = \frac{28.5 - 20}{30 - 20} = 0.85.$$ 

It follows that

$$Fo_2 = Fo_1 = 1.563\times10^{-4}t_2 = 0.150$$

$t_2 = 960s$. <
**PROBLEM 5.32**

**KNOWN:** The chuck of a semiconductor processing tool, initially at a uniform temperature of $T_i = 100\, ^\circ\text{C}$, is cooled on its top surface by supply air at $20\, ^\circ\text{C}$ with a convection coefficient of $50\, \text{W/m}^2\cdot\text{K}$.

**FIND:** (a) Time required for the lower surface to reach $25\, ^\circ\text{C}$, and (b) Compute and plot the time-to-cool as a function of the convection coefficient for the range $10 \leq h \leq 2000\, \text{W/m}^2\cdot\text{K}$; comment on the effectiveness of the head design as a method for cooling the chuck.

**SCHEMATIC:**

---

**ASSUMPTIONS:** (1) One-dimensional, transient conduction in the chuck, (2) Lower surface is perfectly insulated, (3) Uniform convection coefficient and air temperature over the upper surface of the chuck, and (4) Constant properties.

**PROPERTIES:** *Table A.1*, Aluminum alloy 2024 (\(25 + 100\)°C / 2 = 335 K): \(\rho = 2770\, \text{kg/m}^3\), \(c_p = 880\, \text{J/kg} \cdot \text{K}\), \(k = 179\, \text{W/m} \cdot \text{K}\).

**ANALYSIS:** (a) The Biot number for the chuck with $h = 50\, \text{W/m}^2\cdot\text{K}$ is

\[
\text{Bi} = \frac{hL}{k} = \frac{50\, \text{W/m}^2\cdot\text{K} \times 0.025\, \text{m}}{179\, \text{W/m} \cdot \text{K}} = 0.007 \leq 0.1
\]

so that the lumped capacitance method is appropriate. Using Eq. 5.5, with $V/A_s = L$,

\[
t = \frac{\theta_1}{hA_s} \ln \left( \frac{\theta_1}{\theta} \right) \quad \theta = T - T_\infty \quad \theta_1 = T_i - T_\infty
\]

\[
t = \left( 2770\, \text{kg/m}^3 \times 0.025\, \text{m} \times 880\, \text{J/kg} \cdot \text{K} / 50\, \text{W/m}^2 \cdot \text{K} \right) \ln \left( \frac{100 - 20\, ^\circ\text{C}}{25 - 20\, ^\circ\text{C}} \right)
\]

\[
t = 3379\, \text{s} = 56.3\, \text{min}
\]

Continued...
(b) When \( h = 2000 \text{ W/m}^2\text{K}, \) using Eq. (1), find \( Bi = 0.28 > 0.1 \) so that the series solution, Section 5.51, for the plane wall with convection must be used. Using the IHT Transient Conduction, Plane Wall Model, the time-to-cool was calculated as a function of the convection coefficient. Free convection cooling conduction corresponds to \( h \approx 10 \text{ W/m}^2\text{K} \) and the time-to-cool is 282 minutes. With the cooling head design, the time-to-cool can be substantially decreased if the convection coefficient can be increased as shown below.
PROBLEM 5.33

KNOWN: Configuration, initial temperature and charging conditions of a thermal energy storage unit.

FIND: Time required to achieve 75% of maximum possible energy storage and corresponding minimum and maximum temperatures.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, (3) Negligible radiation exchange with surroundings.

ANALYSIS: For the system, find first

\[ \text{Bi} = \frac{hL}{k} = \frac{100 \text{ W/m}^2 \cdot \text{K} \times 0.025 \text{m}}{0.7 \text{ W/m} \cdot \text{K}} = 3.57 \]

indicating that the lumped capacitance method cannot be used.

Groebner chart, Fig. D.3:

\[ \frac{Q}{Q_o} = 0.75 \]

\[ \alpha = \frac{k}{\rho c} = \frac{0.7 \text{ W/m} \cdot \text{K}}{1900 \text{ kg/m}^3 \times 800 \text{ J/kg} \cdot \text{K}} = 4.605 \times 10^{-7} \text{ m}^2 / \text{s} \]

\[ \text{Bi}^2 \text{Fo} = \frac{h^2 \alpha t}{k^2} = \left( \frac{100 \text{ W/m}^2 \cdot \text{K}}{0.7 \text{ W/m} \cdot \text{K}} \right)^2 \times \left( 4.605 \times 10^{-7} \text{ m}^2 / \text{s} \right) \times t(s) = 9.4 \times 10^{-3} t \]

Find Bi²Fo = 11, and substituting numerical values

\[ t = 11/9.4 \times 10^{-3} = 1170 \text{s.} \]  

Heisler chart, Fig. D.1: \( T_{\text{min}} \) is at \( x = 0 \) and \( T_{\text{max}} \) at \( x = L \), with

\[ \text{Fo} = \frac{\alpha t}{L^2} = \frac{4.605 \times 10^{-7} \text{ m}^2 / \text{s} \times 1170 \text{ s}}{(0.025 \text{m})^2} = 0.86 \quad \text{Bi}^{-1} = 0.28. \]

From Fig. D.1, \( \theta_\theta^* = 0.33 \). Hence,

\[ T_\theta = T_\infty + 0.33(T_o - T_\infty) = 600^\circ \text{C} + 0.33(-575^\circ \text{C}) = 410^\circ \text{C} = T_{\text{min}}. \]

From Fig. D.2, \( \theta/\theta_\theta \approx 0.33 \) at \( x = L \), for which

\[ T_{x=L} \approx T_\infty + 0.33(T_o - T_\infty) = 600^\circ \text{C} + 0.33(-190)^\circ \text{C} = 537^\circ \text{C} = T_{\text{max}}. \]

COMMENTS: Comparing masonry (m) with aluminum (Al), see Problem 5.10, \( (\rho c)_\text{Al} > (\rho c)_\text{m} \) and \( k_\text{Al} > k_\text{m} \). Hence, the aluminum can store more energy and can be charged (or discharged) more quickly.
PROBLEM 5.34

KNOWN: Thickness, properties and initial temperature of steel slab. Convection conditions.

FIND: Heating time required to achieve a minimum temperature of 550°C in the slab.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) Negligible radiation effects, (3) Constant properties.

ANALYSIS: With a Biot number of $hL/k = \frac{(250 \text{ W/m}^2 \cdot \text{K} \times 0.05\text{m})}{48 \text{ W/m} \cdot \text{K}} = 0.260$, a lumped capacitance analysis should not be performed. At any time during heating, the lowest temperature in the slab is at the midplane, and from the one-term approximation to the transient thermal response of a plane wall, Eq. (5.41), we obtain

$$\theta_0^* = \frac{T_0 - T_\infty}{T_i - T_\infty} = \frac{(550 - 800)\degree\text{C}}{(200 - 800)\degree\text{C}} = 0.417 = C_1 \exp\left(-\xi_1^2 Fo\right)$$

With $\xi_1 = 0.488\text{ rad}$ and $C_1 = 1.0396$ from Table 5.1 and $\alpha = k / \rho c = 1.115 \times 10^{-5}\text{ m}^2 / \text{s}$,

$$-\xi_1^2 \left(\alpha t / L^2\right) = \ln (0.401) = -0.914$$

$$t = \frac{0.914 L^2}{\xi_1^2 \alpha} = \frac{0.841(0.05\text{m})^2}{(0.488)^2 \times 1.115 \times 10^{-5}\text{ m}^2 / \text{s}} = 861\text{s}$$

COMMENTS: The surface temperature at $t = 861\text{s}$ may be obtained from Eq. (5.40b), where

$$\theta^* = \theta_0^* \cos \left(\xi_1 x^*\right) = 0.417 \cos (0.488\text{ rad}) = 0.368.$$  Hence, $T(\text{L}, 792\text{s}) = T_s = T_\infty + 0.368(T_i - T_\infty) = 800\degree\text{C} - 221\degree\text{C} = 579\degree\text{C}$.  Assuming a surface emissivity of $\varepsilon = 1$ and surroundings that are at $T_s = T_\infty = 800\degree\text{C}$, the radiation heat transfer coefficient corresponding to this surface temperature is

$$h_r = \varepsilon \sigma \left(T_s + T_{\text{sur}}\right) \left(T_s^2 + T_{\text{sur}}^2\right) = 205 \text{ W/m}^2 \cdot \text{K}.$$  Since this value is comparable to the convection coefficient, radiation is not negligible and the desired heating will occur well before $t = 861\text{s}$.  

PROBLEM 5.35

KNOWN: Pipe wall subjected to sudden change in convective surface condition. See Example 5.4.

FIND: (a) Temperature of the inner and outer surface of the pipe, heat flux at the inner surface, and energy transferred to the wall after 8 min; compare results to the hand calculations performed for the Text Example; (b) Time at which the outer surface temperature of the pipe, T(0,t), will reach 25°C; (c) Calculate and plot on a single graph the temperature distributions, T(x,t) vs. x, for the initial condition, the final condition and the intermediate times of 4 and 8 min; explain key features; (d) Calculate and plot the temperature-time history, T(x,t) vs. t, for the locations at the inner and outer pipe surfaces, x = 0 and L, and for the range 0 ≤ t ≤ 16 min. Use the IHT | Models | Transient Conduction | Plane Wall model as the solution tool.

SCHEMATIC:

ASSUMPTIONS: (1) Pipe wall can be approximated as a plane wall, (2) Constant properties, (3) Outer surface of pipe is adiabatic.

ANALYSIS: The IHT model represents the series solution for the plane wall providing temperatures and heat fluxes evaluated at (x,t) and the total energy transferred at the inner wall at (t). Selected portions of the IHT code used to obtain the results tabulated below are shown in the Comments.

(a) The code is used to evaluate the tabulated parameters at t = 8 min for locations x = 0 and L. The agreement is very good between the one-term approximation of the Example and the multiple-term series solution provided by the IHT model.

<table>
<thead>

(b) To determine the time t_o for which T(0,t) = 25°C, the IHT model is solved for t_o after setting x = 0 and T_xt = 25°C. Find, t_o = 4.4 min.

(c) The temperature distributions, T(x,t) vs x, for the initial condition (t = 0), final condition (t → ∞) and intermediate times of 4 and 8 min. are shown on the graph below.

![Graph showing temperature distributions](Continued …..)
The final condition corresponds to the steady-state temperature, \( T(\infty, \infty) = T_\infty \). For the intermediate times, the gradient is zero at the insulated boundary \((x = 0, \text{the pipe exterior})\). As expected, the temperature at \( x = 0 \) will be less than at the boundary experiencing the convection process with the hot oil, \( x = L \). Note, however, that the difference is not very significant. The gradient at the inner wall, \( x = L \), decreases with increasing time.

(d) The temperature history \( T(x,t) \) for the locations at the inner and outer pipe surfaces are shown in the graph below. Note that the temperature difference between the two locations is greatest at the start of the transient process and decreases with increasing time. After a 16 min. duration, the pipe temperature is almost uniform, but yet 3 or 4°C from the steady-state condition.

### Comments:

1. Selected portions of the IHT code for the plane wall model are shown below. Note the relation for the pipe volume, \( \text{vol} \), used in calculating the total heat transferred per unit length over the time interval \( t \).

   ```plaintext
   // Models | Transient Conduction | Plane Wall
   // The temperature distribution is
   T_xt = T_xt_trans("Plane Wall",xstar,Fo,Bi,Ti,Tinf) // Eq 5.39
   //\( T_xt = 25 \) // Part (b) surface temperature, \( x = 0 \)
   // The heat flux in the x direction is
   q_xt = qprime_xt_trans("Plane Wall",x,L,Fo,Bi,k,Ti,Tinf) // Eq 2.6
   // The total heat transfer from the wall over the time interval \( t \) is
   QoverQo = Q_over_Qo_trans("Plane Wall",Fo,Bi) // Eq 5.45
   Qo = \rho * c_p * vol * (T_i - T_{\infty}) // Eq 5.44
   //vol = 2 * \pi * D * L // Appropriate for wall of 2L thickness
   vol = pi * D * L // Pipe wall of diameter D, thickness L and unit length
   Q = QoverQo * Qo // Total energy transferred per unit length
   
   (2) Can you give an explanation for why the inner and outer surface temperatures are not very different? What parameter provides a measure of the temperature non-uniformity in a system during a transient conduction process?
PROBLEM 5.36

KNOWN: Thickness, initial temperature and properties of furnace wall. Convection conditions at inner surface.

FIND: Time required for outer surface to reach a prescribed temperature. Corresponding temperature distribution in wall and at intermediate times.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in a plane wall, (2) Constant properties, (3) Adiabatic outer surface, (4) Fo > 0.2, (5) Negligible radiation from combustion gases.

ANALYSIS: The wall is equivalent to one-half of a wall of thickness 2L with symmetric convection conditions at its two surfaces. With $Bi = hL/k = 100 W/m^2\cdot K \times 0.15m/1.5 W/m\cdot K = 10$ and $Fo > 0.2$, the one-term approximation, Eq. 5.41 may be used to compute the desired time, where

$$\theta^* = (T_0 - T_\infty)/(T_i - T_\infty) = 0.215.$$ From Table 5.1, $C_1 = 1.262$ and $\zeta_1 = 1.4289$. Hence,

$$Fo = -\frac{\ln\left(\theta^*/C_1\right)}{\zeta_1^2} = -\frac{\ln(0.215/1.262)}{(1.4289)^2} = 0.867$$

$$t = \frac{Fo L^2}{\alpha} = \frac{0.867 (0.15m)^2}{\left(1.5 W/m\cdot K/2600 kg/m^3 \times 1000 J/kg\cdot K\right)} = 33,800 s <$$

The corresponding temperature distribution, as well as distributions at $t = 0, 10,000, and 20,000 s$ are plotted below.

COMMENTS: Because $Bi >> 1$, the temperature at the inner surface of the wall increases much more rapidly than at locations within the wall, where temperature gradients are large. The temperature gradients decrease as the wall approaches a steady-state for which there is a uniform temperature of 950°C.
PROBLEM 5.37

KNOWN: Thickness, initial temperature and properties of steel plate. Convection conditions at both surfaces.

FIND: Time required to achieve a minimum temperature.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in plate, (2) Symmetric heating on both sides, (3) Constant properties, (4) Negligible radiation from gases, (5) Fo > 0.2.

ANALYSIS: The smallest temperature exists at the midplane and, with \( Bi = hL/k = 500 \text{ W/m}^2 \cdot \text{K} \times 0.050\text{m}/45 \text{ W/m} \cdot \text{K} = 0.556 \) and Fo > 0.2, may be determined from the one-term approximation of Eq. 5.41. From Table 5.1, \( C_1 = 1.076 \) and \( \zeta_1 = 0.682 \). Hence, with \( \theta_0^* = (T_o - T_\infty)/(T_i - T_\infty) = 0.375 \),

\[
\frac{Fo}{\zeta_1^2} = \ln\left(\frac{\theta_0^*}{C_1}\right) = -\frac{\ln(0.375/1.076)}{(0.682)^2} = 2.266
\]

\[
t = \frac{Fo L^2}{\alpha} = \frac{2.266(0.05\text{m})^2}{\left(45 \text{ W/m} \cdot \text{K} / 7800 \text{ kg/m}^3 \times 500 \text{ J/kg} \cdot \text{K}\right)} = 491\text{s}
\]

COMMENTS: From Eq. 5.40b, the corresponding surface temperature is

\[
T_s = T_\infty + (T_i - T_\infty)\theta_0^* \cos(\zeta_1) = 700^\circ\text{C} - 400^\circ\text{C} \times 0.375 \times 0.776 = 584^\circ\text{C}
\]

Because Bi is not much larger than 0.1, temperature gradients in the steel are moderate.
**PROBLEM 5.38**

**KNOWN:** Plate of thickness $2L = 25\text{ mm}$ at a uniform temperature of $600^\circ\text{C}$ is removed from a hot pressing operation. Case 1, cooled on both sides; case 2, cooled on one side only.

**FIND:** (a) Calculate and plot on one graph the temperature histories for cases 1 and 2 for a 500-second cooling period; use the IHT software; Compare times required for the maximum temperature in the plate to reach $100^\circ\text{C}$; and (b) For both cases, calculate and plot on one graph, the variation with time of the maximum temperature difference in the plate; Comment on the relative magnitudes of the temperature gradients within the plate as a function of time.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional conduction in the plate, (2) Constant properties, and (3) For case 2, with cooling on one side only, the other side is adiabatic.

**PROPERTIES:** Plate (given): $\rho = 3000\text{ kg/m}^3$, $c = 750\text{ J/kg}\cdot\text{K}$, $k = 15\text{ W/m}\cdot\text{K}$.

**ANALYSIS:** (a) From IHT, call up Plane Wall, Transient Conduction from the Models menu. For case 1, the plate thickness is $25\text{ mm}$; for case 2, the plate thickness is $50\text{ mm}$. The plate center ($x = 0$) temperature histories are shown in the graph below. The times required for the center temperatures to reach $100^\circ\text{C}$ are

\[
t_1 = 164\text{ s} \quad t_2 = 367\text{ s}
\]

(b) The plot of $T(0, t) - T(L, t)$, which represents the maximum temperature difference in the plate during the cooling process, is shown below.

**COMMENTS:** (1) From the plate center-temperature history graph, note that it takes more than twice as long for the maximum temperature to reach $100^\circ\text{C}$ with cooling on only one side.

(2) From the maximum temperature-difference graph, as expected, cooling from one side creates a larger maximum temperature difference during the cooling process. The effect could cause microstructure differences, which could adversely affect the mechanical properties within the plate.
Problem 5.39

Known: Properties and thickness L of ceramic coating on rocket nozzle wall. Convection conditions. Initial temperature and maximum allowable wall temperature.

Find: (a) Maximum allowable engine operating time, $t_{\text{max}}$, for $L = 10$ mm, (b) Coating inner and outer surface temperature histories for $L = 10$ and 40 mm.

Schematic:

Assumptions: (1) One-dimensional conduction in a plane wall, (2) Constant properties, (3) Negligible thermal capacitance of metal wall and heat loss through back surface, (4) Negligible contact resistance at wall/ceramic interface, (5) Negligible radiation.

Analysis: (a) Subject to assumptions (3) and (4), the maximum wall temperature corresponds to the ceramic temperature at $x = 0$. Hence, for the ceramic, we wish to determine the time $t_{\text{max}}$ at which $T(0,t) = T_o(t) = 1500$ K. With $Bi = hL/k = 5000 \text{ W/m}^2\cdot\text{K}(0.01 \text{ m})/10 \text{ W/m} \cdot \text{K} = 5$, the lumped capacitance method cannot be used. Assuming $Fo > 0.2$, obtaining $\zeta_1 = 1.3138$ and $C_1 = 1.2402$ from Table 5.1, and evaluating $\theta_0^* = (T_0 - T_{\text{oo}})/(T_1 - T_{\text{oo}}) = 0.4$, Equation 5.41 yields

$$Fo = -\frac{\ln \left( \frac{\theta_0^*/C_1}{\zeta_1^2} \right)}{\zeta_1^2} = -\frac{\ln (0.4/1.2402)}{(1.3138)^2} = 0.656$$

confirming the assumption of $Fo > 0.2$. Hence,

$$t_{\text{max}} = \frac{Fo(L^2)}{\alpha} = \frac{0.656(0.01 \text{ m})^2}{6 \times 10^{-6} \text{ m}^2/\text{s}} = 10.9 \text{ s}$$

(b) Using the IHT Lumped Capacitance Model for a Plane Wall, the inner and outer surface temperature histories were computed and are as follows:

Continued...
PROBLEM 5.39 (Cont.)

The increase in the inner \((x = 0)\) surface temperature lags that of the outer surface, but within \(t \approx 45\)s both temperatures are within a few degrees of the gas temperature for \(L = 0.01\) m. For \(L = 0.04\) m, the increased thermal capacitance of the ceramic slows the approach to steady-state conditions. The thermal response of the inner surface significantly lags that of the outer surface, and it is not until \(t \approx 137\)s that the inner surface reaches 1500 K. At this time there is still a significant temperature difference across the ceramic, with \(T(L,t_{max}) = 2240\) K.

**COMMENTS:** The allowable engine operating time increases with increasing thermal capacitance of the ceramic and hence with increasing \(L\).
PROBLEM 5.40

KNOWN: Initial temperature, thickness and thermal diffusivity of glass plate. Prescribed surface temperature.

FIND: (a) Time to achieve 50% reduction in midplane temperature, (b) Maximum temperature gradient at that time.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties.

ANALYSIS: Prescribed surface temperature is analogous to \( h \to \infty \) and \( T_\infty = T_s \). Hence, \( Bi = \infty \).

Assume validity of one-term approximation to series solution for \( T(x,t) \).

(a) At the midplane,
\[
\theta_0^* = \frac{T_0 - T_s}{T_i - T_s} = 0.50 = C_1 \exp\left(-\zeta_1^2 Fo\right)
\]
\[
\zeta_1 \tan \zeta_1 = Bi = \infty \to \zeta_1 = \pi / 2.
\]

Hence
\[
C_1 = \frac{4 \sin \zeta_1}{2 \zeta_1 + \sin (2 \zeta_1)} = \frac{4}{\pi} = 1.273
\]
\[
Fo = -\frac{\ln \left( \theta_0^*/C_1 \right)}{\zeta_1^2} = 0.379
\]
\[
t = \frac{FoL^2}{\alpha} = \frac{0.379 (0.01 \text{ m})^2}{6 \times 10^{-7} \text{ m}^2/\text{s}} = 63 \text{ s.}
\]

(b) With \( \theta^* = C_1 \exp\left(-\zeta_1^2 Fo\right) \cos \zeta_1 x^* \)
\[
\frac{\partial}{\partial x} T = \frac{(T_i - T_s)}{L} \frac{\partial \theta^*}{\partial x} = -\frac{(T_i - T_s)}{L} \zeta_1 C_1 \exp\left(-\zeta_1^2 Fo\right) \sin \zeta_1 x^*
\]
\[
\frac{\partial}{\partial x} T |_{x^* = 1} = \frac{\partial}{\partial x} T |_{x^* = 1} = -\frac{300 \degree C}{0.01 \text{ m}} \frac{\pi}{2} \cdot 0.5 = -2.36 \times 10^4 \degree C/\text{m.}
\]

COMMENTS: Validity of one-term approximation is confirmed by \( Fo > 0.2 \).
PROBLEM 5.41

KNOWN: Thickness and properties of rubber tire. Convection heating conditions. Initial and final midplane temperature.

FIND: (a) Time to reach final midplane temperature. (b) Effect of accelerated heating.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in a plane wall, (2) Constant properties, (3) Negligible radiation.

ANALYSIS: (a) With $Bi = \frac{hL}{k} = 200 \text{ W/m}^2\text{K}(0.01 \text{ m})/0.14 \text{ W/m} \cdot \text{K} = 14.3$, the lumped capacitance method is clearly inappropriate. Assuming $Fo > 0.2$, Eq. (5.41) may be used with $C_1 = 1.265$ and $\zeta_1 \approx 1.458 \text{ rad}$ from Table 5.1 to obtain

$$\theta^*_0 = \frac{T_0 - T_\infty}{T_1 - T_\infty} = C_1 \exp \left( -\zeta_1^2 Fo \right) = 1.265 \exp \left( -2.126 Fo \right)$$

With $\theta^*_0 = \frac{(T_0 - T_\infty)}{(T_1 - T_\infty)} = \frac{(-50)}{(-175)} = 0.286$, $Fo = -\ln \left( \frac{0.286}{1.265} \right) / 2.126 = 0.70 = \alpha t_f L^2$

$$t_f = \frac{0.7(0.01 \text{ m})^2}{6.35 \times 10^{-8} \text{ m}^2/\text{s}} = 1100 \text{ s}$$

(b) The desired temperature histories were generated using the IHT Transient Conduction Model for a Plane Wall, with $h = 5 \times 10^4 \text{ W/m}^2\text{K}$ used to approximate imposition of a surface temperature of 200°C.

The fact that imposition of a constant surface temperature ($h \to \infty$) does not significantly accelerate the heating process should not be surprising. For $h = 200 \text{ W/m}^2\text{K}$, the Biot number is already quite large ($Bi = 14.3$), and limits to the heating rate are principally due to conduction in the rubber and not to convection at the surface. Any increase in $h$ only serves to reduce what is already a small component of the total thermal resistance.

COMMENTS: The heating rate could be accelerated by increasing the steam temperature, but an upper limit would be associated with avoiding thermal damage to the rubber.
PROBLEM 5.42

KNOWN: Stack or book comprised of 11 metal plates (p) and 10 boards (b) each of 2.36 mm thickness and prescribed thermophysical properties.

FIND: Effective thermal conductivity, $k$, and effective thermal capacitance, $(\rho c_p)$.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) Negligible contact resistance between plates and boards.

PROPERTIES: Metal plate (p, given): $\rho_p = 8000 \text{ kg/m}^3$, $c_{p,p} = 480 \text{ J/kg} \cdot \text{K}$, $k_p = 12 \text{ W/m} \cdot \text{K}$; Circuit boards (b, given): $\rho_b = 1000 \text{ kg/m}^3$, $c_{p,b} = 1500 \text{ J/kg} \cdot \text{K}$, $k_b = 0.30 \text{ W/m} \cdot \text{K}$.

ANALYSIS: The thermal resistance of the book is determined as the sum of the resistance of the boards and plates,

$$ R_{\text{tot}}^* = NR_b^* + MR_p^* $$

where M, N are the number of plates and boards in the book, respectively, and $R_i^* = L_i / k_i$

where $L_i$ and $k_i$ are the thickness and thermal conductivities, respectively.

$$ R_{\text{tot}}^* = M\left(\frac{L_p}{k_p}\right) + N\left(\frac{L_b}{k_b}\right) $$

$$ R_{\text{tot}}^* = 11\left(\frac{0.00236 \text{ m}}{12 \text{ W/m} \cdot \text{K}}\right) + 10\left(\frac{0.00236 \text{ m}}{0.30 \text{ W/m} \cdot \text{K}}\right) $$

$$ R_{\text{tot}}^* = 2.163\times10^{-3} + 7.867\times10^{-2} = 8.083\times10^{-2} \text{ K/W}. $$

The effective thermal conductivity of the book of thickness $(10 + 11) 2.36 \text{ mm}$ is

$$ k = \frac{L}{R_{\text{tot}}^*} = \frac{0.04956 \text{ m}}{8.083\times10^{-2} \text{ K/W}} = 0.613 \text{ W/m} \cdot \text{K}. $$

The thermal capacitance of the stack is

$$ C_{\text{tot}}^* = M\left(\rho_p L_p c_{p} \right) + N\left(\rho_b L_b c_b \right) $$

$$ C_{\text{tot}}^* = 11\left(8000 \text{ kg/m}^3 \times 0.00236 \text{ m} \times 480 \text{ J/kg} \cdot \text{K}\right) + 10\left(1000 \text{ kg/m}^3 \times 0.00236 \text{ m} \times 1500 \text{ J/kg} \cdot \text{K}\right) $$

$$ C_{\text{tot}}^* = 9.969\times10^4 + 3.540\times10^4 = 1.35\times10^5 \text{ J/m}^2 \cdot \text{K}. $$

The effective thermal capacitance of the book is

$$ \left(\rho c_p\right) = \frac{C_{\text{tot}}^*}{L} = 1.351\times10^5 \text{ J/m}^2 \cdot \text{K}/0.04956 \text{ m} = 2.726\times10^6 \text{ J/m}^3 \cdot \text{K}. $$

COMMENTS: The results of the analysis allow for representing the stack as a homogeneous medium with effective properties: $k = 0.613 \text{ W/m} \cdot \text{K}$ and $\alpha = (k/\rho c_p) = 2.249\times10^{-7} \text{ m}^2 /\text{s}$. See for example, Problem 5.38.
PROBLEM 5.43

KNOWN: Stack of circuit board-pressing plates, initially at a uniform temperature, is subjected by upper/lower platens to a higher temperature.

FIND: (a) Elapsed time, $t_e$, required for the mid-plane to reach cure temperature when platens are suddenly changed to $T_s = 190^\circ C$, (b) Energy removal from the stack needed to return its temperature to $T_i$.

SCHEMATIC:

PROPERTIES: Stack (given): $k = 0.613 \, W/m \cdot K$, $\rho c_p = 2.73 \times 10^6 \, J/m^3 \cdot K$; $\alpha = k/\rho c_p = 2.245 \times 10^{-7} \, m^2/s$.

ANALYSIS: (a) Recognize that sudden application of surface temperature corresponds to $h \to \infty$, or $Bi^{-1} = 0$ (Heisler chart) or $Bi \to \infty$ (100, Table 5.1). With $T_s = T_\infty$,

$$\theta_0^* = \frac{T(0,t) - T_s}{T_i - T_s} = \frac{(170 - 190)^\circ C}{(15 - 190)^\circ C} = 0.114.$$  

Using Eq. 5.41 with values of $\zeta_1 = 1.552$ and $C_1 = 1.2731$ at $Bi = 100$ (Table 5.1), find $Fo$

$$\theta_0^* = C_1 \exp\left(-\zeta_1^2 Fo\right)$$

$$Fo = -\frac{1}{\zeta_1^2} \ln\left(\theta_0^*/C_1\right) = -\frac{1}{(1.552)^2} \ln\left(0.114/1.2731\right) = 1.002$$

where $Fo = \alpha t/L^2$,

$$t = \frac{FoL^2}{\alpha} = \frac{1.002 \left(25 \times 10^{-3} \, m\right)^2}{2.245 \times 10^{-7} \, m^2/s} = 2.789 \times 10^3 \, s = 46.5 \, \text{min.} <$$

The Heisler chart, Figure D.1, could also be used to find $Fo$ from values of $\theta_0^*$ and $Bi^{-1} = 0$.

(b) The energy removal is equivalent to the energy gained by the stack per unit area for the time interval $0 \to t_e$. With $Q_o^*$ corresponding to the maximum amount of energy that could be transferred,

$$Q_o^* = \rho c (2L)(T_i - T_\infty) = 2.73 \times 10^6 \, J/m^3 \cdot K \left(2 \times 25 \times 10^{-3} \, m\right)(15 - 190)K = -2.389 \times 10^7 \, J/m^2.$$  

$Q^*$ may be determined from Eq. 5.46,

$$\frac{Q^*}{Q_o^*} = 1 - \frac{\sin \zeta_1}{\zeta_1} \theta_0^* = 1 - \frac{\sin (1.552\text{rad})}{1.552\text{rad}} \times 0.114 = 0.795$$

We conclude that the energy to be removed from the stack per unit area to return it to $T_i$ is

$$Q^* = 0.795Q_o^* = 0.795 \times 2.389 \times 10^7 \, J/m^2 = 1.90 \times 10^7 \, J/m^2. <$$
PROBLEM 5.44

KNOWN: Car windshield, initially at a uniform temperature of -20°C, is suddenly exposed on its interior surface to the defrost system airstream at 30°C. The ice layer on the exterior surface acts as an insulating layer.

FIND: What airstream convection coefficient would allow the exterior surface to reach 0°C in 60 s?

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, transient conduction in the windshield, (2) Constant properties, (3) Exterior surface is perfectly insulated.

PROPERTIES: Windshield (Given): \( \rho = 2200 \text{ kg/m}^3, c_p = 830 \text{ J/kg} \cdot \text{K} \) and \( k = 1.2 \text{ W/m} \cdot \text{K} \).

ANALYSIS: For the prescribed conditions, from Equations 5.31 and 5.33,

\[
\frac{\theta}{\theta_i} = \frac{T(0, 60s) - T_\infty}{T_i - T_\infty} = \frac{(0 - 30)^\circ \text{C}}{(-20 - 30)^\circ \text{C}} = 0.6
\]

\[
Fo = \frac{kt}{\rho c_p L^2} = \frac{1.2 \text{ W/m} \cdot \text{K} \times 60}{2200 \text{ kg/m}^3 \times 830 \text{ J/kg} \cdot \text{K} \times (0.005 \text{ m})^2} = 1.58
\]

The single-term series approximation, Eq. 5.41, along with Table 5.1, requires an iterative solution to find an appropriate Biot number. Alternatively, the Heisler charts, Appendix D, Figure D.1, for the midplane temperature could be used to find

\[
Bi^{-1} = k/hL = 2.5
\]

\[
h = 1.2 \text{ W/m} \cdot \text{K}/2.5 \times 0.005 \text{ m} = 96 \text{ W/m}^2 \cdot \text{K}
\]

COMMENTS: Using the IHT, Transient Conduction, Plane Wall Model, the convection coefficient can be determined by solving the model with an assumed \( h \) and then sweeping over a range of \( h \) until the \( T(0, 60s) \) condition is satisfied. Since the model is based upon multiple terms of the series, the result of \( h = 99 \text{ W/m}^2 \cdot \text{K} \) is more precise than that found using the chart.
PROBLEM 5.45

KNOWN: Thickness, initial temperature and properties of plastic coating. Safe-to-touch temperature. Convection coefficient and air temperature.

FIND: Time for surface to reach safe-to-touch temperature. Corresponding temperature at plastic/wood interface.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in coating, (2) Negligible radiation, (3) Constant properties, (4) Negligible heat of reaction, (5) Negligible heat transfer across plastic/wood interface.

ANALYSIS: With Bi = hL/k = 200 W/m²·K × 0.002m/0.25 W/m·K = 1.6 > 0.1, the lumped capacitance method may not be used. Applying the approximate solution of Eq. 5.40a, with C₁ = 1.155 and ζ₁ = 0.990 from Table 5.1,

\[ \theta^*_s = \frac{T_s - T_\infty}{T_i - T_\infty} = \frac{(42 - 25)\,^\circ C}{(200 - 25)\,^\circ C} = 0.0971 = C_1 \exp\left(-\zeta_1^2 F_o\right) \cos\left(\zeta_1 x^*\right) = 1.155\exp\left(-0.980 F_o\right)\cos\left(0.99\right) \]

Hence, for x^* = 1,

\[ F_o = -\ln\left(\frac{0.0971}{1.155\cos\left(0.99\right)}\right)/(0.99)^2 = 1.914 \]

\[ t = \frac{F_o L^2}{\alpha} = \frac{1.914(0.002m)^2}{1.20\times10^{-7} \text{ m}^2/\text{s}} = 63.8 \text{ s} < \]

From Eq. 5.41, the corresponding interface temperature is

\[ T_o = T_\infty + (T_i - T_\infty)\exp\left(-\zeta_1^2 F_o\right) = 25^\circ C + 175^\circ C\exp\left(-0.98\times1.914\right) = 51.8^\circ C < \]

COMMENTS: By neglecting conduction into the wood and radiation from the surface, the cooling time is overpredicted and is therefore a conservative estimate. However, if energy generation due to solidification of polymer were significant, the cooling time would be longer.
PROBLEM 5.46

KNOWN: Inlet and outlet temperatures of steel rods heat treated by passage through an oven.

FIND: Rod speed, V.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional radial conduction (axial conduction is negligible), (2) Constant properties, (3) Negligible radiation.

PROPERTIES: Table A-1, AISI 1010 Steel (\(\bar{T} = 600\text{K}\)): \(k = 48.8\text{ W/m-K}, \rho = 7832\text{ kg/m}^3, c_p = 559\text{ J/kg-K}, \alpha = (k/\rho c_p) = 1.11 \times 10^{-5}\text{ m}^2/\text{s}\).

ANALYSIS: The time needed to traverse the rod through the oven may be found from Fig. D.4.

\[
\theta_0^* = \frac{\bar{T}_0 - T_\infty}{\bar{T}_i - T_\infty} = \frac{600 - 750}{50 - 750} = 0.214
\]

\[
\text{Bi}^{-1} \equiv \frac{k}{hr_o} = \frac{48.8\text{ W/m-K}}{125\text{ W/m}^2\text{-K}(0.025\text{m})} = 15.6.
\]

Hence,

\[
\text{Fo} = \alpha \frac{t}{r_o^2} = 12.2
\]

\[
t = 12.2\left(0.025\text{m}\right)^2 / 1.11 \times 10^{-5}\text{ m}^2/\text{s} = 687\text{ s}.
\]

The rod velocity is

\[
V = \frac{L}{t} = \frac{5\text{m}}{687\text{s}} = 0.0073\text{ m/s}.
\]

COMMENTS: (1) Since \((h r_o/2)/k = 0.032\), the lumped capacitance method could have been used. From Eq. 5.5 it follows that \(t = 675\text{ s}\).

(2) Radiation effects decrease \(t\) and hence increase \(V\), assuming there is net radiant transfer from the oven walls to the rod.

(3) Since \(\text{Fo} > 0.2\), the approximate analytical solution may be used. With \(\text{Bi} = hr_o/k = 0.0641\), Table 5.1 yields \(\zeta_1 = 0.3549\) rad and \(C_1 = 1.0158\). Hence from Eq. 5.49c

\[
\text{Fo} = -\left(\frac{\epsilon^2}{\zeta_1}\right)^{-1} \ln \left[\frac{\theta_0^*}{C_1}\right] = 12.4,
\]

which is in good agreement with the graphical result.
**PROBLEM 5.47**

**KNOWN:** Hot dog with prescribed thermophysical properties, initially at 6°C, is immersed in boiling water.

**FIND:** Time required to bring centerline temperature to 80°C.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Hot dog can be treated as infinite cylinder, (2) Constant properties.

**ANALYSIS:** The Biot number, based upon Eq. 5.10, is

\[
\text{Bi} = \frac{h L_c}{k} = \frac{h r_0}{k} = \frac{100 \text{ W/m}^2 \cdot \text{K}}{0.52 \text{ W/m} \cdot \text{K}} = 0.96
\]

Since Bi > 0.1, a lumped capacitance analysis is not appropriate. Using the Heisler chart, Figure D.4 with

\[
\text{Bi} = \frac{h r_0}{k} = \frac{100 \text{ W/m}^2 \cdot \text{K} \times 10 \times 10^{-3} \text{ m}}{0.52 \text{ W/m} \cdot \text{K}} = 1.92 \quad \text{or} \quad \text{Bi}^{-1} = 0.52
\]

and \(\theta_* = \frac{\theta_i}{\theta_o} = \frac{T(0,t) - T_\infty}{T_i - T_\infty} = \frac{(80-100) \degree C}{(6-100) \degree C} = 0.21\) \(\theta = \theta_0 \approx 0.45\). From Eq. (1), note that \(\theta_0 = 0.21 \theta_i\) giving

\[
\theta(1,t) = T(r_0,t) - T_\infty = 0.45 \theta_0 = 0.45 \left(0.21[T_i - T_\infty]\right) = 0.45 \times 0.21 \left[6-100\right] \degree C = -8.9 \degree C
\]

\[
T(r_0,t) = T_\infty - 8.9 \degree C = (100-8.9) \degree C = 91.1 \degree C
\]

(3) Since \(\text{Fo} \geq 0.2\), the approximate solution for \(\theta^*\), Eq. 5.49, is valid. From Table 5.1 with Bi = 1.92, find that \(\zeta_1 = 1.3245\) rad and \(C_1 = 1.2334\). Rearranging Eq. 5.49 and substituting values,

\[
\text{Fo} = -\frac{1}{\zeta_1^2} \ln \left(\frac{\theta^*_0}{C_1}\right) = \frac{1}{(1.3245 \text{ rad})^2} \ln \left[\frac{0.213}{1.2334}\right] = 1.00
\]

This result leads to a value of \(t = 9.5\) min or 20% higher than that of the graphical method.

**COMMENTS:** (1) Note that \(L_c = r_o/2\) when evaluating the Biot number for the lumped capacitance analysis; however, in the Heisler charts, \(\text{Bi} = h r_0/k\).

(2) The surface temperature of the hot dog follows from use of Figure D.5 with \(r/r_0 = 1\) and \(\text{Bi}^{-1} = 0.52\); find \(\theta(1,t)/\theta_0 \approx 0.45\). From Eq. (1), note that \(\theta_0 = 0.21 \theta_i\) giving

\[
\theta(1,t) = T(r_0,t) - T_\infty = 0.45 \theta_0 = 0.45 \left(0.21[T_i - T_\infty]\right) = 0.45 \times 0.21 \left[6-100\right] \degree C = -8.9 \degree C
\]

\[
T(r_0,t) = T_\infty - 8.9 \degree C = (100-8.9) \degree C = 91.1 \degree C
\]

(3) Since \(\text{Fo} \geq 0.2\), the approximate solution for \(\theta^*\), Eq. 5.49, is valid. From Table 5.1 with Bi = 1.92, find that \(\zeta_1 = 1.3245\) rad and \(C_1 = 1.2334\). Rearranging Eq. 5.49 and substituting values,

\[
\text{Fo} = -\frac{1}{\zeta_1^2} \ln \left(\frac{\theta^*_0}{C_1}\right) = \frac{1}{(1.3245 \text{ rad})^2} \ln \left[\frac{0.213}{1.2334}\right] = 1.00
\]

This result leads to a value of \(t = 9.5\) min or 20% higher than that of the graphical method.
PROBLEM 5.48

KNOWN: Long rod with prescribed diameter and properties, initially at a uniform temperature, is heated in a forced convection furnace maintained at 750 K with a convection coefficient of \( h = 1000 \text{ W/m}^2\cdot\text{K} \).

FIND: (a) The corresponding center temperature of the rod, \( T(0, t_o) \), when the surface temperature \( T(r_o, t_o) \) is measured as 550 K, (b) Effect of \( h \) on centerline temperature history.

SCHEMATIC:

\[ T_\infty = 750 \text{ K} \]
\[ 100 \leq h \leq 1000 \text{ W/m}^2\cdot\text{K} \]
\[ T(r_o, t_o) = 550 \text{ K} \text{ (Part a)} \]

ASSUMPTIONS: (1) One-dimensional, radial conduction in rod, (2) Constant properties, (3) Rod, when initially placed in furnace, had a uniform (but unknown) temperature, (4) \( Fo \geq 0.2 \).

ANALYSIS: (a) Since the rod was initially at a uniform temperature and \( Fo \geq 0.2 \), the approximate solution for the infinite cylinder is appropriate. From Eq. 5.49b,

\[
\theta^*(r^*, Fo) = \theta_0^*(Fo) J_0(\zeta r^*)
\]

where, for \( r^* = 1 \), the dimensionless temperatures are, from Eq. 5.31,

\[
\theta^*(1, Fo) = T(r_0, t_o) - T_\infty \quad \theta_0^*(Fo) = \frac{T(0, t_o) - T_\infty}{T_i - T_\infty}
\]

Combining Eqs. (2) and (3) with Eq. (1) and rearranging,

\[
\frac{T(r_0, t_o) - T_\infty}{T_i - T_\infty} = \frac{T(0, t_o) - T_\infty}{T_i - T_\infty} J_0(\zeta_1 \cdot 1) - T(0, t_o) = T_\infty + \frac{1}{J_0(\zeta_1)}[T(r_0, t_o) - T_\infty]
\]

The eigenvalue, \( \zeta_1 = 1.0185 \text{ rad} \), follows from Table 5.1 for the Biot number

\[
Bi = \frac{hr_0}{k} = \frac{1000 \text{ W/m}^2\cdot\text{K} \cdot 0.060 \text{ m}}{50 \text{ W/m} \cdot \text{K}} = 0.60.
\]

From Table B-4, with \( \zeta_1 = 1.0185 \text{ rad} \), \( J_0(1.0185) = 0.7568 \). Hence, from Eq. (4)

\[
T(0, t_o) = 750 \text{ K} + \frac{1}{0.7568}[550 - 750] \text{ K} = 486 \text{ K}
\]

(b) Using the IHT Transient Conduction Model for a Cylinder, the following temperature histories were generated.

Continued...
The times required to reach a centerline temperature of 500 K are 367, 85 and 51 s, respectively, for \( h = 100, 500 \) and 1000 W/m\(^2\)-K. The corresponding values of the Biot number are 0.06, 0.30 and 0.60. Hence, even for \( h = 1000 \) W/m\(^2\)-K, the convection resistance is not negligible relative to the conduction resistance and significant reductions in the heating time could still be effected by increasing \( h \) to values considerably in excess of 1000 W/m\(^2\)-K.

COMMENTS: For Part (a), recognize why it is not necessary to know \( T_0 \) or the time \( t_0 \). We require that \( Fo \geq 0.2 \), which for this sphere corresponds to \( t \geq 14 \) s. For this situation, the time dependence of the surface and center are the same.
PROBLEM 5.49

KNOWN: A long cylinder, initially at a uniform temperature, is suddenly quenched in a large oil bath.

FIND: (a) Time required for the surface to reach 500 K, (b) Effect of convection coefficient on surface temperature history.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional radial conduction, (2) Constant properties, (3) Fo > 0.2.

ANALYSIS: (a) Check first whether lumped capacitance method is applicable. For \( h = 50 \text{ W/m}^2 \cdot \text{K} \),

\[
\text{Bi}_c = \frac{hL_c}{k} = \frac{h(r_o/2)}{k} = \frac{50 \text{ W/m}^2 \cdot \text{K} \cdot (0.015 \text{ m}/2)}{1.7 \text{ W/m} \cdot \text{K}} = 0.221.
\]

Since \( \text{Bi}_c > 0.1 \), method is not suited. Using the approximate series solution for the infinite cylinder,

\[
\theta^*(r^*, Fo) = C_1 \exp \left(-\zeta_1^2 Fo\right) \times J_0 \left(\zeta_1 r^*\right)
\]

Solving for \( Fo \) and setting \( r^* = 1 \), find

\[
Fo = -\frac{1}{\zeta_1^2} \ln \left[ \frac{\theta^*}{C_1 J_0 (\zeta_1)} \right]
\]

where \( \theta^* = (1, Fo) = \frac{T(r_0 \cdot t_0) - T_{\infty}}{T_i - T_{\infty}} = \frac{(500 - 350) \text{ K}}{(1000 - 350) \text{ K}} = 0.231. \)

From Table 5.1, with \( \text{Bi} = 0.441 \), find \( \zeta_1 = 0.8882 \text{ rad} \) and \( C_1 = 1.1019. \) From Table B.4, find \( J_0(\zeta_1) = 0.8121. \) Substituting numerical values into Eq. (2),

\[
Fo = -\frac{1}{(0.8882)^2} \ln \left[ \frac{0.231 \times 1.1019 \times 0.8121}{0.8882} \right] = 1.72.
\]

From the definition of the Fourier number, \( Fo = \frac{\alpha t}{r_0^2} \), and \( \alpha = \frac{k}{\rho c} \),

\[
t = \frac{Fo}{\alpha} \cdot \frac{r_0^2}{r_0^2} \frac{\rho c}{k} = 1.72 \left(0.015 \text{ m}\right)^2 \times 400 \text{ kg/m}^3 \times 1600 \text{ J/kg} \cdot \text{K} / 1.7 \text{ W/m} \cdot \text{K} = 145 \text{ s}.
\]

(b) Using the IHT Transient Conduction Model for a Cylinder, the following surface temperature histories were obtained.

Continued...
Increasing the convection coefficient by a factor of 5 has a significant effect on the surface temperature, greatly accelerating its approach to the oil temperature. However, even with $h = 250 \text{ W/m}^2\cdot\text{K}$, $Bi = 1.1$ and the convection resistance remains significant. Hence, in the interest of accelerated cooling, additional benefit could be achieved by further increasing the value of $h$.

**COMMENTS:** For Part (a), note that, since $Fo = 1.72 > 0.2$, the approximate series solution is appropriate.
PROBLEM 5.50

KNOWN: Long pyroceram rod, initially at a uniform temperature of 900 K, and clad with a thin metallic tube giving rise to a thermal contact resistance, is suddenly cooled by convection.

FIND: (a) Time required for rod centerline to reach 600 K, (b) Effect of convection coefficient on cooling rate.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional radial conduction, (2) Thermal resistance and capacitance of metal tube are negligible, (3) Constant properties, (4) $\text{Fo} \geq 0.2$.

PROPERTIES: Table A-2, Pyroceram ($\bar{T} = (600 + 900)/2 = 750$ K): $\rho = 2600$ kg/m$^3$, $c = 1100$ J/kg K, $k = 3.13$ W/m K.

ANALYSIS: (a) The thermal contact and convection resistances can be combined to give an overall heat transfer coefficient. Note that $\frac{1}{h} = \frac{1}{100}$ W/m$^2$ K is expressed per unit length for the outer surface. Hence, for $h = 100$ W/m$^2$ K,

$$U = \frac{1}{\frac{1}{h} + R'_{t,c} (\pi D)} = \frac{1}{1/100 \text{ W/m}^2 \text{ K} + 0.12 \text{ m/K} (\pi \times 0.020 \text{ m})} = 57.0 \text{ W/m}^2 \text{ K}.$$

Using the approximate series solution, Eq. 5.50c, the Fourier number can be expressed as

$$\text{Fo} = -\left(\frac{1}{\zeta}\right) \ln \left(\frac{\theta^*_0}{C_1}\right).$$

From Table 5.1, find $\zeta = 0.5884$ rad and $C_1 = 1.0441$ for

$$\text{Bi} = \frac{U r_0}{k} = \frac{57.0 \text{ W/m}^2 \text{ K}}{0.020 \text{ m}/2} = 0.182.$$

The dimensionless temperature is

$$\theta^*_0 (0, \text{Fo}) = \frac{T(0, t) - T_\infty}{T_1 - T_\infty} = \frac{(600 - 300) K}{(900 - 300) K} = 0.5.$$

Substituting numerical values to find Fo and then the time t,

$$\text{Fo} = \frac{-1}{(0.5884)^2} \ln \frac{0.5}{1.0441} = 2.127$$

$$t = \text{Fo} \frac{r_0^2}{\alpha} = \text{Fo} \frac{r_0^2 \rho c}{k} = \frac{2.127 (0.020 \text{ m}/2)^2 2600 \text{ kg/m}^3 \times 1100 \text{ J/kg} \cdot \text{K}}{3.13 \text{ W/m} \cdot \text{K}} = 194 \text{ s}.$$

(b) The following temperature histories were generated using the IHT Transient conduction Model for a Cylinder.

Continued...
While enhanced cooling is achieved by increasing $h$ from 100 to 500 $\text{W/m}^2\cdot\text{K}$, there is little benefit associated with increasing $h$ from 500 to 1000 $\text{W/m}^2\cdot\text{K}$. The reason is that for $h$ much above 500 $\text{W/m}^2\cdot\text{K}$, the contact resistance becomes the dominant contribution to the total resistance between the fluid and the rod, rendering the effect of further reductions in the convection resistance negligible. Note that, for $h = 100$, 500 and 1000 $\text{W/m}^2\cdot\text{K}$, the corresponding values of $U$ are 57.0, 104.8 and 117.1 $\text{W/m}^2\cdot\text{K}$, respectively.

**COMMENTS:** For Part (a), note that, since $\text{Fo} = 2.127 > 0.2$, Assumption (4) is satisfied.
PROBLEM 5.51

KNOWN: Sapphire rod, initially at a uniform temperature of 800K is suddenly cooled by a convection process; after 35s, the rod is wrapped in insulation.

FIND: Temperature rod reaches after a long time following the insulation wrap.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional radial conduction, (2) Constant properties, (3) No heat losses from the rod when insulation is applied.

PROPERTIES: Table A-2, Aluminum oxide, sapphire (550K): $\rho = 3970 \text{ kg/m}^3$, $c = 1068 \text{ J/kg} \cdot \text{K}$, $k = 22.3 \text{ W/m} \cdot \text{K}$, $\alpha = 5.259 \times 10^{-5} \text{ m}^2/\text{s}$.

ANALYSIS: First calculate the Biot number with $L_C = r_o/2$,

$$Bi = \frac{h L_C}{k} = \frac{h (r_o/2)}{k} = \frac{1600 \text{ W/m}^2 \cdot \text{K} (0.020 \text{ m}/2)}{22.3 \text{ W/m} \cdot \text{K}} = 0.72.$$  

Since $Bi > 0.1$, the rod cannot be approximated as a lumped capacitance system. The temperature distribution during the cooling process, $0 \leq t \leq 35s$, and for the time following the application of insulation, $t > 35s$, will appear as

Eventually ($t \to \infty$), the temperature of the rod will be uniform at $T(\infty)$. To find $T(\infty)$, write the conservation of energy requirement for the rod on a time interval basis, $E_{in} - E_{out} = \Delta E = E_{final} - E_{initial}$.

Using the nomenclature of Section 5.5.3 and basing energy relative to $T_\infty$, the energy balance becomes

$$-Q = \rho \ c V (\bar{T}(\infty) - T_\infty) - Q_O$$

where $Q_O = \rho c V (T_i - T_\infty)$. Dividing through by $Q_O$ and solving for $\bar{T}(\infty)$, find

$$\bar{T}(\infty) = T_\infty + (T_i - T_\infty)(1 - Q/Q_O).$$

From the Groeber chart, Figure D.6, with

$$Bi = \frac{hr_o}{k} = \frac{1600 \text{ W/m}^2 \cdot \text{K} \times 0.020\text{m}}{22.3 \text{ W/m} \cdot \text{K}} = 1.43$$

$$Bi^2 Fo = Bi^2 \left(\frac{\alpha}{t_i} \right)^2 = (1.43)^2 \left(5.259 \times 10^{-6}\text{ m}^2/\text{s} \times 35s / (0.020\text{m})^2 \right) = 0.95.$$  

find $Q/Q_O \approx 0.57$. Hence,

$$\bar{T}(\infty) = 300K + (800 - 300)K (1-0.57) = 515 K.$$  

COMMENTS: From use of Figures D.4 and D.5, find $T(0,35s) = 525K$ and $T(r_o,35s) = 423K$. 
PROBLEM 5.52

KNOWN: Long bar of 70 mm diameter, initially at 90°C, is suddenly immersed in a water bath ($T_\infty = 40^\circ C$, $h = 20 \text{ W/m}^2\cdot\text{K}$).

FIND: (a) Time, $t_f$, that bar should remain in bath in order that, when removed and allowed to equilibrate while isolated from surroundings, it will have a uniform temperature $T(r, \infty) = 55^\circ C$.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional radial conduction, (2) Constant properties.

PROPERTIES: Bar (given): $\rho = 2600 \text{ kg/m}^3$, $c = 1030 \text{ J/kg} \cdot \text{K}$, $k = 3.50 \text{ W/m} \cdot \text{K}$, $\alpha = k/\rho c = 1.31 \times 10^{-6} \text{ m}^2/\text{s}$.

ANALYSIS: Determine first whether conditions are space-wise isothermal

$$Bi = \frac{hLc}{k} = \frac{h(r_o/2)}{k} = \frac{20 \text{ W/m}^2\cdot\text{K}(0.035 \text{ m}/2)}{3.50 \text{ W/m} \cdot \text{K}} = 0.10$$

and since $Bi \geq 0.1$, a Heisler solution is appropriate.

(a) Consider an overall energy balance on the bar during the time interval $\Delta t = t_f$ (the time the bar is in the bath).

$$E_{in} - E_{out} = \Delta E$$

$$0 - Q = E_{final} - E_{initial} = Mc(T_f - T_\infty) - Mc(T_i - T_\infty)$$

$$-Q = Mc(T_f - T_\infty) - Q_o$$

$$Q_o = 1 - \frac{T_f - T_\infty}{T_i - T_\infty} = 1 - \frac{(55 - 40)^\circ C}{(90 - 40)^\circ C} = 0.70$$

where $Q_o$ is the initial energy in the bar (relative to $T_\infty$; Eq. 5.44). With $Bi = hr_o/k = 0.20$ and $Q/Q_o = 0.70$, use Figure D.6 to find $Bi^2Fo = 0.15$; hence $Fo = 0.15/Bi^2 = 3.75$ and

$$t_f = Fo \cdot \frac{\theta_i^2}{\alpha} = 3.75(0.035 \text{ m})^2/1.31\times10^{-6} \text{ m}^2/\text{s} = 3507 \text{ s}.$$ 

(b) To determine $T(r_o, t_f)$, use Figures D.4 and D.5 for $\theta(r_o,0)/\theta_i (Fo = 3.75, Bi^{-1} = 5.0)$ and $\theta_o/\theta_i (Bi^{-1} = 5.0, r/r_o = 1$, respectively, to find

$$T(r_o, t_f) = T_\infty + \frac{\theta(r_o, t)}{\theta_o} \cdot \frac{\theta_o}{\theta_i} \cdot \theta_i = 40^\circ C + 0.25 \times 0.90(90 - 50)^\circ C = 49^\circ C.$$
PROBLEM 5.53

KNOWN: Long plastic rod of diameter $D$ heated uniformly in an oven to $T_i$ and then allowed to convectively cool in ambient air ($T_\infty$, $h$) for a 3 minute period. Minimum temperature of rod should not be less than 200°C and the maximum-minimum temperature within the rod should not exceed 10°C.

FIND: Initial uniform temperature $T_i$ to which rod should be heated. Whether the 10°C internal temperature difference is exceeded.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional radial conduction, (2) Constant properties, (3) Uniform and constant convection coefficients.

PROPERTIES: Plastic rod (given): $k = 0.3 \text{ W/m-K}$, $\rho c_p = 1040 \text{ kJ/m}^3 \cdot \text{K}$.

ANALYSIS: For the worst case condition, the rod cools for 3 minutes and its outer surface is at least 200°C in order that the subsequent pressing operation will be satisfactory. Hence,

$$
\frac{r_0}{r_i} = \frac{k}{\alpha t} = \frac{0.3 \text{ W/m-K}}{0.3 \text{ W/m-K} \times \frac{3 \times 60}{0.015 \text{ m}}} = 0.40
$$

$$
Fo = \frac{r_0^2}{\rho c_p r_i^2} = \frac{1040 \times 10^3 \text{ J/m}^3 \cdot \text{K}}{(0.015 \text{ m})^2} = 0.2308.
$$

Using Eq. 5.49a and $\zeta_1 = 0.8516$ rad and $C_1 = 1.0932$ from Table 5.1,

$$
\theta^* = \frac{T(r_0,t) - T_\infty}{T_i - T_\infty} = C_1J_0(\zeta_1 r_0^*) \exp\left(-\zeta_1^2 Fo\right).
$$

With $r_0^* = 1$, from Table B.4, $J_0 (\zeta_1 \times 1) = J_0 (0.8516) = 0.8263$, giving

$$
\frac{200 - 25}{T_i - 25} = 1.0932 \times 0.8263 \exp\left(-0.8516^2 \times 0.2308\right) \quad T_i = 254^\circ \text{C}.
$$

At this time (3 minutes) what is the difference between the center and surface temperatures of the rod? From Eq. 5.49b,

$$
\frac{\theta^*}{\theta_i} = \frac{T(r_0,t) - T_\infty}{T(0,t) - T_\infty} = \frac{200 - 25}{T(0,t) - 25} = J_0 \left(\zeta_1 r_0^*\right) = 0.8263
$$

which gives $T(0,t) = 237^\circ \text{C}$. Hence,

$$
\Delta T = T(0,180) - T(r_0,180) = (237 - 200)^\circ \text{C} = 37^\circ \text{C}.
$$

Hence, the desired max-min temperature difference sought (10°C) is not achieved.

COMMENTS: $\Delta T$ could be reduced by decreasing the cooling rate; however, $h$ can not be made much smaller. Two solutions are (a) increase ambient air temperature and (b) non-uniformly heat rod in oven by controlling its residence time.
PROBLEM 5.54

KNOWN: Diameter and initial temperature of roller bearings. Temperature of oil bath and convection coefficient. Final centerline temperature. Number of bearings processed per hour.

FIND: Time required to reach centerline temperature. Cooling load.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, radial conduction in rod, (2) Constant properties.

PROPERTIES: Table A.1, St. St. 304 \( T = 548 \text{ K} \): \( \rho = 7900 \text{ kg/m}^3 \), \( k = 19.0 \text{ W/m} \cdot \text{K} \), \( c_p = 546 \text{ J/kg} \cdot \text{K} \), \( \alpha = 4.40 \times 10^{-6} \text{ m}^2/\text{s} \).

ANALYSIS: With \( Bi = h (r_o/2)/k = 0.658 \), the lumped capacitance method cannot be used. From the one-term approximation of Eq. 5.49c for the centerline temperature,

\[
\theta_o^* = \frac{T_o - T_\infty}{T_i - T_\infty} = \frac{50 - 30}{500 - 30} = 0.0426 = C_1 \exp \left( -\zeta_1^2 F_\theta \right) = 1.1382 \exp \left[ -\left( 0.9287 \right)^2 F_\theta \right]
\]

where, for \( Bi = h r_o/k = 1.316 \), \( C_1 = 1.1382 \) and \( \zeta_1 = 0.9287 \) from Table 5.1.

\[
F_\theta = -\ln \left( 0.0374/0.863 \right) / 0.863 = 3.81
\]

\[
t_f = F_\theta r_o^2 / \alpha = 3.81 \left( 0.05 \text{ m} \right)^2 / 4.40 \times 10^{-6} = 2162 \text{ s} = 36 \text{ min}
\]

From Eqs. 5.44 and 5.51, the energy extracted from a single rod is

\[
Q = \rho c V \left( T_i - T_\infty \right) \left[ 1 - \frac{2 \theta_o^*}{\zeta_1} J_1 \left( \zeta_1 \right) \right]
\]

With \( J_1 (0.9287) = 0.416 \) from Table B.4,

\[
Q = 7900 \text{ kg/m}^3 \times 546 \text{ J/kg} \cdot \text{K} \times \pi \left( 0.05 \text{ m} \right)^2 \times 1 \text{ m} \times 470 \text{ K} \times \left[ 1 - \frac{0.0852 \times 0.416}{0.9287} \right] = 1.53 \times 10^7 \text{ J}
\]

The nominal cooling load is

\[
\bar{Q} = \frac{N Q}{t_f} = \frac{10 \times 1.53 \times 10^7 \text{ J}}{2162 \text{ s}} = 70,800 \text{ W} = 7.08 \text{ kW}
\]

COMMENTS: For a centerline temperature of 50°C, Eq. 5.49b yields a surface temperature of

\[
T \left( r_o, t \right) = T_\infty + \left( T_i - T_\infty \right) \theta_o^* J_0 \left( \zeta_1 \right) = 30^\circ \text{C} + 470^\circ \text{C} \times 0.0426 \times 0.795 = 45.9^\circ \text{C}
\]
PROBLEM 5.55

KNOWN: Long rods of 40 mm- and 80-mm diameter at a uniform temperature of 400°C in a curing oven, are removed and cooled by forced convection with air at 25°C. The 40-mm diameter rod takes 280 s to reach a safe-to-handle temperature of 60°C.

FIND: Time it takes for a 80-mm diameter rod to cool to the same safe-to-handle temperature. Comment on the result? Did you anticipate this outcome?

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional radial (cylindrical) conduction in the rods, (2) Constant properties, and (3) Convection coefficient same value for both rods.

PROPERTIES: Rod (given): \( \rho = 2500 \text{ kg/m}^3, \ c = 900 \text{ J/kg-K}, \ k = 15 \text{ W/m-K}. \)

ANALYSIS: Not knowing the convection coefficient, the Biot number cannot be calculated to determine whether the rods behave as spacewise isothermal objects. Using the relations from Section 5.6, Radial Systems with Convection, for the infinite cylinder, Eq. 5.50, evaluate

\[
2F_o = \frac{\alpha t}{r_o^2}
\]

and knowing \( T(r_o, t_o) \), a trial-and-error solution is required to find \( Bi = \frac{h r_o}{k} \) and hence, \( h \). Using the IHT Transient Conduction model for the Cylinder, the following results are readily calculated for the 40-mm rod. With \( t_o = 280 \text{ s} \),

\[
F_o = 4.667 \quad Bi = 0.264 \quad h = 197.7 \text{ W/m}^2 \cdot \text{K}
\]

For the 80-mm rod, with the foregoing value for \( h \), with \( T(r_o, t_o) = 60°C \), find

\[
Bi = 0.528 \quad F_o = 2.413 \quad t_o = 579 \text{ s}
\]

COMMENTS: (1) The time-to-cool, \( t_o \), for the 80-mm rod is slightly more than twice that for the 40-mm rod. Did you anticipate this result? Did you believe the times would be proportional to the diameter squared?

(2) The simplest approach to explaining the relationship between \( t_o \) and the diameter follows from the lumped capacitance analysis, Eq. 5.13, where for the same \( \theta/\theta_i \), we expect \( Bi \cdot F_o \) to be a constant. That is,

\[
\frac{h \cdot r_o \cdot \alpha t_o}{k} = C \cdot \frac{r_o^2}{t_o^2}
\]

yielding \( t_o \sim r_o \) (not \( r_o^2 \)).
PROBLEM 5.56

KNOWN: Initial temperature, density, specific heat and diameter of cylindrical rod. Convection coefficient and temperature of air flow. Time for centerline to reach a prescribed temperature. Dependence of convection coefficient on flow velocity.

FIND: (a) Thermal conductivity of material, (b) Effect of velocity and centerline temperature and temperature histories for selected velocities.

SCHEMATIC:

ASSUMPTIONS: (1) Lumped capacitance analysis can not be used but one-term approximation for an infinite cylinder is appropriate, (2) One-dimensional conduction in r, (3) Constant properties, (4) Negligible radiation, (5) Negligible effect of thermocouple hole on conduction.

ANALYSIS: (a) With \( \Theta^* = \frac{T_o(0,1136s) - T_\infty}{(T_i - T_\infty)} = \frac{40 - 25}{100 - 25} = 0.20 \), Eq. 5.49c yields

\[
\frac{Fo}{\rho c_p r_o^2} = \frac{k(1136s)}{1200 \text{ kg/m}^3 \times 1250 \text{ J/kg \cdot K} \times (0.02 \text{ m})^2} = -\ln \left( \frac{0.2}{C_1} \right) / \zeta_1^2
\]

Because \( C_1 \) and \( \zeta_1 \) depend on \( Bi = hr_o/k \), a trial-and-error procedure must be used. For example, a value of \( k \) may be assumed and used to calculate \( Bi \), which may then be used to obtain \( C_1 \) and \( \zeta_1 \) from Table 5.1. Substituting \( C_1 \) and \( \zeta_1 \) into Eq. (1), \( k \) may be computed and compared with the assumed value. Iteration continues until satisfactory convergence is obtained, with

\( k \approx 0.30 \text{ W/m} \cdot \text{K} \)

and, hence, \( Bi = 3.67, C_1 = 1.45, \zeta_1 = 1.87 \) and \( Fo = 0.568 \). For the above value of \( k \),

\( -\ln \left( \frac{0.2}{C_1} \right) / \zeta_1^2 = 0.567 \), which equals the Fourier number, as prescribed by Eq. (1).

(b) With \( h = 55 \text{ W/m}^2 \cdot \text{K} \) for \( V = 6.8 \text{ m/s} \), \( h = CV^{0.618} \) yields a value of \( C = 16.8 \text{ W} \cdot \text{s}^{0.618} / \text{m}^{2.618} \cdot \text{K} \).

The desired variations of the centerline temperature with velocity (for \( t = 1136 \text{ s} \)) and time (for \( V = 3, 10 \) and \( 20 \text{ m/s} \)) are as follows:

Continued …..
With increasing $V$ from 3 to 20 m/s, $h$ increases from 33 to 107 W/m^2-K, and the enhanced cooling reduces the centerline temperature at the prescribed time. The accelerated cooling associated with increasing $V$ is also revealed by the temperature histories, and the time required to achieve thermal equilibrium between the air and the cylinder decreases with increasing $V$.

**COMMENTS:**

1. For the smallest value of $h = 33$ W/m^2-K, $Bi \equiv h (ro/2)/k = 1.1 >> 0.1$, and use of the lumped capacitance method is clearly inappropriate.

2. The *IHT Transient Conduction Model* for a cylinder was used to perform the calculations of Part (b). Because the model is based on the exact solution, Eq. 5.47a, it is accurate for values of $Fo < 0.2$, as well as $Fo > 0.2$. Although in principle, the model may be used to calculate the thermal conductivity for the conditions of Part (a), convergence is elusive and may only be achieved if the initial guesses are close to the correct results.
PROBLEM 5.57

KNOWN: Diameter, initial temperature and properties of stainless steel rod. Temperature and convection coefficient of coolant.

FIND: Temperature distributions for prescribed convection coefficients and times.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional radial conduction, (2) Constant properties.

ANALYSIS: The IHT model is based on the exact solution to the heat equation, Eq. 5.47. The results are plotted as follows

For $h = 100 \text{ W/m}^2\cdot\text{K}$, $\text{Bi} = hr_0/k = 0.1$, and as expected, the temperature distribution is nearly uniform throughout the rod. For $h = 1000 \text{ W/m}^2\cdot\text{K}$ ($\text{Bi} = 1$), temperature variations within the rod are not negligible. In this case the centerline-to-surface temperature difference is comparable to the surface-to-fluid temperature difference. For $h = 5000 \text{ W/m}^2\cdot\text{K}$ ($\text{Bi} = 5$), temperature variations within the rod are large and $[T(0,t) - T(r_0,t)]$ is substantially larger than $[T(r_0,t) - T_\infty]$.

COMMENTS: With increasing Bi, conduction within the rod, and not convection from the surface, becomes the limiting process for heat loss.
**PROBLEM 5.58**

**KNOWN:** A ball bearing is suddenly immersed in a molten salt bath; heat treatment to harden occurs at locations with $T > 1000K$.

**FIND:** Time required to harden outer layer of 1mm.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional radial conduction, (2) Constant properties, (3) $\text{Fo} \geq 0.2$.

**ANALYSIS:** Since any location within the ball whose temperature exceeds 1000K will be hardened, the problem is to find the time when the location $r = 9\text{mm}$ reaches 1000K. Then a 1mm outer layer will be hardened. Begin by finding the Biot number.

$$Bi = \frac{h \cdot r_o}{k} = \frac{5000 \text{ W/m}^2 \cdot \text{K} \cdot (0.020\text{m}/2\text{h})}{50 \text{ W/m} \cdot \text{K}} = 1.00.$$  

Using the one-term approximate solution for a sphere, find

$$Fo = -\frac{1}{\zeta_1^2} \ln \left[ \frac{\theta^*/C_1}{\zeta_1^*} \sin \left( \frac{\zeta_1^* r^*}{\zeta_1^*} \right) \right].$$

From Table 5.1 with $Bi = 1.00$, for the sphere find $\zeta_1 = 1.5708 \text{ rad}$ and $C_1 = 1.2732$. With $r^* = r/r_o = (9\text{mm}/10\text{mm}) = 0.9$, substitute numerical values.

$$Fo = \frac{-1}{(1.5708)^2} \ln \left[ \frac{(1000-1300)\text{K}}{(300-1300)\text{K}} \cdot \frac{1}{1.2732} \cdot \frac{1}{1.5708 \times 0.9} \sin \left( 1.5708 \times 0.9 \text{ rad} \right) \right] = 0.441.$$  

From the definition of the Fourier number with $\alpha = k/\rho c$,

$$t = Fo \cdot \frac{\rho c}{k} = 0.441 \cdot \frac{7800 \text{ kg/m}^3 \times 500 \text{ J/kg} \cdot \text{K}}{50 \text{ W/m} \cdot \text{K}} = 3.4 \text{s}. <$$

**COMMENTS:** (1) Note the very short time required to harden the ball. At this time it can be easily shown the center temperature is $T(0,3.4s) = 871 \text{ K}$.

(2) The Heisler charts can also be used. From Fig. D.8, with $Bi^{-1} = 1.0$ and $r/r_o = 0.9$, read $\theta/\theta_o = 0.69(\pm 0.03)$. Since 

$$\theta = T - T_\infty = 1000 - 1300 = -300 \text{K} \quad \theta_i = T_i - T_\infty = -1000 \text{K}$$

it follows that

$$\frac{\theta}{\theta_i} = 0.30. \text{ Since } \frac{\theta}{\theta_i} = \frac{\theta}{\theta_o} \cdot \frac{\theta_o}{\theta_i}, \text{ then } \frac{\theta}{\theta_i} = 0.69 \cdot \frac{\theta_o}{\theta_i}$$

and

$$\frac{\theta_o}{\theta_i} = 0.30 / 0.69 = 0.43 \ (\pm 0.02).$$

From Fig. D.7 at $\theta_o/\theta_i = 0.43$, $Bi^{-1} = 1.0$, read $Fo = 0.45 (\pm 0.03)$ and $t = 3.5 (\pm 0.2)\text{s}$. Note the use of tolerances associated with reading the charts to $\pm 5\%$. 

PROBLEM 5.59

KNOWN: An 80mm sphere, initially at a uniform elevated temperature, is quenched in an oil bath with prescribed $T_\infty$, $h$.

FIND: The center temperature of the sphere, $T(0,t)$ at a certain time when the surface temperature is $T(r_0,t) = 150^\circ C$.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional radial conduction, (2) Initial uniform temperature within sphere, (3) Constant properties, (4) $Fo \geq 0.2$.

ANALYSIS: Check first to see if the sphere is spacewise isothermal.

$$Bi_c = \frac{h r_0}{k} = \frac{h (r_0/3)}{k} = \frac{1000\,W/m^2 \cdot K \times 0.040\,m/3}{50\,W/m \cdot K} = 0.26.$$  
Since $Bi_c > 0.1$, lumped capacitance method is not appropriate. Recognize that when $Fo \geq 0.2$, the time dependence of the temperature at any point within the sphere will be the same as the center.

Using the Heisler chart method, Fig. D.8 provides the relation between $T(r_0,t)$ and $T(0,t)$. Find first the Biot number,

$$Bi = \frac{br_0}{k} = \frac{1000\,W/m^2 \cdot K \times 0.040\,m}{50\,W/m \cdot K} = 0.80.$$  
With $Bi^{-1} = 1/0.80 = 1.25$ and $r/r_0 = 1$, read from Fig. D.8,

$$\frac{\theta}{\theta_o} = \frac{T(r_0,t) - T_\infty}{T(0,t) - T_\infty} = 0.67.$$  
It follows that

$$T(0,t) = T_\infty + \frac{1}{0.67} [T(r_0,t) - T_\infty] = 50^\circ C + \frac{1}{0.67} [150 - 50]^\circ C = 199^\circ C.$$  

COMMENTS: (1) There is sufficient information to evaluate $Fo$; hence, we require that the time be sufficiently long after the start of quenching for this solution to be appropriate.

(2) The approximate series solution could also be used to obtain $T(0,t)$. For $Bi = 0.80$ from Table 5.1, $\zeta_1 = 1.5044$ rad. Substituting numerical values, $r^* = 1$,

$$\frac{\theta}{\theta_o} = \frac{T(r_0,t) - T_\infty}{T(0,t) - T_\infty} = \frac{1}{\zeta_1 r^* \sin(\zeta_1 r^*)} = \frac{1}{1.5044} \sin(1.5044 \, \text{rad}) = 0.663.$$  
It follows that $T(0,t) = 201^\circ C$. 
PROBLEM 5.60

KNOWN: Steel ball bearings at an initial, uniform temperature are to be cooled by convection while passing through a refrigerated chamber; bearings are to be cooled to a temperature such that 70% of the thermal energy is removed.

FIND: Residence time of the balls in the 5m-long chamber and recommended drive velocity for the conveyor.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible conduction between ball and conveyor surface, (2) Negligible radiation exchange with surroundings, (3) Constant properties, (4) Uniform convection coefficient over ball’s surface.

ANALYSIS: The Biot number for the lumped capacitance analysis is

\[
\text{Bi} \equiv \frac{hL_c}{k} = \frac{h(r_o/3)}{k} = \frac{1000 \text{ W/m}^2 \cdot \text{K} \times (0.1m/3)}{50 \text{ W/m} \cdot \text{K}} = 0.67.
\]

Since Bi > 0.1, lumped capacitance analysis is not appropriate. In Figure D.9, the internal energy change is shown as a function of Bi and Fo. For

\[
\frac{Q}{Q_o} = 0.70 \quad \text{and} \quad \text{Bi} = \frac{hr_o}{k} = \frac{1000 \text{ W/m}^2 \cdot \text{K} \times 0.1m}{50 \text{ W/m} \cdot \text{K}} = 2.0,
\]

find \( \text{Bi}^2 \cdot \text{Fo} \approx 1.2 \). The Fourier number is

\[
\text{Fo} = \frac{\alpha t}{r_o^2} = \frac{2 \times 10^{-5} \text{ m}^2 / \text{s} \times t}{(0.1 \text{ m})^2} = 2.0 \times 10^{-3} t
\]

giving

\[
t = \frac{\text{Fo}}{2.0 \times 10^{-3}} = \frac{1.2 / \text{Bi}^2}{2.0 \times 10^{-3}} = \frac{1.2 / (2.0)^2}{2.0 \times 10^{-3}} = 150 \text{s}.
\]

The velocity of the conveyor is expressed in terms of the length \( L \) and residence time \( t \). Hence

\[
V = \frac{L}{t} = \frac{5 \text{ m}}{150 \text{ s}} = 0.033 \text{ m/s} = 33 \text{ mm/s}.
\]

COMMENTS: Referring to Eq. 5.10, note that for a sphere, the characteristic length is

\[
L_c = V/A_s = \frac{4}{3} \pi r_o^3 / 4 \pi r_o^2 = \frac{r_o}{3}.
\]

However, when using the Heisler charts, note that \( \text{Bi} = h r_o/k \).
PROBLEM 5.61

KNOWN: Diameter and initial temperature of ball bearings to be quenched in an oil bath.

FIND: (a) Time required for surface to cool to 100°C and the corresponding center temperature,
(b) Oil bath cooling requirements.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional radial conduction in ball bearings, (2) Constant properties.

PROPERTIES: Table A-1, St. St., AISI 304, (T ≈ 500°C): \( k = 22.2 \text{ W/m·K} \), \( c_p = 579 \text{ J/kg·K} \), \( \rho = 7900 \text{ kg/m}^3 \), \( \alpha = 4.85\times10^{-6} \text{ m}^2/\text{s} \).

ANALYSIS: (a) To determine whether use of the lumped capacitance method is suitable, first compute

\[
Bi = \frac{h(r_o/3)}{k} = \frac{1000 \text{ W/m}^2·\text{K} (0.010\text{m}/3)}{22.2 \text{ W/m·K}} = 0.15.
\]

We conclude that, although the lumped capacitance method could be used as a first approximation, the Heisler charts should be used in the interest of improving accuracy. Hence, with

\[
Bi^{-1} = \frac{k}{hr_o} = \frac{22.2 \text{ W/m·K}}{1000 \text{ W/m}^2·\text{K} (0.01\text{m})} = 2.22 \quad \text{and} \quad \frac{r}{r_o} = 1,
\]

Fig. D.8 gives

\[
\frac{\theta (r_o, t)}{\theta_o (t)} = 0.80.
\]

Hence, with

\[
\frac{\theta (r_o, t)}{\theta_i} = \frac{T (r_o, t) - T_\infty}{T_i - T_\infty} = \frac{100 - 40}{850 - 40} = 0.074,
\]

Continued ….
it follows that
\[
\frac{\theta_0}{\theta_i} = \frac{\theta (r_o, t) / \theta_i}{\theta (r_o, t) / \theta_o} = \frac{0.074}{0.80} = 0.093.
\]

From Fig. D.7, with \( \theta_0 / \theta_i = 0.093 \) and \( \text{Bi}^{-1} = k/hr_o = 2.22 \), find
\[
t^* = F_0 = 2.0
\]
\[
t = \frac{r_o^2 F_o}{\alpha} = \frac{(0.01m)^2 (2.0)}{4.85 \times 10^{-6} m^2 / s} = 41s.\]

Also,
\[
\theta_0 = T_o - T_\infty = 0.093(T_i - T_\infty) = 0.093(850 - 40) = 75^\circ C
\]
\[
T_o = 115^\circ C\]

(b) With \( \text{Bi}^2 F_o = (1/2.2)^2 \times 2.0 = 0.41 \), where \( \text{Bi} = (hr_o/k) = 0.45 \), it follows from Fig. D.9 that for a single ball
\[
\frac{Q}{Q_o} \approx 0.93.
\]
Hence, from Eq. 5.44,
\[
Q = 0.93 \rho c_p V (T_i - T_\infty)
\]
\[
Q = 0.93 \times 7900 \text{ kg/m}^3 \times 579 \text{ J/kg} \cdot \text{K} \times \frac{\pi}{6} (0.02m)^3 \times 810^\circ C
\]
\[
Q = 1.44 \times 10^4 \text{ J}
\]
is the amount of energy transferred from a single ball during the cooling process. Hence, the oil bath cooling rate must be
\[
q = 10^4 Q / 3600s
\]
\[
q = 4 \times 10^4 W = 40 \text{ kW}.\]

**COMMENTS:** If the lumped capacitance method is used, the cooling time, obtained from Eq. 5.5, would be \( t = 39.7s \), where the ball is assumed to be uniformly cooled to 100\(^\circ\)C. This result, and the fact that \( T_0 - T(r_o) = 15^\circ C \) at the conclusion, suggests that use of the lumped capacitance method would have been reasonable. Note that, when using the Heisler charts, accuracy to better than 5\% is seldom possible.
PROBLEM 5.62

KNOWN: Diameter and initial temperature of hailstone falling through warm air.

FIND: (a) Time, \( t_m \), required for outer surface to reach melting point, \( T(r_o, t_m) = T_m = 0^\circ C \), (b) Centerpoint temperature at that time, (c) Energy transferred to the stone.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional radial conduction, (2) Constant properties.

PROPERTIES: Table A-3, Ice (253K): \( \rho = 920 \text{ kg/m}^3 \), \( k = 2.03 \text{ W/m} \cdot \text{K} \), \( c_p = 1945 \text{ J/kg} \cdot \text{K} \); \( \alpha = k/\rho c_p = 1.13 \times 10^{-6} \text{ m}^2/\text{s} \).

ANALYSIS: (a) Calculate the lumped capacitance Biot number,

\[
Bi = \frac{h (r_o/3)}{k} = \frac{250 \text{ W/m}^2 \cdot \text{K}(0.0025m/3)}{2.03 \text{ W/m} \cdot \text{K}} = 0.103.
\]

Since \( Bi > 0.1 \), use the Heisler charts for which

\[
\frac{\theta (r_o, t_m)}{\theta_i} = \frac{T(r_o, t_m) - T_\infty}{T_i - T_\infty} = \frac{0 - 5}{-30 - 5} = 0.143
\]

\[
Bi^{-1} = \frac{k}{hr_o} = \frac{250 \text{ W/m}^2 \cdot \text{K} \times 0.0025m}{2.03 \text{ W/m} \cdot \text{K}} = 3.25.
\]

From Fig. D.8, find \( \frac{\theta (r_o, t_m)}{\theta_i} \approx 0.86 \).

It follows that

\[
\frac{\theta_o (t_m)}{\theta_i} = \frac{\theta (r_o, t_m) / \theta_i}{\theta_o (t_m) / \theta_o (t_m)} = \frac{0.143}{0.86} \approx 0.17.
\]

From Fig. D.7 find \( Fo \approx 2.1 \). Hence,

\[
t_m = \frac{Fo r_o^2}{\alpha} = \frac{2.1(0.0025)^2}{1.13 \times 10^{-6} \text{ m}^2/\text{s}} = 12s.
\]

(b) Since \( \frac{\theta_o}{\theta_i} \approx 0.17 \), find

\[
T_0 - T_\infty \approx 0.17(T_i - T_\infty) \approx 0.17(-30 - 5) \approx -6.0^\circ C
\]

\[
T_0 (t_m) \approx -1.0^\circ C.
\]

(c) With \( Bi^2 Fo = (1/3.25)^2 \times 2.1 = 0.2 \), from Fig. D.9, find \( Q/Q_o \approx 0.82 \). From Eq. 5.44,

\[
Q_o = \rho Vc_p \theta_i = (920 \text{ kg/m}^3) \left( \frac{\pi}{6} \right)(0.005m)^3 1945 \text{ J/kg} \cdot \text{K} \cdot (35 \text{K}) = -4.10 \text{ J}
\]

\[
Q = 0.82 Q_o = 0.82(-4.10 \text{ J}) = -3.4 \text{ J}.
\]
KNOWN: Sphere quenching in a constant temperature bath.

FIND: (a) Plot $T(0,t)$ and $T(r_o,t)$ as function of time, (b) Time required for surface to reach 415 K, $t'$, (c) Heat flux when $T(r_o, t') = 415$ K, (d) Energy lost by sphere in cooling to $T(r_o, t') = 415$ K, (e) Steady-state temperature reached after sphere is insulated at $t = t'$, (f) Effect of $h$ on center and surface temperature histories.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional radial conduction, (2) Constant properties, (3) Uniform initial temperature.

ANALYSIS: (a) Calculate Biot number to determine if sphere behaves as spatially isothermal object,

\[
Bi = \frac{hL_c}{k} = \frac{h\left(\frac{r_o}{3}\right)}{k} = \frac{75 \text{ W/m}^2 \cdot \text{K} (0.015 \text{ m})}{1.7 \text{ W/m} \cdot \text{K}} = 0.22.
\]

Hence, temperature gradients exist in the sphere and $T(r,t)$ vs. $t$ appears as shown above.

(b) The Heisler charts may be used to find $t'$ when $T(r_o, t') = 415$ K. Using Fig. D.8 with $r/r_o = 1$ and $Bi = k/hr_o = 1.7 \text{ W/m-K}/(75 \text{ W/m}^2\cdot\text{K} \times 0.015 \text{ m}) = 1.51$, $\theta(1,t')/\theta_{r_o} \approx 0.72$. In order to enter Fig. D.7, we need to determine $\theta_{r_o}/\theta_{r_i}$, which is

\[
\frac{\theta_{r_o}}{\theta_{r_i}} = \frac{\theta(1,t')/\theta_{r_o}}{\theta(1,t')/\theta_{r_i}} = \frac{(415 - 320)\text{K}}{(800 - 320)\text{K}} / 0.72 = 0.275
\]

Hence, for $Bi = 1.51$, $Fo = \alpha t'/r_o^2 = 0.87$ and

\[
t' = Fo \frac{r_o^2}{\alpha} = Fo \cdot \frac{\rho c_p}{k} \cdot \frac{r_o^2}{(0.015 \text{ m})^2} = 0.87 \frac{400 \text{ kg/m}^3 \times 1600 \text{ J/kg} \cdot \text{K}}{1.7 \text{ W/m} \cdot \text{K}} = 74\text{s}
\]

(c) The heat flux at the outer surface at time $t'$ is given by Newton’s law of cooling

\[
q^* = h\left[T(r_o, t') - T_{\infty}\right] = 75 \text{ W/m}^2 \cdot \text{K} [415 - 320] \text{K} = 7125 \text{ W/m}^2 \cdot \text{K}.
\]

The manner in which $q^*$ is calculated indicates that energy is leaving the sphere.

(d) The energy lost by the sphere during the cooling process from $t = 0$ to $t'$ can be determined from the Groebert chart, Fig. D.9. With $Bi = 1/1.51 = 0.67$ and $Bi^2Fo = (1/1.51)^2 \times 0.87 \approx 0.4$, the chart yields $Q/Q_o \approx 0.75$. The energy loss by the sphere with $V = (\pi D^3)/6$ is therefore

\[
Q = 0.85Q_o = 0.85\rho \left(\pi D^3/6\right) c_p (T_i - T_{\infty})
\]

\[
Q = 0.85 \times 400 \text{ kg/m}^3 \left(\pi \left[0.030 \text{ m}\right]^3/6\right) 1600 \text{ J/kg} \cdot \text{K} (800 - 320) \text{K} = 3691\text{J}
\]

Continued...
PROBLEM 5.63 (Cont.)

(e) If at time $t'$ the surface of the sphere is perfectly insulated, eventually the temperature of the sphere will be uniform at $T(\infty)$. Applying conservation of energy to the sphere over a time interval, $E_{in} - E_{out} = \Delta E \equiv E_{final} - E_{initial}$. Hence, $-Q = \rho c V (T(\infty) - T_\infty) - Q_o$, where $Q_o \equiv \rho c V [T_i - T_\infty]$. Dividing by $Q_o$ and regrouping, we obtain

$$T(\infty) = T_\infty + \left(1 - \frac{Q}{Q_o}\right) (T_i - T_\infty) = 320 \text{ K} + (1 - 0.75)(800 - 320) \text{ K} = 440 \text{ K}$$

(f) Using the IHT Transient Conduction Model for a Sphere, the following graphical results were generated.

The quenching process is clearly accelerated by increasing $h$ from 75 to 200 W/m$^2$K and is virtually completed by $t \approx 100$ s for the larger value of $h$. Note that, for both values of $h$, the temperature difference $[T(0,t) - T(r_o,t)]$ decreases with increasing $t$. Although the surface heat flux for $h = 200$ W/m$^2$K is initially larger than that for $h = 75$ W/m$^2$K, the more rapid decline in $T(r_o,t)$ causes it to become smaller at $t \approx 30$s.

**COMMENTS:**
1. There is considerable uncertainty associated with reading $Q/Q_o$ from the Groeber chart, Fig. D.9, and it would be better to use the one-term approximation solutions of Section 5.6.2. With $Bi = 0.662$, from Table 5.1, find $\zeta_1 = 1.319$ rad and $C_1 = 1.188$. Using Eq. 5.50, find $Fp = 0.852$ and $t' = 72.2$ s. Using Eq. 5.52, find $Q/Q_o = 0.775$ and $T(\infty) = 428$ K.

2. Using the Transient Conduction/Sphere model in IHT based upon multiple-term series solution, the following results were obtained: $t' = 72.1$ s; $Q/Q_o = 0.7745$, and $T(\infty) = 428$ K.
PROBLEM 5.64

KNOWN: Two spheres, A and B, initially at uniform temperatures of 800K and simultaneously quenched in large, constant temperature baths each maintained at 320K; properties of the spheres and convection coefficients.

FIND: (a) Show in a qualitative manner, on T-t coordinates, temperatures at the center and the outer surface for each sphere; explain features of the curves; (b) Time required for the outer surface of each sphere to reach 415K, (c) Energy gained by each bath during process of cooling spheres to a surface temperature of 415K.

SCHEMATIC:

![Schematic diagram of spheres A and B with properties given in the text.]

ASSUMPTIONS: (1) One-dimensional radial conduction, (2) Uniform properties, (3) Constant convection coefficient.

ANALYSIS: (a) From knowledge of the Biot number and the thermal time constant, it is possible to qualitatively represent the temperature distributions. From Eq. 5.10, with \( L_c = \frac{r_o}{3} \), find

\[
\text{Bi}_A = \frac{5 \text{ W/m}^2 \cdot \text{K} \left(0.150 \text{m/3}\right)}{170 \text{ W/m} \cdot \text{K}} = 1.47 \times 10^{-3}
\]

\(\text{Bi} = \frac{h \left( \frac{r_o}{3} \right)}{k}\)

\[
\text{Bi}_B = \frac{50 \text{ W/m}^2 \cdot \text{K} \left(0.015 \text{m/3}\right)}{1.7 \text{ W/m} \cdot \text{K}} = 0.147
\]

The thermal time constant for a lumped capacitance system from Eq. 5.7 is

\[
\tau = \left[ \frac{1}{hA_s} \right] \left( \rho V_c \right) \quad \tau_A = \frac{1600 \text{ kg/m}^3 \times (0.150 \text{m})400 \text{ J/kg} \cdot \text{K}}{3 \times 5 \text{ W/m}^2 \cdot \text{K}} = 6400 \text{s}
\]

\[
\tau_B = \frac{400 \text{ kg/m}^3 \times (0.015 \text{m})1600 \text{ J/kg} \cdot \text{K}}{3 \times 50 \text{ W/m}^2 \cdot \text{K}} = 64 \text{s}
\]

When Bi << 0.1, the sphere will cool in a spacewise isothermal manner (Sphere A). For sphere B, Bi > 0.1, hence gradients will be important. Note that the thermal time constant of A is much larger than for B; hence, A will cool much slower. See sketch for these features.

(b) Recognizing that Bi_A < 0.1, Sphere A can be treated as spacewise isothermal and analyzed using the lumped capacitance method. From Eq. 5.6 and 5.7, with T = 415 K

\[
\frac{\theta}{\theta_i} = \frac{T - T_\infty}{T_i - T_\infty} = \exp\left(-t/\tau\right)
\]

Continued …..
Note that since the sphere is nearly isothermal, the surface and inner temperatures are approximately the same.

Since $Bi_B > 0.1$, Sphere B must be treated by the Heisler chart method of solution beginning with Figure D.8. Using

$$Bi_B = \frac{hr_o}{k} = \frac{50 \text{ W/m}^2 \cdot \text{K} \times (0.015 \text{ m})}{1.7 \text{ W/m} \cdot \text{K}} = 0.44 \quad \text{or} \quad Bi_B^{-1} = 2.27,$$

find that for $r/r_o = 1$,

$$\theta (1,t) = \frac{T(r_o,t) - T_\infty}{\theta_o} = \frac{(415 - 320)}{\theta_o} = 0.8. \quad (6)$$

Using Eq. (6) and Figure D.7, find the Fourier number,

$$\theta_o = \frac{T(r_o,t) - T_\infty)}{T_i - T_\infty} = \frac{(415 - 320)K}{(800 - 320)K} = 0.25 \quad Fo = \frac{\alpha t}{r_o^2} = 1.3.$$

Find that $t_B = \frac{Fo r_o^2}{\alpha} = \frac{1.3 \times (0.015 \text{ m})^2}{2.656 \times 10^{-6} \text{ m}^2 / \text{s}} = 110 \text{ s} = 1.8 \text{ min}$

where $\alpha = k/\rho c = 1.7 \text{ W/m} \cdot \text{K/400 kg/m}^3 \times 1600 \text{ J/kg} \cdot \text{K} = 2.656 \times 10^{-6} \text{ m}^2 / \text{s}$.

(c) To determine the energy change by the spheres during the cooling process, apply the conservation of energy requirement on a time interval basis.

**Sphere A:**

$$E_{in} - E_{out} = \Delta E \quad -Q_A = \Delta E = E(t) - E(0).$$

$$Q_A = \rho c V \left[ T(t) - T_i \right] = 1600 \text{ kg/m}^3 \times 400 \text{ J/kg} \cdot \text{K} \times (4/3) \pi (0.150 \text{ m})^3 \times (415 - 800) \text{ K}$$

$$Q_A = 3.483 \times 10^6 \text{ J}.$$  

Note that this simple expression is a consequence of the spacewise isothermal behavior.

**Sphere B:**

$$E_{in} - E_{out} = \Delta E \quad -Q_B = E(t) - E(0).$$

For the nonisothermal sphere, the Groyer chart, Figure D.9, can be used to evaluate $Q_B$.

With $Bi = 0.44$ and $Bi^2Fo = (0.44)^2 \times 1.3 = 2.52$, find $Q/Q_o = 0.74$. The energy transfer from the sphere during the cooling process, using Eq. 5.44, is

$$Q_B = 0.74 \frac{Q_o}{0.74} \left[ \rho c V \left( T_i - T_\infty \right) \right]$$

$$Q_B = 0.75 \times 400 \text{ kg/m}^3 \times 1600 \text{ J/kg} \cdot \text{K} \times (4/3) \pi (0.015 \text{ m})^3 \times (800 - 320) \text{ K} = 3257 \text{ J}.$$

**PROBLEM 5.65**

**KNOWN:** Spheres of 40-mm diameter heated to a uniform temperature of 400°C are suddenly removed from an oven and placed in a forced-air bath operating at 25°C with a convection coefficient of 300 W/m²·K.

**FIND:** (a) Time the spheres must remain in the bath for 80% of the thermal energy to be removed, and (b) Uniform temperature the spheres will reach when removed from the bath at this condition and placed in a carton that prevents further heat loss.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional radial conduction in the spheres, (2) Constant properties, and (3) No heat loss from sphere after removed from the bath and placed into the packing carton.

**PROPERTIES:** Sphere (given): \( \rho = 3000 \text{ kg/m}^3 \), \( c = 850 \text{ J/kg} \cdot \text{K} \), \( k = 15 \text{ W/m} \cdot \text{K} \).

**ANALYSIS:** (a) From Eq. 5.52, the fraction of thermal energy removed during the time interval \( \Delta t = t_0 \) is

\[
\frac{Q}{Q_0} = 1 - 3 \theta_0^* / \xi_1^3 \left[ \sin \left( \xi_1 \right) - \xi_1 \cos \left( \xi_1 \right) \right]
\]

where \( Q/Q_0 = 0.8 \). The Biot number is \( Bi = h r_0 / k = 300 \text{ W/m}^2 \cdot \text{K} \times 0.020 \text{ m/15 W/m} \cdot \text{K} = 0.40 \)

and for the one-term series approximation, from Table 5.1,

\( \xi_1 = 1.0528 \text{ rad} \quad C_1 = 1.1164 \)

The dimensionless temperature \( \theta_0^* \), Eq. 5.31, follows from Eq. 5.50.

\[
\theta_0^* = C_1 \exp \left( -\xi_1^2 Fo \right)
\]

where \( Fo = \alpha t_0 / r_0^2 \). Substituting Eq. (3) into Eq. (1), solve for \( Fo \) and \( t_0 \).

\[
\frac{Q}{Q_0} = 1 - 3 C_1 \exp \left( -\xi_1^2 Fo \right) / \xi_1^3 \left[ \sin \left( \xi_1 \right) - \xi_1 \cos \left( \xi_1 \right) \right]
\]

\( Fo = 1.45 \quad t_0 = 98.6 \text{ s} \)

(b) Performing an overall energy balance on the sphere during the interval of time \( t_0 \leq t \leq \infty \),

\[
E_i - E_{out} = \Delta E = E_f - E_i = 0
\]

where \( E_i \) represents the thermal energy in the sphere at \( t_0 \),

\[
E_i = (1-0.8)Q_0 = (1-0.8) \rho c V (T_i - T_\infty)
\]

and \( E_f \) represents the thermal energy in the sphere at \( t = \infty \),

\[
E_f = \rho c V (T_{avg} - T_\infty)
\]

Combining the relations, find the average temperature

\[
\rho c V \left[ (T_{avg} - T_\infty - (1-0.8)(T_i - T_\infty)) \right] = 0
\]

\( T_{avg} = 100^\circ \text{C} \)
**PROBLEM 5.66**

**KNOWN:** Diameter, density, specific heat and thermal conductivity of Pyrex spheres in packed bed thermal energy storage system. Convection coefficient and inlet gas temperature.

**FIND:** Time required for sphere to acquire 90% of maximum possible thermal energy and the corresponding center temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional radial conduction in sphere, (2) Negligible heat transfer to or from a sphere by radiation or conduction due to contact with adjoining spheres, (3) Constant properties.

**ANALYSIS:** With \(\text{Bi} \equiv h(r_o/3)/k = 75 \text{ W/m}^2\cdot\text{K} (0.0125\text{m})/1.4 \text{ W/m} \cdot \text{K} = 0.67\), the approximate solution for one-dimensional transient conduction in a sphere is used to obtain the desired results. We first use Eq. (5.52) to obtain \(\theta_o^*\).

\[
\theta_o^* = \frac{\xi^3}{3\left[\sin\left(\xi_1\right) - \xi_1 \cos\left(\xi_1\right)\right]} \left(1 - \frac{Q}{Q_o}\right)
\]

With \(\text{Bi} \equiv hr_o/k = 2.01\), \(\zeta_1 = 2.03\) and \(C_1 = 1.48\) from Table 5.1. Hence,

\[
\theta_o^* = \frac{0.1(2.03)^3}{3\left[0.896 - 2.03(-0.443)\right]} = \frac{0.837}{5.386} = 0.155
\]

The center temperature is therefore

\[
T_o = T_{g,i} + 0.155\left(T_i - T_{g,i}\right) = 300^\circ\text{C} - 42.7^\circ\text{C} = 257.3^\circ\text{C}
\]

From Eq. (5.50c), the corresponding time is

\[
t = -\frac{t_o^2}{\alpha \xi_1^2} \ln\left(\frac{\theta_o^*}{C_1}\right)
\]

where \(\alpha = k / \rho c = 1.4 \text{ W/m} \cdot \text{K} / \left(2225 \text{ kg/m}^3 \times 835 \text{ J/kg} \cdot \text{K}\right) = 7.54 \times 10^{-7} \text{ m}^2 / \text{s}\).

\[
t = -\frac{(0.0375\text{m})^2 \ln (0.155/1.48)}{7.54 \times 10^{-7} \text{ m}^2 / \text{s} (2.03)^2} = 1.020\text{s}
\]

**COMMENTS:** The surface temperature at the time of interest may be obtained from Eq. (5.50b). With \(r^* = 1\),

\[
T_s = T_{g,i} + \left(T_i - T_{g,i}\right) \frac{\theta_o^* \sin\left(\xi_1\right)}{\xi_1} = 300^\circ\text{C} - 275^\circ\text{C} \left(\frac{0.155 \times 0.896}{2.03}\right) = 280.9^\circ\text{C}
\]
PROBLEM 5.67

KNOWN: Initial temperature and properties of a solid sphere. Surface temperature after immersion in a fluid of prescribed temperature and convection coefficient.

FIND: (a) Time to reach surface temperature, (b) Effect of thermal diffusivity and conductivity on thermal response.

Schematic:

ASSUMPTIONS: (1) One-dimensional, radial conduction, (2) Constant properties.

ANALYSIS: (a) For \( k = 15 \text{ W/m} \cdot \text{K} \), the Biot number is

\[
\text{Bi} = \frac{h(r_0/3)}{k} = \frac{300 \text{ W/m}^2 \cdot \text{K} \cdot (0.05 \text{ m}/3)}{15 \text{ W/m} \cdot \text{K}} = 0.333.
\]

Hence, the lumped capacitance method cannot be used. From Equation 5.50a,

\[
\frac{T - T_{\infty}}{T_i - T_{\infty}} = C_1 \exp\left(-\frac{\zeta_1^2 \text{Fo}}{\zeta_1 r^*}\right) \sin\left(\frac{\zeta_1 r^*}{\zeta_1 r^*}\right).
\]

At the surface, \( r^* = 1 \). From Table 5.1, for \( \text{Bi} = 1.0 \), \( \zeta_1 = 1.5708 \) rad and \( C_1 = 1.2732 \). Hence,

\[
\frac{60 - 75}{25 - 75} = 0.30 = 1.2732 \exp\left(-1.5708^2 \text{Fo}\right) \sin 90^\circ
\]

\[
\exp(-2.467\text{Fo}) = 0.370
\]

\[
\text{Fo} = \frac{\alpha t}{r_0^2} = 0.403
\]

\[
t = 0.403 \frac{r_0^2}{\alpha} = 0.403 \frac{(0.05 \text{ m})^2}{10^{-5} \text{ m}^2/\text{s}} = 100 \text{s}
\]

(b) Using the IHT Transient Conduction Model for a Sphere to perform the parametric calculations, the effect of \( \alpha \) is plotted for \( k = 15 \text{ W/m} \cdot \text{K} \).
For fixed $k$ and increasing $\alpha$, there is a reduction in the thermal capacity ($\rho c_p$) of the material, and hence the amount of thermal energy which must be added to increase the temperature. With increasing $\alpha$, the material therefore responds more quickly to a change in the thermal environment, with the response at the center lagging that of the surface.

The effect of $k$ is plotted for $\alpha = 10^{-5}$ m$^2$/s.

With increasing $k$ for fixed alpha, there is a corresponding increase in $\rho c_p$, and the material therefore responds more slowly to a thermal change in its surroundings. The thermal response of the center lags that of the surface, with temperature differences, $T(r_o,t) - T(0,t)$, during early stages of solidification increasing with decreasing $k$.

**COMMENTS:** Use of this technique to determine $h$ from measurement of $T(r_o)$ at a prescribed $t$ requires an interative solution of the governing equations.
PROBLEM 5.68

KNOWN: Properties, initial temperature, and convection conditions associated with cooling of glass beads.

FIND: (a) Time required to achieve a prescribed center temperature, (b) Effect of convection coefficient on center and surface temperature histories.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in r, (2) Constant properties, (3) Negligible radiation, (4) $Fo \geq 0.2$.

ANALYSIS: (a) With $h = 400 \text{ W/m}^2\cdot\text{K}$, $Bi = h(r_o/3)/k = 400 \text{ W/m}^2\cdot\text{K}(0.0005 \text{ m})/1.4 \text{ W/m} \cdot \text{K} = 0.143$ and the lumped capacitance method should not be used. From the one-term approximation for the center temperature, Eq. 5.50c,

$$\theta_0^* = \frac{T_0 - T_{\infty}}{T_1 - T_{\infty}} = \frac{80 - 15}{477 - 15} = 0.141 = C_1 \exp\left(-\zeta_1^2 Fo\right)$$

For $Bi = hr_o/k = 0.429$, Table 5.1 yields $\zeta_1 = 1.101 \text{ rad}$ and $C_1 = 1.128$. Hence,

$$Fo = -\frac{1}{\zeta_1^2} \ln\left(\frac{\theta_0^*}{C_1}\right) = -\frac{1}{(1.101)^2} \ln\left(\frac{0.141}{1.128}\right) = 1.715$$

$$t = 1.715r_0^2 \frac{\rho c_p}{k} = 1.715(0.0015 \text{ m})^2 \frac{2200 \text{ kg/m}^3 \cdot \text{m}^3 \cdot \text{s}^2 \cdot \text{K}}{1.4 \text{ W/m} \cdot \text{K}} = 4.85 \text{s}\quad<$$

From Eq. 5.50b, the corresponding surface ($r^* = 1$) temperature is

$$T(r_o, t) = T_{\infty} + (T_1 - T_{\infty})\theta_0^* \frac{\sin\zeta_1}{\zeta_1} = 15^\circ \text{C} + \left(462^\circ \text{C}\right)0.141 \frac{0.892}{1.101} = 67.8^\circ \text{C}\quad<$$

(b) The effect of $h$ on the surface and center temperatures was determined using the IHT Transient Conduction Model for a Sphere.

Continued...
The cooling rate increases with increasing h, particularly from 100 to 400 W/m²-K. The temperature difference between the center and surface decreases with increasing t and, during the early stages of solidification, with decreasing h.

**COMMENTS:** Temperature gradients in the glass are largest during the early stages of solidification and increase with increasing h. Since thermal stresses increase with increasing temperature gradients, the propensity to induce defects due to crack formation in the glass increases with increasing h. Hence, there is a value of h above which product quality would suffer and the process should not be operated.
PROBLEM 5.69

KNOWN: Temperature requirements for cooling the spherical material of Ex. 5.4 in air and in a water bath.

FIND: (a) For step 1, the time required for the center temperature to reach $T(0,t) = 335°C$ while cooling in air at $20°C$ with $h = 10 \text{ W/m}^2\cdot\text{K}$; find the Biot number; do you expect radial gradients to be appreciable?; compare results with hand calculations in Ex. 5.4; (b) For step 2, time required for the center temperature to reach $T(0,t) = 50°C$ while cooling in water bath at $20°C$ with $h = 6000 \text{ W/m}^2\cdot\text{K}$; and (c) For step 2, calculate and plot the temperature history, $T(x,t)$ vs. $t$, for the center and surface of the sphere; explain features; when do you expect the temperature gradients in the sphere to the largest? Use the IHT Models | Transient Conduction | Sphere model as your solution tool.

SCHEMATIC:

**ASSUMPTIONS:** (1) One-dimensional conduction in the radial direction, (2) Constant properties.

**ANALYSIS:** The IHT model represents the series solution for the sphere providing the temperatures evaluated at $(r,t)$. A selected portion of the IHT code used to obtain results is shown in the Comments.

(a) Using the IHT model with step 1 conditions, the time required for $T(0,t_a) = T_{xt} = 335°C$ with $r = 0$ and the Biot number are:
\[
\begin{align*}
  t_a &= 94.2 \text{ s} \\
  \text{Bi} &= 0.0025
\end{align*}
\]
Radial temperature gradients will not be appreciable since $\text{Bi} = 0.0025 \ll 0.1$. The sphere behaves as space-wise isothermal object for the air-cooling process. The result is identical to the lumped-capacitance analysis result of the Text example.

(b) Using the IHT model with step 2 conditions, the time required for $T(0,t_w) = T_{xt} = 50°C$ with $r = 0$ and $T_i = 335°C$ is
\[
  t_w = 3.0 \text{ s}
\]
Radial temperature gradients will be appreciable, since $\text{Bi} = 1.5 >> 0.1$. The sphere does not behave as a space-wise isothermal object for the water-cooling process.

(c) For the step 2 cooling process, the temperature histories for the center and surface of the sphere are calculated using the IHT model.

Continued ….
At early times, the difference between the center and surface temperature is appreciable. It is in this time region that thermal stresses will be a maximum, and if large enough, can cause fracture. Within 6 seconds, the sphere has a uniform temperature equal to that of the water bath.

**COMMENTS:** Selected portions of the IHT sphere model codes for steps 1 and 2 are shown below.

/* Results, for part (a), step 1, air cooling; clearly negligible gradient */
Bi  Fo  t  T_xt  Ti  Tinf  r  ro
0.0025 25.13 94.22 335 400 0 0.005 */

// Models | Transient Conduction | Sphere - Step 1, Air cooling
// The temperature distribution T(r,t) is
T_xt = T_xt_trans("Sphere",rstar,Fo,Bi,Ti,Tinf) // Eq 5.47
T_xt = 335 // Surface temperature

/* Results, for part (b), step 2, water cooling; Ti = 335 C */
Bi  Fo  t  T_xt  Ti  r  ro
1.5 0.7936 2.976 50 335 0 0.005 */

// Models | Transient Conduction | Sphere - Step 2, Water cooling
// The temperature distribution T(r,t) is
T_xt = T_xt_trans("Sphere",rstar,Fo,Bi,Ti,Tinf) // Eq 5.47
T_xt = 335 // Surface temperature from Step 1; initial temperature for Step 2
T_xt = 50 // Center temperature, end of Step 2
PROBLEM 5.70

KNOWN: Two large blocks of different materials – like copper and concrete – at room temperature, 23°C.

FIND: Which block will feel cooler to the touch?

SCHEMATIC:

ASSUMPTIONS: (1) Blocks can be treated as semi-infinite solid, (2) Hand or finger temperature is 37°C.

PROPERTIES: Table A-1, Copper (300K): $\rho = 8933 \text{ kg/m}^3$, $c = 385 \text{ J/kg} \cdot \text{K}$, $k = 401 \text{ W/m} \cdot \text{K};$ Table A-3, Concrete, stone mix (300K): $\rho = 2300 \text{ kg/m}^3$, $c = 880 \text{ J/kg} \cdot \text{K}$, $k = 1.4 \text{ W/m} \cdot \text{K}$.

ANALYSIS: Considering the block as a semi-infinite solid, the heat transfer situation corresponds to a sudden change in surface temperature, Case 1, Figure 5.7. The sensation of coolness is related to the heat flow from the hand or finger to the block. From Eq. 5.58, the surface heat flux is

$$q_s^* (t) = k(T_s - T_i) / (\pi \alpha t)^{1/2}$$

or

$$q_s^* (t) \sim (k \rho c)^{1/2} \text{ since } \alpha = k/\rho c. $$

Hence for the same temperature difference, $T_s - T_i$, and elapsed time, it follows that the heat fluxes for the two materials are related as

$$\frac{q_s^* \text{copper}}{q_s^* \text{concrete}} = \left(\frac{k \rho c}{k \rho c}\right)^{1/2} = \left[\frac{401 \text{ W/m} \cdot \text{K}}{1.4 \text{ W/m} \cdot \text{K}} \times \frac{8933 \text{ kg/m}^3}{2300 \text{ kg/m}^3} \times \frac{385 \text{ J/kg} \cdot \text{K}}{880 \text{ J/kg} \cdot \text{K}}\right]^{1/2} = 22.1$$

Hence, the heat flux to the copper block is more than 20 times larger than to the concrete block. The copper block will therefore feel noticeably cooler than the concrete one.
PROBLEM 5.71

KNOWN: Asphalt pavement, initially at 50°C, is suddenly exposed to a rainstorm reducing the surface temperature to 20°C.

FIND: Total amount of energy removed (J/m^2) from the pavement for a 30 minute period.

SCHEMATIC:

ASSUMPTIONS: (1) Asphalt pavement can be treated as a semi-infinite solid, (2) Effect of rainstorm is to suddenly reduce the surface temperature to 20°C and is maintained at that level for the period of interest.

PROPERTIES: Table A-3, Asphalt (300K): \( \rho = 2115 \text{ kg/m}^3 \), \( c = 920 \text{ J/kg} \cdot \text{K} \), \( k = 0.062 \text{ W/m} \cdot \text{K} \).

ANALYSIS: This solution corresponds to Case 1, Figure 5.7, and the surface heat flux is given by Eq. 5.58 as

\[
q_s^* (t) = k(T_s - T_i) / (\pi \alpha t)^{1/2}
\]

(1)

The energy into the pavement over a period of time is the integral of the surface heat flux expressed as

\[
Q^\prime\prime = \int_0^t q_s^* (t) \, dt.
\]

(2)

Note that \( q_s^* (t) \) is into the solid and, hence, \( Q \) represents energy into the solid. Substituting Eq. (1) for \( q_s^* (t) \) into Eq. (2) and integrating find

\[
Q^\prime\prime = k(T_s - T_i) / (\pi \alpha)^{1/2} \int_0^t t^{-1/2} \, dt = \frac{k(T_s - T_i)}{(\pi \alpha)^{1/2}} \times 2 t^{1/2}.
\]

(3)

Substituting numerical values into Eq. (3) with

\[
\alpha = \frac{k}{\rho c} = \frac{0.062 \text{ W/m} \cdot \text{K}}{2115 \text{ kg/m}^3 \times 920 \text{ J/kg} \cdot \text{K}} = 3.18 \times 10^{-8} \text{ m}^2 / \text{s}
\]

find that for the 30 minute period,

\[
Q^\prime\prime = \frac{0.062 \text{ W/m} \cdot \text{K} (20 - 50) \text{ K}}{(\pi \times 3.18 \times 10^{-8} \text{ m}^2 / \text{s})^{1/2}} \times 2 (30 \times 60 \text{s})^{1/2} = -4.99 \times 10^5 \text{ J/m}^2.
\]

COMMENTS: Note that the sign for \( Q^\prime\prime \) is negative implying that energy is removed from the solid.
**PROBLEM 5.72**

**KNOWN:** Thermophysical properties and initial temperature of thick steel plate. Temperature of water jets used for convection cooling at one surface.

**FIND:** Time required to cool prescribed interior location to a prescribed temperature.

**SCHEMATIC:**

![Schematic diagram showing steel plate, water jets, and temperature conditions.]

**ASSUMPTIONS:** (1) One-dimensional conduction in slab, (2) Validity of semi-infinite medium approximation, (3) Negligible thermal resistance between water jets and slab surface ($T_s = T_\infty$), (4) Constant properties.

**ANALYSIS:** The desired cooling time may be obtained from Eq. (5.57). With $T(0.025\text{ m}, t) = 50^\circ\text{C}$,

$$
\frac{T(x, t) - T_s}{T_i - T_s} = \frac{(50 - 25)^\circ\text{C}}{(300 - 25)^\circ\text{C}} = 0.0909 = \text{erf}\left(\frac{x}{2\sqrt{\alpha t}}\right)
$$

$$
\frac{x}{2\sqrt{\alpha t}} = 0.0807
$$

$$
t = \frac{x^2}{(0.0807)^2} \frac{4\alpha}{0.0261(1.34 \times 10^{-5} \text{ m}^2/\text{s})} = 1793\text{s}
$$

where $\alpha = k/\rho c = 50 \text{ W/m}\cdot\text{K}/(7800 \text{ kg/m}^3 \times 480 \text{ J/kg}\cdot\text{K}) = 1.34 \times 10^{-5} \text{ m}^2/\text{s}$.

**COMMENTS:** (1) Large values of the convection coefficient ($h \sim 10^4 \text{ W/m}^2\cdot\text{K}$) are associated with water jet impingement, and it is reasonable to assume that the surface is immediately quenched to the temperature of the water. (2) The surface heat flux may be determined from Eq. (5.58). In principle, the flux is infinite at $t = 0$ and decays as $t^{1/2}$. 
PROBLEM 5.73

KNOWN: Temperature imposed at the surface of soil initially at 20°C. See Example 5.5.

FIND: (a) Calculate and plot the temperature history at the burial depth of 0.68 m for selected soil thermal diffusivity values, \( \alpha \times 10^{-7} = 1.0, 1.38, \) and 3.0 m\(^2\)/s, (b) Plot the temperature distribution over the depth \( 0 \leq x \leq 1.0 \) m for times of 1, 5, 10, 30, and 60 days with \( \alpha = 1.38 \times 10^{-7} \) m\(^2\)/s, (c) Plot the surface heat flux, \( q_x^s (0, t) \), and the heat flux at the depth of the buried main, \( q_x^s (0.68 \text{m}, t) \), as a function of time for a 60 day period with \( \alpha = 1.38 \times 10^{-7} \) m\(^2\)/s. Compare your results with those in the Comments section of the example. Use the IHT Models | Transient Conduction | Semi-infinite Medium model as the solution tool.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in the x-direction, (2) Soil is a semi-infinite medium, and (3) Constant properties.

ANALYSIS: The IHT model corresponds to the case 1, constant surface temperature sudden boundary condition, Eqs. 5.57 and 5.58. Selected portions of the IHT code used to obtain the graphical results below are shown in the Comments.

(a) The temperature history \( T(x,t) \) for \( x = 0.68 \) m with selected soil thermal diffusivities is shown below. The results are directly comparable to the graph shown in the Ex. 5.5 comments.

Continued …..
(b) The temperature distribution $T(x,t)$ for selected times is shown below. The results are directly comparable to the graph shown in the Ex. 5.5 comments.

![Temperature Distribution Graph]

(c) The heat flux from the soil, $q_x(0,t)$, and the heat flux at the depth of the buried main, $q_x(0.68\text{m},t)$, are calculated and plotted for the time period $0 \leq t \leq 60$ days.

![Heat Flux Graph]

Both the surface and buried-main heat fluxes have a negative sign since heat is flowing in the negative $x$-direction. The surface heat flux is initially very large and, in the limit, approaches that of the buried-main heat flux. The latter is initially zero, and since the effect of the sudden change in surface temperature is delayed for a time period, the heat flux begins to slowly increase.

Continued .....
COMMENTS: (1) Can you explain why the surface and buried-main heat fluxes are nearly the same at \( t = 60 \) days? Are these results consistent with the temperature distributions? What happens to the heat flux values for times much greater than 60 days? Use your IHT model to confirm your explanation.

(2) Selected portions of the IHT code for the semi-infinite medium model are shown below.

```plaintext
// Models | Transient Conduction | Semi-infinite Solid | Constant temperature Ts
/* Model: Semi-infinite solid, initially with a uniform temperature \( T(x,0) = T_i \), suddenly subjected to prescribed surface boundary conditions. */
// The temperature distribution \( (T_x,t) \) is
\[ T_{xt} = T_{xt\_semi\_CST}(x,\alpha,t,Ts,Ti) \]  // Eq 5.55
// The heat flux in the x direction is
\[ q''_{xt} = q_{dprime\_xt\_semi\_CST}(x,\alpha,t,Ts,Ti,k) \]  //Eq 5.56

// Input parameters
/* The independent variables for this system and their assigned numerical values are */
\( T_i = 20 \)  // initial temperature, C
\( k = 0.52 \)  // thermal conductivity, W/m.K; base case condition
\( \alpha = 1.38e^{-7} \)  // thermal diffusivity, m^2/s; base case
\( \alpha = 1.0e^{-7} \)
\( \alpha = 3.0e^{-7} \)
// Calculating at x-location and time t,
x = 0  // m, surface
\( x = 0.68 \)  // m, burial depth
t = \( t_{day} \times 24 \times 3600 \)  // seconds to days time conversion
\( t_{day} = 60 \)
\( t_{day} = 1 \)
\( t_{day} = 5 \)
\( t_{day} = 10 \)
\( t_{day} = 30 \)
\( t_{day} = 20 \)

// Surface condition: constant surface temperature
\( Ts = -15 \)  // surface temperature, K
```

PROBLEM 5.73 (Cont.)
**PROBLEM 5.74**

**KNOWN:** Tile-iron, 254 mm to a side, at 150°C is suddenly brought into contact with tile over a subflooring material initially at $T_i = 25°C$ with prescribed thermophysical properties. Tile adhesive softens in 2 minutes at 50°C, but deteriorates above 120°C.

**FIND:** (a) Time required to lift a tile after being heated by the tile-iron and whether adhesive temperature exceeds 120°C, (2) How much energy has been removed from the tile-iron during the time it has taken to lift the tile.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Tile and subflooring have same thermophysical properties, (2) Thickness of adhesive is negligible compared to that of tile, (3) Tile-subflooring behaves as semi-infinite solid experiencing one-dimensional transient conduction.

**PROPERTIES:** Tile-subflooring (given): $k = 0.15 \text{ W/m} \cdot \text{K}$, $\rho c_p = 1.5 \times 10^6 \text{ J/m}^3 \cdot \text{K}$, $\alpha = k/\rho c_p = 1.00 \times 10^{-7} \text{ m}^2/\text{s}$.

**ANALYSIS:** (a) The tile-subflooring can be approximated as a semi-infinite solid, initially at a uniform temperature $T_i = 25°C$, experiencing a sudden change in surface temperature $T_s = T(0,t) = 150°C$. This corresponds to Case 1, Figure 5.7. The time required to heat the adhesive ($x_o = 4 \text{ mm}$) to 50°C follows from Eq. 5.57

\[
\frac{T(x_o, t_o) - T_s}{T_i - T_s} = \text{erf} \left( \frac{x_o}{2(\alpha t_o)^{1/2}} \right)
\]

\[
\frac{50 - 150}{25 - 150} = \text{erf} \left( \frac{0.004 \text{ m}}{2 \left(1.00 \times 10^{-7} \text{ m}^2/\text{s} \times t_o \right)^{1/2}} \right)
\]

\[
0.80 = \text{erf} \left( 6.325 t_o^{-1/2} \right)
\]

$t_o = 48.7 \text{s} = 0.81 \text{ min}$

using error function values from Table B.2. Since the softening time, $\Delta t_s$, for the adhesive is 2 minutes, the time to lift the tile is

\[
t = t_o + \Delta t_s = (0.81 + 2.0) \text{ min} = 2.81 \text{ min} \quad <
\]

To determine whether the adhesive temperature has exceeded 120°C, calculate its temperature at $t = 2.81 \text{ min}$; that is, find $T(x_o, t)$

\[
\frac{T(x_o, t) - 150}{25 - 150} = \text{erf} \left( \frac{0.004 \text{ m}}{2 \left(1.00 \times 10^{-7} \text{ m}^2/\text{s} \times 2.81 \times 60 \text{ s} \right)^{1/2}} \right)
\]

Continued...
PROBLEM 5.74 (Cont.)

\[ T(x_0, t_\ell) - 150 = -125 \text{erf} (0.4880) = 125 \times 0.5098 \]

\[ T(x_0, t_\ell) = 86^\circ C \]

Since \( T(x_0, t_\ell) < 120^\circ C \), the adhesive will not deteriorate.

(b) The energy required to heat a tile to the lift-off condition is

\[ Q = t_\ell \int_0^{t_\ell} q^s_x (0, t) \cdot A_s \, dt \]

Using Eq. 5.58 for the surface heat flux \( q^s_x (t) = q^s_x (0, t) \), find

\[ Q = \int_0^{t_\ell} \frac{k(T_s - T_i)}{(\pi \alpha)^{1/2}} \frac{A_s}{t^{1/2}} \, dt = \frac{2k(T_s - T_i)}{(\pi \alpha)^{1/2}} A_s t_\ell^{1/2} \]

\[ Q = \frac{2 \times 0.15 \text{ W/m} \cdot \text{K} \times (150 - 25)^\circ \text{C}}{(\pi \times 1.00 \times 10^{-7} \text{ m}^2/\text{s})^{1/2}} \times (0.254 \text{ m})^2 \times (2.81 \times 60 \text{s})^{1/2} = 56 \text{ kJ} \]

COMMENTS:  
(1) Increasing the tile-iron temperature would decrease the time required to soften the adhesive, but the risk of burning the adhesive increases.

(2) From the energy calculation of part (b) we can estimate the size of an electrical heater, if operating continuously during the 2.81 min period, to maintain the tile-iron at a near constant temperature. The power required is

\[ P = \frac{Q}{t_\ell} = \frac{56 \text{ kJ}}{2.81 \times 60 \text{s}} = 330 \text{ W} \]

Of course a much larger electrical heater would be required to initially heat the tile-iron up to the operating temperature in a reasonable period of time.
PROBLEM 5.75

KNOWN: Heat flux gage of prescribed thickness and thermophysical properties ($\rho$, $c_p$, $k$) initially at a uniform temperature, $T_i$, is exposed to a sudden change in surface temperature $T(0,t) = T_s$.

FIND: Relationships for time constant of gage when (a) backside of gage is insulated and (b) gage is imbedded in semi-infinite solid having the same thermophysical properties. Compare with equation given by manufacturer, $\tau = \left(4d^2 \rho \frac{c_p}{k}\right)/\pi^2 k$.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties.

ANALYSIS: The time constant $\tau$ is defined as the time required for the gage to indicate, following a sudden step change, a signal which is 63.2% that of the steady-state value. The manufacturer’s relationship for the time constant

$$\tau = \left(4d^2 \rho \frac{c_p}{k}\right)/\pi^2 k$$

can be written in terms of the Fourier number as

$$Fo = \frac{\alpha \tau}{d^2} = \frac{k}{\rho \frac{c_p}{d^2}} \cdot \frac{\tau}{\pi^2} = \frac{4}{\pi^2} = 0.4053.$$ 

The Fourier number can be determined for the two different installations.

(a) For the gage having its backside insulated, the surface and backside temperatures are $T_s$ and $T(0,t)$, respectively. From the sketch it follows that

$$\theta_0^* = \frac{T(0,t) - T_s}{T_i - T_s} = 0.368.$$ 

From Eq. 5.41,

$$\theta_0^* = 0.368 = C_1 \exp\left(-\frac{\tau^2}{\zeta_1^2}Fo\right)$$

Using Table 5.1 with $Bi = 100$ (as the best approximation for $Bi = hd/k \to \infty$, corresponding to sudden surface temperature change with $h \to \infty$), $\zeta_1 = 1.5552$ rad and $C_1 = 1.2731$. Hence,

$$0.368 = 1.2731 \exp(-1.5552^2 \times Fo_a)$$

$$Fo_a = 0.513.$$ 

Continued …..
(b) For the gage imbedded in a semi-infinite medium having the same thermophysical properties, Table 5.7 (case 1) and Eq. 5.57 yield

\[
\frac{T(x, \tau) - T_s}{T_i - T_s} = 0.368 = \text{erf} \left\{ \frac{d}{2(\alpha \tau)^{1/2}} \right\}
\]

\[
d/2(\alpha \tau)^{1/2} = 0.3972
\]

\[
F_{o_b} = \frac{\alpha \tau}{d^2} = \frac{1}{(2 \times 0.3972)^2} = 1.585
\]

**COMMENTS:** Both models predict higher values of Fo than that suggested by the manufacturer. It is understandable why \( F_{o_b} > F_{o_a} \) since for (b) the gage is thermally connected to an infinite medium, while for (a) it is isolated. From this analysis we conclude that the gage’s transient response will depend upon the manner in which it is applied to the surface or object.
PROBLEM 5.76

KNOWN: Procedure for measuring convection heat transfer coefficient, which involves melting of a surface coating.

FIND: Melting point of coating for prescribed conditions.

SCHEMATIC:

PROPERTIES: Copper rod (Given): $k = 400 \text{ W/m} \cdot \text{K}$, $\alpha = 10^{-4} \text{ m}^2/\text{s}$.

ANALYSIS: Problem corresponds to transient conduction in a semi-infinite solid. The thermal response is given by

$$
\frac{T(x,t) - T_i}{T_\infty - T_i} = \text{erfc}\left(\frac{x}{2(\alpha t)^{1/2}}\right) - \left[\exp\left(\frac{hx}{k} + \frac{h^2\alpha t}{k^2}\right)\right]\text{erfc}\left(\frac{x}{2(\alpha t)^{1/2}} + \frac{h(\alpha t)^{1/2}}{k}\right).
$$

For $x = 0$, $\text{erfc}(0) = 1$ and $T(x,t) = T(0,t) = T_s$. Hence

$$
\frac{T_s - T_i}{T_\infty - T_i} = 1 - \exp\left(\frac{h^2\alpha t}{k^2}\right)\text{erfc}\left(\frac{h(\alpha t)^{1/2}}{k}\right)
$$

with

$$
\frac{h(\alpha t_m)^{1/2}}{k} = \frac{200 \text{ W/m}^2 \cdot \text{K} \left(10^{-4} \text{ m}^2/\text{s}\times400 \text{ s}\right)^{1/2}}{400 \text{ W/m} \cdot \text{K}} = 0.1
$$

$$
T_s = T_m = T_i + (T_\infty - T_i)\left[1 - \exp(0.01)\text{erfc}(0.1)\right]
$$

$$
T_s = 25^\circ\text{C} + 275^\circ\text{C}[1-1.01\times0.888] = 53.5^\circ\text{C}.
$$

COMMENTS: Use of the procedure to evaluate $h$ from measurement of $t_m$ necessitates iterative calculations.
PROBLEM 5.77

KNOWN: Irreversible thermal injury (cell damage) occurs in living tissue maintained at \( T \geq 48^\circ C \) for a duration \( \Delta t \geq 10\text{s} \).

FIND: (a) Extent of damage for 10 seconds of contact with machinery in the temperature range 50 to 100\( ^\circ C \), (b) Temperature histories at selected locations in tissue \( (x = 0.5, 1, 5 \text{ mm}) \) for a machinery temperature of 100\( ^\circ C \).

SCHEMATIC:

ASSUMPTIONS: (1) Portion of worker’s body modeled as semi-infinite medium, initially at a uniform temperature, 37\( ^\circ C \), (2) Tissue properties are constant and equivalent to those of water at 37\( ^\circ C \), (3) Negligible contact resistance.

PROPERTIES: Table A-6, Water, liquid \( (T = 37^\circ C = 310 \text{ K}) \): \( \rho = 1/\nu_f = 993.1 \text{ kg/m}^3 \), \( c = 4178 \text{ J/kg} \cdot \text{K} \), \( k = 0.628 \text{ W/m} \cdot \text{K} \), \( \alpha = k/\rho c = 1.513 \times 10^{-7} \text{ m}^2/\text{s} \).

ANALYSIS: (a) For a given surface temperature -- suddenly applied -- the analysis is directed toward finding the skin depth \( x_b \) for which the tissue will be at \( T_b \geq 48^\circ C \) for more than 10s? From Eq. 5.57,

\[
\frac{T(x_b, t) - T_s}{T_i - T_s} = \text{erf} \left[ \frac{x_b}{2(\alpha t)^{1/2}} \right] = \text{erf} \left[ w \right].
\]

For the two values of \( T_s \), the left-hand side of the equation is

\[
T_s = 100^\circ C: \frac{(48 - 100)^\circ C}{(37 - 100)^\circ C} = 0.825 \quad \quad T_s = 50^\circ C: \frac{(48 - 50)^\circ C}{(37 - 50)^\circ C} = 0.154
\]

The burn depth is

\[
x_b = [w] 2(\alpha t)^{1/2} = [w] 2 \left( 1.513 \times 10^{-7} \text{ m}^2/\text{s} \times t \right)^{1/2} = 7.779 \times 10^{-4} [w] t^{1/2}.
\]

Continued...
PROBLEM 5.77 (Cont.)

Using Table B.2 to evaluate the error function and letting $t = 10$ s, find $x_b$ as

\[
T_s = 100^\circ C: \quad x_b = 7.779 \times 10^{-4}[0.96](10s)^{1/2} = 2.362 \times 10^3 \text{ m} = 2.36 \text{ mm}
\]

\[
T_s = 50^\circ C: \quad x_b = 7.779 \times 10^{-4}[0.137](10s)^{1/2} = 3.37 \times 10^3 \text{ m} = 0.34 \text{ mm}
\]

Recognize that tissue at this depth, $x_b$, has not been damaged, but will become so if $T_s$ is maintained for the next 10s. We conclude that, for $T_s = 50^\circ C$, only superficial damage will occur for a contact period of 20 s.

(b) Temperature histories at the prescribed locations are as follows.

The critical temperature of 48$^\circ C$ is reached within approximately 1 s at $x = 0.5$ mm and within 7 s at $x = 2$ mm.

COMMENTS: Note that the burn depth $x_b$ increases as $t^{1/2}$. 

PROBLEM 5.78

KNOWN: Thermocouple location in thick slab. Initial temperature. Thermocouple measurement two minutes after one surface is brought to temperature of boiling water.

FIND: Thermal conductivity of slab material.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in x, (2) Slab is semi-infinite medium, (3) Constant properties.

PROPERTIES: Slab material (given): \( \rho = 2200 \text{ kg/m}^3 \), \( c = 700 \text{ J/kg} \cdot \text{K} \).

ANALYSIS: For the semi-infinite medium from Eq. 5.57,

\[
\frac{T(0,t) - T_s}{T_i - T_s} = \text{erf} \left[ \frac{x}{2(\alpha t)^{1/2}} \right]
\]

\[
\frac{65 - 100}{30 - 100} = \text{erf} \left[ \frac{0.01 \text{m}}{2(\alpha \times 120 \text{s})^{1/2}} \right]
\]

\[
\text{erf} \left[ \frac{0.01 \text{m}}{2(\alpha \times 120 \text{s})^{1/2}} \right] = 0.5.
\]

From Appendix B, find for \( \text{erf} w = 0.5 \) that \( w = 0.477 \); hence,

\[
\frac{0.01 \text{m}}{2(\alpha \times 120 \text{s})^{1/2}} = 0.477
\]

\[
(\alpha \times 120)^{1/2} = 0.0105
\]

\[
\alpha = 9.156 \times 10^{-7} \text{ m}^2 /\text{s}.
\]

It follows that since \( \alpha = k/\rho c \),

\[
k = \alpha \rho c
\]

\[
k = 9.156 \times 10^{-7} \text{ m}^2 /\text{s} \times 2200 \text{ kg/m}^3 \times 700 \text{ J/kg} \cdot \text{K}
\]

\[
k = 1.41 \text{ W/m} \cdot \text{K}.
\]
**PROBLEM 5.79**

**KNOWN:** Initial temperature, density and specific heat of a material. Convection coefficient and temperature of air flow. Time for embedded thermocouple to reach a prescribed temperature.

**FIND:** Thermal conductivity of material.

**SCHEMATIC:**

Air \[ \to \quad T_\infty = 25^\circ C \quad h = 200 \text{ W/m}^2\text{-K} \]

\[ x_m = 0.01 \text{ m} \]

Material of unknown \( k \)

\[ T_i = 100^\circ C \]
\[ \rho = 950 \text{ kg/m}^3 \]
\[ c_p = 1100 \text{ J/kg-K} \]

Thermocouple junction \( T(0.01 \text{ m}, 5 \text{ min}) \)

**ASSUMPTIONS:** (1) One-dimensional conduction in \( x \), (2) Sample behaves as a semi-infinite medium, (3) Constant properties.

**ANALYSIS:** The thermal response of the sample is given by Case 3, Eq. 5.60,

\[
\frac{T(x,t) - T_i}{T_\infty - T_i} = \text{erfc}\left( \frac{x}{2\sqrt{\alpha t}} \right) - \left[ \exp\left( \frac{hx}{k} + \frac{h^2\alpha t}{k^2} \right) \right] \left[ \text{erfc}\left( \frac{x}{2\sqrt{\alpha t}} + \frac{h\sqrt{\alpha t}}{k} \right) \right]
\]

where, for \( x = 0.01 \text{ m} \) at \( t = 300 \text{ s} \), \([T(x,t) - T_i]/(T_\infty - T_i) = 0.533\). The foregoing equation must be solved iteratively for \( k \), with \( \alpha = k/\rho c_p \). The result is

\[ k = 0.45 \text{ W/m-K} \]

<

with \( \alpha = 4.30 \times 10^{-7} \text{ m}^2/\text{s} \).

**COMMENTS:** The solution may be effected by inserting the *Transient Conduction/Semi-infinite Solid/Surface Conduction Model* of *IHT* into the work space and applying the *IHT Solver*. However, the ability to obtain a converged solution depends strongly on the initial guesses for \( k \) and \( \alpha \).
PROBLEM 5.80

KNOWN: Very thick plate, initially at a uniform temperature, $T_i$, is suddenly exposed to a surface convection cooling process ($T_\infty$, $h$).

FIND: (a) Temperatures at the surface and 45 mm depth after 3 minutes, (b) Effect of thermal diffusivity and conductivity on temperature histories at $x = 0, 0.045$ m.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) Plate approximates semi-infinite medium, (3) Constant properties, (4) Negligible radiation.

ANALYSIS: (a) The temperature distribution for a semi-infinite solid with surface convection is given by Eq. 5.60.

$$
T(x,t) - T_i = \frac{x}{2(\alpha t)^{1/2}} - \left[ \exp \left( \frac{hx}{k} + \frac{h^2 \alpha t}{k^2} \right) \right] \text{erfc} \left( \frac{x}{2(\alpha t)^{1/2}} + \frac{h(\alpha t)^{1/2}}{k} \right) \bigg|_{t=0}
$$

At the surface, $x = 0$, and for $t = 3$ min = 180s,

$$
\frac{T(0,180\text{s}) - 325\,^\circ\text{C}}{(15 - 325)\,^\circ\text{C}} = \text{erfc}(0) - \left[ \exp \left( 0 + \frac{100^2\,\text{W}^2/\text{m}^4\,\text{K}^2 \times 5.6 \times 10^{-6}\,\text{m}^2/\text{s} \times 180\text{s}}{(20\,\text{W/m}\cdot\text{K})^2} \right) \right]
$$

$$
\times \left[ \text{erfc} \left( 0 + \frac{100\,\text{W/m} \cdot \text{K} \times 5.6 \times 10^{-6}\,\text{m}^2/\text{s} \times 180\text{s}^{1/2}}{20\,\text{W/m} \cdot \text{K}} \right) \right]
$$

$$
= 1 - \left[ \exp(0.02520) \right] \times \left[ \text{erfc}(0.159) \right] = 1 - 1.02552 \times (1 - 0.178)
$$

$$
T(0,180\text{s}) = 325\,^\circ\text{C} - (15 - 325)\,^\circ\text{C} \cdot (1 - 1.0255 \times 0.822) <
$$

$$
T(0,180\text{s}) = 325\,^\circ\text{C} - 49.3\,^\circ\text{C} = 276\,^\circ\text{C} .
$$

At the depth $x = 0.045$ m, with $t = 180$ s,

$$
\frac{T(0.045\text{m,}180\text{s}) - 325\,^\circ\text{C}}{(15 - 325)\,^\circ\text{C}} = \text{erfc} \left( \frac{0.045\text{m}}{\sqrt{2 \times 5.6 \times 10^{-6}\,\text{m}^2/\text{s} \times 180\text{s}^{1/2}} + 0.02520} \right)
$$

$$
\times \left[ \text{erfc} \left( \frac{0.045\text{m}}{\sqrt{2 \times 5.6 \times 10^{-6}\,\text{m}^2/\text{s} \times 180\text{s}^{1/2}} + 0.159} \right) \right]
$$

$$
= \text{erfc}(0.7087) + \left[ \exp(0.225 + 0.02520) \right] \times \left[ \text{erfc}(0.7087 + 0.159) \right].
$$

$$
T(0.045\text{m,}180\text{s}) = 325\,^\circ\text{C} + (15 - 325)\,^\circ\text{C} \left[ (1 - 0.684) - 1.284(1 - 0.780) \right] = 315\,^\circ\text{C} <
$$

Continued...
(b) The IHT Transient Conduction Model for a Semi-Infinite Solid was used to generate temperature histories, and for the two locations the effects of varying $\alpha$ and $k$ are as follows.

For fixed $k$, increasing $\alpha$ corresponds to a reduction in the thermal capacitance per unit volume ($\rho c_p$) of the material and hence to a more pronounced reduction in temperature at both surface and interior locations. Similarly, for fixed $\alpha$, decreasing $k$ corresponds to a reduction in $\rho c_p$ and hence to a more pronounced decay in temperature.

**COMMENTS:** In part (a) recognize that Fig. 5.8 could also be used to determine the required temperatures.
PROBLEM 5.81

KNOWN: Thick oak wall, initially at a uniform temperature of 25°C, is suddenly exposed to combustion products at 800°C with a convection coefficient of 20 W/m²·K.

FIND: (a) Time of exposure required for the surface to reach an ignition temperature of 400°C, (b) Temperature distribution at time t = 325s.

SCHEMATIC:

ASSUMPTIONS: (1) Oak wall can be treated as semi-infinite solid, (2) One-dimensional conduction, (3) Constant properties, (4) Negligible radiation.

PROPERTIES: Table A-3, Oak, cross grain (300 K): \( \rho = 545 \text{ kg/m}^3 \), \( c = 2385 \text{ J/kg·K} \), \( k = 0.17 \text{ W/m·K} \), \( \alpha = k/\rho c = 0.17 \text{ W/m·K}/545 \text{ kg/m}^3 \times 2385 \text{ J/kg·K} = 1.31 \times 10^{-7} \text{ m}^2/\text{s} \).

ANALYSIS: (a) This situation corresponds to Case 3 of Figure 5.7. The temperature distribution is given by Eq. 5.60 or by Figure 5.8. Using the figure with

\[
\frac{T(0,t) - T_i}{T_\infty - T_i} = \frac{400 - 25}{800 - 25} = 0.48
\]

and

\[
\frac{x}{2(\alpha t)^{1/2}} = 0
\]

we obtain \( h(\alpha t)^{1/2}/k = 0.75 \), in which case \( t = (0.75k/h\alpha^{1/2})^2 \). Hence,

\[
t = \left( \frac{0.75 \times 0.17 \text{ W/m·K}}{20 \text{ W/m}^2·\text{K}} \left(1.31 \times 10^{-7} \text{ m}^2/\text{s}\right)^{1/2} \right)^2 = 310s
\]

(b) Using the IHT Transient Conduction Model for a Semi-infinite Solid, the following temperature distribution was generated for t = 325s.

The temperature decay would become more pronounced with decreasing \( \alpha \) (decreasing k, increasing \( \rho c_p \)) and in this case the penetration depth of the heating process corresponds to \( x = 0.025 \text{ m} \) at 325s.

COMMENTS: The result of part (a) indicates that, after approximately 5 minutes, the surface of the wall will ignite and combustion will ensue. Once combustion has started, the present model is no longer appropriate.
**PROBLEM 5.82**

**KNOWN:** Thickness, initial temperature and thermophysical properties of concrete firewall. Incident radiant flux and duration of radiant heating. Maximum allowable surface temperatures at the end of heating.

**FIND:** If maximum allowable temperatures are exceeded.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional conduction in wall, (2) Validity of semi-infinite medium approximation, (3) Negligible convection and radiative exchange with the surroundings at the irradiated surface, (4) Negligible heat transfer from the back surface, (5) Constant properties.

**ANALYSIS:** The thermal response of the wall is described by Eq. (5.60)

\[
T(x, t) = T_i + \frac{2q_0^* (\alpha t / \pi)^{1/2}}{k} \exp \left( -\frac{x^2}{4\alpha t} \right) - \frac{q_0^* x}{k} \text{erfc} \left( \frac{x}{2\sqrt{\alpha t}} \right)
\]

where, \( \alpha = k / \rho c_p = 6.92 \times 10^{-7} \text{ m}^2 / \text{s} \) and for \( t = 30 \text{ min} = 1800 \text{ s}, 2q_0^* (\alpha t / \pi)^{1/2} / k = 284.5 \text{ K} \). Hence, at \( x = 0 \),

\[
T(0, 30 \text{ min}) = 25^\circ \text{C} + 284.5^\circ \text{C} = 309.5^\circ \text{C} < 325^\circ \text{C}
\]

At \( x = 0.25 \text{ m}, \left(-\frac{x^2}{4\alpha t}\right) = -12.54, \frac{q_0^* x}{k} = 1.786 \text{ K}, \) and \( \frac{x}{2} (\alpha t)^{1/2} = 3.54 \). Hence,

\[
T(0.25 \text{ m}, 30 \text{ min}) = 25^\circ \text{C} + 284.5^\circ \text{C} \left(3.58 \times 10^{-6}\right) - 1786^\circ \text{C} \times (\sim 0) = 25^\circ \text{C}
\]

Both requirements are met.

**COMMENTS:** The foregoing analysis is conservative since heat transfer at the irradiated surface due to convection and net radiation exchange with the environment have been neglected. If the emissivity of the surface and the temperature of the surroundings are assumed to be \( \varepsilon = 1 \) and \( T_{\text{sur}} = 298 \text{K} \), radiation exchange at \( T_s = 309.5^\circ \text{C} \) would be \( q_{\text{rad}}^* = \varepsilon\sigma \left(T_s^4 - T_{\text{sur}}^4\right) = 6,080 \text{ W/m}^2 \cdot \text{K} \), which is significant (~60% of the prescribed radiation).
PROBLEM 5.83

KNOWN: Initial temperature of copper and glass plates. Initial temperature and properties of finger.

FIND: Whether copper or glass feels cooler to touch.

SCHEMATIC:

ASSUMPTIONS: (1) The finger and the plate behave as semi-infinite solids, (2) Constant properties, (3) Negligible contact resistance.

PROPERTIES: Skin (given): $\rho = 1000 \text{ kg/m}^3$, $c = 4180 \text{ J/kgK}$, $k = 0.625 \text{ W/mK}$; Table A-1 (T = 300K), Copper: $\rho = 8933 \text{ kg/m}^3$, $c = 385 \text{ J/kgK}$, $k = 401 \text{ W/mK}$; Table A-3 (T = 300K), Glass: $\rho = 2500 \text{ kg/m}^3$, $c = 750 \text{ J/kgK}$, $k = 1.4 \text{ W/mK}$.

ANALYSIS: Which material feels cooler depends upon the contact temperature $T_s$ given by Equation 5.63. For the three materials of interest,

\[
(kp \, c)^{\frac{1}{2}}_{\text{skin}} = (0.625 \times 1000 \times 4180)^{\frac{1}{2}} = 1616 \text{ J/m}^2 \cdot \text{K} \cdot \text{s}^{\frac{1}{2}}
\]

\[
(kp \, c)^{\frac{1}{2}}_{\text{cu}} = (401 \times 8933 \times 385)^{\frac{1}{2}} = 37137 \text{ J/m}^2 \cdot \text{K} \cdot \text{s}^{\frac{1}{2}}
\]

\[
(kp \, c)^{\frac{1}{2}}_{\text{glass}} = (1.4 \times 2500 \times 750)^{\frac{1}{2}} = 1620 \text{ J/m}^2 \cdot \text{K} \cdot \text{s}^{\frac{1}{2}}.
\]

Since $(kp \, c)^{\frac{1}{2}}_{\text{cu}} >> (kp \, c)^{\frac{1}{2}}_{\text{glass}}$, the copper will feel much cooler to the touch. From Equation 5.63,

\[
T_s = \frac{(kp \, c)^{\frac{1}{2}}_A \, T_{A,i} + (kp \, c)^{\frac{1}{2}}_B \, T_{B,i}}{(kp \, c)^{\frac{1}{2}}_A + (kp \, c)^{\frac{1}{2}}_B}
\]

\[
T_{s\text{(cu)}} = \frac{1616(310) + 37137(300)}{1616 + 37137} = 300.4 \text{ K} \quad <
\]

\[
T_{s\text{(glass)}} = \frac{1616(310)+1620(300)}{1616+1620} = 305.0 \text{ K}. \quad <
\]

COMMENTS: The extent to which a material’s temperature is affected by a change in its thermal environment is inversely proportional to $(kp\,c)^{\frac{1}{2}}$. Large $k$ implies an ability to spread the effect by conduction; large $\rho\,c$ implies a large capacity for thermal energy storage.
PROBLEM 5.84

KNOWN: Initial temperatures, properties, and thickness of two plates, each insulated on one surface.

FIND: Temperature on insulated surface of one plate at a prescribed time after they are pressed together.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, (3) Negligible contact resistance.

PROPERTIES: Stainless steel (given): \( \rho = 8000 \text{ kg/m}^3 \), \( c = 500 \text{ J/kg} \cdot \text{K} \), \( k = 15 \text{ W/m} \cdot \text{K} \).

ANALYSIS: At the instant that contact is made, the plates behave as semi-infinite slabs and, since the \((\rho kc)\) product is the same for the two plates, Equation 5.63 yields a surface temperature of \( T_s = 350 \text{ K} \).

The interface will remain at this temperature, even after thermal effects penetrate to the insulated surfaces. The transient response of the hot wall may therefore be calculated from Equations 5.40 and 5.41. At the insulated surface \((x^* = 0)\), Equation 5.41 yields

\[
\frac{T_0 - T_s}{T_i - T_s} = C_1 \exp\left(-\xi_1^2 Fo\right)
\]

where, in principle, \( h \to \infty \) and \( T_\infty \to T_s \). From Equation 5.39c, \( Bi \to \infty \) yields \( \xi_1 = 1.5707 \), and from Equation 5.39b

\[
C_1 = \frac{4 \sin \xi_1}{2 \xi_1 + \sin (2 \xi_1)} = 1.273
\]

Also,

\[
Fo = \frac{\alpha t}{L^2} = \frac{3.75 \times 10^{-6} \text{ m}^2 / \text{s} \cdot \text{(60s)}}{(0.02 \text{ m})^2} = 0.563.
\]

Hence,

\[
\frac{T_0 - 350}{400 - 350} = 1.273 \exp\left(-1.5707^2 \times 0.563\right) = 0.318
\]

\[
T_0 = 365.9 \text{ K}.
\]

COMMENTS: Since \( Fo > 0.2 \), the one-term approximation is appropriate.
PROBLEM 5.85

KNOWN: Thickness and properties of liquid coating deposited on a metal substrate. Initial temperature and properties of substrate.

FIND: (a) Expression for time required to completely solidify the liquid, (b) Time required to solidify an alumina coating.

SCHEMATIC:

Alumina
\[ \rho = 3970 \text{ kg/m}^3 \]
\[ h_{sf} = 3.577 \times 10^6 \text{ J/kg} \]

ASSUMPTIONS: (1) Substrate may be approximated as a semi-infinite medium in which there is one-dimensional conduction, (2) Solid and liquid alumina layers remain at fusion temperature throughout solidification (negligible resistance to heat transfer by conduction through solid), (3) Negligible contact resistance at the coating/substrate interface, (4) Negligible solidification contraction, (5) Constant properties.

ANALYSIS: (a) Performing an energy balance on the solid layer, whose thickness \( S \) increases with \( t \), the latent heat released at the solid/liquid interface must be balanced by the rate of heat conduction into the solid. Hence, per unit surface area,

\[ \rho h_{sf} \frac{dS}{dt} = q''_{\text{cond}} \]

where, from Eq. 5.58, \( q''_{\text{cond}} = k \left( T_f - T_i \right) / \left( \pi \alpha_s t \right)^{1/2} \). It follows that

\[ \rho h_{sf} \frac{dS}{dt} = \frac{k_s (T_f - T_i)}{\left( \pi \alpha_s t \right)^{1/2}} \]

\[ \int_0^\delta dS = \frac{k_s (T_f - T_i)}{\rho h_{sf} \left( \pi \alpha_s \right)^{1/2}} \int_0^t dt \]

\[ \delta = \frac{2k_s}{\left( \pi \alpha_s \right)^{1/2}} \left( \frac{T_f - T_i}{\rho h_{sf}} \right) t^{1/2} \]

\[ t = \frac{\pi \alpha_s}{4k_s^2} \left( \frac{\delta h_{sf}}{T_f - T_i} \right)^2 \]

(b) For the prescribed conditions,

\[ t = \frac{\pi}{4(120 \text{ W/m} \cdot \text{K})^2} \left( \frac{0.002 \text{ m} \times 3970 \text{ kg/m}^3 \times 3.577 \times 10^6 \text{ J/kg}}{2018 \text{ K}} \right)^2 = 0.43 \text{s} \]

COMMENTS: Such solidification processes occur over short time spans and are typically termed rapid solidification.
**PROBLEM 5.86**

**KNOWN:** Properties of mold wall and a solidifying metal.

**FIND:** (a) Temperature distribution in mold wall at selected times, (b) Expression for variation of solid layer thickness.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Mold wall may be approximated as a semi-infinite medium in which there is one-dimensional conduction, (2) Solid and liquid metal layers remain at fusion temperature throughout solidification (negligible resistance to heat transfer by conduction through solid), (3) Negligible contact resistance at mold/metal interface, (4) Constant properties.

**ANALYSIS:** (a) As shown in schematic (b), the temperature remains nearly uniform in the metal (at \( T_f \)) throughout the process, while both the temperature and temperature penetration increase with time in the mold wall.

(b) Performing an energy balance for a control surface about the solid layer, the latent energy released due to solidification at the solid/liquid interface is balanced by heat conduction into the solid, \( q_{\text{lat}} = q_{\text{cond}} \), where \( q_{\text{lat}} = \rho h_{sf} \\text{d}S/\text{d}t \) and \( q_{\text{cond}} \) is given by Eq. 5.58. Hence,

\[
\rho h_{sf} \frac{\text{d}S}{\text{d}t} = \frac{k_w (T_f - T_i)}{\pi \alpha_w t^{1/2}}
\]

\[
\int_0^S \text{d}S = \frac{k_w (T_f - T_i)}{\rho h_{sf} (\pi \alpha_w)^{1/2}} t^{1/2} \int_0^t \text{d}t
\]

\[
S = \frac{2k_w (T_f - T_i)}{\rho h_{sf} (\pi \alpha_w)^{1/2}} t^{1/2}
\]

**COMMENTS:** The analysis of part (b) would only apply until the temperature field penetrates to the exterior surface of the mold wall, at which point, it may no longer be approximated as a semi-infinite medium.
PROBLEM 5.87

KNOWN: Steel (plain carbon) billet of square cross-section initially at a uniform temperature of 30°C is placed in a soaking oven and subjected to a convection heating process with prescribed temperature and convection coefficient.

FIND: Time required for billet center temperature to reach 600°C.

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional conduction in \( x_1 \) and \( x_2 \) directions, (2) Constant properties, (3) Heat transfer to billet is by convection only.

PROPERTIES: Table A-1, Steel, plain carbon (\( T = (30+600)/2 = 588K \approx 600K \)): \( \rho = 7854 \text{ kg/m}^3 \), \( c_p = 559 \text{ J/kg} \cdot \text{K} \), \( k = 48.0 \text{ W/m} \cdot \text{K} \), \( \alpha = k/\rho c_p = 1.093 \times 10^{-5} \text{ m}^2/\text{s} \).

ANALYSIS: The billet corresponds to Case (e), Figure 5.11 (infinite rectangular bar). Hence, the temperature distribution is of the form

\[
\theta^* (x_1, x_2, t) = P(x_1, t) \times P(x_2, t)
\]

where \( P(x,t) \) denotes the distribution corresponding to the plane wall. Because of symmetry in the \( x_1 \) and \( x_2 \) directions, the \( P \) functions are identical. Hence,

\[
\frac{\theta(0,0,t)}{\theta_i} = \left[ \frac{\theta_0(0,t)}{\theta_i} \right]^{2 \text{Plane wall}} \quad \text{where} \quad \begin{cases} \theta = T - T_\infty \\ \theta_i = T_i - T_\infty \\ \theta_0 = T(0,t) - T_\infty \end{cases} \quad \text{and} \quad L = 0.15\text{m}.
\]

Substituting numerical values, find

\[
\frac{\theta_0(0,t)}{\theta_i} = \left[ \frac{T(0,0,t) - T_\infty}{T_i - T_\infty} \right]^{1/2} = \left[ \frac{(600 - 750) ^\circ \text{C}}{(30 - 750) ^\circ \text{C}} \right]^{1/2} = 0.46.
\]

Consider now the Heisler chart for the plane wall, Figure D.1. For the values

\[
\theta_0^* = \frac{\theta_0}{\theta_i} \approx 0.46 \quad \text{Bi}^{-1} = \frac{k}{hL} = \frac{48.0 \text{ W/m} \cdot \text{K}}{100 \text{ W/m}^2 \cdot \text{K} \times 0.15\text{m}} = 3.2
\]

find

\[
t^* = Fo = \frac{\alpha t}{L^2} = 3.2.
\]

Hence,

\[
t = \frac{3.2 L^2}{\alpha} = \frac{3.2 (0.15\text{m})^2}{1.093 \times 10^{-5} \text{ m}^2/\text{s}} = 6587\text{s} = 1.83\text{h}.
\]
PROBLEM 5.88

KNOWN: Initial temperature of fire clay brick which is cooled by convection.

FIND: Center and corner temperatures after 50 minutes of cooling.

SCHEMATIC: 

ASSUMPTIONS: (1) Homogeneous medium with constant properties, (2) Negligible radiation effects.

PROPERTIES: Table A-3, Fire clay brick (900K): \( \rho = 2050 \text{ kg/m}^3 \), \( k = 1.0 \text{ W/m-K} \), \( c_p = 960 \text{ J/kg-K} \), \( \alpha = 0.51 \times 10^{-6} \text{ m}^2/\text{s} \).

ANALYSIS: From Fig. 5.11(h), the center temperature is given by

\[
\frac{T(0,0,0,t) - T_\infty}{T_i - T_\infty} = P_1(0,t) \times P_2(0,t) \times P_3(0,t)
\]

where \( P_1 \), \( P_2 \) and \( P_3 \) must be obtained from Fig. D.1.

\[
L_1 = 0.03 \text{m}: \quad \text{Bi}_1 = \frac{hL_1}{k} = 1.50 \quad \text{Fo}_1 = \frac{\alpha t}{L_1^2} = 1.70
\]

\[
L_2 = 0.045 \text{m}: \quad \text{Bi}_2 = \frac{hL_2}{k} = 2.25 \quad \text{Fo}_2 = \frac{\alpha t}{L_2^2} = 0.756
\]

\[
L_3 = 0.10 \text{m}: \quad \text{Bi}_3 = \frac{hL_3}{k} = 5.0 \quad \text{Fo}_3 = \frac{\alpha t}{L_3^2} = 0.153
\]

Hence from Fig. D.1,

\[
P_1(0,t) = 0.22 \quad P_2(0,t) = 0.50 \quad P_3(0,t) = 0.85.
\]

Hence,

\[
\frac{T(0,0,0,t) - T_\infty}{T_i - T_\infty} = 0.22 \times 0.50 \times 0.85 = 0.094
\]

and the center temperature is

\[
T(0,0,0,t) \approx 0.094(1600 - 313)K + 313K = 434K.
\]

Continued .....
PROBLEM 5.88 (Cont.)

The corner temperature is given by

\[ \frac{T(L_1, L_2, L_3, t) - T_\infty}{T_1 - T_\infty} = P(L_1, t) \times P(L_2, t) \times P(L_3, t) \]

where

\[ P(L_1, t) = \frac{\theta(L_1, t)}{\theta_0} \cdot P_1(0, t), \text{ etc.} \]

and similar forms can be written for \( L_2 \) and \( L_3 \). From Fig. D.2,

\[ \frac{\theta(L_1, t)}{\theta_0} \approx 0.55 \quad \frac{\theta(L_2, t)}{\theta_0} \approx 0.43 \quad \frac{\theta(L_3, t)}{\theta_0} \approx 0.25. \]

Hence,

\[ P(L_1, t) \approx 0.55 \times 0.22 = 0.12 \]
\[ P(L_2, t) \approx 0.43 \times 0.50 = 0.22 \]
\[ P(L_3, t) \approx 0.85 \times 0.25 = 0.21 \]

and

\[ \frac{T(L_1, L_2, L_3, t) - T_\infty}{T_1 - T_\infty} \approx 0.12 \times 0.22 \times 0.21 = 0.0056 \]

or

\[ T(L_1, L_2, L_3, t) \approx 0.0056(1600 - 313) \text{K} + 313 \text{K}. \]

The corner temperature is then

\[ T(L_1, L_2, L_3, t) \approx 320 \text{K}. \]

**COMMENTS:** (1) The foregoing temperatures are overpredicted by ignoring radiation, which is significant during the early portion of the transient.

(2) Note that, if the time required to reach a certain temperature were to be determined, an iterative approach would have to be used. The foregoing procedure would be used to compute the temperature for an assumed value of the time, and the calculation would be repeated until the specified temperature were obtained.
**PROBLEM 5.89**

**KNOWN:** Cylindrical copper pin, 100mm long × 50mm diameter, initially at 20°C; end faces are subjected to intense heating, suddenly raising them to 500°C; at the same time, the cylindrical surface is subjected to a convective heating process ($T_{\infty}, h$).

**FIND:** (a) Temperature at center point of cylinder after a time of 8 seconds from sudden application of heat, (b) Consider parameters governing transient diffusion and justify simplifying assumptions that could be applied to this problem.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Two-dimensional conduction, (2) Constant properties and convection heat transfer coefficient.

**PROPERTIES:** Table A-1, Copper, pure ($T = (500 + 20)^\circ C/2 = 500K$): $\rho = 8933$ kg/m$^3$, $c = 407$ J/kg$\cdot$K, $k = 386$ W/m$\cdot$K, $\alpha = k/c = 386$ W/m$\cdot$K/8933 kg/m$^3$, $1.064 \times 10^{-4}$ m$^2$/s.

**ANALYSIS:** (1) The pin can be treated as a two-dimensional system comprised of an infinite cylinder whose surface is exposed to a convection process ($T_{\infty}, h$) and of a plane wall whose surfaces are maintained at a constant temperature ($T_e$). This configuration corresponds to the short cylinder, Case (i) of Fig. 5.11,

$$\frac{\theta(r, x, t)}{\theta_i} = C(r, t) \times P(x, t). \quad (1)$$

For the infinite cylinder, using Fig. D.4, with

$$Bi = \frac{h r_e}{k} = \frac{100 \text{ W/m}^2 \cdot K \left(25 \times 10^{-3} \text{m} \right)}{385 \text{ W/m} \cdot \text{K}} = 6.47 \times 10^{-3} \quad \text{and} \quad Fo = \frac{\alpha t_i}{r_0^2} = \frac{1.064 \times 10^{-4} \text{ m}^2 \div \text{s}}{\left(25 \times 10^{-3} \text{ m} \right)^2} = 1.36,$$

find

$$C(0.8s) = \left[ \frac{\theta(0.8s)}{\theta_i} \right]_{\text{cyl}} = 1. \quad (2)$$

For the infinite plane wall, using Fig. D.1, with

$$Bi = \frac{hL}{k} \rightarrow \infty \quad \text{or} \quad Bi^{-1} \rightarrow 0 \quad \text{and} \quad Fo = \frac{\alpha t}{L^2} = \frac{1.064 \times 10^{-4} \text{ m}^2 / \text{s} \div \text{x8s}}{\left(50 \times 10^{-3} \text{ m} \right)^2} = 0.34,$$

find

$$P(0.8s) = \left[ \frac{\theta(0.8s)}{\theta_i} \right]_{\text{wall}} = 0.5. \quad (3)$$

Combining Eqs. (2) and (3) with Eq. (1), find

$$\frac{\theta(0.8s)}{\theta_i} = \frac{T(0.8s) - T_{\infty}}{T_i - T_{\infty}} \approx 1 \times 0.5 = 0.5$$

$$T(0.8s) = T_{\infty} + 0.5(T_i - T_{\infty}) = 500 + 0.5(20 - 500) = 260^\circ C.$$

(b) The parameters controlling transient conduction with convective boundary conditions are the Biot and Fourier numbers. Since $Bi < 0.1$ for the cylindrical shape, we can assume radial gradients are negligible. That is, we need only consider conduction in the x-direction.
PROBLEM 5.90

**KNOWN:** Cylindrical-shaped meat roast weighing 2.25 kg, initially at 6°C, is placed in an oven and subjected to convection heating with prescribed \((T_\infty, h)\).

**FIND:** Time required for the center to reach a done temperature of 80°C.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Two-dimensional conduction in x and r directions, (2) Uniform and constant properties, (3) Properties approximated as those of water.

**PROPERTIES:** Table A-6, Water, liquid \(\left(\bar{T} = (80 + 6)°C/2 \approx 315K\right)\); \(\rho = 1/v_f = 1/1.009 \times 10^{-3} m^3/kg = 991.1 \text{ kg/m}^3\), \(c_p,f = 4179 \text{ J/kg} \cdot \text{K}\), \(k = 0.634 \text{ W/m} \cdot \text{K}\), \(\alpha = k/\rho c = 1.531 \times 10^{-7} \text{ m}^2/\text{s}\).

**ANALYSIS:** The dimensions of the roast are determined from the requirement \(r_o = L\) and knowledge of its weight and density,

\[
M = \rho V = \rho \cdot 2L \cdot \pi r_o^2 \quad \text{or} \quad r_o = L = \left[\frac{M}{2\pi \rho}\right]^{1/3} = \left[\frac{2.25 \text{ kg}}{2\pi 991.1 \text{ kg/m}^3}\right]^{1/3} = 0.0712\text{ m}. \quad (1)
\]

The roast corresponds to Case (i), Figure 5.11, and the temperature distribution may be expressed as the product of one-dimensional solutions, \(\frac{T(x,r,t) - T_\infty}{T_i - T_\infty} = P(x,t) \times C(r,t)\), where

\(P(x,t)\) and \(C(r,t)\) are defined by Eqs. 5.65 and 5.66, respectively. For the center of the cylinder,

\[
\frac{T(0,0,t) - T_\infty}{T_i - T_\infty} = \frac{(80 - 175)°C}{(6 - 175)°C} = 0.56. \quad (2)
\]

In terms of the product solutions,

\[
\frac{T(0,0,t) - T_\infty}{T_i - T_\infty} = 0.56 = \frac{T(0,t) - T_\infty}{T_i - T_\infty} \times \left[\frac{T(0,t) - T_\infty}{T_i - T_\infty}\right]_{\text{cylinder}} \quad (3)
\]

For each of these shapes, we need to find values of \(\theta_o/\theta_i\) such that their product satisfies Eq. (3). For both shapes,

\[
\text{Bi} = \frac{h r_o}{k} = \frac{hL}{k} = 15 \text{ W/m}^2 \cdot \text{K} \times 0.0712\text{m} = 1.68 \quad \text{or} \quad \text{Bi}^{-1} = 0.6
\]

\[
\text{Fo} = \alpha t/r_o^2 = \alpha t/L^2 = 1.53 \times 10^{-7} \text{ m}^2/\text{s} \times t/(0.0712\text{m})^2 = 3.020 \times 10^{-5} \text{t}.
\]

Continued …..
A trial-and-error solution is necessary. Begin by assuming a value of Fo; obtain the respective θ_o/θ_i values from Figs. D.1 and D.4; test whether their product satisfies Eq. (3). Two trials are shown as follows:

For Trial 2, the product of 0.53 agrees closely with the value of 0.56 from Eq. (2). Hence, it will take approximately 2 ¾ hours to roast the meat.
PROBLEM 5.91

KNOWN: A long alumina rod, initially at a uniform temperature of 850 K, is suddenly exposed to a cooler fluid.

FIND: Temperature of the rod after 30 s, at an exposed end, $T(0,0,t)$, and at an axial distance 6 mm from the end, $T(0,6 \text{ mm}, t)$.

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional conduction in (r,x) directions, (2) Constant properties, (3) Convection coefficient is same on end and cylindrical surfaces.

PROPERTIES: Table A-2, Alumina, polycrystalline aluminum oxide (assume $\bar{T} = (850 + 600)/2 = 725 K$): $\rho = 3970 \text{ kg/m}^3$, $c = 1154 \text{ J/kg·K}$, $k = 12.4 \text{ W/m·K}$.

ANALYSIS: First, check if system behaves as a lumped capacitance. Find

\[
\text{Bi} = \frac{hLc}{k} = \frac{h\left(\frac{r_0}{2}\right)}{k} = \frac{500 \text{ W/m·K} \left(\frac{0.010 \text{ m}}{2}\right)}{12.4 \text{ W/m·K}} = 0.202.
\]

Since $\text{Bi} > 0.1$, rod does not behave as spacewise isothermal object. Hence, treat rod as a semi-infinite cylinder, the multi-dimensional system Case (f), Fig. 5.11.

The product solution can be written as

\[
\theta^*(r,x,t) = \frac{\theta(r,x,t)}{\theta_i} = \frac{\theta(r,t)}{\theta_i} \times \frac{\theta(x,t)}{\theta_i} = C\left(r^*,t^* \right) \times S\left(x^*,t^* \right)
\]

Infinite cylinder, $C(r^*,t^*)$. Using the Heisler charts with $r^* = r = 0$ and

\[
\text{Bi}^{-1} = \left[\frac{h}{k}\right]^{-1} = \left[\frac{500 \text{ W/m}^2\cdot\text{K} \times 0.01 \text{ m}}{12.4 \text{ W/m·K}}\right]^{-1} = 2.48.
\]

Evaluate $\alpha = k/\rho c = 2.71 \times 10^{-6} \text{ m}^2/\text{s}$, find $F_o = \alpha t/r_0^2 = 2.71 \times 10^{-6} \text{ m}^2/\text{s} \times 30 \text{s}/(0.01 \text{ m})^2 = 0.812$. From the Heisler chart, Fig. D.4, with $\text{Bi}^{-1} = 2.48$ and $F_o = 0.812$, read $C(0,t^*) = \theta(0,t)/\theta_i = 0.61$.

Continued ….
PROBLEM 5.91 (Cont.)

Semi-infinite medium, \( S(x^*,t^*) \). Recognize this as Case (3), Fig. 5.7. From Eq. 5.60, note that the LHS needs to be transformed as follows,

\[
\frac{T - T_i}{T_\infty - T_i} = 1 - \frac{T - T_\infty}{T_i - T_\infty} \quad S(x,t) = \frac{T - T_\infty}{T_i - T_\infty}.
\]

Thus,

\[
S(x,t) = 1 - \left\{ \text{erfc}\left[ \frac{x}{2(\alpha t)^{1/2}} \right] - \exp\left[ \frac{hx}{k} + h^2\alpha t}{k^2} \right] \right\} \left[ \text{erfc}\left[ \frac{x}{2(\alpha t)^{1/2}} + \frac{h(\alpha t)^{1/2}}{k} \right] \right].
\]

Evaluating this expression at the surface (\( x = 0 \)) and 6mm from the exposed end, find

\[
S(0,30s) = 1 - \left\{ \text{erfc}\left(0\right) - \exp\left(0 + \frac{500 \text{ W/m}^2 \cdot \text{K}}{12.4 \text{ W/m} \cdot \text{K}} \right) \right\}
\]

\[
S(0,30s) = 1 - \left\{ \exp\left(0.1322\right) \right\} \text{erfc}\left(0.3636\right) = 0.693.
\]

Note that Table B.2 was used to evaluate the complementary error function, \( \text{erfc}(w) \).

\[
S(6\text{mm},30s) = 1 - \left\{ \exp\left(0.1322\right) \right\} \text{erfc}\left(0.3327\right) = 0.835.
\]

The product solution can now be evaluated for each location. At (0,0),

\[
\theta^* (0,0,t) = \frac{T(0,0,30s) - T_\infty}{T_i - T_\infty} = C(0,t^*) \times S(0,t^*) = 0.61 \times 0.693 = 0.423.
\]

Hence,

\[
T(0,0,30s) = T_\infty + 0.423(T_i - T_\infty) = 350K + 0.423(850 - 350)K = 561K.
\]

At (0,6mm),

\[
\theta^* (0,6\text{mm},t) = C(0,t^*) \times S(6\text{mm},t^*) = 0.61 \times 0.835 = 0.509
\]

\[
T(0,6\text{mm},30s) = 604K.
\]

COMMENTS: Note that the temperature at which the properties were evaluated was a good estimate.
**PROBLEM 5.92**

**KNOWN:** Stainless steel cylinder of Ex. 5.7, 80-mm diameter by 60-mm length, initially at 600 K, suddenly quenched in an oil bath at 300 K with \( h = 500 \text{ W/m}^2\cdot\text{K} \). Use the *Transient Conduction, Plane Wall and Cylinder* models of *IHT* to obtain the following solutions.

**FIND:** (a) Calculate the temperatures \( T(r,x,t) \) after 3 min: at the cylinder center, \( T(0,0,3 \text{ min}) \), at the center of a circular face, \( T(0,L,3 \text{ min}) \), and at the midheight of the side, \( T(r_o,0,3 \text{ min}) \); compare your results with those in the example; (b) Calculate and plot temperature histories at the cylinder center, \( T(0,0,t) \), the mid-height of the side, \( T(r_o,0,t) \), for \( 0 \leq t \leq 10 \text{ min} \); comment on the gradients and what effect they might have on phase transformations and thermal stresses; and (c) For \( 0 \leq t \leq 10 \text{ min} \), calculate and plot the temperature histories at the cylinder center, \( T(0,0,t) \), for convection coefficients of 500 and 1000 W/m\(^2\)·K.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Two-dimensional conduction in \( r- \) and \( x- \)coordinates, (2) Constant properties.

**PROPERTIES:** Stainless steel (*Example 5.7*): \( \rho = 7900 \text{ kg/m}^3 \), \( c = 526 \text{ J/kg} \cdot \text{K} \), \( k = 17.4 \text{ W/m} \cdot \text{K} \).

**ANALYSIS:** The following results were obtained using the *Transient Conduction* models for the *Plane Wall and Cylinder* of *IHT*. Salient portions of the code are provided in the Comments.

(a) Following the methodology for a product solution outlined in Example 5.7, the following results were obtained at \( t = t_o = 3 \text{ min} \)

<table>

Continued …..
The temperatures from the one-term series calculations of the Example 5.7 are systematically higher than those resulting from the *IHT* multiple-term series model, which is the more accurate method.

(b) The temperature histories for the center and mid-height of the side locations are shown in the graph below. Note that at early times, the temperature difference between these locations, and hence the gradient, is large. Large differences could cause variations in microstructure and hence, mechanical properties, as well as induce residual thermal stresses.

(c) Effect of doubling the convection coefficient is to increase the quenching rate, but much less than by a factor of two as can be seen in the graph below.

![Graph showing temperature histories](image)

**COMMENTS:** From *IHT* menu for *Transient Conduction|Plane Wall* and *Cylinder*, the models were combined to solve the product solution. Key portions of the code, less the input variables, are copied below.

```plaintext
// Plane wall temperature distribution
// The temperature distribution is
T_xtP = T_xt_trans("Plane Wall",xstar,FoP,BiP,Ti,Tinf)  // Eq 5.39
// The dimensionless parameters are
xstar = x / L
BiP = h * L / k  // Eq 5.9
FoP = alpha * t / L^2  // Eq 5.33
alpha = k / (rho * cp)
// Dimensionless representation, P(x,t)
P_xt = (T_xtP - Tinf) / (Ti - Tinf)

// Cylinder temperature distribution
// The temperature distribution T(r,t) is
T_rtC = T_xt_trans("Cylinder",rstar,FoC,BiC,Ti,Tinf)  // Eq 5.47
// The dimensionless parameters are
rstar = r / ro
BiC = h * ro / k
FoC = alpha * t / ro^2
// Dimensionless representation, C(r,t)
C_rt = (T_rtC - Tinf) / (Ti - Tinf)

// Product solution temperature distribution
(T_xrt - Tinf) / (Ti - Tinf) = P_xt * C_rt
```
**PROBLEM 5.93**

**KNOWN:** Stability criterion for the explicit method requires that the coefficient of the $T_m^p$ term of the one-dimensional, finite-difference equation be zero or positive.

**FIND:** For $Fo > 1/2$, the finite-difference equation will predict values of $T_m^{p+1}$ which violate the Second law of thermodynamics. Consider the prescribed numerical values.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional conduction in $x$, (2) Constant properties, (3) No internal heat generation.

**ANALYSIS:** The explicit form of the finite-difference equation, Eq. 5.73, for an interior node is

$$T_m^{p+1} = Fo \left( T_{m+1}^p + T_{m-1}^p \right) + (1 - 2Fo)T_m^p.$$  

The stability criterion requires that the coefficient of $T_m^p$ be zero or greater. That is,

$$(1 - 2Fo) \geq 0 \quad \text{or} \quad Fo \leq \frac{1}{2}.$$  

For the prescribed temperatures, consider situations for which $Fo = 1$, $1/2$ and $1/4$ and calculate $T_m^{p+1}$.

- For $Fo = 1$,  $T_m^{p+1} = 1(100 + 100) \text{°C} + (1 - 2\times1)50 \text{°C} = 250 \text{°C}$
- For $Fo = 1/2$,  $T_m^{p+1} = 1/2(100 + 100) \text{°C} + (1 - 2\times1/2)50 \text{°C} = 100 \text{°C}$
- For $Fo = 1/4$,  $T_m^{p+1} = 1/4(100 + 100) \text{°C} + (1 - 2\times1/4)50 \text{°C} = 75 \text{°C}$.

Plotting these distributions above, note that when $Fo = 1$, $T_m^{p+1}$ is greater than $100 \text{°C}$, while for $Fo = 1/2$ and $1/4$, $T_m^{p+1} \leq 100 \text{°C}$. The distribution for $Fo = 1$ is thermodynamically impossible: heat is flowing into the node during the time period $\Delta t$, causing its temperature to rise; yet heat is flowing in the direction of increasing temperature. This is a violation of the Second law. When $Fo = 1/2$ or $1/4$, the node temperature increases during $\Delta t$, but the temperature gradients for heat flow are proper. This will be the case when $Fo \leq 1/2$, verifying the stability criterion.
PROBLEM 5.94

KNOWN: Thin rod of diameter D, initially in equilibrium with its surroundings, $T_{\text{sur}}$, suddenly passes a current I; rod is in vacuum enclosure and has prescribed electrical resistivity, $\rho_e$, and other thermophysical properties.

FIND: Transient, finite-difference equation for node $m$.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, transient conduction in rod, (2) Surroundings are much larger than rod, (3) Properties are constant and evaluated at an average temperature, (4) No convection within vacuum enclosure.

ANALYSIS: The finite-difference equation is derived from the energy conservation requirement on the control volume, $A_c \Delta x$, where $A_c = \pi D^2 / 4$ and $P = \pi D$.

The energy balance has the form

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} + \dot{E}_{\text{g}} = \dot{E}_{\text{st}} + q_a + q_b - q_{\text{rad}} + I^2 R_e = \rho cV \frac{T_{m+1}^p - T_m^p}{\Delta t}$$

where $\dot{E}_g = I^2 R_e$ and $R_e = \rho_e \Delta x / A_c$. Using Fourier’s law to express the conduction terms, $q_a$ and $q_b$, and Eq. 1.7 for the radiation exchange term, $q_{\text{rad}}$, find

$$k A_c \frac{T_{m-1}^p - T_m^p}{\Delta x} + k A_c \frac{T_{m+1}^p - T_m^p}{\Delta x} - \varepsilon P \Delta x \sigma \left( T_{m+1}^{4p} - T_{\text{sur}}^4 \right) + I^2 \frac{\rho_e \Delta x}{A_c} = \rho c A_c \Delta x \frac{T_{m+1}^p - T_m^p}{\Delta t}.$$

Divide each term by $\rho c A_c \Delta x / \Delta t$, solve for $T_{m+1}^p$ and regroup to obtain

$$T_{m+1}^p = \frac{k}{\rho c \Delta x^2} \left( T_{m-1}^p + T_{m+1}^p \right) - \left[ 2 \cdot \frac{k}{\rho c \Delta x^2} - 1 \right] T_m^p - \varepsilon P \sigma \frac{\Delta t}{A_c} \left( T_{m+1}^{4p} - T_{\text{sur}}^4 \right) + \frac{I^2 \rho_e \Delta x^2}{A_c^2} \frac{\Delta t}{\rho c}.$$

Recognizing that $\text{Fo} = \alpha \Delta t / \Delta x^2$, regroup to obtain

$$T_{m+1}^p = \text{Fo} \left( T_{m-1}^p + T_{m+1}^p \right) + (1 - 2 \text{Fo}) T_m^p - \frac{\varepsilon P \sigma \Delta x^2}{k A_c} \cdot \text{Fo} \left( T_{m+1}^{4p} - T_{\text{sur}}^4 \right) + \frac{I^2 \rho_e \Delta x^2}{k A_c^2} \cdot \text{Fo}.$$

The stability criterion is based upon the coefficient of the $T_m^p$ term written as

$$\text{Fo} \leq \frac{1}{2}.$$

COMMENTS: Note that we have used the forward-difference representation for the time derivative; see Section 5.9.1. This permits convenient treatment of the non-linear radiation exchange term.
PROBLEM 5.95

KNOWN: One-dimensional wall suddenly subjected to uniform volumetric heating and convective surface conditions.

FIND: Finite-difference equation for node at the surface, $x = -L$.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional transient conduction, (2) Constant properties, (3) Uniform $\dot{q}$.

ANALYSIS: There are two types of finite-difference equations for the explicit and implicit methods of solution. Using the energy balance approach, both types will be derived.

Explicit Method. Perform an energy balance on the surface node shown above,

$$
\dot{E}_{in} - \dot{E}_{out} + \dot{E}_g = \dot{E}_{st} \quad q_{\text{conv}} + q_{\text{cond}} + \dot{q}V = \rho \ c \ V \frac{T_{0}^{p+1} - T_{0}^{p}}{\Delta t} \quad (1)
$$

$$
h(1.1) \left( T_{\infty} - T_{0}^{p} \right) + k(1.1) \left[ \frac{T_{1}^{p} - T_{0}^{p}}{\Delta x} \right] + \dot{q} \left[ 1.1 \cdot \frac{\Delta x}{2} \right] = \rho \ c \left[ 1.1 \cdot \frac{\Delta x}{2} \right] \frac{T_{0}^{p+1} - T_{0}^{p}}{\Delta t} \quad (2)
$$

For the explicit method, the temperatures on the LHS are evaluated at the previous time ($p$). The RHS provides a forward-difference approximation to the time derivative. Divide Eq. (2) by $\rho c \Delta x/2 \Delta t$ and solve for $T_{0}^{p+1}$.

$$
T_{0}^{p+1} = 2 \frac{h \Delta t}{\rho c \Delta x^2} \left( T_{\infty} - T_{0}^{p} \right) + 2 \frac{k \Delta t}{\rho c \Delta x^2} \left( T_{1}^{p} - T_{0}^{p} \right) + \dot{q} \frac{\Delta t}{\rho c} + T_{0}^{p}.
$$

Introducing the Fourier and Biot numbers,

$$
\text{Fo} \equiv \frac{k}{\rho c \Delta t/\Delta x^2} \quad \text{Bi} \equiv \frac{h}{k}
$$

$$
T_{0}^{p+1} = 2 \text{Fo} \left( T_{1}^{p} + \text{Bi} \cdot T_{\infty} + \frac{\dot{q} \Delta x^2}{2k} \right) + (1 - 2 \text{Fo} - 2 \text{Fo} \cdot \text{Bi}) T_{0}^{p}.
$$

The stability criterion requires that the coefficient of $T_{0}^{p}$ be positive. That is,

$$
(1 - 2 \text{Fo} - 2 \text{Fo} \cdot \text{Bi}) \geq 0 \quad \text{or} \quad \text{Fo} \leq 1/2(1 + \text{Bi}). \quad (4)
$$

Implicit Method. Begin as above with an energy balance. In Eq. (2), however, the temperatures on the LHS are evaluated at the new $(p+1)$ time. The RHS provides a backward-difference approximation to the time derivative.

$$
h \left( T_{\infty} - T_{0}^{p+1} \right) + k \left[ \frac{T_{1}^{p+1} - T_{0}^{p+1}}{\Delta x} \right] + \dot{q} \left[ \frac{\Delta x}{2} \right] = \rho \ c \left[ \frac{\Delta x}{2} \right] \frac{T_{0}^{p+1} - T_{0}^{p}}{\Delta t} \quad (5)
$$

$$
(1 + 2 \text{Fo}(\text{Bi} + 1)) T_{0}^{p+1} - 2 \text{Fo} \cdot T_{1}^{p+1} = T_{0}^{p} + 2 \text{Bi} \cdot T_{\infty} + \frac{\dot{q} \Delta x^2}{k}. \quad (6)
$$

COMMENTS: Compare these results (Eqs. 3, 4 and 6) with the appropriate expression in Table 5.2.
PROBLEM 5.96

KNOWN: Plane wall, initially having a linear, steady-state temperature distribution with boundaries maintained at \( T(0,t) = T_1 \) and \( T(L,t) = T_2 \), suddenly experiences a uniform volumetric heat generation due to the electrical current. Boundary conditions \( T_1 \) and \( T_2 \) remain fixed with time.

FIND: (a) On \( T-x \) coordinates, sketch the temperature distributions for the following cases: initial conditions \( (t \leq 0) \), steady-state conditions \( (t \to \infty) \) assuming the maximum temperature exceeds \( T_2 \), and two intermediate times; label important features; (b) For the three-nodal network shown, derive the finite-difference equation using either the implicit or explicit method; (c) With a time increment of \( \Delta t = 5 \) s, obtain values of \( T_m \) for the first 45s of elapsed time; determine the corresponding heat fluxes at the boundaries; and (d) Determine the effect of mesh size by repeating the foregoing analysis using grids of 5 and 11 nodal points.

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional, transient conduction, (2) Uniform volumetric heat generation for \( t \geq 0 \), (3) Constant properties.

PROPERTIES: Wall (Given): \( \rho = 4000 \) kg/m\(^3\), \( c = 500 \) J/kg\( \cdot \)K, \( k = 10 \) W/m\( \cdot \)K.

ANALYSIS: (a) The temperature distribution on \( T-x \) coordinates for the requested cases are shown below. Note the following key features: (1) linear initial temperature distribution, (2) non-symmetrical parabolic steady-state temperature distribution, (3) gradient at \( x = L \) is first positive, then zero and becomes negative, and (4) gradient at \( x = 0 \) is always positive.

(b) Performing an energy balance on the control volume about node \( m \) above, for unit area, find

\[
\dot{E}_{in} - \dot{E}_{out} + \dot{E}_g = \dot{E}_{st}
\]

\[
k \left( \frac{1}{\Delta x} \right) \frac{T_2 - T_m}{\Delta x} + k \left( \frac{1}{\Delta x} \right) \frac{T_1 - T_m}{\Delta x} + \dot{q} \left( 1 \right) \Delta x = \rho \left( 1 \right) c \Delta x \frac{T_m^{p+1} - T_m^p}{\Delta t}
\]

\[
\text{Fo} \left[ T_1 + T_2 - 2T_m \right] + \frac{\dot{q} \Delta t}{\rho c_p} = T_m^{p+1} - T_m^p
\]

For the \( T_m \) term in brackets, use “p” for explicit and “p+1” for implicit form,

**Explicit:** \( T_m^{p+1} = \text{Fo} \left( T_1^p + T_2^p \right) + \left( 1 - 2\text{Fo} \right) T_m^p + \dot{q} \Delta t / \rho c_p \)  \hfill (1)

**Implicit:** \( T_m^{p+1} = \left[ \text{Fo} \left( T_1^{p+1} + T_2^{p+1} \right) + \dot{q} \Delta t / \rho c_p + T_m^p \right] / \left( 1 + 2\text{Fo} \right) \)  \hfill (2)

Continued...
PROBLEM 5.96 (Cont.)

(c) With a time increment $\Delta t = 5\, \text{s}$, the FDEs, Eqs. (1) and (2) become

**Explicit:** \[ \frac{T_{m}^{p+1}}{\Delta t} = 0.5 \frac{T_{m}^{p}}{\Delta t} + 75 \]  \(3\)

**Implicit:** \[ \frac{T_{m}^{p+1}}{\Delta t} = \left( \frac{T_{m}^{p} + 75}{\Delta t} \right) / 1.5 \]  \(4\)

where

\[
F_o = \frac{k \Delta t}{\rho c \Delta x^2} = \frac{10 \, \text{W/m} \cdot \text{K} \times 5 \, \text{s}}{4000 \, \text{kg/m}^3 \times 500 \, \text{J/kg} \cdot \text{K} (0.010 \, \text{m})^2} = 0.25
\]

\[
\frac{\dot{q} \Delta t}{\rho c} = \frac{2 \times 10^7 \, \text{W/m}^3 \times 5 \, \text{s}}{4000 \, \text{kg/m}^3 \times 500 \, \text{J/kg} \cdot \text{K}} = 50 \, \text{K}
\]

Performing the calculations, the results are tabulated as a function of time,

</table>

The heat flux at the boundaries at $t = 45\, \text{s}$ follows from the energy balances on control volumes about the boundary nodes, using the explicit results for $T_{m}^{p}$.

**Node 1:** \[ \dot{E}_{in} - \dot{E}_{out} + \dot{E}_g = \dot{E}_{st} \]

\[
q_x^e (0, t) + k \frac{T_{m}^{p} - T_1}{\Delta x} + \dot{q}(\Delta x/2) = 0
\]

\[
q_x^e (0, t) = -k \left( \frac{T_{m}^{p} - T_1}{\Delta x} \right) / \Delta x - \dot{q}(\Delta x/2)
\]  \(5\)

\[
q_x^e (0, 45\, \text{s}) = -10 \, \text{W/m} \cdot \text{K} (149.8 - 0) \, \text{K}/0.010 \, \text{m} - 2 \times 10^7 \, \text{W/m}^3 \times 0.010 \, \text{m}^2
\]

\[
q_x^e (0, 45\, \text{s}) = -149,800 \, \text{W/m}^2 - 100,000 \, \text{W/m}^2 = -249,800 \, \text{W/m}^2
\]  

**Node 2:** \[ k \frac{T_{m}^{p} - T_2}{\Delta x} - q_x^e (L, t) + \dot{q}(\Delta x/2) = 0 \]

\[
q_x^e (L, t) = k \left( \frac{T_{m}^{p} - T_2}{\Delta x} \right) / \Delta x + \dot{q}(\Delta x/2)
\]  \(6\)

continued...
(d) To determine the effect of mesh size, the above analysis was repeated using grids of 5 and 11 nodal points, $\Delta x = 5$ and 2 mm, respectively. Using the IHT Finite-Difference Equation Tool, the finite-difference equations were obtained and solved for the temperature-time history. Eqs. (5) and (6) were used for the heat flux calculations. The results are tabulated below for $t = 45s$, where $T_m^p (45s)$ is the center node,

<table>

**COMMENTS:**

1. The center temperature and boundary heat fluxes are quite insensitive to mesh size for the condition.

2. The copy of the IHT workspace for the 5 node grid is shown below.

```c
// Mesh size - 5 nodes, deltax = 5 mm
// Nodes a, b(m), and c are interior nodes

// Finite-Difference Equations Tool - nodal equations
/* Node a: interior node; e and w labeled b and 1. */
rho*cp*der(Ta,t) = fd_1d_int(Ta,Tb,T1,k,qdot,deltax)
/* Node b: interior node; e and w labeled c and a. */
rho*cp*der(Tb,t) = fd_1d_int(Tb,Tc,Ta,k,qdot,deltax)
/* Node c: interior node; e and w labeled 2 and b. */
rho*cp*der(Tc,t) = fd_1d_int(Tc,T2,Tb,k,qdot,deltax)

// Assigned Variables:
deltax = 0.005
k = 10
rho = 4000
cp = 500
qdot = 2e7
T1 = 0
T2 = 100

/* Initial Conditions:
Tai = 25
Tbi = 50

```
PROBLEM 5.97

KNOWN: Solid cylinder of plastic material ($\alpha = 6 \times 10^{-7} \text{ m}^2/\text{s}$), initially at uniform temperature of $T_i = 20^\circ\text{C}$, insulated at one end ($T_4$), while other end experiences heating causing its temperature $T_0$ to increase linearly with time at a rate of $a = 1^\circ\text{C/s}$.

FIND: (a) Finite-difference equations for the 4 nodes using the explicit method with $Fo = 1/2$ and (b) Surface temperature $T_0$ when $T_4 = 35^\circ\text{C}$.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, transient conduction in cylinder, (2) Constant properties, and (3) Lateral and end surfaces perfectly insulated.

ANALYSIS: (a) The finite-difference equations using the explicit method for the interior nodes ($m = 1, 2, 3$) follow from Eq. 5.73 with $Fo = 1/2$,

$$T_{m+1}^p = F_0 \left( T_{m+1}^p + T_{m-1}^p \right) + \left( 1 - 2F_0 \right) T_m^p = 0.5 \left( T_{m+1}^p + T_{m-1}^p \right)$$

From an energy balance on the control volume node 4 as shown above yields with $Fo = 1/2$

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_g = \dot{E}_{st}$$

$$q_a + q_b + 0 = \rho c V \left( T_{4}^{p+1} - T_{4}^{p} \right)/\Delta t$$

$$0 + k \left( T_3^p - T_4^p \right)/\Delta x = \rho c (\Delta x/2) \left( T_4^{p+1} - T_4^p \right)/\Delta t$$

$$T_{4}^{p+1} = 2F_0 T_3^p + (1 - 2F_0) T_4^p = T_3^p$$

(b) Performing the calculations, the temperature-time history is tabulated below, where $T_0 = T_i + a \cdot t$ where $a = 1^\circ\text{C/s}$ and $t = p \cdot \Delta t$ with,

$$Fo = \alpha \Delta t/\Delta x^2 = 0.5$$

$$\Delta t = 0.5 \left( 0.006 \text{ m} \right)^2 / 6 \times 10^{-7} \text{ m}^2/\text{s} = 30\text{s}$$

When $T_4(210s, p = 7) = 35^\circ\text{C}$, find $T_0(210s) = 230^\circ\text{C}$. <
PROBLEM 5.98

KNOWN: A 0.12 m thick wall, with thermal diffusivity $1.5 \times 10^{-6} \text{ m}^2/\text{s}$, initially at a uniform temperature of $85^\circ\text{C}$, has one face suddenly lowered to $20^\circ\text{C}$ while the other face is perfectly insulated.

FIND: (a) Using the explicit finite-difference method with space and time increments of $\Delta x = 30 \text{ mm}$ and $\Delta t = 300 \text{s}$, determine the temperature distribution within the wall 45 min after the change in surface temperature; (b) Effect of $\Delta t$ on temperature histories of the surfaces and midplane.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional transient conduction, (2) Constant properties.

ANALYSIS: (a) The finite-difference equations for the interior points, nodes 0, 1, 2, and 3, can be determined from Eq. 5.73,

$$T_{m+1}^p = F_o \left( T_{m-1}^p + T_{m+1}^p \right) + (1 - 2 F_o) T_m^p$$

with

$$F_o = \frac{\alpha \Delta t}{\Delta x^2} = 1.5 \times 10^{-6} \text{ m}^2/\text{s} \times 300 \text{s} / (0.03 \text{ m})^2 = 1/2.$$  \hspace{2cm} (2)

Note that the stability criterion, Eq. 5.74, $F_o \leq 1/2$, is satisfied. Hence, combining Eqs. (1) and (2),

$$T_{m+1}^p = \frac{1}{2} \left( T_{m-1}^p + T_{m+1}^p \right)$$

for $m = 0, 1, 2, 3$. Since the adiabatic plane at $x = 0$ can be treated as a symmetry plane, $T_{m-1} = T_{m+1}$ for node 0 ($m = 0$). The finite-difference solution is generated in the table below using $t = p \cdot \Delta t = 300 \text{ p (s)} = 5 \text{ p (min)}$.

</tbody>
</table>

The temperature distribution can also be determined from the Heisler charts. For the wall,

$$F_o = \frac{\alpha t}{L^2} = \frac{1.5 \times 10^{-6} \text{ m}^2/\text{s} \times (45 \times 60) \text{s}}{(0.12 \text{ m})^2} = 0.28$$

and

$$Bi^{-1} = \frac{k}{hL} = 0.$$
PROBLEM 5.98 (Cont.)

From Figure D.1, for $Bi^{-1} = 0$ and $Fo = 0.28$, find $\theta_o/\theta_i \approx 0.55$. Hence, for $x = 0$

$$\frac{T_0 - T_\infty}{T_i - T_\infty} = \frac{\theta_o}{\theta_i} \quad \text{or} \quad T_0 = T(0, t) = T_\infty + \frac{\theta_o}{\theta_i} (T_i - T_\infty) = 20^\circ C + 0.55(85 - 20)^\circ C = 55.8^\circ C.$$ 

This value is to be compared with $61.7^\circ C$ for the finite-difference method.

(b) Using the IHT Finite-Difference Equation Tool Pad for One-Dimensional Transient Conduction, temperature histories were computed and results are shown for the insulated surface ($T_0$) and the midplane, as well as for the chilled surface ($T_L$).

Apart from small differences during early stages of the transient, there is excellent agreement between results obtained for the two time steps. The temperature decay at the insulated surface must, of course, lag that of the midplane.
PROBLEM 5.99

KNOWN: Thickness, initial temperature and thermophysical properties of molded plastic part. Convection conditions at one surface. Other surface insulated.

FIND: Surface temperatures after one hour of cooling.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in product, (2) Negligible radiation, at cooled surface, (3) Negligible heat transfer at insulated surface, (4) Constant properties.

ANALYSIS: Adopting the implicit scheme, the finite-difference equation for the cooled surface node is given by Eq. (5.88), from which it follows that

\[(1 + 2 \text{Fo} + 2 \text{FoBi}) T_{10}^{p+1} - 2 \text{Fo} T_{9}^{p+1} = 2 \text{FoBi} T_{\infty} + T_{10}^{p}\]

The general form of the finite-difference equation for any interior node (1 to 9) is given by Eq. (5.89),

\[(1 + 2 \text{Fo}) T_m^{p+1} - \text{Fo} \left( T_{m-1}^{p+1} + T_{m+1}^{p+1} \right) = T_m^{p}\]

The finite-difference equation for the insulated surface node may be obtained by applying the symmetry requirement to Eq. (5.89); that is, \(T_{m+1}^{p} = T_{m}^{p}\). Hence,

\[(1 + 2 \text{Fo}) T_{0}^{p+1} - 2 \text{Fo} T_{1}^{p+1} = T_{0}^{p}\]

For the prescribed conditions, \(\text{Bi} = h \Delta x/k = 100 \text{ W/m}^2\cdot\text{K} (0.006\text{m})/0.30 \text{ W/m}\cdot\text{K} = 2\). If the explicit method were used, the most restrictive stability requirement would be given by Eq. (5.79). Hence, for \(\text{Fo}(1+\text{Bi}) \leq 0.5, \text{Fo} \leq 0.167\). With \(\text{Fo} = \alpha \Delta t/\Delta x^2\) and \(\alpha = k/\rho c = 1.67 \times 10^{-7} \text{ m}^2/\text{s}\), the corresponding restriction on the time increment would be \(\Delta t \leq 36\text{s}\). Although no such restriction applies for the implicit method, a value of \(\Delta t = 30\text{s}\) is chosen, and the set of 11 finite-difference equations is solved using the Tools option designated as Finite-Difference Equations, One-Dimensional, and Transient from the IHT Toolpad. At \(t = 3600\text{s}\), the solution yields:

\[T_{10}(3600\text{s}) = 24.1\text{°C} \quad \text{T}_0(3600\text{s}) = 71.5\text{°C}\]

COMMENTS: (1) More accurate results may be obtained from the one-term approximation to the exact solution for one-dimensional, transient conduction in a plane wall. With \(\text{Bi} = hL/k = 20\), Table 5.1 yields \(\zeta_1 = 1.496\text{ rad}\) and \(C_1 = 1.2699\). With \(\text{Fo} = \alpha \Delta t/\Delta x^2 = 0.167\), Eq. (5.41) then yields \(T_0 = T_\infty + (T_1 - T_\infty) C_1 \exp \left(-\zeta_1^2 \text{Fo}\right) = 72.4\text{°C}\), and from Eq. (5.40b), \(T_s = T_\infty + (T_1 - T_\infty) \cos \left(\zeta_1\right) = 24.5\text{°C}\).

Since the finite-difference results do not change with a reduction in the time step \((\Delta t < 30\text{s})\), the difference between the numerical and analytical results is attributed to the use of a coarse grid. To improve the accuracy of the numerical results, a smaller value of \(\Delta x\) should be used.

Continued ….
Although the surface temperatures rapidly approaches that of the coolant, there is a significant lag in the thermal response of the back surface. The different responses are attributable to the small value of $\alpha$ and the large value of $Bi$. 
**PROBLEM 5.100**

**KNOWN:** Plane wall, initially at a uniform temperature \( T_i = 25^\circ C \), is suddenly exposed to convection with a fluid at \( T_\infty = 50^\circ C \) with a convection coefficient \( h = 75 \text{ W/m}^2\text{K} \) at one surface, while the other is exposed to a constant heat flux \( q_o^* = 2000 \text{ W/m}^2 \). See also Problem 2.43.

**FIND:** (a) Using spatial and time increments of \( \Delta x = 5 \text{ mm} \) and \( \Delta t = 20 \text{s} \), compute and plot the temperature distributions in the wall for the initial condition, the steady-state condition, and two intermediate times, (b) On \( q_x^* - x \) coordinates, plot the heat flux distributions corresponding to the four temperature distributions represented in part (a), and (c) On \( q_x^* - t \) coordinates, plot the heat flux at \( x = 0 \) and \( x = L \).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional, transient conduction and (2) Constant properties.

**ANALYSIS:** (a) Using the IHT Finite-Difference Equations, One-Dimensional, Transient Tool, the equations for determining the temperature distribution were obtained and solved with a spatial increment of \( \Delta x = 5 \text{ mm} \). Using the Lookup Table functions, the temperature distributions were plotted as shown below.

(b) The heat flux, \( q_x^* (x,t) \), at each node can be evaluated considering the control volume shown with the schematic above

\[
q_x^* (m,p) = \left( q_x^*_{a,m} + q_x^*_{b,m} \right) / 2 = \left[ k \left( T^p_{m-1} - T^p_m \right) / \Delta x + k \left( T^p_m - T^p_{m+1} \right) / \Delta x \right] / 2 = k \left( T^p_{m-1} - T^p_{m+1} \right) / 2 \Delta x
\]

From knowledge of the temperature distribution, the heat flux at each node for the selected times is computed and plotted below.

(c) The heat fluxes for the locations \( x = 0 \) and \( x = L \), are plotted as a function of time. At the \( x = 0 \) surface, the heat flux is constant, \( q_0^* = 2000 \text{ W/m}^2 \). At the \( x = L \) surface, the heat flux is given by Newton’s law of cooling, \( q_x^* (L,t) = h[T(L,t) - T_\infty] \); at \( t = 0 \), \( q_x^* (L,0) = -1875 \text{ W/m}^2 \). For steady-state conditions, the heat flux \( q_x^* (x,\infty) \) is everywhere constant at \( q_0^* \). Continued...
Comments: The IHT workspace using the Finite-Difference Equations Tool to determine the temperature distributions and heat fluxes is shown below. Some lines of code were omitted to save space on the page.

// Finite-Difference Equations, One-Dimensional, Transient Tool:
// Node 0 - Applied heater flux
// Node 0: surface node (w-orientation); transient conditions; e labeled 1. */

// Node 10 - Convection process:
// Node 10: surface node (e-orientation); transient conditions; w labeled 9.
rho * cp * der(T10,t) = fd_1d_sur_e(T10,T9,k,qdot,deltax,Tinf,h,q'a)
q'a = 0   // Applied heat flux, W/m^2; zero flux shown

// Heat Flux Distribution at Interior Nodes, q"m:
q'1 = k / deltax * (T0 - T2) / 2
q'2 = k / deltax * (T1 - T3) / 2
......
qu'9 = k / deltax * (T8 - T10) / 2

// Heat flux at boundary x= L, q"10
q"xL = h * (T10 - Tinf)

// Assigned Variables:
deltax = 0.005   // Spatial increment, m
k = 1.5         // thermal conductivity, W/m.K
alpha = 7.5e-6   // Thermal diffusivity, m^2/s
cp = 1000       // Specific heat, J/kg.K; arbitrary value
alpha = k / (rho * cp)   // Definition from which rho is calculated
qdot = 0         // Volumetric heat generation rate, W/m^3
Ti = 25         // Initial temperature, C; used also for plotting initial distribution
Tinf = 50       // Fluid temperature, K
h = 75          // Convection coefficient, W/m^2.K

// Solver Conditions: integrated t from 0 to 1200 with 1 s step, log every 2nd value
PROBLEM 5.101

KNOWN: Plane wall, initially at a uniform temperature $T_o = 25^\circ C$, has one surface ($x = L$) suddenly exposed to a convection process with $T_\infty = 50^\circ C$ and $h = 1000 \text{ W/m}^2\cdot\text{K}$, while the other surface ($x = 0$) is maintained at $T_o$. Also, the wall suddenly experiences uniform volumetric heating with $\dot{q} = 1 \times 10^7 \text{ W/m}^3$. See also Problem 2.44.

FIND: (a) Using spatial and time increments of $\Delta x = 4 \text{ mm}$ and $\Delta t = 1\text{ s}$, compute and plot the temperature distributions in the wall for the initial condition, the steady-state condition, and two intermediate times, and (b) On $q_x^* - t$ coordinates, plot the heat flux at $x = 0$ and $x = L$. At what elapsed time is there zero heat flux at $x = L$?

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, transient conduction and (2) Constant properties.

ANALYSIS: (a) Using the IHT Finite-Difference Equations, One-Dimensional, Transient Tool, the temperature distributions were obtained and plotted below.

(b) The heat flux, $q_x^*$, can be expressed in terms of Newton's law of cooling,

$$ q_x^* (L,t) = h \left( T_i^P - T_\infty \right). $$

From the energy balance on the control volume about node 0 shown above,

$$ q_x^* (0,t) + \dot{E}_g + q_a^* = 0 \quad q_x^* (0,t) = -\dot{q} \left( \Delta x / 2 \right) - k \left( T_i^P - T_o \right) / \Delta x $$

From knowledge of the temperature distribution, the heat fluxes are computed and plotted.

COMMENTS: The steady-state analytical solution has the form of Eq. 3.40 where $C_1 = 6500 \text{ m}^{-1}/^\circ C$ and $C_2 = 25^\circ C$. Find $q_x^* (0,\infty) = -3.25 \times 10^5 \text{ W/m}^2$ and $q_x^* (L) = +7.5 \times 10^4 \text{ W/m}^2$. Comparing with the graphical results above, we conclude that steady-state conditions are not reached in 600 s.
**PROBLEM 5.102**

**KNOWN:** Fuel element of Example 5.8 is initially at a uniform temperature of 250°C with no internal generation; suddenly a uniform generation, $\dot{q} = 10^8 \text{W/m}^3$, occurs when the element is inserted into the core while the surfaces experience convection ($T_{\infty}, h$).

**FIND:** Temperature distribution 1.5s after element is inserted into the core.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional transient conduction, (2) Constant properties, (3) $\dot{q} = 0$, initially; at $t > 0$, $\dot{q}$ is uniform.

**ANALYSIS:** As suggested, the explicit method with a space increment of 2mm will be used. Using the nodal network of Example 5.8, the same finite-difference equations may be used.

**Interior nodes, $m = 1, 2, 3, 4$**

$$T_m^{p+1} = Fo \left[ T_{m-1}^p + T_{m+1}^p + \frac{\dot{q}(\Delta x)^2}{2} \right] + (1 - 2Fo)T_m^p. \quad (1)$$

**Midplane node, $m = 0$**

Same as Eq. (1), but with $T_{m-1}^p = T_{m+1}^p$.

**Surface node, $m = 5$**

$$T_5^{p+1} = 2Fo \left[ T_4^p + Bi \cdot T_{\infty} + \frac{\dot{q}(\Delta x)^2}{2k} \right] + (1 - 2Fo - 2Bi \cdot Fo)T_5^p. \quad (2)$$

The most restrictive stability criterion is associated with Eq. (2), $Fo(1+Bi) \leq 1/2$. Consider the following parameters:

$$Bi = \frac{h\Delta x}{k} = \frac{1100 \text{W/m}^2 \cdot \text{K} \times (0.002 \text{m})}{30 \text{W/m} \cdot \text{K}} = 0.0733$$

$$Fo \leq \frac{1/2}{1+Bi} = 0.466$$

$$\Delta t \leq \frac{Fo(\Delta x)^2}{\alpha} = \frac{0.466 \cdot (0.002 \text{m})^2}{5 \times 10^{-6} \text{m}^2 / \text{s}} = 0.373 \text{s.}$$

Continued ….
To be well within the stability limit, select $\Delta t = 0.3s$, which corresponds to

$$F_0 = \frac{\alpha \Delta t}{\Delta x^2} = \frac{5 \times 10^{-6} \text{m}^2/\text{s} \times 0.3 \text{s}}{(0.002 \text{m})^2} = 0.375$$

$$t = p \Delta t = 0.3p \text{s}.$$ 

Substituting numerical values with $q = 10^8 \text{W/m}^3$, the nodal equations become

$$T_{0}^{p+1} = 0.375 \left[ 2T_{1}^{p} + 10^8 \text{W/m}^3 (0.002 \text{m})^2 / 30 \text{W/m.K} \right] + (1 - 2 \times 0.375) T_{0}^{p}$$

$$T_{1}^{p+1} = 0.375 \left[ T_{0}^{p} + T_{2}^{p} + 13.33 \right] + 0.25 T_{0}^{p}$$  \hspace{1cm} (3)

$$T_{2}^{p+1} = 0.375 \left[ T_{1}^{p} + T_{3}^{p} + 13.33 \right] + 0.25 T_{1}^{p}$$  \hspace{1cm} (4)

$$T_{3}^{p+1} = 0.375 \left[ T_{2}^{p} + T_{4}^{p} + 13.33 \right] + 0.25 T_{2}^{p}$$  \hspace{1cm} (5)

$$T_{4}^{p+1} = 0.375 \left[ T_{3}^{p} + T_{5}^{p} + 13.33 \right] + 0.25 T_{3}^{p}$$  \hspace{1cm} (6)

$$T_{5}^{p+1} = 2 \times 0.375 \left[ T_{4}^{p} + 0.0733 \times 250 + \frac{13.33}{2} \right] + (1 - 2 \times 0.375 - 2 \times 0.0733 \times 0.375) T_{5}^{p}$$

$$T_{5}^{p+1} = 0.750 \left[ T_{4}^{p} + 24.99 \right] + 0.195 T_{5}^{p}.$$  \hspace{1cm} (8)

The initial temperature distribution is $T_i = 250^\circ C$ at all nodes. The marching solution, following the procedure of Example 5.8, is represented in the table below.

(b) Using the code, the mid-plane (00) and surface (05) node temperatures are plotted as a function of time.

Continued …..
Note that at t \approx 240 s, the wall has nearly reached the new steady-state condition for which the nodal temperatures (°C) were found as:

\[
\begin{array}{cccccc}
T00 & T01 & T02 & T03 & T04 & T05 \\
465 & 463.7 & 459.7 & 453 & 443.7 & 431.7 \\
\end{array}
\]

**COMMENTS:** (1) Can you validate the new steady-state nodal temperatures from part (b) by comparison against an analytical solution?

(2) Will using a smaller time increment improve the accuracy of the results? Use your code with \( \Delta t = 0.15 \) s to justify your explanation.

(3) Selected portions of the IHT code to obtain the nodal temperature distribution using spatial and time increments of \( \Delta x = 2 \) mm and \( \Delta t = 0.3 \) s, respectively, are shown below. For the solve-integration step, the initial condition for each of the nodes corresponds to the steady-state temperature distribution with \( \dot{q}_1 \).

```cpp
// Tools | Finite-Difference Equations | One-Dimensional | Transient
/* Node 00: surface node (w-orientation); transient conditions; e labeled 01. */
rho * cp * der(T00,t) = fd_1d_sur_w(T00,T01,k,qdot,deltax,Tinf01,h01,q"a00) q"a00 = 0 // Applied heat flux, W/m^2; zero flux shown
Tinf01 = 20 // Arbitrary value
h01 = 1e-8 // Causes boundary to behave as adiabatic
/* Node 01: interior node; e and w labeled 02 and 00. */
rho*cp*der(T01,t) = fd_1d_int(T01,T02,T00,k,qdot,deltax)
/* Node 02: interior node; e and w labeled 03 and 01. */
rho*cp*der(T02,t) = fd_1d_int(T02,T03,T01,k,qdot,deltax)
/* Node 03: interior node; e and w labeled 04 and 02. */
rho*cp*der(T03,t) = fd_1d_int(T03,T04,T02,k,qdot,deltax)
/* Node 04: interior node; e and w labeled 05 and 03. */
rho*cp*der(T04,t) = fd_1d_int(T04,T05,T03,k,qdot,deltax)
/* Node 05: surface node (e-orientation); transient conditions; w labeled 04, */
rho * cp * der(T05,t) = fd_1d_sur_e(T05,T04,k,qdot,deltax,Tinf05,h05,q"a05) q"a05 = 0 // Applied heat flux, W/m^2; zero flux shown
Tinf05 = 250 // Coolant temperature, C
h05 = 1100 // Convection coefficient, W/m^2.K

// Input parameters
qdot = 2e7 // Volumetric rate, W/m^3, step change
deltax = 0.002 // Space increment
k = 30 // Thermophysical properties
alpha = 5e-6
rho = 1000
alpha = k / (rho * cp)

/* Steady-state conditions, with qdot1 = 1e7 W/m^3; initial conditions for step change
T_x = 16.67 * (1 - x^2/L^2) + 340.91 // See text
Seek T_x for x = 0, 2, 4, 6, 8, 10 mm; results used for Ti are
Node  T_x
00  357.6
01  356.9
02  354.9
03  351.6
04  346.9
05  340.9 */
```
**PROBLEM 5.104**

**KNOWN:** Conditions associated with heat generation in a rectangular fuel element with surface cooling. See Example 5.8.

**FIND:** (a) The temperature distribution 1.5 s after the change in the operating power; compare results with those tabulated in the Example, and (b) Plot the temperature histories at the midplane, x = 0, and the surface, x = L, for 0 ≤ t ≤ 400 s; determine the new steady-state temperatures, and approximately how long it takes to reach this condition. Use the finite-element software *FEHT* as your solution tool.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional conduction in the x-direction, (2) Uniform generation, (3) Constant properties.

**ANALYSIS:** Using *FEHT*, an outline of the fuel element is drawn of thickness 10 mm in the x-direction and arbitrary length in the y-direction. The boundary conditions are specified as follows: on the y-planes and the x = 0 plane, treat as adiabatic; on the x = 10 mm plane, specify the convection option. Specify the material properties and the internal generation with \( \dot{q}_1 \). In the *Setup* menu, click on *Steady-state*, and then *Run* to obtain the temperature distribution corresponding to the initial temperature distribution,

\[
T_i(x, 0) = T(x, \dot{q}_1)
\]

before the change in operating power to \( \dot{q}_2 \).

Next, in the *Setup* menu, click on *Transient*; in the *Specify | Internal Generation* box, change the value to \( \dot{q}_2 \); and in the *Run* command, click on *Continue* (not *Calculate*).

(a) The temperature distribution 1.5 s after the change in operating power from the *FEHT* analysis and from the FDE analysis in the Example are tabulated below.

<table>
<thead>
<tr>
<th>x/L</th>
<th>0</th>
<th>0.2</th>
<th>0.4</th>
<th>0.6</th>
<th>0.8</th>
<th>1.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>T(x/L, 1.5 s)</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>FEHT (°C)</strong></td>
<td>360.1</td>
<td>359.4</td>
<td>357.4</td>
<td>354.1</td>
<td>349.3</td>
<td>343.2</td>

<tr>
<td><strong>FDE (°C)</strong></td>
<td>360.08</td>
<td>359.41</td>
<td>357.41</td>
<td>354.07</td>
<td>349.37</td>
<td>343.27</td>
</tr>
</tbody>
</table>

The mesh spacing for the *FEHT* analysis was 0.5 mm and the time increment was 0.005 s. For the FDE analyses, the spatial and time increments were 2 mm and 0.3 s. The agreement between the results from the two numerical methods is within 0.1°C.

(b) Using the *FEHT* code, the temperature histories at the mid-plane (x = 0) and the surface (x = L) are plotted as a function of time.

Continued ....
From the distribution, the steady-state condition (based upon 98% change) is approached in 215 s. The steady-state temperature distributions after the step change in power from the FEHT and FDE analysis in the Example are tabulated below. The agreement between the results from the two numerical methods is within 0.1°C.

<table>
<thead>

<td>443.82</td>
<td>431.82</td>
</tr>
</tbody>
</table>

**COMMENTS:**  
(1) For background information on the **Continue** option, see the Run menu in the FEHT Help section. Using the Run/Calculate command, the steady-state temperature distribution was determined for the q₁ operating power. Using the Run/Continue command (after re-setting the generation to q₂ and clicking on Setup | Transient), this steady-state distribution automatically becomes the initial temperature distribution for the q₂ operating power. This feature allows for conveniently prescribing a non-uniform initial temperature distribution for a transient analysis (rather than specifying values on a node-by-node basis).

(2) Use the View | Tabular Output command to obtain nodal temperatures to the maximum number of significant figures resulting from the analysis.

(3) Can you validate the new steady-state nodal temperatures from part (b) (with q₂, t → ∞) by comparison against an analytical solution?
PROBLEM 5.105

KNOWN: Thickness, initial temperature, speed and thermophysical properties of steel in a thin-slab continuous casting process. Surface convection conditions.

FIND: Time required to cool the outer surface to a prescribed temperature. Corresponding value of the midplane temperature and length of cooling section.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) Negligible radiation at quenched surfaces, (3) Symmetry about the midplane, (4) Constant properties.

ANALYSIS: Adopting the implicit scheme, the finite-difference equation for the cooled surface node is given by Eq. (5.88), from which it follows that

\[(1 + 2 \text{Fo} + 2 \text{Bi}) T_{10}^{p+1} - 2 \text{Fo} T_9^{p+1} = 2 \text{FoBi} T_\infty + T_{10}^p \]

The general form of the finite-difference equation for any interior node (1 to 9) is given by Eq. (5.89),

\[(1 + 2 \text{Fo}) T_m^{p+1} - \text{Fo} \left( T_{m-1}^{p+1} + T_{m+1}^{p+1} \right) = T_m^p \]

The finite-difference equation for the midplane node may be obtained by applying the symmetry requirement to Eq. (5.89); that is, \( T_{m+1}^p = T_{m-1}^p \). Hence,

\[(1 + 2 \text{Fo}) T_{10}^{p+1} - 2 \text{Fo} T_1^{p+1} = T_0^p \]

For the prescribed conditions, \( \text{Bi} = h \Delta x/k = 5000 \text{ W/m}^2\cdot\text{K} \) \((0.010\text{m})/30 \text{ W/m} \cdot \text{K} = 1.67\). If the explicit method were used, the stability requirement would be given by Eq. (5.79). Hence, for \( \text{Fo}(1 + \text{Bi}) \leq 0.5 \), \( \text{Fo} \leq 0.187 \). With \( \text{Fo} = \alpha \Delta t/\Delta x^2 \) and \( \alpha = k/\rho c = 5.49 \times 10^{-6} \text{ m}^2/\text{s} \), the corresponding restriction on the time increment would be \( \Delta t \leq 3.40 \text{s} \). Although no such restriction applies for the implicit method, a value of \( \Delta t = 1 \text{s} \) is chosen, and the set of 11 finite-difference equations is solved using the Tools option designated as \textit{Finite-Difference Equations, One-Dimensional and Transient} from the IHT Toolpad. For \( T_{10} (t) = 300^\circ\text{C} \), the solution yields

\[ t = 161 \text{s} \]

Continued .....

PROBLEM 5.105 (Cont.)

\[ T_0(t) = 1364°C \]

With a casting speed of \( V = 15 \text{ mm/s} \), the length of the cooling section is

\[ L_{CS} = Vt = 0.015 \text{ m/s} \times 161 \text{ s} = 2.42 \text{ m} \]

**COMMENTS:** (1) With \( Fo = \frac{\alpha t}{L^2} = 0.088 < 0.2 \), the one-term approximation to the exact solution for one-dimensional conduction in a plane wall cannot be used to confirm the foregoing results. However, using the exact solution from the *Models, Transient Conduction, Plane Wall* Option of IHT, values of \( T_0 = 1366°C \) and \( T_s = 200.7°C \) are obtained and are in good agreement with the finite-difference predictions. The accuracy of these predictions could still be improved by reducing the value of \( \Delta x \).

(2) Temperature histories for the surface and midplane nodes are plotted for \( 0 < t < 600 \text{s} \).

While \( T_{10} (600\text{s}) = 124°C \), \( T_0 (600\text{s}) \) has only dropped to \( 879°C \). The much slower thermal response at the midplane is attributable to the small value of \( \alpha \) and the large value of \( Bi = 16.67 \).
PROBLEM 5.106

KNOWN: Very thick plate, initially at a uniform temperature, $T_i$, is suddenly exposed to a convection cooling process ($T_\infty$,h).

FIND: Temperatures at the surface and a 45mm depth after 3 minutes using finite-difference method with space and time increments of 15mm and 18s.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional transient conduction, (2) Plate approximates semi-infinite medium, (3) Constant properties.

ANALYSIS: The grid network representing the plate is shown above. The finite-difference equation for node 0 is given by Eq. 5.82 for one-dimensional conditions or Eq. 5.77,

$$T_0^{P+1} = 2Fo(T_i^P + Bi \cdot T_\infty) + (1 - 2Fo - 2Bi \cdot Fo)T_0^P.$$  \hspace{1cm} (1)

The numerical values of Fo and Bi are

$$Fo = \frac{\alpha\Delta t}{\Delta x^2} = \frac{5.6 \times 10^{-6} \text{m}^2/\text{s} \times 18 \text{s}}{(0.015 \text{m})^2} = 0.448$$

$$Bi = \frac{h\Delta x}{k} = \frac{100 \text{W/m}^2 \cdot K \times (15 \times 10^{-3} \text{m})}{20 \text{W/m} \cdot K} = 0.075.$$  

Recognizing that $T_\infty = 15^\circ C$, Eq. (1) has the form

$$T_0^{P+1} = 0.0359 T_0^P + 0.897 T_1^P + 1.01.$$  \hspace{1cm} (2)

It is important to satisfy the stability criterion, Fo $(1+Bi) \leq 1/2$. Substituting values, $0.448 (1+0.075) = 0.482 \leq 1/2$, and the criterion is satisfied.

The finite-difference equation for the interior nodes, $m = 1, 2…$, follows from Eq. 5.73,

$$T_m^{P+1} = Fo(T_{m+1}^P + T_{m-1}^P) + (1 - 2Fo) T_m^P.$$  \hspace{1cm} (3)

Recognizing that the stability criterion, $Fo \leq 1/2$, is satisfied with $Fo = 0.448$,

$$T_m^{P+1} = 0.448(T_{m+1}^P + T_{m-1}^P) + 0.104 T_m^P.$$  \hspace{1cm} (4)

Continued ….
PROBLEM 5.106 (Cont.)

The time scale is related to $p$, the number of steps in the calculation procedure, and $\Delta t$, the time increment,

$$t = p \Delta t. \quad (5)$$

The finite-difference calculations can now be performed using Eqs. (2) and (4). The results are tabulated below.

<table>

<td>180</td>
<td>274.8</td>
<td>291.3</td>
<td>304.1</td>
<td>312.4</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Hence, find

$$T(0, 180\text{s}) = T_0^{10} = 275^\circ \text{C} \quad T(45\text{mm, } 180\text{s}) = T_3^{10} = 312^\circ \text{C}. \quad \text{<}$$

**COMMENTS:** (1) The above results can be readily checked against the analytical solution represented in Fig. 5.8 (see also Eq. 5.60). For $x = 0$ and $t = 180\text{s}$, find

$$\frac{x}{2(\alpha \cdot t)^{1/2}} = 0$$

$$\frac{h(\alpha \cdot t)^{1/2}}{k} = \frac{100 \text{ W/m}^2 \cdot \text{K} \left(5.60 \times 10^{-6} \text{m}^2 / \text{s} \times 180\text{s}\right)^{1/2}}{20 \text{ W/m} \cdot \text{K}} = 0.16$$

for which the figure gives

$$\frac{T - T_i}{T_\infty - T_i} = 0.15$$

so that,

$$T(0, 180\text{s}) = 0.15(T_\infty - T_i) + T_i = 0.15(325 - 325) + 325^\circ \text{C} = 325^\circ \text{C}$$

For $x = 45\text{mm}$, the procedure yields $T(45\text{mm, } 180\text{s}) = 316^\circ \text{C}$. The agreement with the numerical solution is nearly within 1%.
PROBLEM 5.107

KNOWN: Sudden exposure of the surface of a thick slab, initially at a uniform temperature, to convection and to surroundings at a high temperature.

FIND: (a) Explicit, finite-difference equation for the surface node in terms of Fo, Bi, Bi_r, (b) Stability criterion; whether it is more restrictive than that for an interior node and does it change with time, and (c) Temperature at the surface and at 30mm depth for prescribed conditions after 1 minute exposure.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional transient conduction, (2) Thick slab may be approximated as semi-infinite medium, (3) Constant properties, (4) Radiation exchange is between small surface and large surroundings.

ANALYSIS: (a) The explicit form of the FDE for the surface node may be obtained by applying an energy balance to a control volume about the node.

\[
\begin{align*}
E_{in}^* - E_{out}^* &= q_{conv}^* + q_{rad}^* + q_{cond}^* = E_{st}^* \\
&= h(T_{\infty} - T_{o}^p) + h_r(T_{sur} - T_{o}^p) + k \cdot \frac{T_{o}^p - T_{o}^p}{\Delta x} \\
&= \rho c \left[ \frac{\Delta x}{2} \right] T_{o}^{p+1} - T_{o}^p \\
&= 1 - 2Fo(Bi + Bi_r + 1) \geq 0 \quad \text{or} \quad Fo \leq 1/2(Bi + Bi_r + 1).
\end{align*}
\]

(b) The stability criterion for Eq. (6) requires that the coefficient of \( T_{o}^p \) be positive.

\[
1 - 2Fo(Bi + Bi_r + 1) \geq 0 \quad \text{or} \quad Fo \leq 1/2(Bi + Bi_r + 1).
\]

Continued …….
(c) Consider the prescribed conditions with negligible convection (Bi = 0). The FDEs for the thick slab are:

\[
\text{Surface (0)} \quad T_{0}^{P+1} = 2F_{o}\left(B_{i}\cdot F_{o} + B_{i_{r}}\cdot T_{\text{sur}} + T_{1}^{P}\right) + (1 - 2B_{i}\cdot F_{o} - 2B_{i_{r}}\cdot F_{o} - 2F_{o})T_{0}^{P} \tag{8}
\]

\[
\text{Interior (m} \geq 1) \quad T_{m}^{P+1} = F_{o}\left(T_{m+1}^{P} + T_{m-1}^{P}\right) + (1 - 2F_{o})T_{m}^{P} \tag{9, 5, 7, 3}
\]

The stability criterion from Eq. (7) with Bi = 0 is,

\[
F_{o} \leq 1/2(1 + B_{i_{r}}) \tag{10}
\]

To proceed with the explicit, marching solution, we need to select a value of \(\Delta t\) (Fo) that will satisfy the stability criterion. A few trial calculations are helpful. A value of \(\Delta t = 15\) s provides \(F_{o} = 0.105\), and using Eqs. (2) and (5), \(h_{r}(300\text{K}, 1000\text{K}) = 72.3 \text{ W/}m^{2}\cdot\text{K}\) and \(B_{i_{r}} = 0.482\). From the stability criterion, Eq. (10), find \(F_{o} \leq 0.337\). With increasing \(T_{0}^{P}\), \(h_{r}\) and \(B_{i_{r}}\) increase: \(h_{r}(800\text{K}, 1000\text{K}) = 150.6 \text{ W/}m^{2}\cdot\text{K}\), \(B_{i_{r}} = 1.004\) and \(F_{o} \leq 0.249\). Hence, if \(T_{0}^{P} < 800\text{K}, \Delta t = 15\) s or \(F_{o} = 0.105\) satisfies the stability criterion.

Using \(\Delta t = 15\) s or \(F_{o} = 0.105\) with the FDEs, Eqs. (8) and (9), the results of the solution are tabulated below. Note how \(h_{r}^{P}\) and \(B_{i_{r}}^{P}\) are evaluated at each time increment. Note that \(t = p\cdot\Delta t\), where \(\Delta t = 15\) s.

After 60s(p = 4), \(T_{0}(0, 1\text{ min}) = 502.3\text{K}\) and \(T_{3}(30\text{mm, 1 min}) = 300.1\text{K}\).

**COMMENTS:**

1. The form of the FDE representing the surface node agrees with Eq. 5.82 if this equation is reduced to one-dimension.

2. We should recognize that the \(\Delta t = 15\) s time increment represents a coarse step. To improve the accuracy of the solution, a smaller \(\Delta t\) should be chosen.
**PROBLEM 5.108**

**KNOWN:** Thick slab of copper, initially at a uniform temperature, is suddenly exposed to a constant net radiant flux at one surface. See Example 5.9.

**FIND:** (a) The nodal temperatures at nodes 00 and 04 at \( t = 120 \) s; that is, \( T_{00}(0, 120 \) s) and \( T_{04}(0.15 \) m, \( 120 \) s); compare results with those given by the exact solution in Comment 1; will a time increment of \( 0.12 \) s provide more accurate results?; and, (b) Plot the temperature histories for \( x = 0, 150 \) and \( 600 \) mm, and explain key features of your results. Use the IHT Tools | Finite-Difference Equations | One-Dimensional | Transient conduction model builder to obtain the implicit form of the FDEs for the interior nodes. Use space and time increments of \( 37.5 \) mm and \( 1.2 \) s, respectively, for a 17-node network. For the surface node 00, use the FDE derived in Section 2 of the Example.

**SCHEMATIC:**

![Schematic diagram](image)

**ASSUMPTIONS:** (1) One-dimensional conduction in the \( x \)-direction, (2) Slab of thickness 600 mm approximates a semi-infinite medium, and (3) Constant properties.

**ANALYSIS:** The IHT model builder provides the implicit-method FDEs for the interior nodes, 01 – 15. The +\( x \) boundary condition for the node-16 control volume is assumed adiabatic. The FDE for the surface node 00 exposed to the net radiant flux was derived in the Example analysis. Selected portions of the IHT code used to obtain the following results are shown in the Comments.

(a) The 00 and 04 nodal temperatures for \( t = 120 \) s are tabulated below using a time increment of \( \Delta t = 1.2 \) s and \( 0.12 \) s, and compared with the results given from the exact analytical solution, Eq. 5.59.

</tbody>
</table>

The numerical FDE-based results with the different time increments agree quite closely with one another. At the surface, the numerical results are nearly 1 °C less than the result from the exact analytical solution. This difference represents an error of \(-1\%\) \((-1 \) °C / \((120 – 20) \) °C \times 100\). At the \( x = 150 \) mm location, the difference is about -0.4 °C, representing an error of \(-1.5\%). For this situation, the smaller time increment \((0.12 \) s\) did not provide improved accuracy. To improve the accuracy of the numerical model, it would be necessary to reduce the space increment, in addition to using the smaller time increment.

(b) The temperature histories for \( x = 0, 150 \) and \( 600 \) mm (nodes 00, 04, and 16) for the range \( 0 \leq t \leq 150 \) s are as follows.

Continued ….
As expected, the surface temperature, $T_{00} = T(0, t)$, increases markedly at early times. As thermal penetration increases with increasing time, the temperature at the location $x = 150$ mm, $T_{04} = T(150$ mm, $t)$, begins to increase after about 20 s. Note, however, the temperature at the location $x = 600$ mm, $T_{16} = T(600$ mm, $t)$, does not change significantly within the 150 s duration of the applied surface heat flux. Our assumption of treating the $+x$ boundary of the node 16 control volume as adiabatic is justified. A copper plate of 600-mm thickness is a good approximation to a semi-infinite medium at times less than 150 s.

**COMMENTS:** Selected portions of the IHT code with the nodal equations to obtain the temperature distribution are shown below. Note how the FDE for node 00 is written in terms of an energy balance using the $\text{der}(T,t)$ function. The FDE for node 16 assumes that the “east” boundary is adiabatic.
**PROBLEM 5.109**

**KNOWN:** Thick slab of copper as treated in Example 5.9, initially at a uniform temperature, is suddenly exposed to large surroundings at 1000°C (instead of a net radiant flux).

**FIND:** (a) The temperatures $T(0, 120 \text{ s})$ and $T(0.15 \text{ m}, 120\text{ s})$ using the finite-element software FEHT for a surface emissivity of 0.94 and (b) Plot the temperature histories for $x = 0, 150$ and 600 mm, and explain key features of your results.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional conduction in the x-direction, (2) Slab of thickness 600 mm approximates a semi-infinite medium, (3) Slab is small object in large, isothermal surroundings.

**ANALYSIS:** (a) Using FEHT, an outline of the slab is drawn of thickness 600 mm in the x-direction and arbitrary length in the y-direction. Click on Setup | Temperatures in K, to enter all temperatures in kelvins. The boundary conditions are specified as follows: on the y-planes and the x = 600 mm plane, treat as adiabatic; on the surface $(0,y)$, select the convection coefficient option, enter the linearized radiation coefficient after Eq. 1.9 written as

$$0.94 \times 5.67 \times 10^{-8} \times (T + 1273) \times (T^2 + 1273^2)$$

and enter the surroundings temperature, 1273 K, in the fluid temperature box. See the Comments for a view of the input screen. From View|Temperatures, find the results:

$$T(0, 120 \text{ s}) = 339 \text{ K} = 66^\circ \text{C} \quad T(150 \text{ mm}, 120 \text{ s}) = 305\text{K} = 32^\circ \text{C}$$

(b) Using the View | Temperatures command, the temperature histories for $x = 0, 150$ and 600 mm (10 mm mesh, Nodes 18, 23 and 15, respectively) are plotted. As expected, the surface temperature increases markedly at early times. As thermal penetration increases with increasing time, the temperature at the location $x = 150$ mm begins to increase after about 30 s. Note, however, that the temperature at the location $x = 600$ mm does not change significantly within the 150 s exposure to the hot surroundings. Our assumption of treating the boundary at the $x = 600$ mm plane as adiabatic is justified. A copper plate of 600 mm is a good approximation to a semi-infinite medium at times less than 150 s.

Continued …..
PROBLEM 5.109 (Cont.)

**COMMENTS:** The annotated *Input* screen shows the outline of the slab, the boundary conditions, and the triangular mesh before using the *Reduce-mesh* option.
**PROBLEM 5.110**

**KNOWN:** Electric heater sandwiched between two thick plates whose surfaces experience convection. Case 2 corresponds to steady-state operation with a loss of coolant on the $x = -L$ surface. Suddenly, a second loss of coolant condition occurs on the $x = +L$ surface, but the heater remains energized for the next 15 minutes. Case 3 corresponds to the eventual steady-state condition following the second loss of coolant event. See Problem 2.53.

**FIND:** Calculate and plot the temperature time histories at the plate locations $x = 0$, $\pm L$ during the transient period between steady-state distributions for Case 2 and Case 3 using the finite-element approach with *FEHT* and the finite-difference method of solution with *IHT* ($\Delta x = 5$ mm and $\Delta t = 1$ s).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional conduction, (2) Constant properties, (3) Heater has negligible thickness, and (4) Negligible thermal resistance between the heater surfaces and the plates.

**PROPERTIES:** Plate material (*given*); $\rho = 2500$ kg/m$^3$, $c = 700$ J/kg·K, $k = 5$ W/m·K.

**ANALYSIS:** The temperature distribution for Case 2 shown in the above graph represents the initial condition for the period of time following the second loss of coolant event. The boundary conditions at $x = \pm L$ are adiabatic, and the heater flux is maintained at $q_0^* = 4000$ W/m$^2$ for $0 \leq t \leq 15$ min.

Using *FEHT*, the heater is represented as a plate of thickness $L_h = 0.5$ mm with very low thermal capacitance ($\rho = 1$ kg/m and $c = 1$ J/kg·K), very high thermal conductivity ($k = 10,000$ W/m·K), and a uniform volumetric generation rate of $q = q_0^* / L_h = 4000$ W/m$^2 / 0.0005$ m = $8.0 \times 10^6$ W/m$^3$ for $0 \leq t \leq 900$ s. In the Specify | Generation box, the generation was prescribed by the lookup file (see *FEHT* Help): ‘hfvst’,1,2,Time. This *Notepad* file is comprised of four lines, with the values on each line separated by a single tab space:

```
0     8e6
900   8e6
901   0
5000  0
```

The temperature-time histories are shown in the graph below for the surfaces $x = -L$ (lowest curve, 13) and $x = +L$ (19) and the center point $x = 0$ (highest curve, 14). The center point experiences the maximum temperature of 89°C at the time the heater is deactivated, $t = 900$ s.

Continued …..
For the finite-difference method of solution, the nodal arrangement for the system is shown below. The IHT model builder Tools | Finite-Difference Equations | One Dimensional can be used to obtain the FDEs for the internal nodes (02-04, 07-10) and the adiabatic boundary nodes (01, 11).

![Nodal arrangement, FDE solution](image1)

For the heater-plate interface node 06, the FDE for the implicit method is derived from an energy balance on the control volume shown in the schematic above.

\[ \dot{E}_\text{in} - \dot{E}_\text{out} + \dot{E}_\text{gen} = \dot{E}_\text{st} \]

\[ q_a + q_b + q_0 = E_\text{st} \]

\[ k \frac{T_{05}^{p+1} - T_{06}^{p+1}}{\Delta x} + k \frac{T_{07}^{p+1} - T_{06}^{p+1}}{\Delta x} + q_0 = \rho c \Delta x \frac{T_{06}^{p+1} - T_{06}^p}{\Delta t} \]

The IHT code representing selected nodes is shown below for the adiabatic boundary node 01, interior node 02, and the heater-plates interface node 06. Note how the foregoing derived finite-difference equation in implicit form is written in the IHT Workspace. Note also the use of a Lookup Table for representing the heater flux vs. time.

Continued …..
PROGRAM 5.110 (Cont.)

900.5      0
5000       0
*/

The temperature-time histories using the IHT code for the plate locations x = 0, ±L are shown in the graphs below. We chose to show expanded presentations of the histories at early times, just after the second loss of coolant event, t = 0, and around the time the heater is deactivated, t = 900 s.

![Temperature graphs](image1.png)

COMMENTS: (1) The maximum temperature during the transient period is at the center point and occurs at the instant the heater is deactivated, T(0, 900s) = 89°C. After 300 s, note that the two surface temperatures are nearly the same, and never rise above the final steady-state temperature.

(2) Both the FEHT and IHT methods of solution give identical results. Their steady-state solutions agree with the result of an energy balance on a time interval basis yielding Tss = 86.1°C.
PROBLEM 5.111

KNOWN: Plane wall of thickness 2L, initially at a uniform temperature, is suddenly subjected to convection heat transfer.

FIND: The mid-plane, $T(0,t)$, and surface, $T(L,t)$, temperatures at $t = 50$, $100$, $200$ and $500$ s, using the following methods: (a) the one-term series solution; determine also the Biot number; (b) the lumped capacitance solution; and (c) the two- and 5-node finite-difference numerical solutions. Prepare a table summarizing the results and comment on the relative differences of the predicted temperatures.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction in the x-direction, and (2) Constant properties.

ANALYSIS: (a) The results are tabulated below for the mid-plane and surface temperatures using the one-term approximation to the series solution, Eq. 5.40 and 5.41. The Biot number for the heat transfer process is

$$\text{Bi} = h \frac{L}{k} = \frac{500 \text{ W/m}^2}{15 \text{ W/m} \cdot \text{K}} = 0.67$$

Since Bi >> 0.1, we expect an appreciable temperature difference between the mid-plane and surface as the tabulated results indicate (Eq. 5.10).

(b) The results are tabulated below for the wall temperatures using the lumped capacitance method (LCM) of solution, Eq. 5.6. The LCM neglects the internal conduction resistance and since Bi = 0.67 >> 0.1, we expect this method to predict systematically lower temperatures (faster cooling) at the midplane compared to the one-term approximation.

(c) The 2- and 5-node nodal networks representing the wall are shown in the schematic above. The implicit form of the finite-difference equations for the mid-plane, interior (if present) and surface nodes can be derived from energy balances on the nodal control volumes. The time-rate of change of the temperature is expressed in terms of the $IHT$ integral intrinsic function, $\text{der}(T,t)$.

PROBLEM 5.111 (Cont.)

Mid-plane node
\[ k \left( T^2 - T1 \right) / \Delta x = \rho c \left( \Delta x / 2 \right) \cdot \text{der} (T1, t) \]

Interior node (5-node network)
\[ k \left( T1 - T2 \right) / \Delta x + k \left( T3 - T2 \right) / \Delta x = \rho c \Delta x \cdot \text{der} (T2, t) \]

Surface node (shown for 5-node network)
\[ k \left( T4 - T5 \right) / \Delta x + h \left( T\inf - T5 \right) = \rho c \left( \Delta x / 2 \right) \cdot \text{der} (T5, t) \]

With appropriate values for \( \Delta x \), the foregoing FDEs were entered into the IHT workspace and solved for the temperature distributions as a function of time over the range \( 0 \leq t \leq 500 \) s using an integration time step of 1 s. Selected portions of the IHT codes for each of the models are shown in the Comments. The results of the analysis are summarized in the foregoing table.

COMMENTS: (1) Referring to the table above, we can make the following observations about the relative differences and similarities of the estimated temperatures: (a) The one-term series model estimates are the most reliable, and can serve as the benchmark for the other model results; (b) The LCM model overestimates the rate of cooling, and poorly predicts temperatures since the model neglects the effect of internal resistance and \( \text{Bi} = 0.67 >> 0.1 \); (c) The 5-node model results are in excellent agreement with those from the one-term series solution; we can infer that the chosen space and time increments are sufficiently small to provide accurate results; and (d) The 2-node model underestimates the rate of cooling for early times when the time-rate of change is high; but for late times, the agreement is improved.

(2) See the Solver | Intrinsic Functions section of IHT|Help or the IHT Examples menu (Example 5.3) for guidance on using the \( \text{der}(T, t) \) function.

(3) Selected portions of the IHT code for the 2-node network model are shown below.

```
// Writing the finite-difference equations – 2-node model
// Node 1
k * (T2 - T1)/ deltax = rho * cp * (deltax / 2) * der(T1,t)
// Node 2
k * (T1 - T2)/ deltax + h * (Tinf - T2) = rho * cp * (deltax / 2) * der(T2,t)
```

// Input parameters
\[ L = 0.020 \]
\[ \text{deltax} = L \]
\[ \rho = 7800 \] // density, kg/m^3
\[ cp = 440 \] // specific heat, J/kg·K
\[ k = 15 \] // thermal conductivity, W/m·K
\[ h = 500 \] // convection coefficient, W/m^2·K
\[ T\inf = 25 \] // fluid temperature, K

(4) Selected portions of the IHT code for the 5-node network model are shown below.

```
// Writing the finite-difference equations – 5-node model
// Node 1 - midplane
k * (T2 - T1)/ deltax = rho * cp * (deltax / 2) * der(T1,t)
// Interior nodes
k * (T1 - T2)/ deltax + k * (T3 - T2 )/ deltax = rho * cp * deltax  * der(T2,t)
// T3 - T4 nodes
k * (T3 - T4)/ deltax + k * (T5 - T4 )/ deltax = rho * cp * deltax  * der(T4,t)
// Node5 - surface
k * (T4 - T5)/ deltax + h * (Tinf - T5) = rho * cp * (deltax / 2) * der(T5,t)
```

// Input parameters
\[ L = 0.020 \]
\[ \text{deltax} = L / 4 \]
........
........
**PROBLEM 5.112**

**KNOWN:** Plastic film on metal strip initially at 25°C is heated by a laser (85,000 W/m² for \( \Delta t_{on} = 10 \) s), to cure adhesive; convection conditions for ambient air at 25°C with coefficient of 100 W/m²·K.

**FIND:** Temperature histories at center and film edge, \( T(0,t) \) and \( T(x_1,t) \), for \( 0 \leq t \leq 30 \) s, using an implicit, finite-difference method with \( \Delta x = 4 \) mm and \( \Delta t = 1 \) s; determine whether adhesive is cured (\( T_C \geq 90 \)°C for \( \Delta t_c = 10s \)) and whether the degradation temperature of 200°C is exceeded.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional conduction, (2) Constant properties, (3) Uniform convection coefficient on upper and lower surfaces, (4) Thermal resistance and mass of plastic film are negligible, (5) All incident laser flux is absorbed.

**PROPERTIES:** Metal strip (given): \( \rho = 7850 \) kg/m³, \( c_p = 435 \) J/kg·K, \( k = 60 \) W/m·K, \( \alpha = k/\rho c_p = 1.757 \times 10^{-5} \) m²/s.

**ANALYSIS:** (a) Using a space increment of \( \Delta x = 4 \) mm, set up the nodal network shown below. Note that the film half-length is 22mm (rather than 20mm as in Problem 3.97) to simplify the finite-difference equation derivation.

Consider the general control volume and use the conservation of energy requirement to obtain the finite-difference equation.

\[
\dot{E}_{in} - \dot{E}_{out} = \dot{E}_{st}
\]

\[
q_a + q_b + q_{laser} + q_{conv} = Mc_p \frac{T_m^{p+1} - T_m^p}{\Delta t}
\]

Continued …..
Certainly the center region, $T(0,t)$, is fully cured and furthermore, the degradation temperature (200°C) has not been exceeded. From the $T(x_1,t)$ distribution, note that $\Delta t_c \approx 8$ sec, which is 20% less than the 10 s interval sought. Hence, the laser exposure (now 10 s) should be slightly increased and quite likely, the maximum temperature will not exceed 200°C.
PROBLEM 5.113

KNOWN: Insulated rod of prescribed length and diameter, with one end in a fixture at 200°C, reaches a uniform temperature. Suddenly the insulating sleeve is removed and the rod is subjected to a convection process.

FIND: (a) Time required for the mid-length of the rod to reach 100°C, (b) Temperature history $T(x,t \leq t_1)$, where $t_1$ is time at which the midlength reaches 50°C. Temperature distribution at 0, 200s, 400s and $t_1$.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional transient conduction in rod, (2) Uniform $h$ along rod and at end, (3) Negligible radiation exchange between rod and surroundings, (4) Constant properties.

ANALYSIS: (a) Choosing $\Delta x = 0.016$ m, the finite-difference equations for the interior and end nodes are obtained.

Interior Point, $m$:

\[
q_a + q_b + q_c = \rho \cdot A_c \Delta x \cdot c_p \cdot \frac{T_{m+1}^P - T_m^P}{\Delta t}
\]

\[
k \cdot A_c \cdot \frac{T_{m-1}^P - T_m^P}{\Delta x} + kA_c \cdot \frac{T_{m+1}^P - T_m^P}{\Delta x} + hP \Delta x \left(T_\infty - T_m^P\right) = \rho A_c \Delta x c_p \cdot \frac{T_{m+1}^P - T_m^P}{\Delta t}
\]

Regrouping,

\[
T_{m+1}^P = T_m^P \left(1 - 2 \text{Fo} - \text{Bi} \cdot \text{Fo}\right) + \text{Fo} \left(T_{m-1}^P + T_{m+1}^P\right) + \text{Bi} \cdot \text{Fo} T_\infty
\]

where

\[
\text{Fo} = \frac{\alpha \Delta t}{\Delta x^2}
\]

\[
\text{Bi} = h \left[\Delta x^2 / (A_c / P)\right] / k.
\]

From Eq. (1), recognize that the stability of the numerical solution will be assured when the first term on the RHS is positive; that is

Continued...
PROBLEM 5.113 (Cont.)

\[(1 - 2Fo - Bi \cdot Fo) \geq 0 \quad \text{or} \quad Fo \leq 1/(2 + Bi). \tag{4}\]

**Nodal Point 1:** Consider Eq. (1) for the special case that \(T_{m-1}^P = T_o\), which is independent of time. Hence,

\[T_{i+1}^P = T_i^P \left(1 - 2Fo - Bi \cdot Fo\right) + Fo\left(T_o + T_{i+1}^P\right) + Bi \cdot Fo T_{\infty}. \tag{5}\]

**End Nodal Point 10:** \(q_a + q_b + q_c = \rho \cdot A_c \frac{\Delta x}{2} \cdot c_p \frac{T_{10}^{p+1} - T_{10}^P}{\Delta t}\)

\[k \cdot A_c \frac{T_9^P - T_{10}^P}{\Delta x} + hA_c \left(T_{\infty} - T_{10}^P\right) + hP \frac{\Delta x}{2} \left(T_{\infty} - T_{10}^P\right) = \rho A_c \frac{\Delta x}{2} c_p \frac{T_{10}^{p+1} - T_{10}^P}{\Delta t}\]

Regrouping, \(T_{10}^{p+1} = T_{10}^P \left(1 - 2Fo - 2N \cdot Fo - Bi \cdot Fo\right) + 2Fo T_9^P + T_{\infty} \left(2N \cdot Fo + Bi \cdot Fo\right) \tag{6}\)

where \(N = h\Delta x/k. \tag{7}\)

The stability criterion is \(Fo \leq 1/2(1 + N + Bi/2). \tag{8}\)

With the finite-difference equations established, we can now proceed with the numerical solution. Having already specified \(\Delta x = 0.016 \text{ m}\), Bi can now be evaluated. Noting that \(A_c = \pi D^2/4\) and \(P = \pi D\), giving \(A_c/P = D/4, \tag{9}\)

From the stability criteria, Eqs. (4) and (8), for the finite-difference equations, it is recognized that Eq. (8) requires the greater value of Fo. Hence

\[Fo = \frac{1}{2} \left(1 + 0.0324 + \frac{0.208}{2}\right) = 0.440 \tag{10}\]

where from Eq. (7), \(N = \frac{30 \text{ W/m}^2 \cdot \text{K} \times 0.016 \text{ m}}{14.8 \text{ W/m} \cdot \text{K}} = 0.0324. \tag{11}\)

From the definition of Fo, Eq. (2), we obtain the time increment

\[\Delta t = \frac{Fo (\Delta x)^2}{\alpha} = 0.440 (0.016 \text{ m})^2 / 3.63 \times 10^{-6} \text{ m}^2/\text{s} = 31.1 \text{s} \tag{12}\]

and the time relation is \(t = p\Delta t = 31.1t. \tag{13}\)

Using the numerical values for Fo, Bi and N, the finite-difference equations can now be written (°C).

**Nodal Point** \(m \ (2 \leq m \leq 9)\): \(T_{m+1}^P = T_{m}^P \left(1 - 2\times0.440 - 0.208\times0.440\right) + 0.440 \left(T_{m-1}^P + T_{m+1}^P\right) + 0.208\times0.440\times25\)

\[T_{m+1}^P = 0.029 T_m^P + 0.440 \left(T_{m-1}^P + T_{m+1}^P\right) + 2.3 \tag{14}\]

**Nodal Point 1:** \(T_{1+1}^P = 0.029 T_1^P + 0.440 \left(200 + T_2^P\right) + 2.3 = 0.029 T_1^P + 0.440 T_2^P + 90.3 \tag{15}\)

**Nodal Point 10:** \(T_{10}^{p+1} = 0 \times T_{10}^P + 2 \times 0.440 T_9^P + 25 \left(2 \times 0.0324 \times 0.440 + 0.208 \times 0.440\right) = 0.880 T_9^P + 3.0 \tag{16}\)

Continued...
Using finite-difference equations (14-16) with Eq. (13), the calculations may be performed to obtain

and the *LOOKUPVAL2* interpolating function was used with the *Explore* and *Graph* feature of IHT to create the desired plot.

Temperatures decrease with increasing \( x \) and \( t \), and except for early times \( (t < 200s) \) and locations in proximity to the fin tip, the magnitude of the temperature gradient, \( |dT/dx| \), decreases with increasing \( x \). The slight increase in \( |dT/dx| \) observed for \( t = 200s \) and \( x \to 160 \) mm is attributable to significant heat loss from the fin tip.

**COMMENTS:** The steady-state condition may be obtained by extending the finite-difference calculations in time to \( t \approx 2650s \) or from Eq. 3.70.
PROBLEM 5.114

KNOWN: Tantalum rod initially at a uniform temperature, 300K, is suddenly subjected to a current flow of 80A; surroundings (vacuum enclosure) and electrodes maintained at 300K.

FIND: (a) Estimate time required for mid-length to reach 1000K, (b) Determine the steady-state temperature distribution and estimate how long it will take to reach steady-state. Use a finite-difference method with a space increment of 10mm.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, transient conduction in rod, (2) Surroundings are much larger than rod, (3) Properties are constant and evaluated at an average temperature.

PROPERTIES: Table A-1, Tantalum ($\bar{T} = (300+1000)/2 = 650K$): $\rho = 16,600$ kg/m$^3$, $c = 147$ J/kg·K, $k = 58.8$ W/m·K, and $\alpha = k/\rho c = 58.8$ W/m·K/16,600 kg/m$^3 \times 147$ J/kg·K = $2.410 \times 10^{-5}$ m$^2$/s.

ANALYSIS: From the derivation of the previous problem, the finite-difference equation was found to be

$$T_{m+1}^p = F_0 (T_{m-1}^p + T_{m+1}^p) + (1 - 2F_0)T_m^p - \frac{c \rho \alpha \Delta x^2}{k A_c} - F_0 (T_{m+1}^4 - T_{m}^4) + \frac{I^2 \rho_c \alpha \Delta x^2}{k A_c^2} F_0$$

where $F_0 = \alpha \Delta t / \Delta x^2$, $A_c = \pi D^2 / 4$, $P = \pi D$. (2,3,4)

From the stability criterion, let $F_0 = 1/2$ and numerically evaluate terms of Eq. (1).

$$T_{m+1}^p = \frac{1}{2} \left( T_{m-1}^p + T_{m+1}^p \right) - \frac{0.1 \times 5.67 \times 10^{-8} W/m^2 \cdot K \times (0.01m)^2}{58.8 W/m \cdot K} \cdot 1 \left( T_{m+1}^4 - [300K]^4 \right) +$$

$$+ \frac{(80A)^2 \times 95 \times 10^{-8} \Omega \cdot m (0.01m)^2}{58.8 W/m \cdot K \pi [0.003m]^2 / 4} \cdot \frac{1}{2}$$

$$T_{m+1}^p = \frac{1}{2} \left( T_{m-1}^p + T_{m+1}^p \right) - 6.4285 \times 10^{-12} T_{m+1}^4 + 103.53.$$  (5)

Note that this form applies to nodes 0 through 5. For node 0, $T_{m-1} = T_{m+1} = T_1$. Since $F_0 = 1/2$, using Eq. (2), find that

$$\Delta t = \Delta x^2 F_0 / \alpha = (0.01m)^2 \times 1/2 / 2.410 \times 10^{-5} m^2 / s = 2.07s.$$  (6)

Hence, $t = p \Delta t = 2.07p$.  (7)

Continued …..
(a) To estimate the time required for the mid-length to reach 1000K, that is \( T_0 = 1000K \), perform the forward-marching solution beginning with \( T_i = 300K \) at \( p = 0 \). The solution, as tabulated below, utilizes Eq. (5) for successive values of \( p \). Elapsed time is determined by Eq. (7).

</tbody>
</table>

Note that, at \( p \approx 6.9 \) or \( t = 6.9 \times 2.07 = 14.3s \), the mid-point temperature is \( T_0 \approx 1000K \).

(b) The steady-state temperature distribution can be obtained by continuing the marching solution until only small changes in \( T_m \) are noted. From the table above, note that at \( p = 15 \) or \( t = 31s \), the temperature distribution is still changing with time. It is likely that at least 15 more calculation sets are required to see whether steady-state is being approached.

COMMENTS: (1) This problem should be solved with a computer rather than a hand-calculator. For such a situation, it would be appropriate to decrease the spatial increment in order to obtain better estimates of the temperature distribution.

(2) If the rod were very long, the steady-state temperature distribution would be very flat at the mid-length \( x = 0 \). Performing an energy balance on the small control volume shown to the right, find

\[
\dot{E}_g - \dot{E}_{\text{out}} = 0
\]

\[
i^2 \frac{\rho c \Delta x}{A_c} - \varepsilon \sigma P \Delta x \left( T_0^4 - T_{\text{sur}}^4 \right) = 0.
\]

Substituting numerical values, find \( T_0 = 2003K \). It is unlikely that the present rod would ever reach this steady-state, maximum temperature. That is, the effect of conduction along the rod will cause the center temperature to be less than this value.
**PROBLEM 5.115**

**KNOWN:** Support rod spanning a channel whose walls are maintained at \(T_b = 300\) K. Suddenly the rod is exposed to cross flow of hot gases with \(T_\infty = 600\) K and \(h = 75\) W/m\(^2\)-K. After the rod reaches steady-state conditions, the hot gas flow is terminated and the rod cools by free convection and radiation exchange with surroundings.

**FIND:** (a) Compute and plot the midspan temperature as a function of elapsed heating time; compare the steady-state temperature distribution with results from an analytical model of the rod and (b) Compute the midspan temperature as a function of elapsed cooling time and determine the time required for the rod to reach the safe-to-touch temperature of 315 K.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional, transient conduction in rod, (2) Constant properties, (3) During heating process, uniform convection coefficient over rod, (4) During cooling process, free convection coefficient is of the form \(h = C\Delta T^n\) where \(C = 4.4\) W/m\(^2\)-K\(^{1.188}\) and \(n = 0.188\), and (5) During cooling process, surroundings are large with respect to the rod.

**ANALYSIS:** (a) The finite-difference equations for the 10-node mesh shown above can be obtained using the *IHT Finite-Difference Equation, One-Dimensional, Transient Extended Surfaces Tool*. The temperature-time history for the midspan position \(T_{10}\) is shown in the plot below. The steady-state temperature distribution for the rod can be determined from Eq. 3.75, Case B, Table 3.4. This case is treated in the *IHT Extended Surfaces Model, Temperature Distribution and Heat Rate, Rectangular Pin Fin*, for the adiabatic tip condition. The following table compares the steady-state temperature distributions for the numerical and analytical methods.

<table>

</tr>
</tbody>
</table>

The comparison is excellent indicating that the nodal mesh is sufficiently fine to obtain precise results.
PROBLEM 5.115 (Cont.)

(b) The same finite-difference approach can be used to model the cooling process. In using the IHT tool, the following procedure was used: (1) Set up the FDEs with the convection coefficient expressed as $h_m = h_{fc,m} + h_{r,m}$, the sum of the free convection and linearized radiation coefficients based upon nodal temperature $T_m$.

$$h_{fc,m} = C\left(T_m^p - T_\infty\right)$$

$$h_{r,m} = \varepsilon\sigma\left(T_m^p + T_{sur}\right)\left(T_m^p\right)^2 + T_{sur}^2$$

(2) For the initial solve, set $h_{fc,m} = h_{r,m} = 5 \text{ W/m}^2\text{-K}$ and solve, (3) Using the solved results as the Initial Guesses for the next solve, allow $h_{fc,m}$ and $h_{r,m}$ to be unknowns. The temperature-time history for the midspan during the cooling process is shown in the plot below. The time to reach the safe-to-touch temperature, $T_{10}^p = 315 \text{ K}$, is

$$t = 550 \text{ s}$$
**PROBLEM 5.116**

**KNOWN:** Thin metallic foil of thickness, \( w \), whose edges are thermally coupled to a sink at temperature, \( T_{\text{sink}} \), initially at a uniform temperature \( T_i = T_{\text{sink}} \), is suddenly exposed on the top surface to an ion beam heat flux, \( q_s'' \), and experiences radiation exchange with the vacuum enclosure walls at \( T_{\text{sur}} \). Consider also the situation when the foil is operating under steady-state conditions when suddenly the ion beam is deactivated.

**FIND:** (a) Compute and plot the midspan temperature-time history during the *heating* process; determine the elapsed time that this point on the foil reaches a temperature within 1 K of the steady-state value, and (b) Compute and plot the midspan temperature-time history during the *cooling* process from steady-state operation; determine the elapsed time that this point on the foil reaches the *safe-to-touch* temperature of 315 K.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional, transient conduction in the foil, (2) Constant properties, (3) Upper and lower surfaces of foil experience radiation exchange with the large surroundings, (4) Ion beam incident on upper surface only, (4) Foil is of unit width normal to the page.

**ANALYSIS:** (a) The finite-difference equations for the 10-node mesh shown above can be obtained using the *IHT Finite-Difference Equation, One-Dimensional, Transient, Extended Surfaces Tool*. In formulating the energy-balance functions, the following steps were taken: (1) the FDE function coefficient \( h \) must be identified for each node, e.g., \( h_1 \) and (2) coefficient can be represented by the linearized radiation coefficient, e.g., \( h_1 = \varepsilon \sigma \left( T_1 + T_{\text{sur}} \right) \left( T_1^2 + T_{\text{sur}}^2 \right) \), (3) set \( q''_a = q''_b = 0 \) since the ion beam is incident on only the top surface of the foil, and (4) when solving, the initial condition corresponds to \( T_i = 300 \) K for each node. The temperature-time history of the midspan position is shown below. The time to reach within 1 K of the steady-state temperature (374.1 K) is

\[
T_{10}(t_h) = 373 \text{ K} \quad \text{or} \quad t_h = 136 \text{ s}
\]

(b) The same IHT workspace may be used to obtain the temperature-time history for the cooling process by taking these steps: (1) set \( q''_s = 0 \), (2) specify the initial conditions as the steady-state temperature (K) distribution tabulated below,

<table>
<thead>
<tr>
<th>( T_1 )</th>
<th>( T_2 )</th>
<th>( T_3 )</th>
<th>( T_4 )</th>
<th>( T_5 )</th>
<th>( T_6 )</th>
<th>( T_7 )</th>
<th>( T_8 )</th>
<th>( T_9 )</th>
<th>( T_{10} )</th>
</tr>
</thead>
<tbody>
<tr>
<td>374.1</td>
<td>374.0</td>
<td>373.5</td>
<td>372.5</td>
<td>370.9</td>
<td>368.2</td>
<td>363.7</td>
<td>356.6</td>
<td>345.3</td>
<td>327.4</td>
</tr>
</tbody>
</table>

(3) when performing the integration of the independent time variable, set the start value as 200 s and (4) save the results for the heating process in Data Set A. The temperature-time history for the heating and cooling processes can be made using Data Browser results from the Working and A Data Sets. The time required for the midspan to reach the *safe-to-touch* temperature is

\[
T_{10}(t_c) = 315 \text{ K} \quad \text{or} \quad t_c = 73 \text{ s}
\]

 alpha = k / (rho * cp) // Definition
PROBLEM 5.117

KNOWN: Stack or book of steel plates (sp) and circuit boards (b) subjected to a prescribed platen heating schedule $T_p(t)$. See Problem 5.42 for other details of the book.

FIND: (a) Using the implicit numerical method with $\Delta x = 2.36\text{mm}$ and $\Delta t = 60\text{s}$, find the mid-plane temperature $T(0,t)$ of the book and determine whether curing will occur (> $170\degree\text{C}$ for 5 minutes), (b) Determine how long it will take $T(0,t)$ to reach $37\degree\text{C}$ following reduction of the platen temperature to $15\degree\text{C}$ (at $t = 50\text{ minutes}$), (c) Validate code by using a sudden change of platen temperature from 15 to $190\degree\text{C}$ and compare with the solution of Problem 5.38.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) Negligible contact resistance between plates, boards and platens.

PROPERTIES: Steel plates (sp, given): $\rho_{sp} = 8000\text{ kg/m}^3$, $c_{p,sp} = 480\text{ J/kg} \cdot \text{K}$, $k_{sp} = 12\text{ W/m} \cdot \text{K}$; Circuit boards (b, given): $\rho_b = 1000\text{ kg/m}^3$, $c_{p,b} = 1500\text{ J/kg} \cdot \text{K}$, $k_b = 0.30\text{ W/m} \cdot \text{K}$.

ANALYSIS: (a) Using the suggested space increment $\Delta x = 2.36\text{mm}$, the model grid spacing treating the steel plates (sp) and circuit boards (b) as discrete elements, we need to derive the nodal equations for the interior nodes (2-11) and the node next to the platen (1). Begin by defining appropriate control volumes and apply the conservation of energy requirement.

*Effective thermal conductivity, $k_e$: Consider an adjacent steel plate-board arrangement. The thermal resistance between the nodes $i$ and $j$ is

$$R_{ij} = \frac{\Delta x}{k_e} = \frac{\Delta x/2}{k_b} + \frac{\Delta x/2}{k_{sp}}$$

$$k_e = \frac{2}{1/k_b + 1/k_{sp}} = \frac{2}{1/0.3 + 1/12} = 0.585\text{ W/m} \cdot \text{K}$$

Odd-numbered nodes, $3 \leq m \leq 11$ - steel plates (sp): Treat as interior nodes using Eq. 5.89 with

$$\alpha_{sp} = \frac{k_e}{\rho_{sp}c_{sp}} = \frac{0.585\text{ W/m} \cdot \text{K}}{8000\text{ kg/m}^3 \times 480\text{ J/kg} \cdot \text{K}} = 1.523 \times 10^{-7}\text{ m}^2/\text{s}$$

$$F_t = \frac{\alpha_{sp}\Delta t}{\Delta x^2} = \frac{1.523 \times 10^{-7}\text{ m}^2/\text{s} \times 60\text{s}}{(0.00236\text{ m})^2} = 1.641$$

Continued ….
PROBLEM 5.117 (Cont.)

to obtain, with m as odd-numbered,
\[
(1 + 2F_{om}) T_m^{p+1} - F_{om} \left( T_{m-1}^{p+1} + T_{m+1}^{p+1} \right) = T_m^p
\]  
(1)

Even-numbered nodes, \(2 \leq n \leq 10\) - circuit boards (b): Using Eq. 5.89 and evaluating \(\alpha_b\) and \(F_{on}\)

\[
\alpha_b = \frac{k_e}{\rho_b c_b} = 3.900 \times 10^{-7} \text{ m}^2/\text{s} \quad F_{on} = 4.201
\]

\[
(1 + 2F_{on}) T_n^{p+1} - F_{on} \left( T_{n-1}^{p+1} + T_{n+1}^{p+1} \right) = T_n^p
\]  
(2)

Plate next to platen, \(n = 1\) - steel plate (sp): The finite-difference equation for the plate node (\(n = 1\)) next to the platen follows from a control volume analysis.

\[
\dot{E}_{in} - \dot{E}_{out} = \dot{E}_{st}
\]

\[
q_a^* + q_b^* = \rho_{sp} \Delta c_{sp} \frac{T^{p+1} - T_1^p}{\Delta t}
\]

where

\[
q_a^* = \frac{k_{sp}}{\Delta x/2} T_p(t) - T_1^{p+1}
\]

\[
q_b^* = \frac{k_e}{\Delta x} T_2^{p+1} - T_1^{p+1}
\]

and \(T_p(t) = T_p(p)\) is the platen temperature which is changed with time according to the heating schedule. Regrouping find,

\[
\left( 1 + F_{om} \left( 1 + \frac{2k_{sp}}{k_e} \right) \right) T_1^{p+1} - F_{om} T_2^{p+1} - \frac{2k_{sp}}{k_e} F_{om} T_p(p) = T_1^p
\]  
(3)

where \(2k_{sp}/k_e = 2 \times 12 \text{ W/m-K}/0.585 \text{ W/m-K} = 41.03\).

Using the nodal Eqs. (1) - (3), an inversion method of solution was effected and the temperature distributions are shown on the following page.

Temperature distributions - discussion: As expected, the temperatures of the nodes near the center of the book considerably lag those nearer the platen. The criterion for cure is \(T \geq 170^\circ C = 443 \text{ K for } \Delta t_c = 5 \text{ min = 300 sec}\). From the temperature distributions, note that node 10 just reaches 443 K after 50 minutes and will not be cured. It appears that the region about node 5 will be cured.

(b) The time required for the book to reach \(37^\circ C = 310 \text{ K}\) can likewise be seen from the temperature distribution results. The plates/boards nearest the platen will cool to the safe handling temperature with 1000 s = 16 min, but those near the center of the stack will require in excess of 2000 s = 32 min.

Continued …..
(c) It is important when validating computer codes to have the program work a “problem” which has an exact analytical solution. You should select the problem such that all features of the code are tested.
PROBLEM 5.118

KNOWN: Reaction and composite clutch plates, initially at a uniform temperature, $T_i = 40^\circ C$, are subjected to the frictional-heat flux shown in the engagement energy curve, $q_f$ vs. $t$.

FIND: (a) On T-t coordinates, sketch the temperature histories at the mid-plane of the reaction plate, at the interface between the clutch pair, and at the mid-plane of the composite plate; identify key features; (b) Perform an energy balance on the clutch pair over a time interval basis and calculate the steady-state temperature resulting from a clutch engagement; (c) Obtain the temperature histories using the finite-element approach with FEHT and the finite-difference method of solution with IHT ($\Delta x = 0.1$ mm and $\Delta t = 1$ ms). Calculate and plot the frictional heat fluxes to the reaction and composite plates, $q_{rp}$ and $q_{cp}$, respectively, as a function of time. Comment on the features of the temperature and frictional-heat flux histories.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, (2) Negligible heat transfer to the surroundings.

PROPERTIES: Steel, $\rho_s = 7800$ kg/m$^3$, $c_s = 500$ J/kg·K, $k_s = 40$ W/m·K; Friction material, $\rho_{fm} = 1150$ kg/m$^3$, $c_{fm} = 1650$ J/kg·K, and $k_{fm} = 4$ W/m·K.

ANALYSIS: (a) The temperature histories for specified locations in the system are sketched on T-t coordinates below.

Initially, the temperature at all locations is uniform at $T_i$. Since there is negligible heat transfer to the surroundings, eventually the system will reach a uniform, steady-state temperature $T(\infty)$. During the engagement period, the interface temperature increases much more rapidly than at the mid-planes of the reaction (rp) and composite (cp) plates. The interface temperature should be the maximum within the system and could occur before lock-up, $t = t_{lu}$.

Continued …..
PROBLEM 5.118 (Cont.)

(b) To determine the steady-state temperature following the engagement period, apply the conservation of energy requirement on the clutch pair on a time-interval basis, Eq. 1.11b.

\[
q(t) = 1.6 \times 10^7 \text{ W/m}^2, \quad 0 \leq t \leq t_{lu}
\]

\[
T_i = 40^\circ C, \quad T(t \rightarrow \infty) = T(\infty)
\]

Clutch pair - energy balance

The final and initial states correspond to uniform temperatures of \(T(\infty)\) and \(T_i\), respectively. The energy input is determined from the engagement energy curve, \(q_f^*\) vs. \(t\).

\[
E_n^* - E_{out}^* + E_{gen}^* = \Delta E_{st}^*
\]

\[
E_{in}^* = E_{out}^* = 0
\]

\[
\int_0^{t_{lu}} q_f^* (t) \, dt = E_f^* - E_i^* = \left[ \rho_s c_s \left( L_{rp}/2 + L_{cp}/2 \right) + \rho_{fm} c_{fm} L_{fm} \right] (T_f - T_i)
\]

Substituting numerical values, with \(T_i = 40^\circ C\) and \(T_f = T(\infty)\).

\[
0.5 \, q_o^* \, t_{lu} = \left[ \rho_s c_s \left( L_{rp}/2 + L_{cp}/2 \right) + \rho_{fm} c_{fm} L_{fm} \right] (T(\infty) - T_i)
\]

\[
0.5 \times 1.6 \times 10^7 \text{ W/m}^2 \times 0.100 \text{ s} = \left[ 7800 \text{ kg/m}^3 \times 500 \text{ J/kg-K} \times 0.001 + 0.0005 \text{ m} \right] (T(\infty) - 40) ^\circ C
\]

\[
T(\infty) = 158^\circ C
\]

(c) **Finite-element method of solution, FEHT.** The clutch pair is comprised of the reaction plate (1 mm), an interface region (0.1 mm), and the composite plate (cp) as shown below.

---

Continued (2)...
PROBLEM 5.118 (Cont.)

The external boundaries of the system are made adiabatic. The interface region provides the means to represent the frictional heat flux, specified with negligible thermal resistance and capacitance. The generation rate is prescribed as

\[ \dot{q} = 1.6 \times 10^{11} (1 - \text{Time}/0.1) \text{W/m}^3 \quad 0 \leq \text{Time} \leq t_{lu} \]

where the first coefficient is evaluated as \( q_o = 0.1 \times 10^{-3} \text{m} \) and the 0.1 mm parameter is the thickness of the region. Using the Run command, the integration is performed from 0 to 0.1 s with a time step of \( 1 \times 10^{-6} \) s. Then, using the Specify|Generation command, the generation rate is set to zero and the Run|Continue command is executed. The temperature history is shown below.

(c) Finite-difference method of solution, IHT. The nodal arrangement for the clutch pair is shown below with \( \Delta x = 0.1 \) mm and \( \Delta t = 1 \) ms. Nodes 02-10, 13-16 and 18-21 are interior nodes, and their finite-difference equations (FDE) can be called into the Workspace using Tools|Finite Difference Equations|One-Dimensional|Transient. Nodes 01 and 22 represent the mid-planes for the reaction and composite plates, respectively, with adiabatic boundaries. The FDE for node 17 is derived from an energy balance on its control volume (CV) considering different properties in each half of the CV. The FDE for node 11 and 12 are likewise derived using energy balances on their CVs. At the interface, the following conditions must be satisfied

\[ T_{11} = T_{12} \quad q_{11}^f = q_{rp}^f + q_{cp}^f \]

The frictional heat flux is represented by a Lookup Table, which along with the FDEs, are shown in the IHT code listed in Comment 2.
The temperature and heat flux histories are plotted below. The steady-state temperature was found as 156.5°C, which is in reasonable agreement with the energy balance result from part (a).

**COMMENTS:**

(1) The temperature histories resulting from the FEHT and IHT based solutions are in agreement. The interface temperature peaks near 225°C after 75 ms, and begins dropping toward the steady-state condition. The mid-plane of the reaction plate peaks around 100 ms, nearly reaching 200°C. The temperature of the mid-plane of the composite plate increases slowly toward the steady-state condition.

(2) The calculated temperature-time histories for the clutch pair display similar features as expected from our initial sketches on T vs. t coordinates, part a. The maximum temperature for the composite is very high, subjecting the bonded frictional material to high thermal stresses as well as accelerating deterioration. For the reaction steel plate, the temperatures are moderate, but there is a significant gradient that could give rise to thermal stresses and hence, warping. Note that for the composite plate, the steel section is nearly isothermal and is less likely to experience warping.

(2) The IHT code representing the FDE for the 22 nodes and the frictional heat flux relation is shown below. Note use of the *Lookup Table* for representing the frictional heat flux vs. time boundary condition for nodes 11 and 12.

PROBLEM 5.119

KNOWN: Hamburger patties of thickness 2L = 10, 20 and 30 mm, initially at a uniform temperature T_i = 20°C, are grilled on both sides by a convection process characterized by T_\infty = 100°C and h = 5000 W/m²-K.

FIND: (a) Determine the relationship between time-to-doneness, t_d, and patty thickness. Doneness criteria is 60°C at the center. Use FEHT and the IHT Models|Transient Conduction|Plane Wall. (b) Using the results from part (a), estimate the time-to-doneness if the initial temperature is 5°C rather than 20°C. Calculate values using the IHT model, and determine the relationship between time-to-doneness and initial temperature.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional conduction, and (2) Constant properties are approximated as those of water at 300 K.

PROPERTIES: Table A-6, Water (300K), \( \rho = 1000 \text{ kg/m}^3 \), c = 4179 J/kg K, k = 0.613 W/m K.

ANALYSIS: (a) To determine T(0, t_d), the center point temperature at the time-to-doneness time, t_d, a one-dimensional shape as shown in the FEHT screen below is drawn, and the material properties, boundary conditions, and initial temperature are specified. With the Run|Calculate command, the early integration steps are made very fine to accommodate the large temperature-time changes occurring near x = L. Use the Run|Continue command (see FEHT HELP) for the second and subsequent steps of the integration. This sequence of Start-(Step)-Stop values was used: 0 (0.001) 0.1 (0.01) 1 (0.1) 120 (1.0) 840 s.

Continued.....
PROBLEM 5.119 (Cont.)

Using the View|Temperature vs. Time command, the temperature-time histories for the x/L = 0 (center), 0.5, and 1.0 (grill side) are plotted and shown below for the 2L = 10 mm thick patty.

Using the View|Temperatures command, the time slider can be adjusted to read \( t_d \), when the center point, \( x = 0 \), reaches 60°C. See the summary table below.

The IHT ready-to-solve model in Models|Transient Conduction|Plane Wall is based upon Eq. 5.40 and permits direct calculation of \( t_d \) when \( T(0,t_d) = 60^\circ C \) for patty thickness 2L = 10, 20 and 30 mm and initial temperatures of 20 and 5°C. The IHT code is provided in Comment 3, and the results are tabulated below.

<table>

</table>

Considering the IHT results for \( T_i = 20^\circ C \), note that when the thickness is doubled from 10 to 20 mm, \( t_d \) is \( (264.5/67.7=) 3.9 \) times larger. When the thickness is trebled, from 10 to 30 mm, \( t_d \) is \( (590.4/67.7=) 8.7 \) times larger. We conclude that, \( t_d \) is nearly proportional to \( L^2 \), rather than linearly proportional to thickness.

Continued …..
PROBLEM 5.119 (Cont.)

(b) The temperature span for the cooking process ranges from \(T_\infty = 100\) to \(T_i = 20\) or \(5^\circ C\). The differences are \((100-20) = 80\) or \((100-5) = 95^\circ C\). If \(t_d\) is proportional to the overall temperature span, then we expect \(t_d\) for the cases with \(T_i = 5^\circ C\) to be a factor of \((95/80 =) 1.19\) higher (approximately \(20\%\) ) than with \(T_i = 20^\circ C\). From the tabulated results above, for the thickness \(2L = 10, 20\) and \(30\) mm, the \(t_d\) with \(T_i = 5^\circ C\) are \((80.2/67.7 =) 1.18\), \((312 / 264.5 =) 1.18\), and \((699.1/590.4 =) 1.18\), respectively, higher than with \(T_i = 20^\circ C\). We conclude that \(t_d\) is nearly proportional to the temperature span \((T_\infty - T_i)\).

COMMENTS:  (1) The results from the FEHT and IHT calculations are in excellent agreement. For this analysis, the FEHT model is more convenient to use as it provides direct calculations of the time-to-doneness. The FEHT tool allows the user to watch the cooking process. Use the View \(\mid\) Temperature Contours command, click on the from start-to-stop button, and observe how color band changes represent the temperature distribution as a function of time.

(2) It is good practice to check software tool analyses against hand calculations. Besides providing experience with the basic equations, you can check whether the tool was used or functioned properly. Using the one-term series solution, Eq. 5.40:

\[
\theta_0^* = \frac{T(0,t_d) - T_\infty}{T_1 - T_\infty} = C_1 \exp\left(-\zeta^2 Fo\right)
\]

\[Fo = \alpha t_d / L^2\]

\[C_1, \zeta = (Bi), \ Table 5.1\]

<table>
<thead>
<tr>
<th>(T_i (^\circ C))</th>
<th>(2L (\text{mm}))</th>
<th>(\theta_0^*)</th>
<th>(Bi)</th>
<th>(C_1)</th>
<th>(\zeta_1)</th>
<th>(Fo)</th>

<td>73.41</td>
<td>1.2729</td>
<td>1.5471</td>
<td>0.4622</td>
<td>709</td>
</tr>
</tbody>
</table>

The results are slightly higher than those from the IHT model, which is based upon a multiple- rather than single-term series solution.

(3) The IHT code used to obtain the tabulated results is shown below. Note that \(T_xt_trans\) is an intrinsic heat transfer function dropped into the Workspace from the Models window (see IHT Help\midSolver\midIntrinsic Functions\midHeat Transfer Functions).

```plaintext
// Models | Transient Conduction | Plane Wall
/* Model: Plane wall of thickness 2L, initially with a uniform temperature \(T(x,0) = T_i\), suddenly subjected to convection conditions \((T_\infty,h)\). */

// The temperature distribution is
\[T_xt = T_xt_trans("Plane Wall",xstar,Fo,Bi,Ti,Tinf)\]  // Eq 5.39

// The dimensionless parameters are
\[xstar = x / L\]
\[Bi = h * L / k\]  // Eq 5.9
\[Fo= \alpha r / L^2\]  // Eq 5.33
\[\alpha = k / (\rho c)\]

// Input parameters
x = 0  // Center point of meat
L = 0.005  // Meat half-thickness, m
/L = 0.010  // Meat half-thickness, m
/L = 0.015  // Meat half-thickness, m
T_xt = 60  // Doneness temperature requirement at center, x = 0; C
Ti = 20  // Initial uniform temperature
/Ti = 5
rho = 1000  // Water properties at 300 K
cp = 4179
k = 0.613
h = 5000  // Convection boundary conditions
Tinf = 100
```
**PROBLEM 5.120**

**KNOWN:** A process mixture at 200°C flows at a rate of 207 kg/min onto a 1-m wide conveyor belt traveling with a velocity of 36 m/min. The underside of the belt is cooled by a water spray.

**FIND:** The surface temperature of the mixture at the end of the conveyor belt, \( T_{e,s} \), using (a) IHT for writing and solving the FDEs, and (b) FEHT. Validate your numerical codes against an appropriate analytical method of solution.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional conduction in the x-direction at any z-location, (2) Negligible heat transfer from mixture upper surface to ambient air, and (3) Constant properties.

**PROPERTIES:** Process mixture (m), \( \rho_m = 960 \text{ kg/m}^3, c_m = 1700 \text{ J/kg} \cdot \text{K}, \) and \( k_m = 1.5 \text{ W/m} \cdot \text{K}; \)
Conveyor belt (b), \( \rho_b = 8000 \text{ kg/m}^3, c_b = 460 \text{ J/kg} \cdot \text{K}, \) and \( k_b = 15 \text{ W/m} \cdot \text{K}. \)

**ANALYSIS:** From the conservation of mass requirement, the thickness of the mixture on the conveyor belt can be determined.

\[
\dot{m} = \rho_m A_c V \quad \text{where} \quad A_c = W L_m
\]

\[
207 \text{ kg/min} \times \frac{1 \text{ min}}{60 \text{ s}} = 960 \text{ kg/m}^3 \times 1 \text{ m} \times L_m \times 36 \text{ m} / \text{min} \times 1 \text{ min}/60 \text{ s}
\]

\[
L_m = 0.0060 \text{ m} = 6 \text{ mm}
\]

The time that the mixture is in contact with the steel conveyor belt, referred to as the residence time, is

\[
t_{\text{res}} = \frac{L_c}{V} = 30 \text{ m}/(36 \text{ m/min} \times 1 \text{ min}/60 \text{ s}) = 50 \text{ s}
\]

The composite system comprised of the belt, \( L_b = 3 \text{ mm} \), and mixture, \( L_m = 6 \text{ mm} \), as represented in the schematic above, is initially at a uniform temperature \( T(x,0) = T_i = 200^\circ \text{C} \) while at location \( z = 0 \), and suddenly is exposed to convection cooling (\( T_{\infty}, h \)). We will calculate the mixture upper surface temperature after 50 s, \( T(0, t_{\text{res}}) = T_{e,s} \).

(a) The nodal arrangement for the composite system is shown in the schematic below. The IHT model builder Tools|Finite-Difference Equations|Transient can be used to obtain the FDEs for nodes 01-12 and 14-19.

Continued ….
For the mixture-belt interface node 13, the FDE for the implicit method is derived from an energy balance on the control volume about the node as shown above.

\[
\dot{E}_{in}^\sigma - \dot{E}_{out}^\sigma = \dot{E}_{st}^\sigma
\]

\[
q_a^\sigma + q_b^\sigma = \dot{E}_{st, m}^\sigma + \dot{E}_{st, b}^\sigma
\]

\[
k_m \frac{T_{12}^{p+1} - T_{13}^{p+1}}{\Delta x} + k_b \frac{T_{14}^{p+1} - T_{13}^{p+1}}{\Delta x} = \left( \rho_m c_m + \rho_b c_b \right) \left( \Delta x / 2 \right) \frac{T_{13}^{p+1} - T_{13}^p}{\Delta t}
\]

*IHT* code representing selected FDEs, nodes 01, 02, 13 and 19, is shown in Comment 4 below (\(\Delta x = 0.5 \text{ mm}, \ \Delta t = 0.1 \text{ s}\)). Note how the FDE for node 13 derived above is written in the *Workspace*. From the analysis, find

\[T_{e,s} = T(0, 50s) = 54.8^\circ C\]

(b) Using *FEHT*, the composite system is drawn and the material properties, boundary conditions, and initial temperature are specified. The screen representing the system is shown below in Comment 5 with annotations on key features. From the analysis, find

\[T_{e,s} = T(0, 50s) = 54.7^\circ C\]

**COMMENTS:**

(1) Both numerical methods, *IHT* and *FEHT*, yielded the same result, 55°C. For the safety of plant personnel working in the area of the conveyor exit, the mixture exit temperature should be lower, like 43°C.

(2) By giving both regions of the composite the same properties, the analytical solution for the plane wall with convection, Section 5.5, Eq. 5.40, can be used to validate the *IHT* and *FEHT* codes. Using the *IHT Models|Transient Conduction|Plane Wall* for a 9-mm thickness wall with mixture thermophysical properties, we calculated the temperatures after 50 s for three locations: \(T(0, 50s) = 91.4^\circ C; \ T(6 \text{ mm, 50s}) = 63.6^\circ C; \ \text{and} \ T(3 \text{ mm, 50s}) = 91.4^\circ C\). The results from the *IHT* and *FEHT* codes agreed exactly.

(3) In view of the high heat removal rate on the belt lower surface, it is reasonable to assume that negligible heat loss is occurring by convection on the top surface of the mixture.

Continued .....
(4) The *IHT* code representing selected FDEs, nodes 01, 02, 13 and 19, is shown below. The FDE for node 13 was derived from an energy balance, while the others are written from the *Tools* pad.

```plaintext
// Finite difference equations from Tools, Nodes 01 -12 (mixture) and 14-19 (belt)
/* Node 01: surface node (w-orientation); transient conditions; e labeled 02. */
rhom * cm * der(T01,t) = fd_1d_sur_w(T01,T02,km,qdot,deltax,Tinf01,h01,q'a01)
q'a01 = 0         // Applied heat flux, W/m^2; zero flux shown
qdot = 0
Tinf01 = 20      // Arbitrary value
h01 = 1e-6       // Causes boundary to behave as adiabatic

/* Node 02: interior node; e and w labeled 03 and 01. */
rhom*cm*der(T02,t) = fd_1d_int(T02,T03,T01,km,qdot,deltax)

/* Node 19: surface node (e-orientation); transient conditions; w labeled 18. */
rhob * cb * der(T19,t) = fd_1d_sur_e(T19,T18,kb,qdot,deltax,Tinf19,h19,q'a19)
q'a19 = 0         // Applied heat flux, W/m^2; zero flux shown
Tinf19 = 30
h19 = 3000

// Finite-difference equation from energy balance on CV, Node 13
km*(T12 - T13)/deltax + kb*(T14 - T13)/deltax = (rhom*cm + rhob*cb) *(deltax/2)*der(T13,t)
```

(5) The screen from the *FEHT* analysis is shown below. It is important to use small time steps in the integration at early times. Use the *View|Temperatures* command to find the temperature of the mixture surface at t_res = 50 s.
PROBLEM 5.121

KNOWN: Thin, circular-disc subjected to induction heating causing a uniform heat generation in a prescribed region; upper surface exposed to convection process.

FIND: (a) Transient finite-difference equation for a node in the region subjected to induction heating, (b) Sketch the steady-state temperature distribution on T-r coordinates; identify important features.

SCHEMATIC:

ASSUMPTIONS: (1) Thickness \( w \ll r_o \), such that conduction is one-dimensional in \( r \)-direction, (2) In prescribed region, \( q \) is uniform, (3) Bottom surface of disc is insulated, (4) Constant properties.

ANALYSIS: (a) Consider the nodal point arrangement for the region subjected to induction heating. The size of the control volume is \( V = 2\pi r_m \cdot \Delta r \cdot w \). The energy conservation requirement for the node \( m \) has the form

\[
\dot{E}_{in} - \dot{E}_{out} + \dot{E}_g = \dot{E}_{st}
\]

with \( q_a + q_b + q_{conv} + \dot{q}V = \dot{E}_{st} \).

Recognizing that \( q_a \) and \( q_b \) are conduction terms and \( q_{conv} \) is the convection process,

\[
k \left[ 2\pi \left[ r_m - \frac{\Delta r}{2} \right] w \right] T_{m-1}^p - T_m^p \Delta r + k \left[ 2\pi \left[ r_m + \frac{\Delta r}{2} \right] w \right] T_m^p \Delta r
\]

\[
+ h \left[ 2\pi r_m \cdot \Delta r \left( T_{\infty} - T_m^p \right) \right] + \dot{q} \left[ 2\pi r_m \cdot \Delta r \cdot w \right] = \rho c_p \left[ 2\pi r_m \cdot \Delta r \cdot w \right] \frac{T_{m+1}^p - T_m^p}{\Delta t}.
\]

Upon regrouping, the finite-difference equation has the form,

\[
T_m^{p+1} = F_0 \left[ 1 - \frac{\Delta r}{2r_m} \right] T_{m-1}^p + \left[ 1 + \frac{\Delta r}{2r_m} \right] T_{m+1}^p + Bi \left[ \frac{\Delta r}{w} \right] T_{\infty} + \frac{\dot{q} \Delta r^2}{k} \left[ 1 - 2F_0 - Bi \cdot F_0 \left[ \frac{\Delta r}{w} \right] \right] T_m^p < \]

where \( F_0 = \alpha \Delta t/\Delta r^2 \) and \( Bi = h\Delta r/k \).

(b) The steady-state temperature distribution has these features:

1. Zero gradient at \( r = 0, r_0 \)
2. No discontinuity at \( r_1, r_2 \)
3. \( T_{max} \) occurs in region \( r_1 < r < r_2 \)

Note also, distribution will not be linear anywhere; distribution is not parabolic in \( r_1 < r < r_2 \) region.
PROBLEM 5.122

KNOWN: An electrical cable experiencing uniform volumetric generation; the lower half is well insulated while the upper half experiences convection.

FIND: (a) Explicit, finite-difference equations for an interior node \( (m,n) \), the center node \( (0,0) \), and an outer surface node \( (M,n) \) for the convective and insulated boundaries, and (b) Stability criterion for each FDE; identify the most restrictive criterion.

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional \((r,\phi)\), transient conduction, (2) Constant properties, (3) Uniform \( \dot{q} \).

ANALYSIS: The explicit, finite-difference equations may be obtained by applying energy balances to appropriate control volumes about the node of interest. Note the coordinate system defined above where \((r,\phi) \to (m\Delta r, n\Delta \phi)\). The stability criterion is determined from the coefficient associated with the node of interest.

**Interior Node \((m,n)\).** The control volume for an interior node is

\[
V = m_{\Delta \phi} \cdot r_{\Delta r} \cdot \ell
\]

(with \( r_{m} = m_{\Delta r}, \ell = 1 \)) where \( \ell \) is the length normal to the page. The conservation of energy requirement is

\[
\dot{E}_{in} - \dot{E}_{out} + \dot{E}_{g} = \dot{E}_{st}
\]

\[
\begin{align*}
(q_{1} + q_{2})_{r} + (q_{3} + q_{4})_{\phi} + \dot{q}V &= \rho \cdot cV \frac{T_{m+1,n}^{p} - T_{m,n}^{p}}{\Delta t} \\
k \cdot \left[ m - \frac{1}{2} \right] \Delta r \cdot \Delta \phi \cdot \frac{T_{m-1,n}^{p} - T_{m,n}^{p}}{\Delta r} + k \cdot \left[ m + \frac{1}{2} \right] \Delta r \cdot \Delta \phi \cdot \frac{T_{m+1,n}^{p} - T_{m,n}^{p}}{\Delta r} + k \cdot \Delta r \cdot \frac{T_{m,n+1}^{p} - T_{m,n}^{p}}{(m\Delta r)\Delta \phi} + \dot{q} \cdot (m\Delta r \cdot \Delta \phi) \cdot \Delta r &= \rho \cdot c \left( m\Delta r \cdot \Delta \phi \right) \cdot \Delta r \cdot \frac{T_{m,n+1}^{p} - T_{m,n}^{p}}{\Delta t} \quad (1)
\end{align*}
\]

Define the Fourier number as

\[
F_{o} = \frac{k}{\rho \cdot c} \cdot \frac{\Delta t}{\Delta t^{2}} = \frac{\alpha \Delta t}{\Delta r^{2}} \quad (2)
\]

and then regroup the terms of Eq. (1) to obtain the FDE,

\[
T_{m,n}^{p+1} = F_{o} \left\{ \frac{m-1/2}{m} T_{m-1,n}^{p} + \frac{m+1/2}{m} T_{m+1,n}^{p} + \frac{1}{(m\Delta \phi)^{2}} \left( T_{m,n+1}^{p} + T_{m,n-1}^{p} \right) + \frac{\dot{q}}{k} \Delta r^{2} \right\}
\]

\[
+ \left\{ -F_{o} \left[ 2 + \frac{2}{(m\Delta \phi)^{2}} \right] + 1 \right\} T_{m,n}^{p}
\]

(3) <

Continued …..
The stability criterion requires that the last term on the right-hand side in braces be positive. That is, the coefficient of $T_{m,n}^p$ must be positive and the stability criterion is

$$Fo \leq \frac{1}{2} \left[ 1 + 1/(m\Delta\phi)^2 \right]$$

(4)

Note that, for $m \gg 1/2$ and $(m\Delta\phi)^2 \gg 1$, the FDE takes the form of a 1-D cartesian system.

**Center Node (0,0).** For the control volume,

$$V = \pi \left( \Delta r/2 \right)^2 \cdot 1$$. The energy balance is

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_g = \dot{E}_st$$

where $\dot{E}_{in} = \Sigma q_n$.

$$\sum_{n=0}^{N} k \left( \frac{\Delta r}{\Delta \phi} \right) \cdot T_{1,n}^p - T_{0,n}^p + \dot{q} \pi \left( \frac{\Delta r}{2} \right)^2$$

$$= \rho c \pi \left( \frac{\Delta r}{2} \right)^2 \cdot T_{p+1}^p - T_{0,n}^p \frac{\Delta t}{\Delta r}$$

(5)

where $N = (2\pi/\Delta\phi) - 1$, the total number of $q_n$. Using the definition of $Fo$, find

$$T_{p+1}^p = 4Fo \left\{ \frac{1}{N+1} \sum_{n=0}^{N} \frac{T_{1,n}^p + \dot{q} \Delta r}{4k} \right\} \left(1 - 4Fo\right) T_{0,n}^p <$$

(7)

By inspection, the stability criterion is $Fo \leq 1/4$.

**Surface Nodes (M,n).** The control volume for the surface node is $V = (M - 1/4)\Delta r \Delta \phi \Delta r/2$.

From the energy balance,

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_g = (q_1 + q_2)_{r} + (q_3 + q_4)_{n} \cdot \dot{q} V = \dot{E}_st$$

$$k \cdot (M - 1/2) \Delta r \cdot \Delta \phi \cdot \frac{T_{M-1,n}^p - T_{M,n}^p}{\Delta r} + \left( M \Delta r \cdot \Delta \phi \right) \left( T_{\infty} - T_{M,n}^p \right) + k \cdot \frac{\Delta r}{2} \cdot \frac{T_{M,n+1}^p - T_{M,n}^p}{(M\Delta r) \Delta \phi}$$

$$+ k \cdot \frac{\Delta r}{2} \cdot \frac{T_{M-1,n}^p - T_{M,n}^p}{(M\Delta r) \Delta \phi} + \dot{q} \left[ (M - 1/4) \Delta r \cdot \Delta \phi \cdot \frac{\Delta r}{2} \right] \cdot \frac{T_{M,n+1}^p - T_{M,n}^p}{\Delta t}$$

Regrouping and using the definitions for $Fo = \alpha \Delta t/\Delta r^2$ and $Bi = h\Delta r/k$,

$$T_{m,n+1}^p = \frac{1}{2} \left\{ \frac{M - 1/2}{M - 1/4} T_{M-1,n}^p + \frac{1}{(M - 1/4)M(\Delta \phi)^2} \left( T_{M,n+1}^p - T_{M,n-1}^p \right) + 2Bi \cdot T_{\infty} + \frac{\dot{q}}{k} \Delta r^2 \right\} \frac{T_{M,n}^p}{k}$$

(8)

The stability criterion is

$$Fo \leq \frac{1}{2} \left[ \frac{M - 1/2}{M - 1/4} + Bi \cdot \frac{M}{M - 1/4} + \frac{1}{(M - 1/4)M(\Delta \phi)^2} \right]$$

(9)

To determine which stability criterion is most restrictive, compare Eqs. (4), (7) and (9). The most restrictive (lowest $Fo$) has the largest denominator. For small values of $m$, it is not evident whether Eq. (7) is more restrictive than Eq. (4); Eq. (4) depends upon magnitude of $\Delta \phi$. Likewise, it is not clear whether Eq. (9) will be more or less restrictive than Eq. (7). Numerical values must be substituted.
**PROBLEM 5.123**

**KNOWN:** Initial temperature distribution in two bars that are to be soldered together; interface contact resistance.

**FIND:** (a) Explicit FDE for $T_{4,2}$ in terms of $F_o$ and $B_i = \Delta x/k \ R_{t,c}$; stability criterion, (b) $T_{4,2}$ one time step after contact is made if $F_o = 0.01$ and value of $\Delta t$; whether the stability criterion is satisfied.

**SCHEMATIC:**

**PROPERTIES:** Table A-1, Steel, AISI 1010 (1000K): $k = 31.3 \text{ W/m-K}$, $c = 1168 \text{ J/kg-K}$, $\rho = 7832 \text{ kg/m}^3$.

**ASSUMPTIONS:** (1) Two-dimensional transient conduction, (2) Constant properties, (3) Interfacial solder layer has negligible thickness.

**ANALYSIS:** (a) From an energy balance on the control volume $V = (\Delta x/2) \Delta y$. 1.

$$E_{in} - E_{out} + E_g = E_{st}$$

$$q_a + q_b + q_c + q_d = \rho c \frac{T_{4,2}^p - T_{4,2}^0}{\Delta t}.$$ Note that $q_a = \left(\Delta t/R_{t,c}\right) A_c$ while the remaining $q_i$ are conduction terms,

$$\frac{1}{R_{t,c}} \left(T_{3,2}^p - T_{4,2}^p\right) \Delta y + k \left(\Delta x/2\right) \left(\frac{T_{4,3}^p - T_{4,2}^p}{\Delta y}\right) + k \left(\Delta y/2\right) \left(\frac{T_{4,1}^p - T_{4,2}^p}{\Delta y}\right) = \rho c \left[\left(\Delta x/2\right) \cdot \Delta y\right] \frac{T_{4,2}^{p+1} - T_{4,2}^p}{\Delta t}.$$ Defining $F_o \equiv \left(k/ \rho \ c\right) \Delta t/ \Delta x^2$ and $B_i \equiv \Delta y/R_{t,c} k$, regroup to obtain

$$T_{4,2}^{p+1} = F_o \left(T_{4,3}^p + 2T_{3,2}^p + T_{4,1}^p + 2B_i T_{3,2}^p\right) + (1 - 4F_o - 2F_oB_i) T_{4,2}^p.$$ The stability criterion requires the coefficient of the $T_{4,2}^p$ term be zero or positive,

$$(1 - 4F_o - 2F_oB_i) \geq 0 \quad \text{or} \quad F_o \leq 1/(4 + 2B_i)$$

(b) For $F_o = 0.01$ and $B_i = 0.020m/\left(2 \times 10^{-5} \text{ m}^2 \cdot \text{K/W} \times 31.3 \text{ W/m-K}\right) = 31.95$,

$$T_{4,2}^{p+1} = 0.01\left(1000 + 2 \times 900 + 1000 + 2 \times 31.95 \times 700\right)K + (1 - 4 \times 0.01 - 2 \times 0.01 \times 31.95)1000K$$

$$T_{4,2}^{p+1} = 485.30K + 321.00K = 806.3K.$$ With $F_o = 0.01$, the time step is

$$\Delta t \approx F_o \Delta x^2 \left(\rho \ c/k\right) = 0.01 \left(0.020m\right)^2 \left(7832 \text{ kg/m}^3 \times 1168 \text{ J/kg-K} / 31.3 \text{ W/m-K}\right) = 1.17s.$$ With $B_i = 31.95$ and $F_o = 0.01$, the stability criterion, $F_o \leq 0.015$, is satisfied.
PROBLEM 5.124

KNOWN: Stainless steel cylinder of Ex. 5.7, 80-mm diameter by 60-mm length, initially at 600 K, suddenly quenched in an oil bath at 300 K with \( h = 500 \text{ W/m}^2\cdot\text{K} \). Use the ready-to-solve model in the Examples menu of FEHT to obtain the following solutions.

FIND: (a) Calculate the temperatures \( T(r, x, t) \) after 3 min: at the cylinder center, \( T(0, 0, 3 \text{ mm}) \), at the center of a circular face, \( T(0, L, 3 \text{ min}) \), and at the midheight of the side, \( T(r_o, 0, 3 \text{ min}) \); compare your results with those in the example; (b) Calculate and plot temperature histories at the cylinder center, \( T(0, 0, t) \), the mid-height of the side, \( T(r_o, 0, t) \), for \( 0 \leq t \leq 10 \text{ min} \); use the View/Temperature vs. Time command; comment on the gradients and what effect they might have on phase transformations and thermal stresses; (c) Using the results for the total integration time of 10 min, use the View/Temperature Contours command; describe the major features of the cooling process shown in this display; create and display a 10-isotherm temperature distribution for \( t = 3 \text{ min} \); and (d) For the locations of part (a), calculate the temperatures after 3 min if the convection coefficient is doubled (\( h = 1000 \text{ W/m}^2\cdot\text{K} \)); for these two conditions, determine how long the cylinder needs to remain in the oil bath to achieve a safe-to touch surface temperature of 316 K. Tabulate and comment on the results of your analysis.

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional conduction in \( r \)- and \( x \)-coordinates, (2) Constant properties.

PROPERTIES: Stainless steel (Example 5.7): \( \rho = 7900 \text{ kg/m}^3 \), \( c = 256 \text{ J/kg} \cdot \text{K} \), \( k = 17.4 \text{ W/m} \cdot \text{K} \).

ANALYSIS: (a) The FEHT ready-to-solve model for Example 5.7 is accessed through the Examples menu and the annotated Input page is shown below. The following steps were used to obtain the solution: (1) Use the Draw \( \rightarrow \) Reduce Mesh command three times to create the 512-element mesh; (2) In Run, click on Check, (3) In Run, press Calculate and hit OK to initiate the solver; and (4) Go to the View menu, select Tabular Output and read the nodal temperatures 4, 1, and 3 at \( t = t_o = 180 \text{ s} \). The tabulated results below include those from the \( n \)-term series solution used in the IHT software.

Continued .....
Note that the one-term series solution results of Example 5.7 are systematically lower than those from the 512-element, finite-difference FEHT analyses. The FEHT results are in excellent agreement with the IHT n-term series solutions for the x = 0 plane nodes (4,3), except for the x = L plane node (1).

(b) Using the View Temperature vs. Time command, the temperature histories for nodes 4, 1, and 3 are plotted in the graph shown below. There is very small temperature difference between the locations on the surface, (node 1; 0, L) and (node 3; r₀, 0). But, the temperature difference between these surface locations and the cylinder center (node 4; 0, 0) is large at early times. Such differences wherein locations cool at considerably different rates could cause variations in microstructure and hence, mechanical properties, as well as induce thermal stresses.

Continued .....
PROBLEM 5.124 (Cont.)

(c) Use the View|Temperature Contours command with the shaded band option for the isotherm contours. Selecting the From Start to Stop time option, see the display of the contours as the cylinder cools during the quench process. The “movie” shows that cooling initiates at the corner (r₀, L, t) and the isotherms quickly become circular and travel toward the center (0,0,t). The 10-isotherm distribution for t = 3 min is shown below.

(d) Using the FEHT model with convection coefficients of 500 and 1000 W/m²·K, the temperatures at t = t₀ = 180 s for the three locations of part (a) are tabulated below.

<table>
<thead>
<tr>
<th>Location</th>
<th>h = 500 W/m²·K</th>
<th>h = 1000 W/m²·K</th>
</tr>
</thead>
<tbody>
<tr>
<td>T(0, 0, t₀), K</td>
<td>402.7</td>
<td>352.8</td>
</tr>
<tr>
<td>T(0, L, t₀), K</td>
<td>368.7</td>
<td>325.8</td>
</tr>
<tr>
<td>T(r₀, 0, t₀), K</td>
<td>362.5</td>
<td>322.1</td>
</tr>
</tbody>
</table>

Note that the effect of doubling the convection coefficient is to reduce the temperature at these locations by about 40°C. The time the cylinder needs to remain in the oil bath to achieve the safe-to-touch surface temperature of 316 K can be determined by examining the temperature history of the location (node1; 0, L). For the two convection conditions, the results are tabulated below. Doubling the coefficient reduces the cooling process time by 40%.

<table>
<thead>
<tr>
<th>T(0, L, t₀)</th>
<th>h (W/m²·K)</th>
<th>t₀ (s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>316</td>
<td>500</td>
<td>370</td>
</tr>
<tr>
<td>316</td>
<td>1000</td>
<td>219</td>
</tr>
</tbody>
</table>
Problem 5.125

Known: Flue of square cross-section, initially at a uniform temperature is suddenly exposed to hot flue gases. See Problem 4.57.

Find: Temperature distribution in the wall 5, 10, 50 and 100 hours after introduction of gases using the implicit finite-difference method.

Schematic:

Assumptions: (1) Two-dimensional transient conduction, (2) Constant properties.

Properties: Flue (given): \( k = 0.85 \text{ W/m·K}, \alpha = 5.5 \times 10^{-7} \text{ m}^2/\text{s} \).

Analysis: The network representing the flue cross-sectional area is shown with \( \Delta x = \Delta y = 50\text{ mm} \). Initially all nodes are at \( T_i = 25^\circ C \) when suddenly the interior and exterior surfaces are exposed to convection processes, \( (T_{\infty, i}, h_i) \) and \( (T_{\infty, o}, h_o) \), respectively Referring to the network above, note that there are four types of nodes: interior (02, 03, 06, 07, 10, 11, 14, 15, 17, 18, 20); plane surfaces with convection (interior – 01, 05, 09); interior corner with convection (13), plane surfaces with convection (exterior – 04, 08, 12, 16, 19, 21); and, exterior corner with convection. The system of finite-difference equations representing the network is obtained using IHT[Tools|Finite-difference equations|Two-dimensional|Transient]. The IHT code is shown in Comment 2 and the results for \( t = 5, 10, 50 \) and 100 hour are tabulated below.

Node 17
\[
(1 + 4F_o)T_{17}^{p+1} - F_o\left(T_{18}^{p+1} + T_{14}^{p+1} + T_{18}^{p+1} + T_{14}^{p+1}\right) = T_{17}^p
\]

Node 13
\[
\left[1 + 4F_o\left(1 + \frac{1}{3}B_{i_o}\right)\right]T_{13}^{p+1} - \frac{2}{3}F_o\left(2T_{14}^{p+1} + T_9 + 2T_{14}^{p+1} + T_9^{p+1}\right) = T_{13}^p + \frac{4}{3}B_{i_o} \cdot F_o \cdot T_{\infty, i}
\]

Node 12
\[
(1 + 2F_o\left(2 + B_{i_o}\right))T_{12}^{p+1} - F_o\left(2T_{11}^{p+1} + T_{16}^{p+1} + T_{16}^{p+1}\right) = T_{12}^p + 2B_{i_o} \cdot F_o \cdot T_{\infty, o}
\]

Node 22
\[
\left(1 + 4F_o\left(1 + B_{i_o}\right)\right)T_{22}^{p+1} - 2F_o\left(T_{21}^{p+1} + T_{21}^{p+1}\right) = T_{22}^p + 4B_{i_o} \cdot F_o \cdot T_{\infty, o}
\]

Numerical values for the relevant parameters are:
\[
F_o = \frac{\alpha\Delta t}{\Delta x^2} = \frac{5.5 \times 10^{-6} \text{ m}^2/\text{s} \times 3600 \text{s}}{(0.050\text{ m})^2} = 7.92000
\]

\[
B_{i_o} = \frac{h_o \Delta x}{k} = \frac{5 \text{ W/m}^2 \cdot \text{K} \times 0.050\text{ m}}{0.85 \text{ W/m} \cdot \text{K}} = 0.29412
\]

\[
B_{i_i} = \frac{h_i \Delta x}{k} = \frac{100 \text{ W/m}^2 \cdot \text{K} \times 0.050\text{ m}}{0.85 \text{ W/m} \cdot \text{K}} = 5.88235
\]

The system of FDEs can be represented in matrix notation, \([A][T] = [C]\). The coefficient matrix \([A]\) and terms for the right-hand side matrix \([C]\) are given on the following page.

Continued .....
For this problem a stock computer program was used to obtain the solution matrix [T]. The initial temperature distribution was \( T_m^0 = 298K \). The results are tabulated below.

</table>

**COMMENTS:** (1) Note that the steady-state condition is reached by \( t = 5 \) hours; this can be seen by comparing the distributions for \( t = 50 \) and 100 hours. Within 10 hours, the flue is within a few degrees of the steady-state condition.

Continued ….
PROBLEM 5.125 (Cont.)

(2) The IHT code for performing the numerical solution is shown in its entirety below. Use has been made of symmetry in writing the FDEs. The tabulated results above were obtained by copying from the IHT Browser and pasting the desired columns into EXCEL.

// From Tools|Finite-difference equations|Two-dimensional|Transient
// Interior surface nodes, 01, 05, 09, 13
/* Node 01: plane surface node, s-orientation; e, w, n labeled 05, 05, 02.

</table>

In Problem 4.57, the temperature distribution was determined using the FDEs written for steady-state conditions, but with a finer network, Δx = Δy = 25 mm. By comparison, the results for the coarser network are slightly higher, within a fraction of 1°C, along the mid-section of the flue, but notably higher in the vicinity of inner corner. (For example, node 13 is 2.6°C higher with the coarser mesh.)
PROBLEM 5.126

KNOWN: Electrical heating elements embedded in a ceramic plate as described in Problem 4.75; initially plate is at a uniform temperature and suddenly heaters are energized.

FIND: Time required for the difference between the surface and initial temperatures to reach 95% of the difference for steady-state conditions using the implicit, finite-difference method.

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional conduction, (2) Constant properties, (3) No internal generation except for Node 7, (4) Heating element approximates a line source; wire diameter is negligible.

ANALYSIS: The grid for the symmetry element above consists of 12 nodes. Nodes 1-3 are points on a surface experiencing convection; nodes 4-12 are interior nodes; node 7 is a special case with internal generation and because of symmetry, \( q_{ht} = 25 \text{ W/m} \). Their finite-difference equations are derived as follows

**Surface Node 2.** From an energy balance on the prescribed control volume with \( \Delta x/\Delta y = 3 \),

\[
\dot{E}_{in} = \dot{E}_{st} = q_a' + q_b' + q_c' + q_d' = \rho \ c \ V \ \frac{T_{2,1}^{p+1} - T_2^p}{\Delta t} + k \ \frac{\Delta y}{2} \ \frac{T_{2,1}^{p+1} - T_2^p}{\Delta x} + h \Delta x \left( T_{\infty} - T_2^{p+1} \right)
\]

\[
+ k \ \frac{\Delta y}{2} \ \frac{T_{3,2}^{p+1} - T_2^p}{\Delta x} + k \Delta x \left( T_3^{p+1} - T_2^{p+1} \right) = \rho \ c \ \frac{\Delta x}{2} \left( \frac{\Delta y}{2} \right) \ \frac{T_2^{p+1} - T_2^p}{\Delta t}.
\]

Continued ….
PROBLEM 5.126 (Cont.)

Divide by \( k \), use the following definitions, and regroup to obtain the finite-difference equations.

\[
N \equiv h\Delta x/k = 100 \text{ W/m}^2 \cdot \text{K} \times 0.006 \text{ m}/2 \text{ W/m} \cdot \text{K} = 0.3000
\]
\[
\text{Fo} \equiv \left( k/\rho \cdot c \right) \Delta t/\Delta x \cdot \Delta y = \alpha \Delta t/\Delta x \cdot \Delta y = 1.5 \times 10^{-6} \text{ m}^2/\text{s} \times 1/(0.006 \times 0.002) \text{ m}^2 = 0.1250
\]
\[
\frac{1}{2} \frac{\Delta y}{\Delta x} \left( T_{1}^{p+1} - T_{2}^{p+1} \right) + N \left( T_{\infty} - T_{2}^{p+1} \right) + \frac{1}{2} \frac{\Delta y}{\Delta x} \left( T_{3}^{p+1} - T_{2}^{p+1} \right)
\]
\[
+ \frac{\Delta x}{\Delta y} \left( T_{5}^{p+1} - T_{2}^{p+1} \right) = \frac{1}{2\text{Fo}} \left( T_{2}^{p+1} - T_{2}^{p} \right)
\]
\[
\frac{1}{2} \frac{\Delta y}{\Delta x} T_{1}^{p+1} - \left[ \frac{\Delta x}{\Delta y} + N + \frac{\Delta y}{\Delta x} + \frac{1}{2\text{Fo}} \right] T_{2}^{p+1} + \frac{1}{2} \frac{\Delta x}{\Delta y} T_{3}^{p+1}
\]
\[
+ \frac{\Delta x}{\Delta y} T_{5}^{p+1} = -NT_{\infty} - \frac{1}{2\text{Fo}} T_{2}^{p}.
\]

Substituting numerical values for \( \text{Fo} \) and \( N \), and using \( T_{\infty} = 30^\circ \text{C} \) and \( \Delta x/\Delta y = 3 \), find
\[
0.16667T_{1}^{p+1} - 7.63333T_{2}^{p+1} + 0.16667T_{3}^{p+1} + 3.00000T_{5}^{p+1} = 9.0000 - 4.00000T_{2}^{p}.
\]

By inspection and use of Eq. (3), the FDEs for Nodes 1 and 3 can be inferred.

**Interior Node 7.** From an energy balance on the prescribed control volume with \( \Delta x/\Delta y = 3 \),
\[
\dot{E}_{i}^{' +} + \dot{E}_{g}^{' +} = \dot{E}_{st}^{' +}
\]
where \( \dot{E}_{g}^{' +} = 2q_{ht}^{' +} \) and \( \dot{E}_{i}^{' +} \) represents the conduction terms \(-q_{a}^{' +} + q_{b}^{' +} + q_{c}^{' +} + q_{d}^{' +}\),
\[
k\Delta y \frac{T_{8}^{p+1} - T_{7}^{p+1}}{\Delta x} + k\Delta x \frac{T_{4}^{p+1} - T_{7}^{p+1}}{\Delta y} + k\Delta y \frac{T_{8}^{p+1} - T_{7}^{p+1}}{\Delta x}
\]
\[
+ k\Delta x \frac{T_{10}^{p+1} - T_{7}^{p+1}}{\Delta y} + 2q_{ht}^{' +} = \rho \cdot c \left( \Delta x \cdot \Delta y \right) \frac{T_{7}^{p+1} - T_{7}^{p}}{\Delta t}.
\]

Using the definition of \( \text{Fo} \), Eq. (2), and regrouping, find
\[
\frac{1}{2} \frac{\Delta x}{\Delta y} T_{4}^{p+1} - \left[ \frac{\Delta x}{\Delta y} + \frac{\Delta y}{\Delta x} + \frac{1}{2\text{Fo}} \right] T_{7}^{p+1}
\]
\[
+ \frac{\Delta x}{\Delta y} T_{8}^{p+1} + \frac{1}{2} \frac{\Delta x}{\Delta y} T_{10}^{p+1} = -q_{ht}^{' +} / k - \frac{1}{2\text{Fo}} T_{7}^{p}
\]
\[
1.50000T_{4}^{p+1} - 7.33333T_{7}^{p+1} + 0.33333T_{8}^{p+1} + 1.50000T_{10}^{p+1} = -12.5000 - 4.00000T_{7}^{p}.
\]

Continued ….
Recognizing the form of Eq. (5), it is a simple matter to infer the FDE for the remaining interior points for which \( q_{ih} = 0 \). In matrix notation \([A][T] = [C]\), the coefficient matrix \([A]\) and RHS matrix \([C]\) are:

\[
\begin{array}{cccccccccccc}
\text{THE COEFFICIENT MATRIX, } [A] & & & [C] \\
-7.633330 & 0.333330 & 0 & 3.000000 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0.166670 & -7.633330 & 0.166670 & 0 & 3.000000 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0.333330 & -7.633330 & 0 & 3.000000 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
1.500000 & 0 & 0 & -7.333330 & 0.333330 & 0 & 1.500000 & 0 & 0 & 0 & 0 & 0 \\
0 & 3.000000 & 0 & 0.333330 & -14.666670 & 0.333330 & 0 & 3.000000 & 0 & 0 & 0 & 0 \\
0 & 0 & 1.500000 & 0 & 0.333330 & -7.333330 & 0 & 0 & 1.500000 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\end{array}
\]

Recall that the problem asks for the time required to reach 95% of the difference for steady-state conditions. This provides information on approximately how long it takes for the plate to come to a steady operating condition. If you worked Problem 4.71, you know the steady-state temperature distribution. Then you can proceed to find the \( T_m^P \) values with increasing time until the first node reaches the required limit. We should not expect the nodes to reach their limit at the same time.

Not knowing the steady-state temperature distribution, use the implicit FDE in matrix form above to step through time \( \rightarrow \infty \) to the steady-state solution; that is, proceed to \( p \rightarrow 10, 20, 30, \ldots \) until the solution matrix \([T]\) does not change. The results of the analysis are tabulated below. Column 1 labeled \( T_m(\infty) \) is the steady-state distribution. Column 2, \( T_m(95\%) \), is the 95% limit being sought as per the graph directly above. The third column is the temperature distribution at \( t = t_o = 248s \), \( T_m(248s) \); at this elapsed time, Node 1 has reached its limit. Can you explain why this node was the first to reach this limit? Which nodes will be the last to reach their limits?

PROBLEM 5.127

KNOWN: Nodal network and operating conditions for a water-cooled plate.

FIND: Transient temperature response.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction.

ANALYSIS: The energy balance method must be applied to each nodal region. Grouping similar regions, the following results are obtained.

Nodes 1 and 5:

\[
\begin{align*}
\left( 1 + \frac{2\alpha \Delta t}{\Delta x^2} + \frac{2\alpha \Delta t}{\Delta y^2} \right) T_{p+1}^{1} - \frac{2\alpha \Delta t}{\Delta x^2} T_{p+1}^{2} - \frac{2\alpha \Delta t}{\Delta y^2} T_{p+1}^{6} &= T_{1}^{p} \\
\left( 1 + \frac{2\alpha \Delta t}{\Delta x^2} + \frac{2\alpha \Delta t}{\Delta y^2} \right) T_{p+1}^{5} - \frac{2\alpha \Delta t}{\Delta x^2} T_{p+1}^{4} - \frac{2\alpha \Delta t}{\Delta y^2} T_{p+1}^{10} &= T_{5}^{p}
\end{align*}
\]

Nodes 2, 3, 4:

\[
\begin{align*}
\left( 1 + \frac{2\alpha \Delta t}{\Delta x^2} + \frac{2\alpha \Delta t}{\Delta y^2} \right) T_{p+1}^{m,n} - \frac{\alpha \Delta t}{\Delta x^2} T_{p+1}^{m-1,n} - \frac{\alpha \Delta t}{\Delta x^2} T_{p+1}^{m+1,n} - \frac{2\alpha \Delta t}{\Delta y^2} T_{p+1}^{m,n-1} &= T_{m,n}^{p}
\end{align*}
\]

Nodes 6 and 14:

\[
\begin{align*}
\left( 1 + \frac{2\alpha \Delta t}{\Delta x^2} + \frac{2\alpha \Delta t}{\Delta y^2} + \frac{2h\alpha \Delta t}{k\Delta y} \right) T_{p+1}^{6} - \frac{2\alpha \Delta t}{\Delta x^2} T_{p+1}^{1} - \frac{2\alpha \Delta t}{\Delta y^2} T_{p+1}^{7} &= \frac{2h\alpha \Delta t}{k\Delta y} T_{\infty} + T_{6}^{p} \\
\left( 1 + \frac{2\alpha \Delta t}{\Delta x^2} + \frac{2\alpha \Delta t}{\Delta y^2} + \frac{2h\alpha \Delta t}{k\Delta y} \right) T_{p+1}^{14} - \frac{2\alpha \Delta t}{\Delta x^2} T_{p+1}^{15} - \frac{2\alpha \Delta t}{\Delta y^2} T_{p+1}^{19} &= \frac{2h\alpha \Delta t}{k\Delta y} T_{\infty} + T_{14}^{p}
\end{align*}
\]

PROBLEM 5.127 (Cont.)

Nodes 7 and 15:

\[
\begin{align*}
1 + \frac{2\alpha \Delta t}{\Delta x^2} + \frac{2\alpha \Delta t}{\Delta y^2} + \frac{2h\alpha \Delta t}{k\Delta y} & \left( T_{p+1}^7 - \frac{2\alpha \Delta t}{\Delta y^2} T_{p+1}^2 - \frac{\alpha \Delta t}{\Delta x^2} T_{6}^p - \frac{\alpha \Delta t}{k\Delta x^2} T_{8}^p \right) = \frac{2h\alpha \Delta t}{k\Delta y} T_{\infty} + T_{p}^7 \\
1 + \frac{2\alpha \Delta t}{\Delta x^2} + \frac{2\alpha \Delta t}{\Delta y^2} + \frac{2h\alpha \Delta t}{k\Delta y} & \left( T_{p+1}^{15} - \frac{\alpha \Delta t}{\Delta x^2} T_{14}^{p+1} - \frac{\alpha \Delta t}{\Delta y^2} T_{16}^{p+1} - \frac{2\alpha \Delta t}{k\Delta y} T_{20}^{p+1} \right) = \frac{2h\alpha \Delta t}{k\Delta y} T_{\infty} + T_{15}^{p+1}
\end{align*}
\]

Nodes 8 and 16:

\[
\begin{align*}
1 + \frac{2\alpha \Delta t}{\Delta x^2} + \frac{2\alpha \Delta t}{\Delta y^2} + \frac{2h\alpha \Delta t}{k\Delta y} & \left( T_{p+1}^{9} - \frac{2\alpha \Delta t}{\Delta y^2} T_{p+1}^{11} + \frac{4\alpha \Delta t}{3\Delta y^2} T_{8}^{p+1} - \frac{2\alpha \Delta t}{3\Delta x^2} T_{7}^{p+1} \right) = \frac{2\alpha \Delta t}{3\Delta x^2} T_{9}^{p+1} - \frac{2\alpha \Delta t}{3\Delta y^2} T_{11}^{p+1} + \frac{2h\alpha \Delta t}{3k} \left( \frac{1}{\Delta x} + \frac{1}{\Delta y} \right) T_{\infty} + T_{8}^{p+1}
\end{align*}
\]

Node 11:

\[
\begin{align*}
1 + \frac{2\alpha \Delta t}{\Delta x^2} + \frac{2\alpha \Delta t}{\Delta y^2} + \frac{2h\alpha \Delta t}{k\Delta x} & \left( T_{p+1}^{11} - \frac{\alpha \Delta t}{\Delta y^2} T_{8}^{p+1} + \frac{2\alpha \Delta t}{\Delta x^2} T_{12}^{p+1} - \frac{2\alpha \Delta t}{\Delta y^2} T_{16}^{p+1} \right) = \frac{2h\alpha \Delta t}{k\Delta x} T_{\infty} + T_{11}^{p+1}
\end{align*}
\]

Nodes 9, 12, 17, 20, 21, 22:

\[
\begin{align*}
1 + \frac{2\alpha \Delta t}{\Delta x^2} + \frac{2\alpha \Delta t}{\Delta y^2} \left( T_{m,n}^{p+1} - \frac{\alpha \Delta t}{\Delta y^2} \left( T_{m,n+1}^{p+1} + T_{m,n-1}^{p+1} \right) - \frac{2\alpha \Delta t}{\Delta x^2} \left( T_{m-1,n}^{p+1} + T_{m+1,n}^{p+1} \right) \right) = T_{m,n}^{p+1}
\end{align*}
\]

Nodes 10, 13, 18, 23:

\[
\begin{align*}
1 + \frac{2\alpha \Delta t}{\Delta x^2} + \frac{2\alpha \Delta t}{\Delta y^2} \left( T_{m,n}^{p+1} - \frac{\alpha \Delta t}{\Delta y^2} \left( T_{m,n+1}^{p+1} + T_{m,n-1}^{p+1} \right) - \frac{2\alpha \Delta t}{\Delta x^2} T_{m-1,n}^{p+1} \right) = T_{m,n}^{p+1}
\end{align*}
\]

Node 19:

\[
\begin{align*}
1 + \frac{2\alpha \Delta t}{\Delta x^2} + \frac{2\alpha \Delta t}{\Delta y^2} \left( T_{19}^{p+1} - \frac{\alpha \Delta t}{\Delta y^2} \left( T_{14}^{p+1} + T_{24}^{p+1} \right) - \frac{2\alpha \Delta t}{\Delta x^2} T_{20}^{p+1} \right) = T_{19}^{p+1}
\end{align*}
\]

Nodes 24, 28:

\[
\begin{align*}
1 + \frac{2\alpha \Delta t}{\Delta x^2} + \frac{2\alpha \Delta t}{\Delta y^2} & \left( T_{24}^{p+1} - \frac{2\alpha \Delta t}{\Delta y^2} T_{19}^{p+1} - \frac{2\alpha \Delta t}{\Delta x^2} T_{25}^{p+1} \right) = \frac{2q_{\infty} \alpha \Delta t}{k\Delta y} + T_{24}^{p+1}
\end{align*}
\]

\[
\begin{align*}
1 + \frac{2\alpha \Delta t}{\Delta x^2} + \frac{2\alpha \Delta t}{\Delta y^2} & \left( T_{28}^{p+1} - \frac{2\alpha \Delta t}{\Delta y^2} T_{23}^{p+1} - \frac{2\alpha \Delta t}{\Delta x^2} T_{27}^{p+1} \right) = \frac{2q_{\infty} \alpha \Delta t}{k\Delta y} + T_{28}^{p+1}
\end{align*}
\]

Continued ....
PROBLEM 5.127 (Cont.)

Nodes 25, 26, 27:

\[
\left(1 + \frac{2\alpha\Delta t}{\Delta x^2} + \frac{2\alpha\Delta t}{\Delta y^2}\right)T_{m,n}^{p+1} - \frac{2\alpha\Delta t}{\Delta y^2} T_{m,n+1}^{p+1} - \frac{\alpha\Delta t}{\Delta x^2} \left(T_{m-1,n}^{p+1} + T_{m+1,n}^{p+1}\right) = \frac{2q_o\alpha\Delta t}{k\Delta y} + T_{m,n}^{p+1}
\]

The convection heat rate is

\[
q_{\text{conv}} = h \left(\frac{\Delta x}{2}\right) (T_6 - T_\infty) + \Delta x (T_7 - T_\infty) + (\Delta x + \Delta y) (T_8 - T_\infty) / 2 + \Delta y (T_{11} - T_\infty) + (\Delta x + \Delta y) (T_{16} - T_\infty) / 2 + \Delta x (T_{15} - T_\infty) + (\Delta x/2) (T_{14} - T_\infty) = q_{\text{out}}.
\]

The heat input is

\[
q'_{\text{in}} = q_o'' (4\Delta x)
\]

and, on a percentage basis, the ratio is

\[
n \equiv \left(\frac{q'_{\text{conv}}}{q'_{\text{in}}}\right) \times 100.
\]

Results of the calculations (in °C) are as follows:

COMMENTS: Temperatures at t = 23 s are everywhere within 0.13°C of the final steady-state values.
**PROBLEM 5.128**

**KNOWN:** Cubic-shaped furnace, with prescribed operating temperature and convection heat transfer on the exterior surfaces.

**FIND:** Time required for the furnace to cool to a safe working temperature corresponding to an inner wall temperature of 35°C considering convection cooling on (a) the exterior surfaces and (b) on both the exterior and interior surfaces.

**SCHEMATIC:**

- **(a) Adiabatic inner surface**
- **(b) Cooled inner surface**

**ASSUMPTIONS:** (1) Two-dimensional conduction through the furnace walls and (2) Constant properties.

**ANALYSIS:** Assuming two-dimensional conduction through the walls and taking advantage of symmetry for the cubical shape, the analysis considers the quarter section shown in the schematic above. For part (a), with no cooling on the interior during the cool-down process, the inner surface boundary condition is adiabatic. For part (b), with cooling on both the exterior and interior, the boundary conditions are prescribed by the convection process. The boundaries through the centerline of the wall and the diagonal through the corner are symmetry planes and considered as adiabatic. We have chosen to use the finite-element software FEHT as the solution tool.

Using FEHT, an outline of the symmetrical wall section is drawn, and the material properties are specified. To determine the initial conditions for the cool-down process, we will first find the temperature distribution for steady-state operation. As such, specify the boundary condition for the inner surface as a constant temperature of 900°C; the other boundaries are as earlier described. In the Setup menu, click on Steady-State, and then Run to obtain the steady-state temperature distribution.

This distribution represents the initial temperature distribution, \( T_i(x, y, 0) \), for the wall at the onset of the cool-down process.

Next, in the Setup menu, click on Transient; for the nodes on the inner surface, in the Specify | Boundary Conditions menu, deselect the Temperature box (900°C) and set the Flux box to zero for the adiabatic condition (part (a)); and, in the Run command, click on Continue (not Calculate). Be sure to change the integration time scale from seconds to hours.

Because of the high ratio of wall section width (nearly 8.5 m) to the thickness (1 m), the conduction heat transfer through the section is nearly one-dimensional. We chose the \( x,y \)-section 1 m to the right of the centerline (1 m, y) as the location for examining the temperature-time history, and determining the cool-down time for the inner surface to reach the safe working temperature of 35°C.

Continued …..
PROBLEM 5.128 (Cont.)

Time-to-cool, Part (a), Adiabatic inner surface. From the above temperature history, the cool-down time, $t_a$, corresponds to the condition when $T_a (1 \text{ m}, 0, t_a) = 35^\circ\text{C}$. As seen from the history, this location is the last to cool. From the View | Tabular Output, find that

$$t_a = 1306 \text{ h} = 54 \text{ days}$$

Continued ....
PROBLEM 5.128 (Cont.)

Time-to-cool, Part (b), Cooled inner surface. From the above temperature history, note that the center portion of the wall, and not the inner surface, is the last to cool. The inner surface cools to 35°C in approximately 175 h or 7 days. However, if the cooling process on the inner surface were discontinued, its temperature would increase and eventually exceed the desired safe working temperature. To assure the safe condition will be met, estimate the cool down time as, \( t_b \), corresponding to the condition when \( T_b (1 \text{ m}, 0.75 \text{ m}, t_b) = 35°C \). From the View | Tabular Output, find that

\[
t_b = 311 \text{ h} = 13 \text{ days}
\]

COMMENTS: (1) Assuming the furnace can be approximated by a two-dimensional symmetrical section greatly simplifies our analysis by not having to deal with three-dimensional corner effects. We justify this assumption on the basis that the corners represent a much shorter heat path than the straight wall section. Considering corner effects would reduce the cool-down time estimates; hence, our analysis provides a conservative estimate.

(2) For background information on the Continue option, see the Run menu in the FEHT Help section. Using the Run | Calculate command, the steady-state temperature distribution was determined for the normal operating condition of the furnace. Using the Run | Continue command (after clicking on Setup | Transient), this steady-state distribution automatically becomes the initial temperature distribution for the cool-down transient process. This feature allows for conveniently prescribing a non-uniform initial temperature distribution for a transient analysis (rather than specifying values on a node-by-node basis).
PROBLEM 5.129

KNOWN: Door panel with ribbed cross-section, initially at a uniform temperature of 275°C, is ejected from the hot extrusion press and experiences convection cooling with ambient air at 25°C and a convection coefficient of 10 W/m²·K.

FIND: (a) Using the FEHT View|Temperature vs. Time command, create a graph with temperature-time histories of selected locations on the panel surface, T(x,0,t). Comment on whether you see noticeable differential cooling in the region above the rib that might explain the appearance defect; and Using the View|Temperature Contours command with the shaded-band option for the isotherm contours, select the From start to stop time option, and view the temperature contours as the panel cools. Describe the major features of the cooling process you have seen. Use other options of this command to create a 10-isotherm temperature distribution at some time that illustrates important features. How would you re-design the ribbed panel in order to reduce this thermally induced paint defect situation, yet retain the stiffening function required of the ribs?

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional conduction in the panel, (2) Uniform convection coefficient over the upper and lower surfaces of the panel, (3) Constant properties.

PROPERTIES: Door panel material (given): \( \rho = 1050 \text{ kg/m}^3 \), \( c = 800 \text{ J/kg·K} \), \( k = 0.5 \text{ W/m·K} \).

ANALYSIS:

(a) Using the Draw command, the shape of the symmetrical element of the panel (darkened region in schematic) was generated and elements formed as shown below. The symmetry lines represent adiabatic surfaces, while the boundary conditions for the exposed web and rib surfaces are characterized by \( (T_\infty, h) \).

Continued …..
After running the calculation for the time period 0 to 400 s with a 1-second time step, the temperature-time histories for three locations were obtained and the graph is shown below.

As expected, the region directly over the rib (0,0) cooled the slowest, while the extreme portion of the web (0, 13 mm) cooled the fastest. The largest temperature differences between these two locations occur during the time period 50 to 150 s. The maximum difference does not exceed 25°C.

Continued ….
(b) It is possible that the temperature gradients within the web-rib regions – rather than just the upper surface temperature differentials – might be important for understanding the panel’s response to cooling. Using the Temperature Contours command (with the From start to stop option), we saw that the center portion of the web and the end of the rib cooled quickly, but that the region on the rib centerline (0, 3-5 mm), was the hottest region. The isotherms corresponding to t = 100 s are shown below. For this condition, the temperature differential is about 21°C.

From our analyses, we have identified two possibilities to consider. First, there is a significant surface temperature distribution across the panel during the cooling process. Second, the web and the extended portion of the rib cool at about the same rate, and with only a modest normal temperature gradient. The last region to cool is at the location where the rib is thickest (0, 3-5 mm). The large temperature gradient along the centerline toward the surface may be the cause of microstructure variations, which could influence the adherence of paint. An obvious re-design consideration is to reduce the thickness of the rib at the web joint, thereby reducing the temperature gradients in that region. This fix comes at the expense of decreasing the spacing between the ribs.
PROBLEM 6.1

KNOWN: Variation of $h_x$ with $x$ for laminar flow over a flat plate.

FIND: Ratio of average coefficient, $\bar{h}_x$, to local coefficient, $h_x$, at $x$.

SCHEMATIC:

ANALYSIS: The average value of $h_x$ between 0 and $x$ is

$$\bar{h}_x = \frac{1}{x} \int_0^x h_x \, dx = \frac{C}{x} \int_0^x x^{-1/2} \, dx$$

$$\bar{h}_x = \frac{C}{x} \cdot 2x^{1/2} = 2Cx^{-1/2}$$

$$\bar{h}_x = 2h_x.$$ 

Hence, $\frac{\bar{h}_x}{h_x} = 2.$

COMMENTS: Both the local and average coefficients decrease with increasing distance $x$ from the leading edge, as shown in the sketch below.
PROBLEM 6.2

KNOWN: Variation of local convection coefficient with \( x \) for free convection from a vertical heated plate.

FIND: Ratio of average to local convection coefficient.

SCHEMATIC:

ANALYSIS: The average coefficient from 0 to \( x \) is

\[
\bar{h}_x = \frac{1}{x} \int_0^x h_x \, dx = \frac{C}{x} \int_0^x x^{-1/4} \, dx
\]

\[
\bar{h}_x = \frac{4}{3} \cdot \frac{C}{x} \cdot x^{3/4} = \frac{4}{3} \cdot \frac{C}{x^{-1/4}} = \frac{4}{3} h_x.
\]

Hence,

\[
\frac{\bar{h}_x}{h_x} = \frac{4}{3}.
\]

The variations with distance of the local and average convection coefficients are shown in the sketch.

COMMENTS: Note that \( \bar{h}_x / h_x = 4/3 \) is independent of \( x \). Hence the average coefficient for an entire plate of length \( L \) is \( \bar{h}_L = \frac{4}{3} h_L \), where \( h_L \) is the local coefficient at \( x = L \). Note also that the average exceeds the local. Why?
Problem 6.3

Known: Expression for the local heat transfer coefficient of a circular, hot gas jet at $T_\infty$ directed normal to a circular plate at $T_s$ of radius $r_0$.

Find: Heat transfer rate to the plate by convection.

Schematic:

Assumptions: (1) Steady-state conditions, (2) Flow is axisymmetric about the plate, (3) For $h(r)$, $a$ and $b$ are constants and $n \neq -2$.

Analysis: The convective heat transfer rate to the plate follows from Newton's law of cooling

$$q_{conv} = \int_A dq_{conv} = \int_A h(r) \cdot dA \cdot (T_\infty - T_s).$$

The local heat transfer coefficient is known to have the form,

$$h(r) = a + br^n$$

and the differential area on the plate surface is

$$dA = 2\pi r \, dr.$$

Hence, the heat rate is

$$q_{conv} = \int_0^{r_0} \left( a + br^n \right) \cdot 2\pi r \, dr \cdot (T_\infty - T_s)$$

$$q_{conv} = 2\pi \left( T_\infty - T_s \right) \left[ \frac{a}{2} r^2 + \frac{b}{n+2} r^{n+2} \right]_0^{r_0}$$

$$q_{conv} = 2\pi \left[ \frac{a}{2} r_0^2 + \frac{b}{n+2} r_0^{n+2} \right] (T_\infty - T_s).$$

Comments: Note the importance of the requirement, $n \neq -2$. Typically, the radius of the jet is much smaller than that of the plate.
PROBLEM 6.4

KNOWN: Distribution of local convection coefficient for obstructed parallel flow over a flat plate.

FIND: Average heat transfer coefficient and ratio of average to local at the trailing edge.

SCHEMATIC:

ANALYSIS: The average convection coefficient is

\[ \bar{h}_L = \frac{1}{L} \int_0^L h_x dx = \frac{1}{L} \int_0^L \left(0.7 + 13.6x - 3.4x^2\right) dx \]

\[ \bar{h}_L = \frac{1}{L} \left(0.7L + 6.8L^2 - 1.13L^3\right) = 0.7 + 6.8L - 1.13L^2 \]

\[ \bar{h}_L = 0.7 + 6.8(3) - 1.13(9) = 10.9 \text{ W/m}^2 \cdot \text{K}. \]

The local coefficient at \( x = 3 \text{m} \) is

\[ h_L = 0.7 + 13.6(3) - 3.4(9) = 10.9 \text{ W/m}^2 \cdot \text{K}. \]

Hence,

\[ \frac{\bar{h}_L}{h_L} = 1.0. \]

COMMENTS: The result \( \frac{\bar{h}_L}{h_L} = 1.0 \) is unique to \( x = 3 \text{m} \) and is a consequence of the existence of a maximum for \( h_x(x) \). The maximum occurs at \( x = 2 \text{m} \), where \( \left( dh_x / dx \right) = 0 \) and \( \left( d^2h_x / dx^2 < 0 \right) \).
**PROBLEM 6.5**

**KNOWN:** Temperature distribution in boundary layer for air flow over a flat plate.

**FIND:** Variation of local convection coefficient along the plate and value of average coefficient.

**SCHEMATIC:**

![Schematic](image.png)

**ANALYSIS:** From Eq. 6.17,

\[
h = -\frac{k}{(T_s - T_\infty)} \left( \frac{\partial T}{\partial y} \right)_{y=0} + \frac{k}{(T_s - T_\infty)} \left( 70 \times 600x \right)
\]

where \( T_s = T(x,0) = 90^\circ C \). Evaluating \( k \) at the arithmetic mean of the freestream and surface temperatures, \( \bar{T} = (20 + 90)^\circ C/2 = 55^\circ C = 328 K \), Table A.4 yields \( k = 0.0284 \text{ W/m-K} \). Hence, with \( T_s - T_\infty = 70^\circ C = 70 K \),

\[
h = \frac{0.0284 \text{ W/m-K} \left( 42,000x \right) \text{ K/m}}{70 K} = 17x \left( \text{W/m}^2 \cdot \text{K} \right)
\]

and the convection coefficient increases linearly with \( x \).

![Graph](image.png)

The average coefficient over the range \( 0 \leq x \leq 5 \text{ m} \) is

\[
\bar{h} = \frac{1}{L} \int_0^L h \, dx = \frac{17}{5} \int_0^5 x \, dx = \frac{17}{5} \left[ \frac{x^2}{2} \right]_0^5 = 42.5 \text{ W/m}^2 \cdot \text{K}
\]
PROBLEM 6.6

KNOWN: Variation of local convection coefficient with distance x from a heated plate with a uniform temperature $T_s$.

FIND: (a) An expression for the average coefficient $\bar{h}_{12}$ for the section of length $(x_2 - x_1)$ in terms of $C$, $x_1$ and $x_2$, and (b) An expression for $\bar{h}_{12}$ in terms of $x_1$ and $x_2$, and the average coefficients $\bar{h}_1$ and $\bar{h}_2$, corresponding to lengths $x_1$ and $x_2$, respectively.

SCHEMATIC:

ASSUMPTIONS: (1) Laminar flow over a plate with uniform surface temperature, $T_s$, and (2) Spatial variation of local coefficient is of the form $h_x = Cx^{-1/2}$, where $C$ is a constant.

ANALYSIS: (a) The heat transfer rate per unit width from a longitudinal section, $x_2 - x_1$, can be expressed as

$$q'_{12} = \bar{h}_{12} (x_2 - x_1) (T_s - T_\infty)$$

where $\bar{h}_{12}$ is the average coefficient for the section of length $(x_2 - x_1)$. The heat rate can also be written in terms of the local coefficient, Eq. (6.3), as

$$q'_{12} = \int_{x_1}^{x_2} h_x \, dx (T_s - T_\infty) = (T_s - T_\infty) \int_{x_1}^{x_2} h_x \, dx$$

Combining Eq. (1) and (2),

$$\bar{h}_{12} = \frac{1}{(x_2 - x_1)} \int_{x_1}^{x_2} h_x \, dx$$

and substituting for the form of the local coefficient, $h_x = Cx^{-1/2}$, find that

$$\bar{h}_{12} = \frac{1}{(x_2 - x_1)} \int_{x_1}^{x_2} Cx^{-1/2} \, dx = \frac{C}{x_2 - x_1} \left[ x^{1/2} \right]_x^{x_2} = 2Cx^{1/2} \left( x_2^{1/2} - x_1^{1/2} \right) / (x_2 - x_1)$$

(b) The heat rate, given as Eq. (1), can also be expressed as

$$q'_{12} = \bar{h}_2 x_2 (T_s - T_\infty) - \bar{h}_1 x_1 (T_s - T_\infty)$$

which is the difference between the heat rate for the plate over the section (0 - $x_2$) and over the section (0 - $x_1$). Combining Eqs. (1) and (5), find,

$$\bar{h}_{12} = \frac{\bar{h}_2 x_2 - \bar{h}_1 x_1}{x_2 - x_1}$$

COMMENTS: (1) Note that, from Eq. 6.6,

$$\bar{h}_x = \frac{1}{2} \int_0^x h_x \, dx = \frac{1}{x} \int_0^x Cx^{-1/2} \, dx = 2Cx^{-1/2}$$

or $\bar{h}_x = 2h_x$. Substituting Eq. (7) into Eq. (6), see that the result is the same as Eq. (4).
PROBLEM 6.7

KNOWN: Radial distribution of local convection coefficient for flow normal to a circular disk.

FIND: Expression for average Nusselt number.

SCHEMATIC:

ASSUMPTIONS: Constant properties

ANALYSIS: The average convection coefficient is

\[
\bar{h} = \frac{1}{A_s \cdot A_s} \int h dA_s
\]

\[
\bar{h} = \frac{1}{\pi r_o^2} \int_0^{r_o} k \frac{D}{D} \left[ 1 + a \left( \frac{r}{r_o} \right)^n \right] 2\pi rdr
\]

\[
\bar{h} = \frac{k \text{Nu}_o}{r_o^3} \left[ \frac{r^2}{2} + \frac{a r^{n+2}}{(n+2)r_o^n} \right]_{r=0}^{r=r_o}
\]

where \( \text{Nu}_o \) is the Nusselt number at the stagnation point \( r = 0 \). Hence,

\[
\overline{\text{Nu}}_D = \bar{h}D = \frac{kD}{\text{Nu}}_o \left[ \frac{(r/r_o)^2}{2} + \frac{a}{(n+2)} \left( \frac{r}{r_o} \right)^{n+2} \right]_{r=0}^{r=r_o}
\]

\[
\overline{\text{Nu}}_D = \text{Nu}_o \left[ 1 + 2a \left( \frac{r}{r_o} \right)^{n+2} \right]_{0}^{r=r_o}
\]

\[
\overline{\text{Nu}}_D = \text{Nu}_o \left[ 1 + 2a/(n+2) \right] \cdot 0.814Re_D^{1/2}Pr^{0.36}.
\]

COMMENTS: The increase in \( h(r) \) with \( r \) may be explained in terms of the sharp turn which the boundary layer flow must make around the edge of the disk. The boundary layer accelerates and its thickness decreases as it makes the turn, causing the local convection coefficient to increase.
PROBLEM 6.8

**KNOWN:** Convection correlation and temperature of an impinging air jet. Dimensions and initial temperature of a heated copper disk. Properties of the air and copper.

**FIND:** Effect of jet velocity on temperature decay of disk following jet impingement.

**SCHEMATIC:**

![Schematic diagram showing air jet impinging on a heated copper disk](image)

**ASSUMPTIONS:** (1) Validity of lumped capacitance analysis, (2) Negligible heat transfer from sides and bottom of disk, (3) Constant properties.

**ANALYSIS:** Performing an energy balance on the disk, it follows that

$$\frac{dT}{dt} = -\frac{h(T-T_\infty) + h_r(T-T_{\text{sur}})}{\rho c L}$$

where, $h_r = \varepsilon \sigma (T + T_{\text{sur}}) \left( T^2 + T_{\text{sur}}^2 \right)$ and, from the solution to Problem 6.7,

$$\overline{h} = \frac{k}{D} \overline{\text{Nu}_D} = \frac{k}{D} \left( 1 + \frac{2a}{n+2} \right) 0.814 \text{Re}_D^{1/2} \text{Pr}^{0.36}$$

With $a = 0.30$ and $n = 2$, it follows that

$$\overline{h} = (k/D) 0.936 \text{Re}_D^{1/2} \text{Pr}^{0.36}$$

where $\text{Re}_D = VD/\nu$. Using the *Lumped Capacitance Model* of IHT, the following temperature histories were determined.

Continued …..
The temperature decay becomes more pronounced with increasing V, and a final temperature of 400 K is reached at t = 2760, 1455 and 976s for V = 4, 20 and 50 m/s, respectively.

**COMMENTS:** The maximum Biot number, \( Bi = \left( \bar{h} + h_r \right) L / k_{Cu} \), is associated with V = 50 m/s (maximum \( \bar{h} \) of 169 W/m²-K) and t = 0 (maximum \( h_r \) of 64 W/m²-K), in which case the maximum Biot number is \( Bi = (233 \text{ W/m}^2\text{K})(0.025 \text{ m})/(386 \text{ W/m-K}) = 0.015 < 0.1 \). Hence, the lumped capacitance approximation is valid.
PROBLEM 6.9

KNOWN: Local convection coefficient on rotating disk. Radius and surface temperature of disk. Temperature of stagnant air.

FIND: Local heat flux and total heat rate. Nature of boundary layer.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible heat transfer from back surface and edge of disk.

ANALYSIS: If the local convection coefficient is independent of radius, the local heat flux at every point on the disk is

\[ q^* = h(T_s - T_\infty) = 20 \text{ W/m}^2\cdot\text{K} (50 - 20)\,^\circ\text{C} = 600 \text{ W/m}^2 \]

Since \( h \) is independent of location, \( \bar{h} = h = 20 \text{ W/m}^2\cdot\text{K} \) and the total power requirement is

\[ P_{\text{elec}} = q = \bar{h} A_s (T_s - T_\infty) = \bar{h} \pi r_0^2 (T_s - T_\infty) \]

\[ P_{\text{elec}} = \left( 20 \text{ W/m}^2\cdot\text{K} \right) \pi (0.1\text{m})^2 (50 - 20)\,^\circ\text{C} = 18.9 \text{ W} \]

If the convection coefficient is independent of radius, the boundary layer must be of uniform thickness \( \delta \). Within the boundary layer, air flow is principally in the circumferential direction. The circumferential velocity component \( u_\theta \) corresponds to the rotational velocity of the disk at the surface \((y = 0)\) and increases with increasing \( r \) \((u_\theta = \Omega r)\). The velocity decreases with increasing distance \( y \) from the surface, approaching zero at the outer edge of the boundary layer \((y \to \delta)\).
PROBLEM 6.10

KNOWN: Form of the velocity and temperature profiles for flow over a surface.

FIND: Expressions for the friction and convection coefficients.

SCHEMATIC:

ANALYSIS: The shear stress at the wall is

\[ \tau_s = \mu \left( \frac{\partial u}{\partial y} \right)_{y=0} = \mu \left[ A + 2By - 3Cy^2 \right]_{y=0} = A \mu. \]

Hence, the friction coefficient has the form,

\[ C_f = \frac{\tau_s}{\rho u_{\infty}^2 / 2} = \frac{2A \mu}{\rho u_{\infty}^2}. \]

The convection coefficient is

\[ h = \frac{-k_f}{T_s - T_{\infty}} \left( \frac{\partial T}{\partial y} \right)_{y=0} = \frac{-k_f \left[ E + 2Fy - 3Gy^2 \right]}{D - T_{\infty}}_{y=0} \]

\[ h = \frac{-k_f E}{D - T_{\infty}}. \]

COMMENTS: It is a simple matter to obtain the important surface parameters from knowledge of the corresponding boundary layer profiles. However, it is rarely a simple matter to determine the form of the profile.
**PROBLEM 6.11**

**KNOWN:** Surface temperatures of a steel wall and temperature of water flowing over the wall.

**FIND:** (a) Convection coefficient, (b) Temperature gradient in wall and in water at wall surface.

**SCHEMATIC:**

![Schematic diagram](image)

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional heat transfer in x, (3) Constant properties.

**PROPERTIES:** Table A-1, Steel Type AISI 1010 (70°C = 343K), \( k_s = 61.7 \, \text{W/m} \cdot \text{K} \); Table A-6, Water (32.5°C = 305K), \( k_f = 0.62 \, \text{W/m} \cdot \text{K} \).

**ANALYSIS:**

(a) Applying an energy balance to the control surface at \( x = 0 \), it follows that

\[
q''_{x, \text{cond}} - q''_{x, \text{conv}} = 0
\]

and using the appropriate rate equations,

\[
k_s \frac{T_{s,2} - T_{s,1}}{L} = h \left( T_{s,1} - T_\infty \right).
\]

Hence,

\[
h = k_s \frac{T_{s,2} - T_{s,1}}{L} \frac{T_{s,1} - T_\infty}{0.35\text{m}} = 61.7 \, \text{W/m} \cdot \text{K} \frac{60^\circ \text{C}}{15^\circ \text{C}} = 705 \, \text{W/m}^2 \cdot \text{K}.
\]

(b) The gradient in the wall at the surface is

\[
\left( \frac{dT}{dx} \right)_s = -\frac{T_{s,2} - T_{s,1}}{L} = -\frac{60^\circ \text{C}}{0.35\text{m}} = -171.4^\circ \text{C/m}.
\]

In the water at \( x = 0 \), the definition of \( h \) gives

\[
\left( \frac{dT}{dx} \right)_{f,x=0} = -\frac{h}{k_f} \left( T_{s,1} - T_\infty \right)
\]

\[
\left( \frac{dT}{dx} \right)_{f,x=0} = -\frac{705 \, \text{W/m}^2 \cdot \text{K}}{0.62 \, \text{W/m} \cdot \text{K}} \left( 15^\circ \text{C} \right) = -17,056^\circ \text{C/m}.
\]

**COMMENTS:** Note the relative magnitudes of the gradients. Why is there such a large difference?
PROBLEM 6.12

KNOWN: Boundary layer temperature distribution.

FIND: Surface heat flux.

SCHEMATIC:

PROPERTIES: Table A-4, Air (T_s = 300K): k = 0.0263 W/m·K.

ANALYSIS: Applying Fourier's law at y = 0, the heat flux is

\[ q_s^* = -k \left( \frac{\partial T}{\partial y} \right)_{y=0} = -k (T_\infty - T_s) \left[ Pr \frac{u_\infty}{\nu} \right] \exp \left[ -Pr \frac{u_\infty y}{\nu} \right] \left| y=0 \right] \]

\[ q_s^* = -k (T_\infty - T_s) Pr \frac{u_\infty}{\nu} \]

\[ q_s^* = -0.0263 \text{ W/m·K} (100\text{K})0.7 \times 5000 \text{ 1/m.} \]

\[ q_s^* = -9205 \text{ W/m}^2. \]

COMMENTS: (1) Negative flux implies convection heat transfer to the surface.

(2) Note use of k at T_s to evaluate q_s^* from Fourier’s law.
**PROBLEM 6.13**

**KNOWN:** Air flow over a flat plate of length \( L = 1 \) m under conditions for which transition from laminar to turbulent flow occurs at \( x_c = 0.5 \) m based upon the critical Reynolds number, \( \text{Re}_{x_c} = 5 \times 10^5 \). Forms for the local convection coefficients in the laminar and turbulent regions.

**FIND:** (a) Velocity of the air flow using thermophysical properties evaluated at 350 K, (b) An expression for the average coefficient \( \overline{h}_{\text{lan}}(x) \), as a function of distance from the leading edge, \( x \), for the laminar region, \( 0 \leq x \leq x_c \), (c) An expression for the average coefficient \( \overline{h}_{\text{turb}}(x) \), as a function of distance from the leading edge, \( x \), for the turbulent region, \( x_c \leq x \leq L \), and (d) Compute and plot the local and average convection coefficients, \( h_x \) and \( \overline{h}_x \), respectively, as a function of \( x \) for \( 0 \leq x \leq L \).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Forms for the local coefficients in the laminar and turbulent regions, \( h_{\text{lan}} = C_{\text{lan}} x^{-0.5} \) and \( h_{\text{turb}} = C_{\text{turb}} x^{-0.2} \) where \( C_{\text{lan}} = 8.845 \text{ W/m}^{3/2} \cdot \text{K} \), \( C_{\text{turb}} = 49.75 \text{ W/m}^{2} \cdot \text{K}^{0.8} \), and \( x \) has units (m).

**PROPERTIES:** Table A.4, Air (\( T = 350 \) K): \( k = 0.030 \text{ W/m} \cdot \text{K} \), \( \nu = 20.92 \times 10^{-6} \text{ m}^2/\text{s} \), \( \Pr = 0.700 \).

**ANALYSIS:** (a) Using air properties evaluated at 350 K with \( x_c = 0.5 \) m, 
\[
\text{Re}_{x_c} = \frac{u_{\infty} x_c}{\nu} = 5 \times 10^5 \quad u_{\infty} = 5 \times 10^5 \frac{\nu}{x_c} = 5 \times 10^5 \times 20.92 \times 10^{-6} \text{ m}^2/\text{s}/0.5 \text{ m} = 20.9 \text{ m/s} <
\]

(b) From Eq. 6.5, the average coefficient in the laminar region, \( 0 \leq x \leq x_c \), is 
\[
\overline{h}_{\text{lan}}(x) = \frac{1}{x} \int_0^x h_{\text{lan}}(x) \, dx = \frac{1}{x} C_{\text{lan}} \int_0^x x^{-0.5} \, dx = \frac{1}{x} C_{\text{lan}} x^{0.5} = 2C_{\text{lan}} x^{-0.5} = 2h_{\text{lan}}(x) \quad (1)
\]

(c) The average coefficient in the turbulent region, \( x_c \leq x \leq L \), is
\[
\overline{h}_{\text{turb}}(x) = \frac{1}{x} \left[ \int_0^{x_c} h_{\text{lan}}(x) \, dx + \int_{x_c}^x h_{\text{turb}}(x) \, dx \right] = \left[ C_{\text{lan}} x_c^{0.5} \frac{x}{0.5} + C_{\text{turb}} x_{0.8} \frac{x}{0.8} \right] \quad (2)
\]

(d) The local and average coefficients, Eqs. (1) and (2) are plotted below as a function of \( x \) for the range \( 0 \leq x \leq L \).
**PROBLEM 6.14**

**KNOWN:** Air speed and temperature in a wind tunnel.

**FIND:** (a) Minimum plate length to achieve a Reynolds number of $10^8$, (b) Distance from leading edge at which transition would occur.

**SCHEMATIC:**

![Diagram showing air flow and plate dimensions](image)

**ASSUMPTIONS:** (1) Isothermal conditions, $T_s = T_\infty$.

**PROPERTIES:** Table A-4, Air ($25^\circ C = 298K$): $\nu = 15.71 \times 10^{-6} \text{ m}^2/\text{s}$.

**ANALYSIS:** (a) The Reynolds number is

$$Re_x = \frac{\rho u_\infty x}{\mu} = \frac{u_\infty x}{\nu}.$$  

To achieve a Reynolds number of $1 \times 10^8$, the minimum plate length is then

$$L_{\text{min}} = \frac{Re_x \nu}{u_\infty} = \frac{1 \times 10^8 \left(15.71 \times 10^{-6} \text{ m}^2/\text{s}\right)}{50 \text{ m/s}}$$

$$L_{\text{min}} = 31.4 \text{ m}.$$  

(b) For a transition Reynolds number of $5 \times 10^5$

$$x_c = \frac{Re_{x,c} \nu}{u_\infty} = \frac{5 \times 10^5 \left(15.71 \times 10^{-6} \text{ m}^2/\text{s}\right)}{50 \text{ m/s}}$$

$$x_c = 0.157 \text{ m}.$$  

**COMMENTS:** Note that

$$\frac{x_c}{L} = \frac{Re_{x,c}}{Re_L}$$

This expression may be used to quickly establish the location of transition from knowledge of $Re_{x,c}$ and $Re_L$. 

**PROBLEM 6.15**

**KNOWN:** Transition Reynolds number. Velocity and temperature of atmospheric air, water, engine oil and mercury flow over a flat plate.

**FIND:** Distance from leading edge at which transition occurs for each fluid.

**SCHEMATIC:**

**ASSUMPTIONS:** Transition Reynolds number is $Re_{x,c} = 5 \times 10^5$.

**PROPERTIES:** For the fluids at $T = 300K$;

<table>
<thead>
<tr>
<th>Fluid</th>
<th>Table</th>

**COMMENTS:** Due to the effect which viscous forces have on attenuating the instabilities which bring about transition, the distance required to achieve transition increases with increasing $\nu$. 
**PROBLEM 6.16**

**KNOWN:** Two-dimensional flow conditions for which \( v = 0 \) and \( T = T(y) \).

**FIND:** (a) Verify that \( u = u(y) \), (b) Derive the x-momentum equation, (c) Derive the energy equation.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Incompressible fluid with constant properties, (3) Negligible body forces, (4) \( v = 0 \), (5) \( T = T(y) \) or \( \frac{\partial T}{\partial x} = 0 \), (6) Thermal energy generation occurs only by viscous dissipation.

**ANALYSIS:**

(a) From the mass continuity equation, it follows from the prescribed conditions that \( \frac{\partial u}{\partial x} = 0 \). Hence \( u = u(y) \).

(b) From Newton’s second law of motion, \( \Sigma F_x = (\text{Rate of increase of fluid momentum})_x \),

\[
\left[ p - \left( p + \frac{\partial p}{\partial x} \right) \right] \text{dy} \cdot 1 + \left[ -\tau + \left( \tau + \frac{\partial \tau}{\partial y} \right) \text{dy} \right] \text{dx} \cdot 1 = \left\{ \left( \rho \ u \right) + \frac{\partial}{\partial x} \left[ \left( \rho \ u \right)^2 \right] \text{dx} \right\} \text{dy} \cdot 1 - \left( \rho \ u \right) \text{u dy} \cdot 1
\]

Hence, with \( \tau = \mu \left( \frac{\partial u}{\partial y} \right) \), it follows that

\[
-\frac{\partial p}{\partial x} + \frac{\partial \tau}{\partial y} = \frac{\partial}{\partial x} \left[ \left( \rho \ u \right) \right] = 0 \quad \frac{\partial p}{\partial x} = \mu \frac{\partial^2 u}{\partial y^2}.
\]

(c) From the conservation of energy requirement and the prescribed conditions, it follows that \( \dot{E}_{in} - \dot{E}_{out} = 0 \), or

\[
\left[ pu + \rho \ u \left( e + u^2 / 2 \right) \right] \text{dy} \cdot 1 + \left[ -k \frac{\partial T}{\partial y} + \tau u + \frac{\partial (\tau u)}{\partial y} \right] \text{dy} \cdot 1
\]

\[
-\left\{ pu + \frac{\partial}{\partial x} \left( pu \right) dx + \rho \ u \left( e + u^2 / 2 \right) + \frac{\partial}{\partial x} \left[ \rho \ u \left( e + u^2 / 2 \right) \right] \text{dx} \right\} \text{dy} \cdot 1 - \left\{ \tau u - k \frac{\partial T}{\partial y} \right\} \text{dy} \cdot 1 = 0
\]

or,

\[
\frac{\partial (\tau u)}{\partial y} - \frac{\partial}{\partial x} \left( pu \right) - \frac{\partial}{\partial x} \left[ \rho \ u \left( e + u^2 / 2 \right) \right] + \frac{\partial}{\partial y} \left[ k \frac{\partial T}{\partial y} \right] = 0
\]

\[
\tau \frac{\partial u}{\partial y} + u \frac{\partial \tau}{\partial y} - \frac{\partial p}{\partial x} + \kappa \frac{\partial^2 T}{\partial y^2} = 0.
\]

Noting that the second and third terms cancel from the momentum equation,

\[
\mu \left[ \frac{\partial u}{\partial y} \right]^2 + k \left[ \frac{\partial^2 T}{\partial y^2} \right] = 0.
\]
**PROBLEM 6.17**

**KNOWN:** Oil properties, journal and bearing temperatures, and journal speed for a lightly loaded journal bearing.

**FIND:** Maximum oil temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Incompressible fluid with constant properties, (3) Clearance is much less than journal radius and flow is Couette.

**ANALYSIS:** The temperature distribution corresponds to the result obtained in the text Example on Couette flow,

\[
T(y) = T_0 + \frac{\mu}{2k} \left( \frac{y}{L} - \frac{y^2}{L^2} \right)
\]

The position of maximum temperature is obtained from

\[
\frac{dT}{dy} = 0 = \frac{\mu}{2k} \left( \frac{1}{L} - \frac{2y}{L^2} \right)
\]

or,

\[
y = L/2.
\]

The temperature is a maximum at this point since \(d^2T/dy^2 < 0\). Hence,

\[
T_{\text{max}} = T(L/2) = T_0 + \frac{\mu}{2k} U^2 \left[ \frac{1}{L} - \frac{1}{4} \right] = T_0 + \frac{\mu U^2}{8k}
\]

\[
T_{\text{max}} = 40^\circ C + \frac{10^{-2} \text{kg/s} \cdot \text{m} (10 \text{m/s})^2}{8 \times 0.15 \text{ W/m} \cdot \text{K}}
\]

\[
T_{\text{max}} = 40.83^\circ C.
\]

**COMMENTS:** Note that \(T_{\text{max}}\) increases with increasing \(\mu\) and \(U\), decreases with increasing \(k\), and is independent of \(L\).
PROBLEM 6.18

KNOWN: Diameter, clearance, rotational speed and fluid properties of a lightly loaded journal bearing. Temperature of bearing.

FIND: (a) Temperature distribution in the fluid, (b) Rate of heat transfer from bearing and operating power.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Incompressible fluid with constant properties, (3) Couette flow.

PROPERTIES: Oil (Given): \( \rho = 800 \text{ kg/m}^3 \), \( \nu = 10^{-5} \text{ m}^2/\text{s} \), \( k = 0.13 \text{ W/m-K} \); \( \mu = \rho \nu = 8 \times 10^{-3} \text{ kg/s} \cdot \text{m} \).

ANALYSIS: (a) For Couette flow, the velocity distribution is linear, \( u(y) = U(y/L) \), and the energy equation and general form of the temperature distribution are

\[
\frac{k}{\mu} \frac{d^2T}{dy^2} = -\mu \left[ \frac{U}{L} \right]^2 \quad \text{and} \quad T = -\frac{\mu}{2k} \left[ \frac{U}{L} \right]^2 y + C_1 y + C_2.
\]

Considering the boundary conditions \( \frac{dT}{dy} |_{y=L} = 0 \) and \( T(0) = T_0 \), find \( C_2 = T_0 \) and \( C_1 = \frac{\mu U^2}{2L} \).

Hence,

\[
T = T_0 + \left( \frac{\mu U^2}{k} \right) \left[ \frac{(y/L)}{1/2 (y/L)^2} \right].
\]

(b) Applying Fourier's law at \( y = 0 \), the rate of heat transfer per unit length to the bearing is

\[
q' = -k (\pi D) \frac{dT}{dy} \bigg|_{y=0} = - \left( \frac{\pi D}{L} \right) \frac{\mu U^2}{L} = - \left( \frac{\pi \times 75 \times 10^{-3} \text{ m}}{0.25 \times 10^{-3} \text{ m}} \right)^2 \frac{8 \times 10^{-3} \text{ kg/s} \cdot \text{m} \cdot (14.14 \text{ m/s})^2}{0.25 \times 10^{-3} \text{ m}} = -1507.5 \text{ W/m}
\]

where the velocity is determined as

\[
U = (D/2) \omega = 0.0375 \text{ m} \times 3600 \text{ rev/min} \left( 2\pi \text{ rad/rev} \right) / \left( 60 \text{ s/min} \right) = 14.14 \text{ m/s}.
\]

The journal power requirement is

\[
P' = F(y=L) U = \tau_s(y=L) \cdot \pi D \cdot U
\]

\[
P' = 452.5 \text{ kg/s}^2 \cdot \text{m} \left( \pi \times 75 \times 10^{-3} \text{ m} \right) 14.14 \text{ m/s} = 1507.5 \text{ kg} \cdot \text{m/s}^3 = 1507.5 \text{ W/m}
\]

where the shear stress at \( y = L \) is

\[
\tau_s(y=L) = \mu \left( \frac{\partial u}{\partial y} \right) \bigg|_{y=L} = \mu \frac{U}{L} = 8 \times 10^{-3} \text{ kg/s} \cdot \text{m} \left( \frac{14.14 \text{ m/s}}{0.25 \times 10^{-3} \text{ m}} \right) = 452.5 \text{ kg/s}^2 \cdot \text{m}.
\]

COMMENTS: Note that \( q' = P' \), which is consistent with the energy conservation requirement.
PROBLEM 6.19

KNOWN: Conditions associated with the Couette flow of air or water.

FIND: (a) Force and power requirements per unit surface area, (b) Viscous dissipation, (c) Maximum fluid temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Fully-developed Couette flow, (2) Incompressible fluid with constant properties.

PROPERTIES: \( \text{Table A-4, Air (300K): } \mu = 184.6 \times 10^{-7} \text{ N} \cdot \text{s/m}^2, \text{ } k = 26.3 \times 10^{-3} \text{ W/m} \cdot \text{K}; \text{ Table A-6, Water (300K): } \mu = 855 \times 10^{-6} \text{ N} \cdot \text{s/m}^2, \text{ } k = 0.613 \text{ W/m} \cdot \text{K.} \)

ANALYSIS: (a) The force per unit area is associated with the shear stress. Hence, with the linear velocity profile for Couette flow, \( \tau = \mu \left( \frac{dU}{dy} \right) = \mu \left( \frac{U}{L} \right) \).

Air:
\[
\tau_{\text{air}} = 184.6 \times 10^{-7} \text{ N} \cdot \text{s/m}^2 \times \frac{200 \text{ m/s}}{0.005 \text{ m}} = 0.738 \text{ N/m}^2
\]

Water:
\[
\tau_{\text{water}} = 855 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 \times \frac{200 \text{ m/s}}{0.005 \text{ m}} = 34.2 \text{ N/m}^2.
\]

With the required power given by \( P/A = \tau \cdot U \),

Air:
\[
(P/A)_{\text{air}} = \left( 0.738 \text{ N/m}^2 \right) 200 \text{ m/s} = 147.6 \text{ W/m}^2 < \]

Water:
\[
(P/A)_{\text{water}} = \left( 34.2 \text{ N/m}^2 \right) 200 \text{ m/s} = 6840 \text{ W/m}^2.
\]

(b) The viscous dissipation is \( \mu \Phi = \mu \left( \frac{dU}{dy} \right)^2 = \mu \left( \frac{U}{L} \right)^2 \). Hence,

Air:
\[
(\mu \Phi)_{\text{air}} = 184.6 \times 10^{-7} \text{ N} \cdot \text{s/m}^2 \left[ \frac{200 \text{ m/s}}{0.005 \text{ m}} \right]^2 = 2.95 \times 10^4 \text{ W/m}^3
\]

Water:
\[
(\mu \Phi)_{\text{water}} = 855 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 \left[ \frac{200 \text{ m/s}}{0.005 \text{ m}} \right]^2 = 1.37 \times 10^6 \text{ W/m}^3.
\]

(c) From the solution to Part 4 of the text Example, the location of the maximum temperature corresponds to \( y_{\text{max}} = L/2 \). Hence, \( T_{\text{max}} = T_0 + \mu U^2 / 8k \) and

Air:
\[
(T_{\text{max}})_{\text{air}} = 27 \text{°C} + \frac{184.6 \times 10^{-7} \text{ N} \cdot \text{s/m}^2 \left( 200 \text{ m/s} \right)^2}{8 \times 0.0263 \text{ W/m} \cdot \text{K}} = 30.5 \text{°C}
\]

Water:
\[
(T_{\text{max}})_{\text{water}} = 27 \text{°C} + \frac{855 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 \left( 200 \text{ m/s} \right)^2}{8 \times 0.613 \text{ W/m} \cdot \text{K}} = 34.0 \text{°C}.
\]

COMMENTS: (1) The viscous dissipation associated with the entire fluid layer, \( \mu \Phi (L \cdot A) \), must equal the power, \( P \). (2) Although \( (\mu \Phi)_{\text{water}} \gg (\mu \Phi)_{\text{air}} \), \( k_{\text{water}} \gg k_{\text{air}} \). Hence, \( T_{\text{max,water}} \approx T_{\text{max,air}} \).
**PROBLEM 6.20**

**KNOWN:** Velocity and temperature difference of plates maintaining Couette flow. Mean temperature of air, water or oil between the plates.

**FIND:** (a) Pr·Ec product for each fluid, (b) Pr·Ec product for air with plate at sonic velocity.

**SCHEMATIC:**

\[ T_0 - T_L = 25^\circ C \]

\[ T_L \rightarrow U = 10m/s \text{ or } c \]

\[ T_0 \]

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Couette flow, (3) Air is at 1 atm.

**PROPERTIES:** *Table A-4*, Air (300K, 1atm), \( c_p = 1007 \text{ J/kg} \cdot \text{K}, \text{ Pr} = 0.707, \gamma = 1.4, R = 287.02 \text{ J/kg} \cdot \text{K}; *Table A-6*, Water (300K): \( c_p = 4179 \text{ J/kg} \cdot \text{K}, \text{ Pr} = 5.83; *Table A-5*, Engine oil (300K), \( c_p = 1909 \text{ J/kg} \cdot \text{K}, \text{ Pr} = 6400.

**ANALYSIS:** The product of the Prandtl and Eckert numbers is dimensionless, 

\[
\text{Pr} \cdot \text{Ec} = \text{Pr} \left( \frac{U^2}{c_p \Delta T} \right) \left( \frac{m^2/s^2}{(J/kg \cdot K)} \right) \left( \frac{m^2/s^2}{(kg \cdot m^2/s^2)/kg} \right). 
\]

Substituting numerical values, find

<table>
<thead>
<tr>
<th></th>
<th>Air</th>
<th>Water</th>
<th>Oil</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pr·Ec</td>
<td>0.0028</td>
<td>0.0056</td>
<td>13.41</td>
</tr>
</tbody>
</table>

(b) For an ideal gas, the speed of sound is

\[
c = (\gamma \cdot \frac{R}{T})^{1/2}
\]

where \( R \), the gas constant for air, is \( R_u/u = 8.315 \text{ kJ/kmol} \cdot \text{K}/(28.97 \text{ kg/kmol}) = 287.02 \text{ J/kg} \cdot \text{K}. \) Hence, at 300K for air,

\[
U = c = (1.4 \times 287.02 \text{ J/kg} \cdot \text{K} \times 300\text{K})^{1/2} = 347.2 \text{ m/s}.
\]

For sonic velocities, it follows that

\[
\text{Pr} \cdot \text{Ec} = 0.707 \frac{(347.2 \text{ m/s})^2}{1007 \text{ J/kg} \cdot \text{K} \times 25\text{K}} = 3.38.
\]

**COMMENTS:** From the above results it follows that viscous dissipation effects must be considered in the high speed flow of gases and in oil flows at moderate speeds. For Pr·Ec to be less than 0.1 in air with \( \Delta T = 25^\circ C \), \( U \) should be < 60 m/s.
PROBLEM 6.21

KNOWN: Couette flow with moving plate isothermal and stationary plate insulated.

FIND: Temperature of stationary plate and heat flux at the moving plate.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Incompressible fluid with constant properties, (3) Couette flow.

ANALYSIS: The energy equation is given by

\[ 0 = k \left[ \frac{\partial^2 T}{\partial y^2} \right] + \mu \left[ \frac{\partial u}{\partial y} \right]^2 \]

Integrating twice find the general form of the temperature distribution,

\[ \frac{\partial^2 T}{\partial y^2} = -\frac{\mu U^2}{kL} \left[ \frac{\partial u}{\partial y} \right]^2 \]

\[ \frac{\partial T}{\partial y} = -\frac{\mu U^2}{2kL} y + C_1 \]

\[ T(y) = -\frac{\mu U^2}{2kL} y^2 + C_1 y + C_2. \]

Consider the boundary conditions to evaluate the constants,

\[ \frac{\partial T}{\partial y} \bigg|_{y=0} = 0 \quad \rightarrow \quad C_1 = 0 \quad \text{and} \quad T(L) = T_L \quad \rightarrow \quad C_2 = T_L + \frac{\mu U^2}{2k}. \]

Hence, the temperature distribution is

\[ T(y) = T_L + \left[ \frac{\mu U^2}{2k} \right] \left[ 1 - \left( \frac{y}{L} \right)^2 \right]. \]

The temperature of the lower plate \((y = 0)\) is

\[ T(0) = T_L + \left[ \frac{\mu U^2}{2k} \right]. \]

The heat flux to the upper plate \((y = L)\) is

\[ q^*(L) = -k \frac{\partial T}{\partial y} \bigg|_{y=L} = \frac{\mu U^2}{L}. \]

COMMENTS: The heat flux at the top surface may also be obtained by integrating the viscous dissipation over the fluid layer height. For a control volume about a unit area of the fluid layer,

\[ \dot{E}_g = \dot{E}_{\text{out}} \]

\[ \int_0^L \mu \left[ \frac{\partial u}{\partial y} \right]^2 dy = q^*(L) \quad \rightarrow \quad q^*(L) = \frac{\mu U^2}{L}. \]
**PROBLEM 6.22**

**KNOWN:** Couette flow with heat transfer. Lower (insulated) plate moves with speed \( U \) and upper plate is stationary with prescribed thermal conductivity and thickness. Outer surface of upper plate maintained at constant temperature, \( T_{sp} = 40^\circ C \).

**FIND:** (a) On \( T-y \) coordinates, sketch the temperature distribution in the oil and the stationary plate, and (b) An expression for the temperature at the lower surface of the oil film, \( T(0) = T_o \), in terms of the plate speed \( U \), the stationary plate parameters \( (T_{sp}, k_{sp}, L_{sp}) \) and the oil parameters \( (\mu, k_o, L_o) \). Determine this temperature for the prescribed conditions.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Fully developed Couette flow and (3) Incompressible fluid with constant properties.

**ANALYSIS:** (a) The temperature distribution is shown above with these key features: linear in plate, parabolic in oil film, discontinuity at plate-oil interface, and zero gradient at lower plate surface.

(b) From Example 6.4, the general solution to the conservation equations for the temperature distribution in the oil film is

\[
T_o(y) = -Ay^2 + C_3y + C_4
\]

where

\[
A = \frac{\mu}{2k_o} \left( \frac{U}{L_o} \right)^2
\]

and the boundary conditions are,

At \( y = 0 \), insulated boundary \( \left( \frac{dT_o}{dy} \right)_{y=0} = 0 \); \( C_3 = 0 \)

At \( y = L_o \), heat fluxes in oil and plate are equal, \( q^o(L_o) = q^{sp}(L_o) \)

Continued...
PROBLEM 6.22 (Cont.)

\[-k \left( \frac{dT_o}{dy} \right)_{y=L_o} = \frac{T_o (L_o) - T_{sp}}{R_{sp}} \quad \left\{ \frac{dT_o}{dy} \right\}_{y=L} = -2AL_o \quad R_{sp} = \frac{L_{sp}}{k_{sp}} \quad T_o (L) = -AL_o^2 + C_4 \]

\[C_4 = T_{sp} + AL_o^2 \left[ 1 + 2 \frac{k_o L_{sp}}{L_o k_{sp}} \right] \]

Hence, the temperature distribution at the lower surface is

\[T_o (0) = -A + C_4 \]

\[T_o (0) = T_{sp} + \frac{\mu}{2k_o} U^2 \left[ 1 + 2 \frac{k_o L_{sp}}{L_o k_{sp}} \right] \]

Substituting numerical values, find

\[T_o (0) = 40^\circ C + \frac{0.799 \text{ N} \cdot \text{s/m}^2}{2 \times 0.145 \text{ W/m} \cdot \text{K}} (5 \text{ m/s})^2 \left[ 1 + 2 \frac{0.145}{5 \times 3} \right] = 116.9^\circ C \]

**COMMENTS:**

(1) Give a physical explanation about why the maximum temperature occurs at the lower surface.

(2) Sketch the temperature distribution if the upper plate moved with a speed U while the lower plate is stationary and all other conditions remain the same.
**PROBLEM 6.23**

**KNOWN:** Shaft of diameter 100 mm rotating at 9000 rpm in a journal bearing of 70 mm length. Uniform gap of 1 mm separates the shaft and bearing filled with lubricant. Outer surface of bearing is water-cooled and maintained at $T_{wc} = 30 \degree C$.

**FIND:** (a) Viscous dissipation in the lubricant, $\mu \Phi$ (W/m$^3$), (b) Heat transfer rate from the lubricant, assuming no heat lost through the shaft, and (c) Temperatures of the bearing and shaft, $T_b$ and $T_s$.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Fully developed Couette flow, (3) Incompressible fluid with constant properties, and (4) Negligible heat lost through the shaft.

**ANALYSIS:** (a) The viscous dissipation, $\mu \Phi$, Eq. 6.40, for Couette flow from Example 6.4, is

$$
\Phi = \mu \left( \frac{du}{dy} \right) = \mu \left( \frac{U}{L} \right)^2 = 0.03 \frac{N \cdot s}{m^2} \left( \frac{47.1 \frac{m}{s}}{0.001 \frac{m}{s}} \right)^2 = 6.65 \times 10^7 \frac{W}{m^3}
$$

where the velocity distribution is linear and the tangential velocity of the shaft is

$$
U = \pi DN = \pi (0.100 \text{ m}) \times 9000 \text{ rpm} \times \left( \frac{\text{min}}{60 \text{s}} \right) = 47.1 \text{ m/s}.
$$

(b) The heat transfer rate from the lubricant volume $\forall$ through the bearing is

$$
q = \mu \Phi \cdot \forall = \mu \Phi \left( \pi D \cdot L \cdot \ell \right) = 6.65 \times 10^7 \frac{W}{m^3} \left( \pi \times 0.100 \text{ m} \times 0.001 \text{ m} \times 0.070 \text{ m} \right) = 1462 \text{ W}
$$

where $\ell = 70$ mm is the length of the bearing normal to the page.

Continued...
(c) From Fourier’s law, the heat rate through the bearing material of inner and outer diameters, \( D_i \) and \( D_o \), and thermal conductivity \( k_b \) is, from Eq. (3.27),

\[
q_r = \frac{2\pi \ell k_b (T_b - T_{wc})}{\ln(D_o/D_i)}
\]

\[
T_b = T_{wc} + \frac{q_r \ln(D_o/D_i)}{2\pi k_b}
\]

\[
T_b = 30^\circ C + \frac{1462 W \ln(200/100)}{2\pi \times 0.070 m \times 45 W/m \cdot K} = 81.2^\circ C
\]

To determine the temperature of the shaft, \( T(0) = T_s \), first the temperature distribution must be found beginning with the general solution, Example 6.4,

\[
T(y) = -\frac{\mu}{2k} \left( \frac{U}{L} \right)^2 y^2 + C_3 y + C_4
\]

The boundary conditions are, at \( y = 0 \), the surface is adiabatic

\[
\frac{dT}{dy}\bigg|_{y=0} = 0 \quad C_3 = 0
\]

and at \( y = L \), the temperature is that of the bearing, \( T_b \)

\[
T(L) = T_b = -\frac{\mu}{2k} \left( \frac{U}{L} \right)^2 L^2 + 0 + C_4 \quad C_4 = T_b + \frac{\mu}{2k} U^2
\]

Hence, the temperature distribution is

\[
T(y) = T_b + \frac{\mu}{2k} U^2 \left( 1 - \frac{y^2}{L^2} \right)
\]

and the temperature at the shaft, \( y = 0 \), is

\[
T_s = T(0) = T_b + \frac{\mu}{2k} U^2 = 81.3^\circ C + \frac{0.03 N \cdot s/m^2}{2 \times 0.15 W/m \cdot K} (47.1 m/s)^2 = 303^\circ C
\]
PROBLEM 6.24

KNOWN: Couette flow with heat transfer.

FIND: (a) Dimensionless form of temperature distribution, (b) Conditions for which top plate is adiabatic, (c) Expression for heat transfer to lower plate when top plate is adiabatic.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) incompressible fluid with constant properties, (3) Negligible body forces, (4) Couette flow.

ANALYSIS: (a) From Example 6.4, the temperature distribution is

\[
T = T_0 + \frac{\mu}{2k} U^2 \left[ \frac{y}{L} - \left( \frac{y}{L} \right)^2 \right] + \left( T_L - T_0 \right) \frac{y}{L}
\]

or, with

\[
\theta = \frac{T - T_0}{T_L - T_0}, \quad \eta = y/L,
\]

\[
\text{Pr} = \frac{c_p \mu}{k}, \quad \text{Ec} = \frac{U^2}{c_p (T_L - T_0)}
\]

\[
\theta = \frac{\text{Pr} \cdot \text{Ec}}{2} \left( \eta - \eta^2 \right) + \eta = \eta \left[ 1 + \frac{1}{2} \text{Pr} \cdot \text{Ec} (1 - \eta) \right]
\]

(b) For there to be zero heat transfer at the top plate, \( dT/dy \) |\( y=L \) = 0. Hence,

\[
\frac{dT}{d\eta} \bigg|_{\eta=1} = \frac{\text{Pr} \cdot \text{Ec}}{2} (1 - 2\eta) |_{\eta=1} + 1 = -\frac{\text{Pr} \cdot \text{Ec}}{2} + 1 = 0
\]

There is no heat transfer at the top plate if,

\[
\text{Ec} \cdot \text{Pr} = 2.
\]

(c) The heat transfer rate to the lower plate (per unit area) is

\[
q_0' = -k \frac{dT}{dy} \bigg|_{y=0} = -k \left( \frac{T_L - T_0}{L} \right) \frac{d\theta}{d\eta} \bigg|_{\eta=0}
\]

\[
q_0' = -k \frac{T_L - T_0}{L} \left[ \frac{\text{Pr} \cdot \text{Ec}}{2} (1 - 2\eta) |_{\eta=0} + 1 \right]
\]

\[
q_0' = -k \frac{T_L - T_0}{L} \left( \frac{\text{Pr} \cdot \text{Ec}}{2} + 1 \right) = -2k \left( T_L - T_0 \right)/L
\]

Continued...
PROBLEM 6.24 (Cont.)

(d) Using Eq. (1), the dimensionless temperature distribution is plotted as a function of dimensionless distance, \( \eta = \frac{y}{L} \). When Pr\cdot Ec = 0, there is no dissipation and the temperature distribution is linear, so that heat transfer is by conduction only. As Pr\cdot Ec increases, viscous dissipation becomes more important. When Pr\cdot Ec = 2, heat transfer to the upper plate is zero. When Pr\cdot Ec > 2, the heat rate is out of the oil film at both surfaces.
PROBLEM 6.25

KNOWN: Steady, incompressible, laminar flow between infinite parallel plates at different temperatures.

FIND: (a) Form of continuity equation, (b) Form of momentum equations and velocity profile. Relationship of pressure gradient to maximum velocity, (c) Form of energy equation and temperature distribution. Heat flux at top surface.

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional flow (no variations in z) between infinite, parallel plates, (2) Negligible body forces, (3) No internal energy generation, (4) Incompressible fluid with constant properties.

ANALYSIS: (a) For two-dimensional, steady conditions, the continuity equation is

$$\frac{\partial (\rho u)}{\partial x} + \frac{\partial (\rho v)}{\partial y} = 0.$$  

Hence, for an incompressible fluid (constant $\rho$) in parallel flow ($v = 0$),

$$\frac{\partial u}{\partial x} = 0.$$  

The flow is fully developed in the sense that, irrespective of $y$, $u$ is independent of $x$.

(b) With the above result and the prescribed conditions, the momentum equations reduce to

$$0 = -\frac{\partial p}{\partial x} + \mu \frac{\partial^2 u}{\partial y^2} \quad 0 = -\frac{\partial p}{\partial y}.$$  

Since $p$ is independent of $y$, $\partial p/\partial x = dp/dx$ is independent of $y$ and

$$\mu \frac{\partial^2 u}{\partial y^2} = \frac{d^2 u}{dy^2} = \frac{dp}{dx}.$$  

Since the left-hand side can, at most, depend only on $y$ and the right-hand side is independent of $y$, both sides must equal the same constant $C$. That is,

$$\mu \frac{d^2 u}{dy^2} = C.$$  

Hence, the velocity distribution has the form

$$u(y) = \frac{C}{2\mu} y^2 + C_1 y + C_2.$$  

Using the boundary conditions to evaluate the constants,

$$u(0) = 0 \quad \rightarrow \quad C_2 = 0 \quad \text{and} \quad u(L) = 0 \quad \rightarrow \quad C_1 = -CL/2\mu.$$  

Continued …..
PROBLEM 6.25 (Cont.)

The velocity profile is
\[ u(y) = \frac{C}{2\mu} \left( y^2 - Ly \right). \]

The profile is symmetric about the midplane, in which case the maximum velocity exists at \( y = L/2 \). Hence,
\[ u(L/2) = u_{\text{max}} = \frac{C}{2\mu} \left[ -\frac{L^2}{4} \right] \quad \text{or} \quad u_{\text{max}} = -\frac{L^2}{8\mu} \frac{dp}{dx}. \]<

(c) For fully developed thermal conditions, \( \partial T/\partial x = 0 \) and temperature depends only on \( y \). Hence with \( v = 0, \partial u/\partial x = 0 \), and the prescribed assumptions, the energy equation becomes
\[ \rho u \frac{\partial i}{\partial x} = k \frac{d^2T}{dy^2} + u \frac{dp}{dx} + \mu \left[ \frac{du}{dy} \right]^2. \]

With \( i = e + p/\rho \),
\[ \frac{\partial i}{\partial x} = \frac{\partial e}{\partial x} + \frac{1}{\rho} \frac{dp}{dx} \quad \text{where} \quad \frac{\partial e}{\partial x} = \frac{\partial e}{\partial T} \frac{\partial T}{\partial x} + \frac{\partial e}{\partial \rho} \frac{\partial \rho}{\partial x} = 0. \]

Hence, the energy equation becomes
\[ 0 = k \frac{d^2T}{dy^2} + \mu \left[ \frac{du}{dy} \right]^2. \]<

With \( du/\text{dy} = (C/2\mu) (2y - L) \), it follows that
\[ \frac{d^2T}{dy^2} = -\frac{C^2}{4k\mu} \left( 4y^2 - 4Ly + L^2 \right). \]

Integrating twice,
\[ T(y) = -\frac{C^2}{4k\mu} \left[ \frac{y^4}{3} - \frac{2Ly^3}{3} + \frac{L^2y^2}{2} \right] + C_3y + C_4. \]

Using the boundary conditions to evaluate the constants,
\[ T(0) = T_2 \quad \rightarrow \quad C_4 = T_2 \quad \text{and} \quad T(L) = T_1 \quad \rightarrow \quad C_3 = \frac{C^2L^3}{24k\mu} + \frac{(T_1 - T_2)}{L}. \]

Hence,
\[ T(y) = T_2 + \left[ \frac{y}{L} \right] (T_1 - T_2) - \frac{C^2}{4k\mu} \left[ \frac{y^4}{3} - \frac{2Ly^3}{3} + \frac{L^2y^2}{2} - \frac{L^3y}{6} \right]. \]<

From Fourier’s law,
\[ q''(L) = -k \frac{\partial T}{\partial y}_{y=L} = k \frac{T_2 - T_1}{L} + \frac{C^2}{4\mu} \left[ \frac{4}{3}L^3 - 2L^2 + \frac{L^3}{6} \right]. \]
\[ q''(L) = k \frac{T_2 - T_1}{L} + \frac{C^2L^3}{24\mu}. \]<

COMMENTS: The third and second terms on the right-hand sides of the temperature distribution and heat flux, respectively, represents the effects of viscous dissipation. If \( C \) is large (due to large \( \mu \) or \( u_{\text{max}} \)), viscous dissipation is significant. If \( C \) is small, conduction effects dominate.
**PROBLEM 6.26**

**KNOWN:** Pressure independence of $\mu$, $k$ and $c_p$.

**FIND:** Pressure dependence of $\nu$ and $\alpha$ for air at 350K and $p = 1, 10$ atm.

**ASSUMPTIONS:** Perfect gas behavior for air.

**PROPERTIES:** *Table A-4*, Air (350K, 1 atm): $\nu = 20.92 \times 10^{-6} \text{ m}^2/\text{s}$, $\alpha = 29.9 \times 10^{-6} \text{ m}^2/\text{s}$.

**ANALYSIS:** The kinematic viscosity and thermal diffusivity are, respectively,

$$
\nu = \frac{\mu}{\rho} \quad \alpha = \frac{k}{\rho} \frac{c_p}{c_p}.
$$

Hence, $\nu$ and $\alpha$ are inversely proportional to $\rho$.

For an *incompressible liquid*, $\rho$ is constant.

Hence $\nu$ and $\alpha$ are independent of pressure. \(<\)

For a *perfect gas*, $\rho = p/RT$.

Hence, $\rho$ is directly proportional to $p$, in which case $\nu$ and $\alpha$ vary inversely with pressure. It follows that $\nu$ and $\alpha$ are inversely proportional to pressure. \(<\)

To calculate $\nu$ or $\alpha$ for a *perfect gas* at $p \neq 1$ atm,

$$
\nu(p) = \nu(1 \text{ atm}) \cdot \frac{1}{p}, \quad \alpha(p) = \alpha(1 \text{ atm}) \cdot \frac{1}{p}.
$$

Hence, for air at 350K,

<table>
<thead>
<tr>
<th>$p$(atm)</th>
<th>$\nu$(m$^2$/s)</th>
<th>$\alpha$(m$^2$/s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>$20.92 \times 10^{-6}$</td>
<td>$29.9 \times 10^{-6}$</td>
</tr>
<tr>
<td>10</td>
<td>$2.09 \times 10^{-6}$</td>
<td>$2.99 \times 10^{-6}$</td>
</tr>
</tbody>
</table>

**COMMENTS:** For the incompressible liquid and the perfect gas, $Pr = \nu/\alpha$ is independent of pressure.
PROBLEM 6.27

KNOWN: Characteristic length, surface temperature and average heat flux for an object placed in an airstream of prescribed temperature and velocity.

FIND: Average convection coefficient if characteristic length of object is increased by a factor of five and air velocity is decreased by a factor of five.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties.

ANALYSIS: For a particular geometry, \( \overline{Nu}_L = f(Re_L, Pr) \).

The Reynolds numbers for each case are

\[
\text{Case 1: } Re_{L,1} = \frac{V_1 L_1}{v_1} = \frac{(100\text{ m/s}) 1\text{ m}}{100 \text{ m}^2/\text{s}} = 100 \text{ m}^2/\text{s} \\
\text{Case 2: } Re_{L,2} = \frac{V_2 L_2}{v_2} = \frac{(20\text{ m/s}) 5\text{ m}}{100 \text{ m}^2/\text{s}} = 100 \text{ m}^2/\text{s}.
\]

Hence, with \( v_1 = v_2, Re_{L,1} = Re_{L,2} \). Since \( Pr_1 = Pr_2 \), it follows that \( \overline{Nu}_{L,2} = \overline{Nu}_{L,1} \).

Hence,

\[
\overline{h}_2 L_2 / k_2 = \overline{h}_1 L_1 / k_1 \\
\overline{h}_2 = \overline{h}_1 \frac{L_1}{L_2} = 0.2 \overline{h}_1.
\]

For Case 1, using the rate equation, the convection coefficient is

\[
q_1 = \overline{h}_1 A_1 (T_s - T_\infty)_1 \\
\overline{h}_1 = \frac{(q_1 / A_1)}{(T_s - T_\infty)_1} = \frac{20,000 \text{ W/m}^2}{(400 - 300) \text{ K}} = 200 \text{ W/m}^2 \cdot \text{K}.
\]

Hence, it follows that for Case 2

\[
\overline{h}_2 = 0.2 \times 200 \text{ W/m}^2 \cdot \text{K} = 40 \text{ W/m}^2 \cdot \text{K}. \quad \checkmark
\]

COMMENTS: If \( Re_{L,2} \) were not equal to \( Re_{L,1} \), it would be necessary to know the specific form of \( f(Re_L, Pr) \) before \( \overline{h}_2 \) could be determined.
PROBLEM 6.28

KNOWN: Heat transfer rate from a turbine blade for prescribed operating conditions.

FIND: Heat transfer rate from a larger blade operating under different conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Surface area A is directly proportional to characteristic length L, (4) Negligible radiation, (5) Blade shapes are geometrically similar.

ANALYSIS: For a prescribed geometry, 

\[ \overline{Nu} = \frac{\overline{h}L}{k} = f(Re_L, Pr) \]

The Reynolds numbers for the blades are 

\[ Re_{L,1} = \left( \frac{V_1 L_1}{\nu} \right) = 15/\nu \quad Re_{L,2} = \left( \frac{V_2 L_2}{\nu} \right) = 15/\nu. \]

Hence, with constant properties, \( Re_{L,1} = Re_{L,2} \). Also, \( Pr_1 = Pr_2 \). Therefore,

\[ \frac{\overline{Nu}_2}{\overline{Nu}_1} = \left( \frac{\overline{h}_2 L_2 / k}{\overline{h}_1 L_1 / k} \right) = \left( \frac{\overline{h}_2}{\overline{h}_1} \right) = \left( \frac{L_1}{L_2} \right) \left( \frac{q_1}{A_1 (T_s,1 - T_\infty)} \right). \]

Hence, the heat rate for the second blade is

\[ q_2 = \overline{h}_2 A_2 (T_{s,2} - T_\infty) = \frac{L_1}{L_2} \frac{A_2}{A_1} \left( \frac{T_{s,2} - T_\infty}{T_{s,1} - T_\infty} \right) q_1 \]

\[ q_2 = \frac{T_{s,2} - T_\infty}{T_{s,1} - T_\infty} q_1 = \frac{(400 - 35)}{(300 - 35)} (1500 \text{ W}) \]

\[ q_2 = 2066 \text{ W}. \]

COMMENTS: The slight variation of \( \nu \) from Case 1 to Case 2 would cause \( Re_{L,2} \) to differ from \( Re_{L,1} \). However, for the prescribed conditions, this non-constant property effect is small.
PROBLEM 6.29

KNOWN: Experimental measurements of the heat transfer coefficient for a square bar in cross flow.

FIND: (a) $h$ for the condition when $L = 1\text{m}$ and $V = 15\text{m/s}$, (b) $h$ for the condition when $L = 1\text{m}$ and $V = 30\text{m/s}$, (c) Effect of defining a side as the characteristic length.

SCHEMATIC:

ASSUMPTIONS: (1) Functional form $\overline{Nu} = CRe^mPr^n$ applies with $C$, $m$, $n$ being constants, (2) Constant properties.

ANALYSIS: (a) For the experiments and the condition $L = 1\text{m}$ and $V = 15\text{m/s}$, it follows that $Pr$ as well as $C$, $m$, and $n$ are constants. Hence

$$hL \propto (VL)^m.$$  

Using the experimental results, find $m$. Substituting values

$$\frac{h_1L_1}{h_2L_2} = \left[ \frac{V_1L_1}{V_2L_2} \right]^m$$

$$\frac{50 \times 0.5}{40 \times 0.5} = \left[ \frac{20 \times 0.5}{15 \times 0.5} \right]^m$$

giving $m = 0.782$. It follows then for $L = 1\text{m}$ and $V = 15\text{m/s}$,

$$h = h_1 \frac{L_1}{L} \left[ \frac{V \cdot L}{V_1 \cdot L_1} \right]^m = 50 \frac{W}{m^2 \cdot K} \cdot 0.5 \left[ \frac{15 \times 1.0}{20 \times 0.5} \right]^{0.782} = 34.3 \frac{W}{m^2 \cdot K}. \quad <$$

(b) For the condition $L = 1\text{m}$ and $V = 30\text{m/s}$, find

$$h = h_1 \frac{L_1}{L} \left[ \frac{V \cdot L}{V_1 \cdot L_1} \right]^m = 50 \frac{W}{m^2 \cdot K} \times 0.5 \left[ \frac{30 \times 1.0}{20 \times 0.5} \right]^{0.782} = 59.0 \frac{W}{m^2 \cdot K}. \quad <$$

(c) If the characteristic length were chosen as a side rather than the diagonal, the value of $C$ would change. However, the coefficients $m$ and $n$ would not change.

COMMENTS: The foregoing Nusselt number relation is used frequently in heat transfer analysis, providing appropriate scaling for the effects of length, velocity, and fluid properties on the heat transfer coefficient.
**PROBLEM 6.30**

**KNOWN:** Local Nusselt number correlation for flow over a roughened surface.

**FIND:** Ratio of average heat transfer coefficient to local coefficient.

**SCHEMATIC:**

![Schematic](image)

**ANALYSIS:** The local convection coefficient is obtained from the prescribed correlation,

\[ h_x = \frac{k}{\xi} = 0.04 k \frac{Re_x^{0.9} Pr^{1/3}}{x} \]

\[ h_x = 0.04 k \left[ \frac{V}{V} \right]^{0.9} \frac{Pr^{1/3}}{x} \equiv C_1 x^{-0.1}. \]

To determine the average heat transfer coefficient for the length zero to \( x \),

\[ \bar{h}_x = \frac{1}{x} \int_0^x h_x \, dx = \frac{1}{x} C_1 \int_0^x x^{-0.1} \, dx \]

\[ \bar{h}_x = \frac{C_1 x^{0.9}}{0.9} = 1.11 C_1 x^{-0.1}. \]

Hence, the ratio of the average to local coefficient is

\[ \frac{\bar{h}_x}{h_x} = \frac{1.11 C_1 x^{-0.1}}{C_1 x^{-0.1}} = 1.11. \]

**COMMENTS:** Note that \( \frac{Nu_x}{Nu_x} \) is also equal to 1.11. Note, however, that

\[ Nu_x \neq \frac{1}{x} \int_0^x Nu_x \, dx. \]
PROBLEM 6.31

KNOWN: Freestream velocity and average convection heat transfer associated with fluid flow over a surface of prescribed characteristic length.

FIND: Values of $\bar{Nu}_L$, $Re_L$, $Pr$, $\bar{j}_H$ for (a) air, (b) engine oil, (c) mercury, (d) water.

SCHEMATIC:

PROPERTIES: For the fluids at 300K:

<table>
<thead>
<tr>
<th>Fluid</th>

COMMENTS: Note the wide range of Pr associated with the fluids.
PROBLEM 6.32

KNOWN: Variation of $h_x$ with $x$ for flow over a flat plate.

FIND: Ratio of average Nusselt number for the entire plate to the local Nusselt number at $x = L$.

SCHEMATIC:

ANALYSIS: The expressions for the local and average Nusselt numbers are

$$\overline{Nu_L} = \frac{h_{LL}}{k} = \frac{\left(CL^{-1/2}\right) L}{k} = \frac{CL^{1/2}}{k}$$

where

$$\overline{h_L} = \frac{1}{L} \int_0^L h_x \, dx = \frac{C}{L} \int_0^L x^{-1/2} dx = \frac{2C}{L} L^{1/2} = 2CL^{-1/2}.$$ 

Hence,

$$\overline{Nu_L} = \frac{2CL^{-1/2}(L)}{k} = \frac{2CL^{1/2}}{k}$$

and

$$\frac{\overline{Nu_L}}{Nu_L} = 2.$$  

COMMENTS: Note the manner in which $\overline{Nu_L}$ is defined in terms of $\overline{h_L}$. Also note that

$$\overline{Nu_L} \neq \frac{1}{L} \int_0^L Nu_x \, dx.$$
PROBLEM 6.33

KNOWN: Laminar boundary layer flow of air at 20°C and 1 atm having $\delta_t = 1.13 \delta$.

FIND: Ratio $\delta / \delta_t$ when fluid is ethylene glycol for same conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Laminar flow.

PROPERTIES: Table A-4, Air (293K, 1 atm): $Pr = 0.709$; Table A-5, Ethylene glycol (293K): $Pr = 211$.

ANALYSIS: The Prandtl number strongly influences relative growth of the velocity, $\delta$, and thermal, $\delta_t$, boundary layers. For laminar flow, the approximate relationship is given by

$$Pr^n \approx \frac{\delta}{\delta_t}$$

where $n$ is a positive coefficient. Substituting the values for air

$$0.709^n = \frac{1}{1.13}$$

find that $n = 0.355$. Hence, for ethylene glycol it follows that

$$\frac{\delta}{\delta_t} = Pr^{0.355} = 211^{0.355} = 6.69.$$ <

COMMENTS: (1) For laminar flow, generally we find $n = 0.33$. In which case, $\delta / \delta_t = 5.85$.

(2) Recognize the physical importance of $\nu > \alpha$, which gives large values of the Prandtl number, and causes $\delta > \delta_t$. 
PROBLEM 6.34

KNOWN: Air, water, engine oil or mercury at 300K in laminar, parallel flow over a flat plate.

FIND: Sketch of velocity and thermal boundary layer thickness.

ASSUMPTIONS: (1) Laminar flow.

PROPERTIES: For the fluids at 300K:

<table>
<thead>
<tr>
<th>Fluid</th>
<th>Table</th>
<th>Pr</th>
</tr>
</thead>
<tbody>
<tr>
<td>Air</td>
<td>A.4</td>
<td>0.71</td>
</tr>
<tr>
<td>Water</td>
<td>A.6</td>
<td>5.83</td>
</tr>
<tr>
<td>Engine Oil</td>
<td>A.5</td>
<td>6400</td>
</tr>
<tr>
<td>Mercury</td>
<td>A.5</td>
<td>0.025</td>
</tr>
</tbody>
</table>

ANALYSIS: For laminar, boundary layer flow over a flat plate.

\[ \frac{\delta}{\delta_t} \sim Pr^n \]

where \( n > 0 \). Hence, the boundary layers appear as shown below.

Air:

Water:

Engine Oil:

Mercury:

COMMENTS: Although Pr strongly influences relative boundary layer development in laminar flow, its influence is weak for turbulent flow.
**PROBLEM 6.35**

**KNOWN:** Expression for the local heat transfer coefficient of air at prescribed velocity and temperature flowing over electronic elements on a circuit board and heat dissipation rate for a 4 × 4 mm chip located 120 mm from the leading edge.

**FIND:** Surface temperature of the chip surface, $T_s$.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Power dissipated within chip is lost by convection across the upper surface only, (3) Chip surface is isothermal, (4) The average heat transfer coefficient for the chip surface is equivalent to the local value at $x = L$.

**PROPERTIES:** Table A-4, Air (assume $T_s = 45^\circ C$, $T_f = (45 + 25)/2 = 35^\circ C = 308 K$, 1 atm): $\nu = 16.69 \times 10^{-6} m^2/s$, $k = 26.9 \times 10^{-3} W/m \cdot K$, $Pr = 0.703$.

**ANALYSIS:** From an energy balance on the chip (see above),

$$q_{conv} = \dot{E}_g = 30 W.$$  

(1)

Newton’s law of cooling for the upper chip surface can be written as

$$T_s = T_\infty + \frac{q_{conv}}{h \cdot A_{chip}}$$

(2)

where $A_{chip} = \ell^2$. Assume that the average heat transfer coefficient $\overline{h}$ over the chip surface is equivalent to the local coefficient evaluated at $x = L$. That is, $\overline{h}_{chip} = h_x (L)$ where the local coefficient can be evaluated from the special correlation for this situation,

$$Nu_x = \frac{h_x x}{k} = 0.04 \left[ \frac{V_x}{\nu} \right]^{0.85} Pr^{1/3}$$

and substituting numerical values with $x = L$, find

$$h_x = 0.04 \left[ \frac{0.0269 W/m \cdot K \cdot 10 m/s \times 0.120 m}{16.69 \times 10^{-6} m^2/s} \right]^{0.85} Pr^{1/3} (0.703)^{1/3} = 107 W/m^2 \cdot K.$$ 

The surface temperature of the chip is from Eq. (2),

$$T_s = 25^\circ C + 30 \times 10^{-3} W/107 W/m^2 \cdot K \times (0.004 m)^2 = 42.5^\circ C.$$  

**COMMENTS:** (1) Note that the estimated value for $T_f$ used to evaluate the air properties was reasonable. (2) Alternatively, we could have evaluated $\overline{h}_{chip}$ by performing the integration of the local value, $h(x)$. 
PROBLEM 6.36

KNOWN: Location and dimensions of computer chip on a circuit board. Form of the convection correlation. Maximum allowable chip temperature and surface emissivity. Temperature of cooling air and surroundings.

FIND: Effect of air velocity on maximum power dissipation, first without and then with consideration of radiation effects.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Negligible temperature variations in chip, (3) Heat transfer exclusively from the top surface of the chip, (4) The local heat transfer coefficient at \( x = L \) provides a good approximation to the average heat transfer coefficient for the chip surface.

PROPERTIES: Table A.4, air (\( \bar{T} = (T_\infty + T_C)/2 = 328 \) K): \( \nu = 18.71 \times 10^{-6} \) m\(^2\)/s, \( k = 0.0284 \) W/m·K, \( Pr = 0.703 \).

ANALYSIS: Performing an energy balance for a control surface about the chip, we obtain \( P_c = q_{\text{conv}} + q_{\text{rad}} \), where \( q_{\text{conv}} = \bar{h}A_s(T_C - T_\infty) \), \( q_{\text{rad}} = h_fA_s(T_C - T_{\text{sur}}) \), and \( h_f = \varepsilon\sigma(T_C + T_{\text{sur}})(T_C^2 + T_{\text{sur}}^2) \). With \( \bar{h} = h_L \), the convection coefficient may be determined from the correlation provided in Problem 6.35 (\( Nu_L = 0.04 Re_L^{0.85} Pr^{1/3} \)). Hence,

\[
P_c = \varepsilon^2 \left[ 0.04(k/L)Re_L^{0.85} Pr^{1/3}(T_C - T_\infty) + \varepsilon\sigma(T_C + T_{\text{sur}})(T_C^2 + T_{\text{sur}}^2)(T_C - T_{\text{sur}}) \right]
\]

where \( Re_L = VL/\nu \). Computing the right side of this expression for \( \varepsilon = 0 \) and \( \varepsilon = 0.85 \), we obtain the following results.

Since \( h_L \) increases as \( V^{0.85} \), the chip power must increase with \( V \) in the same manner. Radiation exchange increases \( P_c \) by a fixed, but small (6 mW) amount. While \( h_L \) varies from 14.5 to 223 W/m\(^2\)·K over the prescribed velocity range, \( h_f = 6.5 \) W/m\(^2\)·K is a constant, independent of \( V \).

COMMENTS: Alternatively, \( \bar{h} \) could have been evaluated by integrating \( h_x \) over the range 118 \( \leq x \leq 122 \) mm to obtain the appropriate average. However, the value would be extremely close to \( h_{x=L} \).
PROBLEM 6.37

KNOWN: Form of Nusselt number for flow of air or a dielectric liquid over components of a circuit card.

FIND: Ratios of time constants associated with intermittent heating and cooling. Fluid that provides faster thermal response.

PROPERTIES: Prescribed. Air: \( k = 0.026 \, \text{W/mK}, \nu = 2 \times 10^{-5} \, \text{m}^2/\text{s}, \text{Pr} = 0.71 \). Dielectric liquid: \( k = 0.064 \, \text{W/mK}, \nu = 10^{-6} \, \text{m}^2/\text{s}, \text{Pr} = 25 \).

ANALYSIS: From Eq. 5.7, the thermal time constant is

\[
\tau_t = \frac{\rho \sqrt{c}}{h A_s}
\]

Since the only variable that changes with the fluid is the convection coefficient, where

\[
\bar{h} = \frac{k}{L} \frac{Nu_L}{L} = \frac{k}{L} \text{Re}^m \text{Pr}^n = \frac{k}{L} C \left( \frac{V L}{\nu} \right)^m \text{Pr}^n
\]

the desired ratio reduces to

\[
\frac{\tau_{t, \text{air}}}{\tau_{t, \text{dielectric}}} = \frac{\bar{h}_d}{\bar{h}_a} = \frac{k_d}{k_a} \left( \frac{\nu_a}{\nu_d} \right)^m \left( \frac{\text{Pr}_d}{\text{Pr}_a} \right)^n
\]

\[
\frac{\tau_{t, \text{a}}}{\tau_{t, \text{d}}} = \frac{0.064}{0.026} \left( \frac{2 \times 10^{-5}}{10^{-6}} \right)^{0.8} \left( \frac{25}{0.71} \right)^{0.33} = 88.6
\]

Since its time constant is nearly two orders of magnitude smaller than that of the air, the dielectric liquid is clearly the fluid of choice.

COMMENTS: The accelerated testing procedure suggested by this problem is commonly used to test the durability of electronic packages.
**PROBLEM 6.38**

**KNOWN:** Form of the Nusselt number correlation for forced convection and fluid properties.

**FIND:** Expression for figure of merit \( F_F \) and values for air, water and a dielectric liquid.

**PROPERTIES:** Prescribed. Air: \( k = 0.026 \text{ W/m}\cdot\text{K}, \nu = 1.5 \times 10^{-5} \text{ m}^2/\text{s}, \text{Pr} = 0.70 \). Water: \( k = 0.600 \text{ W/m}\cdot\text{K}, \nu = 10^{-6} \text{ m}^2/\text{s}, \text{Pr} = 5.0 \). Dielectric liquid: \( k = 0.064 \text{ W/m}\cdot\text{K}, \nu = 10^{-6} \text{ m}^2/\text{s}, \text{Pr} = 25 \)

**ANALYSIS:** With \( \text{Nu}_L \sim \text{Re}_L^{m} \text{Pr}^{n} \), the convection coefficient may be expressed as

\[
h \sim \frac{k}{L} \left( \frac{VL}{v} \right)^{m} \text{Pr}^{n} \sim \frac{V^{m}}{L^{1-m}} \left( \frac{k\text{Pr}^{n}}{v^{m}} \right)
\]

The figure of merit is therefore

\[
F_F = \frac{k\text{Pr}^{n}}{v^{m}}
\]

and for the three fluids, with \( m = 0.80 \) and \( n = 0.33 \),

\[
F_F \left( \text{W} \cdot \text{s}^{0.8} \cdot \text{m}^{2.6} \cdot \text{K} \right) \quad \begin{array}{ccc}
\text{Air} & \text{Water} & \text{Dielectric} \\
167 & 64,400 & 11,700
\end{array}
\]

Water is clearly the superior heat transfer fluid, while air is the least effective.

**COMMENTS:** The figure of merit indicates that heat transfer is enhanced by fluids of large \( k \), large \( \text{Pr} \) and small \( v \).
PROBLEM 6.39

FIND: Minimum value of convection coefficient needed to prevent condensation on interior surface of windshield.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) One-dimensional heat transfer, (3) Constant properties.

PROPERTIES: Table A-3, glass: $k_g = 1.4 \text{ W/m}\cdot\text{K}$. Prescribed, air: $k = 0.023 \text{ W/m}\cdot\text{K}$, $v = 12.5 \times 10^{-6} \text{ m}^2/\text{s}$, $Pr = 0.70$.

ANALYSIS: From the prescribed thermal circuit, conservation of energy yields

$$\frac{T_{\infty,i} - T_{S,i}}{1/h_i} = \frac{T_{S,i} - T_{\infty,o}}{t/k_g + 1/h_o}$$

where $h_o$ may be obtained from the correlation

$$\frac{Nu_L}{k} = \frac{h_o L}{k} = 0.30 \text{Re}_L^{0.8} Pr^{1/3}$$

With $V = (70 \text{ mph} \times 1585 \text{ m/mile})/3600 \text{ s/h} = 30.8 \text{ m/s}$, $Re_D = (30.8 \text{ m/s} \times 0.800 \text{ m})/12.5 \times 10^{-6} \text{ m}^2/\text{s}$ = $1.97 \times 10^6$ and

$$h_o = \frac{0.023 \text{ W/m}\cdot\text{K}}{0.800 \text{ m}} \times 0.30 \left(1.97 \times 10^6\right)^{0.8} \left(0.70\right)^{1/3} = 83.1 \text{ W/m}^2\cdot\text{K}$$

From the energy balance, with $T_{S,i} = T_{dp} = 10^\circ\text{C}$

$$h_i = \frac{\left(T_{S,i} - T_{\infty,o}\right)}{\left(T_{\infty,i} - T_{S,i}\right)} \left(\frac{t}{k_g} + \frac{1}{h_o}\right)^{-1}$$

$$h_i = \frac{\left(10 + 15\right)\circ\text{C}}{(50 - 10)\circ\text{C}} \left(\frac{0.006 \text{ m}}{1.4 \text{ W/m}\cdot\text{K}} + \frac{1}{83.1 \text{ W/m}^2\cdot\text{K}}\right)^{-1}$$

$$h_i = 38.3 \text{ W/m}^2\cdot\text{K}$$

COMMENTS: The output of the fan in the automobile’s heater/defroster system must maintain a velocity for flow over the inner surface that is large enough to provide the foregoing value of $h_i$. In addition, the output of the heater must be sufficient to maintain the prescribed value of $T_{\infty,i}$ at this velocity.
PROBLEM 6.40

KNOWN: Drag force and air flow conditions associated with a flat plate.

FIND: Rate of heat transfer from the plate.

SCHEMATIC:

ASSUMPTIONS: (1) Chilton-Colburn analogy is applicable.

PROPERTIES: Table A-4, Air (70°C, 1 atm): \( \rho = 1.018 \text{ kg/m}^3, c_p = 1009 \text{ J/kg} \cdot \text{K}, \text{Pr} = 0.70, \nu = 20.22 \times 10^{-6} \text{ m}^2/\text{s}. \)

ANALYSIS: The rate of heat transfer from the plate is

\[
q = 2\overline{h} \left( L^2 \right) (T_s - T_\infty)
\]

where \( \overline{h} \) may be obtained from the Chilton-Colburn analogy,

\[
\frac{\overline{h}}{\overline{H}} = \frac{\overline{C_f}}{2} = \frac{\overline{St} \text{Pr}^{2/3}}{\frac{\overline{h}}{\rho \ u_\infty \ c_p} \text{Pr}^{2/3}}
\]

\[
\frac{\overline{C_f}}{2} = \frac{1}{\rho \ u_\infty^2 / 2} \frac{\tau_s}{\nu} = \frac{1}{2} \frac{(0.075 \text{ N}/2)/(0.2 \text{ m})^2}{1.018 \text{ kg/m}^3 \times (40 \text{ m/s})^2 / 2} = 5.76 \times 10^{-4}.
\]

Hence,

\[
\overline{h} = \frac{\overline{C_f}}{2} \rho \ u_\infty \ c_p \Pr^{-2/3}
\]

\[
\overline{h} = 5.76 \times 10^{-4} \left( 1.018 \text{ kg/m}^3 \right) \times 40 \text{ m/s} \times \left( 1009 \text{ J/kg} \cdot \text{K} \right) \times (0.70)^{-2/3}
\]

\[
\overline{h} = 30 \text{ W/m}^2 \cdot \text{K}.
\]

The heat rate is

\[
q = 2\left( 30 \text{ W/m}^2 \cdot \text{K} \right) (0.2 \text{ m})^2 (120 - 20) \degree \text{ C}
\]

\[
q = 240 \text{ W}.
\]

COMMENTS: Although the flow is laminar over the entire surface (\( \text{Re}_L = u_\infty L/\nu = 40 \text{ m/s} \times 0.2 \text{ m} / 20.22 \times 10^{-6} \text{ m}^2/\text{s} = 4.0 \times 10^5 \)), the pressure gradient is zero and the Chilton-Colburn analogy is applicable to average, as well as local, surface conditions. Note that the only contribution to the drag force is made by the surface shear stress.
**PROBLEM 6.41**

**KNOWN:** Air flow conditions and drag force associated with a heater of prescribed surface temperature and area.

**FIND:** Required heater power.

**SCHEMATIC:**

![Schematic Diagram]

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Reynolds analogy is applicable, (3) Bottom surface is adiabatic.

**PROPERTIES:** *Table A-4*, Air \((T_f = 350\text{K}, 1\text{atm})\): \(\rho = 0.995 \text{kg/m}^3\), \(c_p = 1009 \text{J/kg-K}\), \(Pr = 0.700\).

**ANALYSIS:** The average shear stress and friction coefficient are

\[
\tau_s = \frac{F_d}{A} = \frac{0.25 \text{ N}}{0.25 \text{ m}^2} = 1 \text{ N/m}^2
\]

\[
C_f = \frac{\tau_s}{\rho \frac{u}{2}} = \frac{1 \text{ N/m}^2}{0.995 \text{ kg/m}^3 (15 \text{m/s})^2 / 2} = 8.93 \times 10^{-3}.
\]

From the Reynolds analogy,

\[
\frac{St}{Pr} = \frac{\tau_s}{\rho \frac{u}{2} c_p} = \frac{C_f}{2} Pr^{-2/3}.
\]

Solving for \(\bar{h}\) and substituting numerical values, find

\[
\bar{h} = 0.995 \text{kg/m}^3 \left(15 \text{m/s}\right) 1009 \text{J/kg-K} \left(8.93 \times 10^{-3} / 2\right) \left(0.7\right)^{-2/3}
\]

\[
\bar{h} = 85 \text{W/m}^2 \cdot \text{K}.
\]

Hence, the heat rate is

\[
q = \bar{h} A \left(T_s - T_{\infty}\right) = 85 \text{W/m}^2 \cdot \text{K} \left(0.25 \text{m}^2\right) (140 - 15) \text{°C}
\]

\[
q = 2.66 \text{kW}.
\]

**COMMENTS:** Due to bottom heat losses, which have been assumed negligible, the actual power requirement would exceed 2.66 kW.
PROBLEM 6.42

KNOWN: Heat transfer correlation associated with parallel flow over a rough flat plate. Velocity and temperature of air flow over the plate.

FIND: Surface shear stress 1 m from the leading edge.

SCHEMATIC:

ASSUMPTIONS: (1) Modified Reynolds analogy is applicable, (2) Constant properties.

PROPERTIES: Table A-4, Air (300K, 1atm): \( \nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}, \text{Pr} = 0.71, \rho = 1.16 \text{ kg/m}^3 \).

ANALYSIS: Applying the Chilton-Colburn analogy

\[
\frac{C_f}{2} = St_x \frac{Pr^{2/3}}{Re_x} = \frac{Nu_x Pr^{2/3}}{Re_x Pr^{1/3}} = \frac{0.04 \ Re_x^{0.9} Pr^{1/3}}{Re_x Pr^{2/3}}
\]

where

\[
Re_x = \frac{u_\infty x}{\nu} = \frac{50 \text{ m/s} \times 1 \text{ m}}{15.89 \times 10^{-6} \text{ m}^2/\text{s}} = 3.15 \times 10^6.
\]

Hence, the friction coefficient is

\[
C_f = 0.08 \left(3.15 \times 10^6\right)^{-0.1} = 0.0179 = \frac{\tau_s}{\rho \ u_\infty^2 / 2}
\]

and the surface shear stress is

\[
\tau_s = C_f \left(\rho \ u_\infty^2 / 2\right) = 0.0179 \times 1.16 \text{ kg/m}^3 (50 \text{ m/s})^2 / 2
\]

\[\tau_s = 25.96 \text{ kg/m} \cdot \text{s}^2 = 25.96 \text{ N/m}^2.\]

COMMENTS: Note that turbulent flow will exist at the designated location.
**PROBLEM 6.43**

**KNOWN:** Nominal operating conditions of aircraft and characteristic length and average friction coefficient of wing.

**FIND:** Average heat flux needed to maintain prescribed surface temperature of wing.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Applicability of modified Reynolds analogy, (2) Constant properties.

**PROPERTIES:** Prescribed, Air: \( ν = 16.3 \times 10^{-6} \text{ m}^2/\text{s} \), \( k = 0.022 \text{ W/m} \cdot \text{K} \), \( Pr = 0.72 \).

**ANALYSIS:** The average heat flux that must be maintained over the surface of the air foil is

\[
\overline{q'} = \overline{h} (T_s - T_\infty),
\]

where the average convection coefficient may be obtained from the modified Reynolds analogy.

\[
\frac{C_f}{2} = S t \frac{Pr^{2/3}}{Re L Pr^{1/3}} = \frac{Nu L}{Re L Pr^{1/3}}
\]

Hence, with \( Re_L = V L / ν = 100 \text{ m/s} (2 \text{ m}) / 16.3 \times 10^{-6} \text{ m}^2/\text{s} = 1.23 \times 10^7 \),

\[
\overline{Nu}_L = \frac{0.0025}{2} \left(1.23 \times 10^7\right) (0.72)^{1/3} = 13,780
\]

\[
\overline{h} = \frac{k}{L \overline{Nu}_L} = \frac{0.022 \text{ W/m} \cdot \text{K}}{2 \text{ m}} (13,780) = 152 \text{ W/m}^2 \cdot \text{K}
\]

\[
\overline{q'} = 152 \text{ W/m}^2 \cdot \text{K} \left[ 5 - (-23) \right]^\circ \text{C} = 4260 \text{ W/m}^2
\]

**COMMENTS:** If the flow is turbulent over the entire airfoil, the modified Reynolds analogy provides a good measure of the relationship between surface friction and heat transfer. The relation becomes more approximate with increasing laminar boundary layer development on the surface and increasing values of the magnitude of the pressure gradient.
PROBLEM 6.44

KNOWN: Average frictional shear stress of $\tau_s = 0.0625 \text{ N/m}^2$ on upper surface of circuit board with densely packed integrated circuits (ICs)

FIND: Allowable power dissipation from the upper surface of the board if the average surface temperature of the ICs must not exceed a rise of 25°C above ambient air temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) The modified Reynolds analogy is applicable, (3) Negligible heat transfer from bottom side of the circuit board, and (4) Thermophysical properties required for the analysis evaluated at 300 K.

PROPERTIES: Table A-4, Air ($T_f = 300 \text{ K}, 1 \text{ atm}$): $\rho = 1.161 \text{ kg/m}^3$, $c_p = 1007 \text{ J/kg} \cdot \text{K}$, $Pr = 0.707$.

ANALYSIS: The power dissipation from the circuit board can be calculated from the convection rate equation assuming an excess temperature $(T_s - T_\infty) = 25^\circ\text{C}$.

\[
q = \overline{h} A_s \left( T_s - T_\infty \right)
\]  

(1)

The average convection coefficient can be estimated from the Reynolds analogy and the measured average frictional shear stress $\tau_s$.

\[
\overline{C_f} = \frac{Pr^{2/3}}{St} \quad \overline{C_f} = \frac{\tau_s}{\rho \frac{V^2}{2}} \quad \overline{St} = \frac{\overline{h}}{\rho \frac{V}{c_p}} \quad (2, 3, 4)
\]

With $V = u_\infty$ and substituting numerical values, find $\overline{h}$.

\[
\frac{\tau_s}{\rho \frac{V^2}{2}} = \frac{\overline{h}}{\rho \frac{V}{c_p}} Pr^{2/3} \quad \overline{h} = \frac{\tau_s c_p}{V} Pr^{-2/3}
\]

\[
\overline{h} = \frac{0.0625 \text{ N/m}^2 \times 1007 \text{ J/kg} \cdot \text{K}}{2 \text{ m/s}} \left(0.707\right)^{-2/3} = 39.7 \text{ W/m}^2 \cdot \text{K}
\]

Substituting this result into Eq. (1), the allowable power dissipation is

\[
q = 39.7 \text{ W/m}^2 \cdot \text{K} \times (0.120 \times 0.120) \text{m}^2 \times 25 \text{ K} = 14.3 \text{ W}
\]

COMMENTS: For this analyses using the modified or Chilton-Colburn analogy, we found $C_f = 0.0269$ and $St = 0.0170$. Using the Reynolds analogy, the results are slightly different with $\overline{h} = 31.5 \text{ W/m}^2 \cdot \text{K}$ and $q = 11.3 \text{ W}$. 
PROBLEM 6.45

KNOWN: Evaporation rate of water from a lake.

FIND: The convection mass transfer coefficient, $\bar{h}_m$.

SCHEMATIC:

ASSUMPTIONS: (1) Equilibrium at water vapor-liquid surface, (2) Isothermal conditions, (3) Perfect gas behavior of water vapor, (4) Air at standard atmospheric pressure.

PROPERTIES: Table A-6, Saturated water vapor (300K): $p_{A,\text{sat}} = 0.03531 \text{ bar}$, $\rho_{A,\text{sat}} = 1/\nu_g = 0.02556 \text{ kg/m}^3$.

ANALYSIS: The convection mass transfer (evaporation) rate equation can be written in the form

$$\bar{h}_m \frac{\nu_A}{\rho_{A,s}} \frac{n_A}{\rho_{A,\infty}}$$

where

$$\rho_{A,s} = \rho_{A,\text{sat}},$$

the saturation density at the temperature of the water and

$$\rho_{A,\infty} = \phi \rho_{A,\text{sat}}$$

which follows from the definition of the relative humidity, $\phi = p_A/p_{A,\text{sat}}$ and perfect gas behavior. Hence,

$$\bar{h}_m = \frac{n_A}{\rho_{A,\text{sat}} (1 - \phi)}$$

and substituting numerical values, find

$$\bar{h}_m = \frac{0.1 \text{ kg/m}^2 \cdot \text{h} \times 1/3600 \text{ s/h}}{0.02556 \text{ kg/m}^3 (1 - 0.3)} = 1.55 \times 10^{-3} \text{ m/s.}$$

COMMENTS: (1) From knowledge of $\rho_{A,\text{sat}}$, the perfect gas law could be used to obtain the saturation density.

$$\rho_{A,\text{sat}} = \frac{p_{A,\text{sat}} M_A}{\rho T} = \frac{0.03531 \text{ bar} \times 18 \text{ kg/kmol}}{8.314 \times 10^{-2} \text{ m}^3 \cdot \text{bar/kmol} \cdot \text{K} (300\text{K})} = 0.02548 \text{ kg/m}^3.$$  

This value is within 0.3% of that obtained from Table A-6.

(2) Note that psychrometric charts could also be used to obtain $\rho_{A,\text{sat}}$ and $\rho_{A,\infty}$. 

PROBLEM 6.46

KNOWN: Evaporation rate from pan of water of prescribed diameter. Water temperature. Air temperature and relative humidity.

FIND: (a) Convection mass transfer coefficient, (b) Evaporation rate for increased relative humidity, (c) Evaporation rate for increased temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Water vapor is saturated at liquid interface and may be approximated as a perfect gas.

PROPERTIES: Table A-6, Saturated water vapor (T_s = 296K): \( \rho_{A,s} = v_g^{-1} = (49.4 \text{ m}^3/\text{kg})^{-1} = 0.0202 \text{ kg/m}^3 \); (T_s = 320 K): \( \rho_{A,s} = v_g^{-1} = \left(13.98 \text{ m}^3/\text{kg}\right)^{-1} = 0.0715 \text{ kg/m}^3 \).

ANALYSIS: (a) Since evaporation is a convection mass transfer process, the rate equation has the form \( \dot{m}_{\text{evap}} = \dot{h}_m \rho_{A,s} (\rho_{A,s} - \rho_{A,\infty}) \) and the mass transfer coefficient is

\[
\dot{h}_m = \frac{\dot{m}_{\text{evap}}}{\left(\pi D^2/4\right) (\rho_{A,s} - \rho_{A,\infty})} = \frac{1.5 \times 10^{-5} \text{ kg/s}}{0.0179 \text{ m/s}} = 0.0179 \text{ m/s} <
\]

with \( T_s = T_\infty = 23^\circ \text{C} \) and \( \phi_\infty = 0 \).

(b) If the relative humidity of the ambient air is increased to 50%, the ratio of the evaporation rates is

\[
\frac{\dot{m}_{\text{evap}}(\phi_\infty = 0.5)}{\dot{m}_{\text{evap}}(\phi_\infty = 0)} = \frac{\dot{h}_m \rho_{A,s}(T_s - \phi_\infty \rho_{A,s}(T_\infty))}{\dot{h}_m \rho_{A,s}(T_s)} = 1 - \phi_\infty \frac{\rho_{A,s}(T_\infty)}{\rho_{A,s}(T_s)}.
\]

Hence, \( \dot{m}_{\text{evap}}(\phi_\infty = 0.5) = 1.5 \times 10^{-5} \text{ kg/s} \left[1 - 0.5 \frac{0.0202 \text{ kg/m}^3}{0.0715 \text{ kg/m}^3}\right] = 0.75 \times 10^{-5} \text{ kg/s} \).

(c) If the temperature of the ambient air is increased from 23°C to 47°C, with \( \phi_\infty = 0 \) for both cases, the ratio of the evaporation rates is

\[
\frac{\dot{m}_{\text{evap}}(T_s = T_\infty = 47^\circ \text{C})}{\dot{m}_{\text{evap}}(T_s = T_\infty = 23^\circ \text{C})} = \frac{\dot{h}_m \rho_{A,s}(47^\circ \text{C})}{\dot{h}_m \rho_{A,s}(23^\circ \text{C})} = \frac{\rho_{A,s}(47^\circ \text{C})}{\rho_{A,s}(23^\circ \text{C})}.
\]

Hence, \( \dot{m}_{\text{evap}}(T_s = T_\infty = 47^\circ \text{C}) = 1.5 \times 10^{-5} \text{ kg/s} \frac{0.0715 \text{ kg/m}^3}{0.0202 \text{ kg/m}^3} = 5.31 \times 10^{-5} \text{ kg/s} <
\]

COMMENTS: Note the highly nonlinear dependence of the evaporation rate on the water temperature. For a 24°C rise in \( T_s \), \( \dot{m}_{\text{evap}} \) increases by 350%. 
PROBLEM 6.47

KNOWN: Water temperature and air temperature and relative humidity. Surface recession rate.

FIND: Mass evaporation rate per unit area. Convection mass transfer coefficient.

SCHEMATIC:

ASSUMPTIONS: (1) Water vapor may be approximated as a perfect gas, (2) No water inflow; outflow is only due to evaporation.

PROPERTIES: Table A-6, Saturated water: Vapor (305K), $\rho_g = v_g^{-1} = 0.0336 \text{ kg/m}^3$; Liquid (305K), $\rho_f = v_f^{-1} = 995 \text{ kg/m}^3$.

ANALYSIS: Applying conservation of species to a control volume about the water,

$$-M_{A,\text{out}} = M_{A,\text{st}}$$

$$-m_{\text{evap}} A = \frac{d}{dt}(\rho_f V) = \frac{d}{dt}(\rho_f A H) = \rho_f A \frac{dH}{dt}.$$ 

Substituting numerical values, find

$$m_{\text{evap}} = -\rho_f \frac{dH}{dt} = -995 \text{kg/m}^3 \left(-10^{-4} \text{ m/h}\right) \left(1/3600 \text{ s/h}\right)$$

$$m_{\text{evap}} = 2.76 \times 10^{-5} \text{kg/s} \cdot \text{m}^2.$$ <

Because evaporation is a convection mass transfer process, it also follows that

$$m_{\text{evap}} = n_A$$

or in terms of the rate equation,

$$m_{\text{evap}} = h_m \left(\rho_{A,s} - \rho_{A,\infty}\right) = h_m \left[\rho_{A,\text{sat}} (T_s) - \phi_{\infty} \rho_{A,\text{sat}} (T_{\infty})\right]$$

$$m_{\text{evap}} = h_m \rho_{A,\text{sat}} (305\text{K}) \left(1 - \phi_{\infty}\right).$$

and solving for the convection mass transfer coefficient,

$$h_m = \frac{m_{\text{evap}}}{\rho_{A,\text{sat}} (305\text{K}) \left(1 - \phi_{\infty}\right)} = \frac{2.76 \times 10^{-5} \text{kg/s} \cdot \text{m}^2}{0.0336 \text{ kg/m}^3 \left(1 - 0.4\right)} \quad <$$

$$h_m = 1.37 \times 10^{-3} \text{m/s}.$$ <

COMMENTS: Conservation of species has been applied in exactly the same way as a conservation of energy. Note the sign convention.
PROBLEM 6.48

KNOWN: CO$_2$ concentration in air and at the surface of a green leaf. Convection mass transfer coefficient.

FIND: Rate of photosynthesis per unit area of leaf.

SCHEMATIC:

ANALYSIS: Assuming that the CO$_2$ (species A) is consumed as a reactant in photosynthesis at the same rate that it is transferred across the atmospheric boundary layer, the rate of photosynthesis per unit leaf surface area is given by the rate equation,

$$n_A^* = h_m (\rho_{A,\infty} - \rho_{A,s}).$$

Substituting numerical values, find

$$n_A^* = 10^{-2} \text{ m/s} \left( 6 \times 10^{-4} - 5 \times 10^{-4} \right) \text{ kg/m}^3$$

$$n_A^* = 10^{-6} \text{ kg/s} \cdot \text{m}^2.$$

COMMENTS: (1) It is recognized that CO$_2$ transport is from the air to the leaf, and ($\rho_{A,s} - \rho_{A,\infty}$) in the rate equation has been replaced by ($\rho_{A,\infty} - \rho_{A,s}$).

(2) The atmospheric concentration of CO$_2$ is known to be increasing by approximately 0.3% per year. This increase in $\rho_{A,\infty}$ will have the effect of increasing the photosynthesis rate and hence plant biomass production.
**PROBLEM 6.49**

**KNOWN:** Species concentration profile, $C_A(y)$, in a boundary layer at a particular location for flow over a surface.

**FIND:** Expression for the mass transfer coefficient, $h_m$, in terms of the profile constants, $C_{A,\infty}$ and $D_{AB}$. Expression for the molar convection flux, $N_A^\ast$.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Parameters $D$, $E$, and $F$ are constants at any location $x$, (2) $D_{AB}$, the mass diffusion coefficient of $A$ through $B$, is known.

**ANALYSIS:** The convection mass transfer coefficient is defined in terms of the concentration gradient at the wall,

$$h_m(x) = -D_{AB} \frac{\partial C_A / \partial y}_{y=0} \left( \frac{C_{A,s} - C_{A,\infty}}{C_{A,s} - C_{A,\infty}} \right).$$

The gradient at the surface follows from the profile, $C_A(y)$,

$$\frac{\partial C_A}{\partial y}_{y=0} = \frac{\partial}{\partial y} \left( Dy^2 + Ey + F \right)_{y=0} = +E.$$

Hence,

$$h_m(x) = -D_{AB} E \left( \frac{C_{A,s} - C_{A,\infty}}{C_{A,s} - C_{A,\infty}} \right) \left( F - C_{A,\infty} \right).$$

The molar flux follows from the rate equation,

$$N_A^\ast = h_m \left( C_{A,s} - C_{A,\infty} \right) = \frac{-D_{AB} E}{\left( C_{A,s} - C_{A,\infty} \right)} \left( C_{A,s} - C_{A,\infty} \right).$$

$$N_A^\ast = -D_{AB} E.$$ 

**COMMENTS:** It is important to recognize that the influence of species $B$ is present in the property $D_{AB}$. Otherwise, all the parameters relate to species $A$. 
PROBLEM 6.50

KNOWN: Steady, incompressible flow of binary mixture between infinite parallel plates with different species concentrations.

FIND: Form of species continuity equation and concentration distribution. Species flux at upper surface.

SCHEMATIC:

ASSUMPTIONS: (1) Two-dimensional flow, (2) No chemical reactions, (3) Constant properties.

ANALYSIS: For fully developed conditions, \( \frac{\partial C_A}{\partial x} = 0 \). Hence with \( v = 0 \), the species conservation equation reduces to

\[
\frac{d^2 C_A}{dy^2} = 0.
\]

Integrating twice, the general form of the species concentration distribution is

\[
C_A(y) = C_1 y + C_2.
\]

Using appropriate boundary conditions and evaluating the constants,

\[
C_A(0) = C_{A,2} \quad \rightarrow \quad C_2 = C_{A,2}
\]

\[
C_A(L) = C_{A,1} \quad \rightarrow \quad C_1 = \left( C_{A,1} - C_{A,2} \right) / L,
\]

the concentration distribution is

\[
C_A(y) = C_{A,2} + \left( \frac{y}{L} \right) \left( C_{A,1} - C_{A,2} \right).
\]

From Fick’s law, the species flux is

\[
N_A^* (L) = -D_{AB} \frac{dC_A}{dy} \bigg|_{y=L} = \frac{D_{AB}}{L} \left( C_{A,2} - C_{A,1} \right).
\]

COMMENTS: An analogy between heat and mass transfer exists if viscous dissipation is negligible. The energy equation is then \( \frac{d^2 T}{dy^2} = 0 \). Hence, both heat and species transfer are influenced only by diffusion. Expressions for \( T(y) \) and \( q^* (L) \) are analogous to those for \( C_A(y) \) and \( N_A^* (L) \).
PROBLEM 6.51

KNOWN: Flow conditions between two parallel plates, across which vapor transfer occurs.

FIND: (a) Variation of vapor molar concentration between the plates and mass rate of water production per unit area, (b) Heat required to sustain the process.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Fully developed, incompressible flow with constant properties, (3) Negligible body forces, (4) No chemical reactions, (5) All work interactions, including viscous dissipation, are negligible.

ANALYSIS: (a) The flow will be fully developed in terms of the vapor concentration field, as well as the velocity and temperature fields. Hence

\[
\frac{\partial C_A}{\partial x} = 0 \quad \text{or} \quad C_A(x,y) = C_A(y).
\]

Also, with \(\frac{\partial C_A}{\partial t} = 0, \dot{N}_A = 0, v = 0 \text{ and constant } D_{AB}\), the species conservation equation reduces to

\[
\frac{d^2 C_A}{dy^2} = 0.
\]

Separating and integrating twice,

\[
C_A(y) = C_1(y) + C_2.
\]

Applying the boundary conditions,

\[
C_A(0) = C_{A,0} \quad \Rightarrow \quad C_2 = C_{A,0}
\]

\[
C_A(L) = C_{A,L} \quad \Rightarrow \quad C_{A,L} = C_1L + C_2 \quad C_1 = -\frac{C_{A,0} - C_{A,L}}{L}
\]

find the species concentration distribution,

\[
C_A(y) = C_{A,0} - \left( C_{A,0} - C_{A,L} \right) \left( y/L \right).
\]

From Fick’s law, Eq. 6.19, the species transfer rate is

\[
N_A^s = N_{A,s} = -D_{AB} \frac{\partial C_A}{\partial y} \bigg|_{y=0} = D_{AB} \frac{C_{A,0} - C_{A,L}}{L}.
\]

Continued ….
PROBLEM 6.51 (Cont.)

Multiplying by the molecular weight of water vapor, \( M_A \), the mass rate of water production per unit area is

\[
n_A^* = M_A N_A^* = M_A D_{AB} \frac{C_{A,0} - C_{A,L}}{L}.
\]

(b) Heat must be supplied to the bottom surface in an amount equal to the latent and sensible heat transfer from the surface,

\[
q^* = q_{\text{lat}}^* + q_{\text{sen}}^*
\]

\[
q^* = n_{A,s}^* \ h_{fg}\ \left[ -k \ \frac{dT}{dy} \right]_{y=0}.
\]

The temperature distribution may be obtained by solving the energy equation, which, for the prescribed conditions, reduces to

\[
\frac{d^2 T}{dy^2} = 0.
\]

Separating and integrating twice,

\[
T(y) = C_1 y + C_2.
\]

Applying the boundary conditions,

\[
T(0) = T_0 \quad \Rightarrow \quad C_2 = T_0
\]

\[
T(L) = T_L \quad \Rightarrow \quad C_1 = (T_1 - T_0)/L
\]

find the temperature distribution,

\[
T(y) = T_0 - (T_0 - T_L) y/L.
\]

Hence,

\[
-k \ \left[ \frac{dT}{dy} \right]_{y=0} = k \ (T_0 - T_L)/L.
\]

Accordingly,

\[
q^* = M_A D_{AB} \frac{C_{A,0} - C_{A,L}}{L} h_{fg} + k \ (T_0 - T_L)/L.
\]

COMMENTS: Despite the existence of the flow, species and energy transfer across the air are uninfluenced by advection and transfer is only by diffusion. If the flow were not fully developed, advection would have a significant influence on the species concentration and temperature fields and hence on the rate of species and energy transfer. The foregoing results would, of course, apply in the case of no air flow. The physical condition is an example of Poiseuille flow with heat and mass transfer.
PROBLEM 6.52

FIND: (a) Describe physical significance of terms in these equations, (b) Identify approximations and special conditions used to reduce these equations to the boundary layer equations, Eqs. 6.33 and 6.34, (c) Identify the conditions under which these two boundary layer equations have the same form and, hence, an analogy will exist.

ANALYSIS: (a) The energy conservation equation, Eq. E.24, has the form

\[ \rho u \frac{\partial i}{\partial x} + \rho v \frac{\partial i}{\partial y} = \frac{\partial}{\partial x} \left[ k \frac{\partial T}{\partial x} \right] + \frac{\partial}{\partial y} \left[ k \frac{\partial T}{\partial y} \right] + \left[ u \frac{\partial p}{\partial x} + v \frac{\partial p}{\partial y} \right] + \mu \Phi + \dot{q}. \]

The terms, as identified, have the following physical significance:

1. Change of enthalpy (thermal + flow work) advected in x and y directions,
2. Change of conduction flux in x and y directions,
3. Work done by static pressure forces,
4. Word done by viscous stresses,
5. Rate of energy generation.

The species mass conservation equation for a constant total concentration has the form

\[ u \frac{\partial C_A}{\partial x} + v \frac{\partial C_A}{\partial y} = \frac{\partial}{\partial x} \left[ D_{AB} \frac{\partial C_A}{\partial x} \right] + \frac{\partial}{\partial y} \left[ D_{AB} \frac{\partial C_A}{\partial y} \right] + \dot{N}_A, \]

The terms are:

1. Change in species transport due to advection in x and y directions,
2. Change in species transport by diffusion in x and y directions, and
3. Rate of species generation.

(b) The special conditions used to reduce the above equations to the boundary layer equations are:

- Constant properties, incompressible flow, non-reacting species \( \dot{N}_A = 0 \), without internal heat generation \( \dot{q} = 0 \), species diffusion has negligible effect on the thermal boundary layer, \( u(\partial p/\partial x) \) is negligible. The approximations are,

Velocity boundary layer:

\[ \left\{ \begin{array}{c} u \gg v, \\
\partial u/\partial y \gg \partial u/\partial x, \partial v/\partial y \gg \partial v/\partial x \end{array} \right\} \]

Thermal b.l.: \( \frac{\partial T}{\partial y} \gg \frac{\partial T}{\partial x} \)  
Concentration b.l.: \( \frac{\partial C_A}{\partial y} \gg \frac{\partial C_A}{\partial x} \).

The resulting simplified boundary layer equations are

\[ u \frac{\partial T}{\partial x} + v \frac{\partial T}{\partial y} = \alpha \frac{\partial^2 T}{\partial y^2} + \left[ \frac{\partial u}{\partial y} \right]^2 \]
\[ u \frac{\partial C_A}{\partial x} + v \frac{\partial C_A}{\partial y} = D_{AB} \frac{\partial^2 C_A}{\partial y^2} \]

where the terms are: 1. Adective transport, 2. Diffusion, and 3. Viscous dissipation.

(c) When viscous dissipation effects are negligible, the two boundary layer equations have identical form. If the boundary conditions for each equation are of the same form, an analogy between heat and mass (species) transfer exists.
PROBLEM 6.53

FIND: (a) Liquid momentum equation and velocity distribution for the x-direction. Maximum velocity, (b) Continuity equation and density distribution of the gas in the liquid, (c) Expression for the local Sherwood number, (d) Total gas absorption rate for the film, (e) Mass rate of NH$_3$ removal by a water film for prescribed conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) The film is in fully developed, laminar flow, (3) Negligible shear stress at the liquid-gas interface, (4) Constant properties, (5) Negligible gas concentration at x = 0 and y = δ, (6) No chemical reactions in the liquid, (7) Total mass density is constant, (8) Liquid may be approximated as semi-infinite to gas transport.

PROPERTIES: Table A-6, Water, liquid (300K): ρ$_f$ = 1/ν$_f$ = 997 kg/m$^3$, μ = 855 × 10$^{-6}$ N·s/m$^2$, ν = μ/ρ$_f$ = 0.855 × 10$^{-6}$ m$^2$/s.

ANALYSIS: (a) For fully developed flow (v = w = 0, ∂u/∂x = 0), the x-momentum equation is

\[ \mu \left( \frac{\partial^2 u}{\partial y^2} \right) = - (\rho g) \cos \phi. \]

Integrating,

\[ \frac{\partial u}{\partial y} \bigg|_{y=0} = \frac{u}{2\nu} (\frac{\delta^2 - y^2}{2\nu}) \]

Hence,

\[ u_{\text{max}} = \left( \frac{g \cos \phi \delta^2}{2\nu} \right) \]

(b) Species transport within the liquid is influenced by diffusion in the y-direction and convection in the x-direction. Hence, the species continuity equation with u assumed equal to $u_{\text{max}}$ throughout the region of gas penetration is

Continued …..
PROBLEM 6.53 (Cont.)

\[
\frac{u \partial \rho_A}{\partial x} = D_{AB} \frac{\partial^2 \rho_A}{\partial y^2} \quad \frac{\partial^2 \rho_A}{\partial y^2} = \frac{u_{\text{max}}}{D_{AB}} \frac{\partial \rho_A}{\partial x}.
\]

Appropriate boundary conditions are: \( \rho_A(x,0) = \rho_{A,o} \) and \( \rho_A(x,\infty) = 0 \) and the entrance condition is: \( \rho_A(0,y) = 0 \). The problem is therefore analogous to transient conduction in a semi-infinite medium due to a sudden change in surface temperature. From Section 5.7, the solution is then

\[
\frac{\rho_A - \rho_{A,o}}{0 - \rho_{A,o}} = \text{erf} \left( \frac{y}{2(D_{AB}^2 u_{\text{max}})^{1/2}} \right) \quad \rho_A = \left( \frac{\rho_{A,o}}{2(D_{AB}^2 u_{\text{max}})^{1/2}} \right) \text{erfc} \left( \frac{y}{2(D_{AB}^2 u_{\text{max}})^{1/2}} \right)
\]

(c) The Sherwood number is defined as

\[
Sh_x = \frac{h_{m,x} x}{D_{AB}} \quad \text{where} \quad h_{m,x} \equiv \frac{n_{A,x}}{\rho_{A,o}} = -\frac{D_{AB}}{\rho_{A,o}} \frac{\partial \rho_A}{\partial y} \bigg|_{y=0}
\]

\[
\frac{\partial \rho_A}{\partial y} \bigg|_{y=0} = -\rho_{A,o} \frac{2}{(\pi)^{1/2}} \exp \left[ \frac{-y^2 u_{\text{max}}}{4 D_{AB}^2} \right] \frac{1}{2(D_{AB}^2 u_{\text{max}})^{1/2}} \bigg|_{y=0} = -\rho_{A,o} \left( \frac{u_{\text{max}}}{\pi D_{AB}^2} \right)^{1/2}
\]

Hence,

\[
h_{m,x} = \left[ \frac{u_{\text{max}} D_{AB}}{\pi} \right]^{1/2} \quad Sh_x = \frac{1}{(\pi)^{1/2}} \left[ \frac{u_{\text{max}} x}{D_{AB}} \right]^{1/2} = \frac{1}{(\pi)^{1/2}} \left[ \frac{u_{\text{max}}}{\nu} \right]^{1/2} \left[ \frac{\nu}{D_{AB}} \right]^{1/2}
\]

and with \( \text{Re}_x \equiv \frac{u_{\text{max}} x}{\nu} \),

\[
Sh_x = \left[ \frac{1}{(\pi)^{1/2}} \right] \text{Re}_x^{1/2} \quad \text{Sc}^{1/2} = 0.564 \text{Re}_x^{1/2} \quad \text{Sc}^{1/2}.
\]

(d) The total gas absorption rate may be expressed as

\[
n_A = \frac{h_{m,x}}{W L} \eta_{A,o}
\]

where the average mass transfer convection coefficient is

\[
\overline{h}_{m,x} = \frac{1}{L} \int_0^L h_{m,x} \, dx = \frac{1}{L} \left[ \frac{u_{\text{max}} D_{AB}}{\pi} \right]^{1/2} \left[ \frac{L}{x^{1/2}} \right] \int_0^L \, dx = \left[ \frac{4u_{\text{max}} D_{AB}}{\pi L} \right]^{1/2}
\]

Hence, the absorption rate per unit width is

\[
n_A / W = \left( \frac{4u_{\text{max}} D_{AB} L}{\pi} \right)^{1/2} \rho_{A,o}.
\]

(e) From the foregoing results, it follows that the ammonia absorption rate is

\[
n_A = \left[ \frac{4u_{\text{max}} D_{AB} L}{\pi} \right]^{1/2} \eta_{A,o} = \left[ \frac{4 g \cos \phi \delta^2 D_{AB} L}{2\pi \nu} \right]^{1/2} \eta_{A,o}.
\]

Substituting numerical values,

\[
n_A = \left[ \frac{4 \times 9.8 \text{ m/s}^2 \times 1 \times 10^{-3} \text{ m}^2 \left(2 \times 10^{-9} \text{ m}^2/\text{s}\right)^2 2 \text{m}}{2 \times 20.855 \times 10^6 \text{ m}^2/\text{s}} \right]^{1/2} \left( \frac{0.157 \text{ m}}{25 \text{ kg/m}^3} \right) = 6.71 \times 10^{-4} \text{ kg/s}.
\]

**COMMENTS:** Note that \( \rho_{A,o} \neq \rho_{A,\infty} \), where \( \rho_{A,\infty} \) is the mass density of the gas phase. The value of \( \rho_{A,o} \) depends upon the pressure of the gas and the solubility of the gas in the liquid.
PROBLEM 6.54

KNOWN: Cross flow of gas X over object with prescribed characteristic length L, Reynolds number, and average heat transfer coefficient. Thermophysical properties of gas X, liquid Y, and vapor Y.

FIND: Average mass transfer coefficient for same object when impregnated with liquid Y and subjected to same flow conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Heat and mass transfer analogy is applicable, (2) Vapor Y behaves as perfect gas

PROPERTIES: (Given) \( \nu \text{ (m}^2/\text{s)} \) \( k\text{(W/m} \cdot \text{K)} \) \( \alpha \text{(m}^2/\text{s)} \)

<table>
<thead>

Mixture of gas X - vapor Y: \( Sc = 0.72 \)

ANALYSIS: The heat-mass transfer analogy may be written as

\[
\overline{Nu}_L = \frac{\overline{h}_{L\text{L}}}{k} = f \left( Re_L, Pr \right) \quad \overline{Sh}_L = \frac{\overline{h}_{m,L\text{L}}}{D_{AB}} = f \left( Re_L, Sc \right)
\]

The flow conditions are the same for both situations. Check values of \( Pr \) and \( Sc \). For \( Pr \), the properties are those for gas X (B).

\[
Pr = \frac{\nu_B}{\alpha_B} = \frac{21 \times 10^{-6} \text{ m}^2/\text{s}}{29 \times 10^{-6} \text{ m}^2/\text{s}} = 0.72
\]

while \( Sc = 0.72 \) for the gas X (B) - vapor Y (A) mixture. It follows for this situation

\[
\overline{Nu}_L = \frac{\overline{h}_{L\text{L}}}{k} = \overline{Sh}_L = \frac{\overline{h}_{m,L\text{L}}}{D_{AB}} \quad \text{or} \quad \overline{h}_{m,L\text{L}} = \overline{h}_{L\text{L}} \frac{D_{AB}}{k}.
\]

Recognizing that

\[
D_{AB} = \frac{\nu_B}{Sc} = \frac{21.6 \times 10^{-6} \text{ m}^2/\text{s}}{(0.72)} = 30.0 \times 10^{-6} \text{ m}^2/\text{s}
\]

and substituting numerical values, find

\[
\overline{h}_{m,L\text{L}} = 25 \text{ W/m}^2 \cdot \text{K} \times \frac{30.0 \times 10^{-6} \text{ m}^2/\text{s}}{0.030 \text{ W/m} \cdot \text{K}} = 0.0250 \text{ m/s}.
\]

COMMENTS: Note that none of the thermophysical properties of liquid or vapor Y are required for the solution. Only the gas X properties and the Schmidt number (gas X - vapor Y) are required.
PROBLEM 6.55

KNOWN: Free stream velocity and average convection mass transfer coefficient for fluid flow over a surface of prescribed characteristic length.

FIND: Values of $\overline{Sh}_L$, $Re_L$, $Sc$ and $\overline{j}_m$ for (a) air flow over water, (b) air flow over naphthalene, and (c) warm glycerol over ice.

SCHEMATIC:

PROPERTIES: For the fluids at 300K:

<table>
<thead>
<tr>
<th>Table</th>
<th>Fluid(s)</th>
<th>$\nu (m^2/s) \times 10^{-6}$</th>
<th>$D_{AB}(m^2/s)$</th>

<tr>
<td>A-8</td>
<td>Water - Glycerol</td>
<td>-</td>
<td>$0.94 \times 10^{-9}$</td>
</tr>
</tbody>
</table>

ANALYSIS: (a) Water (vapor) - Air:

$$\overline{Sh}_L = \frac{\overline{h}_m L}{D_{AB}} = \frac{(0.01 m/s)1 m}{0.26 \times 10^{-4} m^2/s} = 385$$

$$Re_L = \frac{\nu L}{\nu} = \frac{15.89 \times 10^{-6} m^2/s}{1 m/s} = 6.29 \times 10^4$$

$$Sc = \frac{\nu}{D_{AB}} = \frac{0.16 \times 10^{-6} m^2/s}{0.26 \times 10^{-6} m^2/s} = 0.62$$

$$\overline{j}_m = \overline{St}_m Sc^{2/3} = \frac{\overline{h}_m}{\nu} Sc^{2/3} = \frac{0.01 m/s}{1 m/s} (0.62)^{2/3} = 0.0073.$$  

(b) Naphthalene (vapor) - Air:

$$\overline{Sh}_L = 1613 \quad Re_L = 6.29 \times 10^4 \quad Sc = 2.56 \quad \overline{j}_m = 0.0187.$$  

(c) Water (liquid) - Glycerol:

$$\overline{Sh}_L = 1.06 \times 10^7 \quad Re_L = 1577 \quad Sc = 6.74 \times 10^5 \quad \overline{j}_m = 76.9.$$  

COMMENTS: Note the association of $\nu$ with the freestream fluid B.
PROBLEM 6.56

KNOWN: Characteristic length, surface temperature, average heat flux and airstream conditions associated with an object of irregular shape.

FIND: Whether similar behavior exists for alternative conditions, and average convection coefficient for similar cases.

$q^*, \text{ W/m}^2$ | 12,000 | - | - | - | - |
|h, W/m$^2 \cdot \text{K}$ | 240 | - | - | - | - |
| $D_{AB} \times 10^{-44}, \text{ m}^2 / \text{s}$ | - | - | - | 1.12 | 1.12 |

ASSUMPTIONS: (1) Heat and mass transfer analogy is applicable; that is, $f(\text{Re}_L, \text{Pr}) = f(\text{Re}_L, \text{Sc})$, see Eqs. 6.57 and 6.61.

PROPERTIES: Table A-4, Air $(300 \text{K}, 1 \text{ atm})$: $v_1 = 15.89 \times 10^{-6} \text{ m}^2 / \text{s}$, Pr$_1 = 0.71$, $k_1 = 0.0263 \text{ W/m} \cdot \text{K}$.

ANALYSIS: $\text{Re}_{L,1} = v_1 L_1 / \nu_1 = (100 \text{ m/s} \times 1 \text{ m}) / 15.89 \times 10^{-6} \text{ m}^2 / \text{s} = 6.29 \times 10^6$ and Pr$_1 = 0.71$.

Case 2: $\text{Re}_{L,2} = \frac{v_2 L_2}{\nu_2} = \frac{50 \text{ m/s} \times 2 \text{ m}}{15.89 \times 10^{-6} \text{ m}^2 / \text{s}} = 6.29 \times 10^6$, Pr$_2 = 0.71$.

From Eq. 6.57 it follows that Case 2 is analogous to Case 1. Hence $\bar{\text{Nu}}_2 = \bar{\text{Nu}}_1$ and

$$\bar{h}_2 = \frac{h_1 L_1}{k_1} = \frac{k_2}{L_2} = \frac{h_1 L_1}{L_2} = \frac{240}{2 \text{ m}} \frac{1 \text{ m}}{2 \text{ m}} = 120 \text{ W/m}^2 \cdot \text{K}.$$  <

Case 3: With $p = 0.2 \text{ atm}$, $v_3 = 79.45 \times 10^{-6} \text{ m}^2 / \text{s}$ and $\text{Re}_{L,3} = \frac{v_3 L_3}{\nu_3} = \frac{50 \text{ m/s} \times 2 \text{ m}}{79.45 \times 10^{-6} \text{ m}^2 / \text{s}} = 1.26 \times 10^6$, Pr$_3 = 0.71$.

Since $\text{Re}_{L,3} \neq \text{Re}_{L,1}$, Case 3 is not analogous to Case 1.  <

Case 4: $\text{Re}_{L,4} = \text{Re}_{L,1}$, Sc$_4 = \frac{v_4}{D_{AB,4}} = \frac{15.89 \times 10^{-6} \text{ m}^2 / \text{s}}{1.12 \times 10^{-4} \text{ m}^2 / \text{s}} = 0.142 \neq \text{Pr}_1$.

Hence, Case 4 is not analogous to Case 1.  <

Case 5: $\text{Re}_{L,5} = \frac{v_5 L_5}{\nu_5} = \frac{250 \text{ m/s} \times 2 \text{ m}}{79.45 \times 10^{-6} \text{ m}^2 / \text{s}} = 6.29 \times 10^6 = \text{Re}_{L,1}$

$\text{Sc}_5 = \frac{v_5}{D_{AB,5}} = \frac{79.45 \times 10^{-6} \text{ m}^2 / \text{s}}{1.12 \times 10^{-4} \text{ m}^2 / \text{s}} = 0.71 = \text{Pr}_1$.

Hence, conditions are analogous to Case 1, and with $\bar{\text{Sh}}_5 = \bar{\text{Nu}}_1$,

$$\bar{h}_5 = \frac{h_1 L_1}{k_1} \frac{D_{AB,5}}{L_5} = \frac{240 \text{ W/m} \cdot \text{K}}{2 \text{ m}^2 / \text{s}} \frac{1 \text{ m}}{2 \text{ m} \times 0.0263 \text{ W/m} \cdot \text{K}} = 0.51 \text{ m/s}.$$  <

COMMENTS: Note that Pr, $k$ and Sc are independent of pressure, while $V$ and $D_{AB}$ vary inversely with pressure.
PROBLEM 6.57

KNOWN: Surface temperature and heat loss from a runner’s body on a cool, spring day. Surface temperature and ambient air-conditions for a warm summer day.

FIND: (a) Water loss on summer day, (b) Total heat loss on summer day.

SCHEMATIC:

ASSUMPTIONS: (1) Heat and mass transfer analogy is applicable. Hence, from Eqs. 6.57 and 6.61, \( f(Re_L, Pr) \) is of same form as \( f(Re_L, Sc) \), (2) Negligible surface evaporation for Case 1, (3) Constant properties, (4) Water vapor is saturated for Case 2 surface and may be approximated as a perfect gas.

PROPERTIES: Air (given): \( \nu = 1.6 \times 10^{-5} \text{ m}^2/\text{s} \), \( k = 0.026 \text{ W/m} \cdot \text{K} \), \( Pr = 0.70 \); Water vapor-air (given): \( D_{AB} = 2.3 \times 10^{-5} \text{ m}^2/\text{s} \); Table A-6, Saturated water vapor (\( T_{\infty} = 303 \text{K} \)):
\[
\rho_{A,\text{sat}} = v^{-1}_g = 0.030 \text{ kg/m}^3; \quad (T_{\infty} = 308 \text{K}) : \quad \rho_{A,\text{sat}} = v^{-1}_g = 0.039 \text{ kg/m}^3, \quad h_{fg} = 2419 \text{ kJ/kg}.
\]

ANALYSIS: (a) With \( Re_L = Re_L,1 \) and \( Sc = \nu/D_{AB} = 1.6 \times 10^{-5} \text{ m}^2/\text{s}/2.3 \times 10^{-5} \text{ m}^2/\text{s} = 0.70 = Pr \), it follows that \( \bar{Sh}_L = \bar{Nu}_L \). Hence
\[
\frac{\bar{h}_{mL}}{D_{AB}} = \frac{\bar{h}_m}{k} = \frac{\bar{h}_m}{k} \frac{q_l}{A_s (T_s - T_{\infty})} \frac{D_{AB}}{k} = \frac{500 \text{ W}}{A_s (20 \text{K})} \frac{2.3 \times 10^{-5} \text{ m}^2/\text{s}}{0.026 \text{ W/m} \cdot \text{K}} = \left[ \frac{0.0221}{A_s} \right] \text{m/s}.
\]
Hence, from the rate equation, with \( A_s \) as the wetted surface
\[
n_A = \frac{\bar{h}_m A_s (\rho_{A,s} - \rho_{A,\infty})}{\bar{h}_{m}} = \left[ \frac{0.0221}{A_s} \right] \frac{m}{s} A_s \left[ \rho_{A,s} (T_{s,2}) - \phi_{\infty} \rho_{A,\text{sat}} (T_{\infty,2}) \right]
\]
\[
n_A = 0.0221 \text{ m}^3/\text{s} (0.039 - 0.6 \times 0.030) \text{kg/m}^3 = 4.64 \times 10^{-4} \text{kg/s}.
\]
(b) The total heat loss for Case 2 is comprised of sensible and latent contributions, where
\[
q_2 = q_{\text{sen}} + q_{\text{lat}} = \bar{h}_A s (T_{s,2} - T_{\infty,2}) + n_A h_{fg}.
\]
Hence, with \( \bar{h}_A s = q_1/(T_{s,1} - T_{\infty,1}) = 25 \text{ W/K} \),
\[
q_2 = 25 \text{ W/K } (35 - 30) ^{\circ} \text{ C} + 4.64 \times 10^{-4} \text{kg/s} \times 2.419 \times 10^6 \text{ J/kg}
\]
\[
q_2 = 125 \text{ W} + 1122 \text{ W} = 1247 \text{ W}.
\]

COMMENTS: Note the significance of the evaporative cooling effect.
PROBLEM 6.58

KNOWN: Heat transfer results for an irregularly shaped object.

FIND: (a) The concentration, \( C_A \), and partial pressure, \( p_A \), of vapor in an airstream for a drying process of an object of similar shape, (b) Average mass transfer flux, \( n_A^* \left( \text{kg/s} \cdot \text{m}^2 \right) \).

SCHEMATIC:

ASSUMPTIONS: (1) Heat-mass transfer analogy applies, (b) Perfect gas behavior.

PROPERTIES: Table A-4, Air (323K, 1 atm): \( v = 18.20 \times 10^{-6} \text{ m}^2/\text{s}, \Pr = 0.703, \ k = 28.0 \times 10^{-3} \text{ W/m} \cdot \text{K}; \) Plastic vapor (given): \( \mu_A = 82 \text{ kg/kmol}, p_{\text{sat}}(50^\circ \text{C}) = 0.0323 \text{ atm}, D_{AB} = 2.6 \times 10^{-5} \text{ m}^2/\text{s}. \)

ANALYSIS: (a) Calculate Reynolds numbers

\[
Re_1 = \frac{V_1 L_1}{v} = \frac{120 \text{ m/s} \times 1 \text{ m}}{18.2 \times 10^{-6} \text{ m}^2/\text{s}} = 6.59 \times 10^6
\]

\[
Re_2 = \frac{V_2 L_2}{v} = \frac{60 \text{ m/s} \times 2 \text{ m}}{18.2 \times 10^{-6} \text{ m}^2/\text{s}} = 6.59 \times 10^6.
\]

Note that

\[
Pr_1 = 0.703 \quad Sc_2 = \frac{v}{D_{AB}} = \frac{18.2 \times 10^{-6} \text{ m}^2/\text{s}}{2.6 \times 10^{-5} \text{ m}^2/\text{s}} = 0.700.
\]

Since \( Re_1 = Re_2 \) and \( Pr_1 = Sc_2 \), the dimensionless solutions to the energy and species equations are identical. That is, from Eqs. 6.54 and 6.58,

\[
T^* \left( x^*, y^* \right) = C_A^* \left( x^*, y^* \right)
\]

\[
\frac{T - T_S}{T_{\infty} - T_S} = \frac{C_A - C_{A,s}}{C_{A,\infty} - C_{A,s}}
\]

(1)

where \( T^* \) and \( C_A^* \) are defined by Eqs. 6.37 and 6.38, respectively. Now, determine

\[
\frac{p_{A,sat}}{RT} = \left( 0.0323 \text{ atm/8.205} \times 10^{-2} \text{ m}^3/\text{atm/kmol} \cdot \text{K} \times (273 + 50) \text{ K} \right)
\]

\[
C_{A,s} = 1.219 \times 10^{-3} \text{ kmol/kg}.
\]

Continued …..
PROBLEM 6.58 (Cont.)

Substituting numerical values in Eq. (1),

\[ C_A = C_{A,s} + \left( C_{A,\infty} - C_{A,s} \right) \frac{T - T_s}{T_{\infty} - T_s} \]

\[ C_A = 1.219 \times 10^{-3} \text{ kmol/m}^3 + \left( 0 - 1.219 \times 10^{-3} \right) \text{ kmol/m}^3 \left( \frac{80 - 100}{0 - 100} \right) ^\circ \text{C} \]

\[ C_A = 0.975 \times 10^{-3} \text{ kmol/m}^3. \]

The vapor pressure is then

\[ p_A = C_A \mathcal{RT} = 0.0258 \text{ atm.} \]

(b) For case 1, \( q^* = 2000 \text{ W/m}^2 \). The rate equations are

\[ q^* = \bar{h} (T_s - T_{\infty}) \quad (2) \]

\[ n_A^* = \bar{h}_m \left( C_{A,s} - C_{A,\infty} \right) M_A. \quad (3) \]

From the analogy

\[ \overline{Nu_L} = \overline{Sh_L} \quad \rightarrow \quad \frac{\bar{h} L_1}{k} = \frac{\bar{h}_m L_2}{D_{AB}} \quad \text{or} \quad \frac{\bar{h}}{\bar{h}_m} = \frac{L_2}{L_1} \frac{k}{D_{AB}}. \quad (4) \]

Combining Eqs. (2) - (4),

\[ n_A^* = q^* \frac{\bar{h}_m}{\bar{h}} \frac{\left( C_{A,s} - C_{A,\infty} \right) M_A}{(T_s - T_{\infty})} = q^* \frac{L_1 D_{AB}}{L_2 k} \frac{\left( C_{A,s} - C_{A,\infty} \right) M_A}{(T_s - T_{\infty})} \]

which numerically gives

\[ n_A^* = 2000 \text{ W/m}^2 \frac{1 \text{ m} \left( 2.6 \times 10^{-5} \text{ m}^2 / \text{s} \right)}{2 \text{ m} \left( 28 \times 10^{-3} \text{ W/m} \cdot \text{K} \right)} \frac{\left( 1.219 \times 10^{-3} - 0 \right) \text{ kmol/m}^3 \left( 82 \text{ kg/kmol} \right)}{(100 - 0) \text{ K}} \]

\[ n_A^* = 9.28 \times 10^{-4} \text{ kg/s} \cdot \text{m}^2. \]

COMMENTS: Recognize that the analogy between heat and mass transfer applies when the conservation equations and boundary conditions are of the same form.
PROBLEM 6.59

KNOWN: Convection heat transfer correlation for flow over a contoured surface.

FIND: (a) Evaporation rate from a water film on the surface, (b) Steady-state film temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (b) Constant properties, (c) Negligible radiation, (d) Heat and mass transfer analogy is applicable.

PROPERTIES: Table A-4, Air (300K, 1 atm): \( k = 0.0263 \text{ W/m}\cdot\text{K}, \nu = 15.89\times10^{-6} \text{ m}^2/\text{s}, \text{Pr} = 0.707; \)
Table A-6, Water (\( T_s \approx 280\text{K} \)): \( \nu_g = 130.4 \text{ m}^3/\text{kg}, h_{fg} = 2485 \text{ kJ/kg}; \) Table A-8, Water-air (\( T \approx 298\text{K} \)): \( D_{AB} = 0.26\times10^{-4} \text{ m}^2/\text{s}. \)

ANALYSIS: (a) The mass evaporation rate is \( \dot{m}_{\text{evap}} = n_A = \bar{h}_m \left[ \rho_{A,\text{sat}} (T_s) - \phi_{\infty} \rho_{A,\text{sat}} (T_{\infty}) \right] = \bar{h}_m \rho \rho_{A,\text{sat}} (T_s). \)

From the heat and mass transfer analogy: \( \text{Sh}_L = 0.43 \text{Re}_L^{0.58} \text{Sc}^{0.4} \)

\[
\begin{align*}
\text{Re}_L & = \frac{VL}{\nu} = \frac{(10 \text{ m/s}) 1\text{ m}}{15.89\times10^{-6} \text{ m}^2/\text{s}} = 6.29\times10^5 \\
\text{Sc} & = \frac{\nu}{D_{AB}} = \frac{15.89\times10^{-6} \text{ m}^2/\text{s}}{26\times10^{-4} \text{ m}^2/\text{s}} = 0.61 \\
\text{Sh}_L & = 0.43 (6.29\times10^5)^{0.58} (0.61)^{0.4} = 814 \\
\bar{h}_m & = \frac{D_{AB}}{L} \text{Sh}_L = \frac{0.26\times10^{-4} \text{ m}^2/\text{s}}{1\text{ m}} (814) = 0.0212 \text{ m/s} \\
\rho_{A,\text{sat}} (T_s) & = \nu_g (T_s)^{-1} = 0.0077 \text{ kg/m}^3.
\end{align*}
\]
Hence, \( \dot{m}_{\text{evap}} = 0.0212\text{m/s} \times 1\text{m}^2 \times 0.0077\text{kg/m}^3 = 1.63\times10^{-4} \text{ kg/s}. \)

(b) From a surface energy balance, \( q_{\text{conv}}'' = q_{\text{evap}}'' \), or

\[
\bar{h}_L (T_{\infty} - T_s) = \dot{m}_{\text{evap}} h_{fg} \\
T_s = T_{\infty} - \left( \frac{\dot{m}_{\text{evap}} h_{fg}}{\bar{h}_L} \right).
\]

With \( \text{Nu}_L = 0.43 (6.29\times10^5)^{0.58} (0.707)^{0.4} = 864 \)

\[
\begin{align*}
\bar{h}_L & = \frac{k}{L \text{Nu}_L} = \frac{0.0263 \text{ W/m}\cdot\text{K}}{864} = 22.7 \text{ W/m}^2\cdot\text{K} \\
\bar{h}_L & = \frac{1.63\times10^{-4} \text{ kg/s} \cdot \text{m}^2}{22.7 \text{ W/m}^2\cdot\text{K} (2.485\times10^6 \text{ J/kg})} = 282.2\text{K}.
\end{align*}
\]

COMMENTS: The saturated vapor density, \( \rho_{A,\text{sat}} \), is strongly temperature dependent, and if the initial guess of \( T_s \) needed for its evaluation differed from the above result by more than a few degrees, the density would have to be evaluated at the new temperature and the calculations repeated.
PROBLEM 6.60

KNOWN: Surface area and temperature of a coated turbine blade. Temperature and pressure of air flow over the blade. Molecular weight and saturation vapor pressure of the naphthalene coating. Duration of air flow and corresponding mass loss of naphthalene due to sublimation.

FIND: Average convection heat transfer coefficient.

SCHEMATIC:

ASSUMPTIONS: (1) Applicability of heat and mass transfer analogy, (2) Negligible change in $A_s$ due to mass loss, (3) Naphthalene vapor behaves as an ideal gas, (4) Solid/vapor equilibrium at surface of coating, (5) Negligible vapor density in freestream of air flow.

PROPERTIES: *Table A-4*, Air ($T = 300K$): $\rho = 1.161 \text{ kg/m}^3$, $c_p = 1007 \text{ J/kg} \cdot \text{K}$, $\alpha = 22.5 \times 10^{-6} \text{ m}^2/\text{s}$.

*Table A-8*, Naphthalene vapor/air ($T = 300K$): $D_{AB} = 0.62 \times 10^{-5} \text{ m}^2/\text{s}$.

ANALYSIS: From the rate equation for convection mass transfer, the average convection mass transfer coefficient may be expressed as

$$\bar{h}_m = \frac{n_a}{A_s \left( \rho_{A,s} - \rho_{A,\infty} \right)} = \frac{\Delta m / \Delta t}{A_s \rho_{A,s}}$$

where

$$\rho_{A,s} = \rho_{A,sat} \left( T_s \right) = \frac{m \rho_{A,sat}}{9RT_s} = \frac{(128.16 \text{ kg/kmol})1.33 \times 10^{-4} \text{ bar}}{0.08314 \text{ m} \cdot \text{bar/kmol} \cdot \text{K} (300\text{K})} = 6.83 \times 10^{-4} \text{ kg/m}^3$$

Hence,

$$\bar{h}_m = \frac{0.008 \text{ kg} / (30 \text{ min} \times 60 \text{ s/min})}{0.05 \text{ m}^2 \left( 6.83 \times 10^{-4} \text{ kg/m}^3 \right)} = 0.13 \text{ m/s}$$

Using the heat and mass transfer analogy with $n = 1/3$, we then obtain

$$\bar{h} = \bar{h}_m \rho c_p Le^{2/3} = \bar{h}_m \rho c_p \left( \frac{\alpha}{D_{AB}} \right)^{2/3} = 0.130 \text{ m/s} \left( 1.161 \text{ kg/m}^3 \right) \times$$

$$1007 \text{ J/kg} \cdot \text{K} \left(22.5 \times 10^{-6} / 0.62 \times 10^{-5}\right)^{2/3} = 359 \text{ W/m}^2 \cdot \text{K}$$

COMMENTS: The naphthalene sublimation technique has been used extensively to determine convection coefficients associated with complex flows and geometries.
PROBLEM 6.61

KNOWN: Mass transfer experimental results on a half-sized model representing an engine strut.

FIND: (a) The coefficients C and m of the correlation \( \frac{\bar{Sh}_L}{n!} = \frac{C^{1/3}}{r!(n-r)!} \) for the mass transfer results, (b) Average heat transfer coefficient, \( \overline{h} \), for the full-sized strut with prescribed operating conditions, (c) Change in total heat rate if characteristic length \( L_H \) is doubled.

SCHEMATIC: Mass transfer Heat transfer

ASSUMPTIONS: Analogy exists between heat and mass transfer.

PROPERTIES: Table A-4, Air \( T = (T_{\infty} + T_s) / 2 = 400K, \) 1 atm: \( V = 26.41 \times 10^{-6} m^2/s, k = 0.0338 W/m \cdot K, Pr = 0.690; \) \( T = 300K \): \( V_B = 15.89 \times 10^{-6} m^2/s; \) Table A-8, Naphthalene-air \( (300K, 1 \ atm) \): \( \nu_B = 0.62 \times 10^{-5} m/s, Sc = \nu_B / D_{AB} = 15.89 \times 10^{-6} m^2/s/0.62 \times 10^{-5} m^2/s = 2.56. \)

ANALYSIS: (a) The correlation for the mass transfer experimental results is of the form \( \bar{Sh}_L = CRe_L^{m}Sc^{1/3} \). The constants C,m may be evaluated from two data sets of \( \bar{Sh}_L \) and \( Re_L \); choosing the middle sets (2,3):

\[
\frac{\left( \frac{\bar{Sh}_L}{n!} \right)_{2}}{\left( \frac{\bar{Sh}_L}{n!} \right)_{3}} = \frac{\left( \frac{Re_L}{n!} \right)_{2}}{\left( \frac{Re_L}{n!} \right)_{3}} \text{ or } m = \frac{\log \left( \frac{\bar{Sh}_L}{n!} \right)_{2}/\left( \frac{\bar{Sh}_L}{n!} \right)_{3}}{\log \left( \frac{Re_L}{n!} \right)_{2}/\left( \frac{Re_L}{n!} \right)_{3}} = \log \left[ \frac{491/568}{120,000/144,000} \right] = 0.80. \]

Then, using set 2, find
\[
C = \frac{\left( \frac{\bar{Sh}_L}{n!} \right)_{2}}{\left( \frac{Re_L}{n!} \right)_{2}^{1/3}} \left( \frac{Re_L}{n!} \right)_{2}^{1/3} = \frac{491}{(120,000)^{0.8}} \times 2.56^{1/3} = 0.031. \]

(b) For the heat transfer analysis of the strut, the correlation will be of the form \( \overline{Nu}_L = \overline{h}_L \cdot L_H / k = 0.031 Re_L^{0.8} Pr^{1/3} \) where \( Re_L = V L_H / \nu \) and the constants C,m were determined in Part (a). Substituting numerical values,

\[
\overline{h}_L = \overline{Nu}_L \cdot \frac{k}{L_H} = 0.031 \left[ \frac{60 m/s \times 0.06 m}{26.41 \times 10^{-6} m^2/s} \right]^{0.8} \times 0.690^{1/3} \times 0.0338 W/m \cdot K / 0.06 m = 198 W/m^2 \cdot K. \]

(c) The total heat rate for the strut of characteristic length \( L_H \) is \( q = \overline{h} \cdot A_s (T_s - T_{\infty}) \), where \( A_s = 2.2 L_H^{-1} \) and

\[
\overline{h} \sim \overline{Nu}_L \cdot L_H^{-1} \sim Re_L^{0.8} \cdot L_H^{-1} \sim \overline{h}_L \cdot 0.8 \cdot L_H^{-1} \sim L_H^{0.2} \cdot A_s \sim L_H^{0.8} \]

Hence, \( q \sim \overline{h} \cdot A_s \sim \left( L_H^{-0.2} \right) \left( L_H^{0.8} \right) \sim L_H^{0.8}. \) If the characteristic length were doubled, the heat rate would be increased by a factor of (2)^{0.8} = 1.74.
PROBLEM 6.62

KNOWN: Boundary layer temperature distribution for flow of dry air over water film.

FIND: Evaporative mass flux and whether net energy transfer is to or from the water.

SCHEMATIC:

ASSUMPTIONS: (1) Heat and mass transfer analogy is applicable, (2) Water is well insulated from below.

PROPERTIES: Table A-4, Air ($T_s = 300K$, 1 atm): $k = 0.0263 \text{ W/m-K}$; Table A-6, Water vapor ($T_s = 300K$): $\rho_{A,s} = v_g^{-1} = 0.0256 \text{ kg/m}^3$, $h_{fg} = 2.438 \times 10^6 \text{ J/kg}$; Table A-8, Air-water vapor ($T_s = 300K$): $D_{AB} = 0.26 \times 10^{-4} \text{ m}^2 / \text{s}$.

ANALYSIS: From the heat and mass transfer analogy,

$$\frac{\rho_A - \rho_{A,s}}{\rho_{A,\infty} - \rho_{A,s}} = 1 - \exp \left[ -Sc \frac{u_{\infty} y}{v} \right] .$$

Using Fick’s law at the surface ($y = 0$), the species flux is

$$n_A^* = -D_{AB} \frac{\partial \rho_A}{\partial y} \bigg|_{y=0} = + \rho_{A,s} D_{AB} Sc \frac{u_{\infty}}{v} .$$

$$n_A^* = 0.0256 \text{ kg/m}^3 \times 0.26 \times 10^{-4} \text{ m}^2 / \text{s} \times 0.6 \times 5000 \text{ m}^{-1} = 2.00 \times 10^{-3} \text{ kg/s} \cdot \text{m}^2 .$$

The net heat flux to the water has the form

$$q_{\text{net}}^* = q_{\text{conv}}^* - q_{\text{evap}}^* = +k \frac{\partial T}{\partial y} \bigg|_{y=0} - n_A^* h_{fg} = k(T_{\infty} - T_s) Pr \frac{u_{\infty}}{v} - n_A^* h_{fg}$$

and substituting numerical values, find

$$q_{\text{net}}^* = 0.0263 \frac{W}{\text{m} \cdot \text{K}} (100K) 0.7 \times 5000 \text{ m}^{-1} - 2 \times 10^{-3} \frac{\text{kg}}{\text{s} \cdot \text{m}^2} \times 2.438 \times 10^6 \text{ J/kg}$$

$$q_{\text{net}}^* = 9205 \text{ W/m}^2 - 4876 \text{ W/m}^2 = 4329 \text{ W/m}^2 .$$

Since $q_{\text{net}}^* > 0$, the net heat transfer is to the water.

COMMENTS: Note use of properties ($D_{AB}$ and $k$) evaluated at $T_s$ to determine surface fluxes.
PROBLEM 6.63

KNOWN: Distribution of local convection heat transfer coefficient for obstructed flow over a flat plate with surface and air temperatures of 310K and 290K, respectively.

FIND: Average convection mass transfer coefficient.

SCHEMATIC:

ASSUMPTIONS: Heat and mass transfer analogy is applicable.

PROPERTIES: Table A-4, Air \( T_f = \left( T_s + T_\infty \right)/2 = \left( 310 + 290 \right) K/2 = 300 \) K, 1 atm:
\( k = 0.0263 \) W/m K, \( v = 15.89 \times 10^{-6} \) m/s, \( \text{Pr} = 0.707 \). Table A-8, Air-napthalene (300K, 1 atm):
\( D_{AB} = 0.62 \times 10^{-5} \) m/s, \( \text{Sc} = v/D_{AB} = 2.56 \).

ANALYSIS: The average heat transfer coefficient is
\[
\overline{h}_L = \frac{1}{L} \int_0^L h_x dx = \frac{1}{L} \int_0^L \left( 0.7 + 13.6x - 3.4x^2 \right) dx
\]
\[
\overline{h}_L = 0.7 + 6.8L - 1.13L^2 = 10.9 \text{ W/m}^2 \cdot \text{K}.
\]

Applying the heat and mass transfer analogy with \( n = 1/3 \), Equation 6.66 yields
\[
\frac{\overline{Nu}_L}{Pr^{1/3}} = \frac{\overline{Sh}_L}{Sc^{1/3}}
\]

Hence,
\[
\frac{\overline{h}_{m,L}}{D_{AB}} = \frac{\overline{h}_L}{k} \frac{Sc^{1/3}}{Pr^{1/3}}
\]
\[
\overline{h}_{m,L} = \frac{\overline{h}_L D_{AB} Sc^{1/3}}{k Pr^{1/3}} = 10.9 \text{ W/m}^2 \cdot \text{K} \left( \frac{0.62 \times 10^{-5} \text{ m}^2 / \text{s}}{0.0263 \text{ W/m} \cdot \text{K}} \right)^{1/3} \left( \frac{2.56}{0.707} \right)^{1/3}
\]
\[
\overline{h}_{m,L} = 0.00395 \text{ m/s}.
\]

COMMENTS: The napthalene sublimation method provides a useful tool for determining local convection coefficients.
PROBLEM 6.64

KNOWN: Radial distribution of local Sherwood number for uniform flow normal to a circular disk.

FIND: (a) Expression for average Nusselt number. (b) Heat rate for prescribed conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Constant properties, (2) Applicability of heat and mass transfer analogy.

PROPERTIES: Table A-4, Air \(T = 75^\circ C = 348 \text{ K}\): \(k = 0.0299 \text{ W/m} \cdot \text{K}, \text{Pr} = 0.70\).

ANALYSIS: (a) From the heat and mass transfer analogy, Equation 6.66,

\[
\overline{\text{Nu}_D} = \frac{\overline{\text{Sh}_D}}{\text{Pr}^{0.36}} = \frac{\text{Sh}_D}{\text{Sc}^{0.36}}
\]

where

\[
\overline{\text{Sh}_D} = \frac{1}{A_s} \int_{A_s} \text{Sh}_D(r) dA_s = \frac{\text{Sh}_D}{\pi r_0^2} 2\pi \int_0^{r_0} \left[1 + a \left(\frac{r}{r_0}\right)^n\right] dr
\]

\[
\overline{\text{Sh}_D} = \frac{2\text{Sh}_D}{r_0^2} \left[\frac{r^2}{2} + \frac{ar^n + 2}{(n + 2)r_0^n}\right]_0^{r_0} = \text{Sh}_D \left[1 + 2a/(n + 2)\right]
\]

Hence,

\[
\overline{\text{Nu}_D} = 0.814 \left[1 + 2a/(n + 2)\right] \text{Re}_D^{1/2} \text{Pr}^{0.36}.
\]

(b) The heat rate for these conditions is

\[
q = \overline{\text{h}} A (T_s - T_\infty) = 0.814 \left[1 + 2a/(n + 2)\right] \frac{\text{K}}{\text{D}} \text{Re}_D^{1/2} \text{Pr}^{0.36} \left(\frac{\pi D^2}{4}\right)^{1/2} (T_s - T_\infty)
\]

\[
q = 0.814 \left(1 + 2.4/7.5\right) 0.0299 \text{ W/m} \cdot \text{K} \left(\pi 0.02 \text{ m/4}\right) \left(5 \times 10^4\right)^{1/2} (0.07)^{0.36} (100^\circ C)
\]

\[q = 9.92 \text{ W}.
\]

COMMENTS: The increase in \(h(r)\) with \(r\) may be explained in terms of the sharp turn which the boundary layer flow must make around the edge of the disk. The boundary layer accelerates and its thickness decreases as it makes the turn, causing the local convection coefficient to increase.
PROBLEM 6.65

KNOWN: Convection heat transfer correlation for wetted surface of a sand grouse. Initial water content of surface. Velocity of bird and ambient air conditions.

FIND: Flight distance for depletion of 50% of initial water content.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Vapor behaves as a perfect gas, (3) Constant properties, (4) Applicability of heat and mass transfer analogy.

PROPERTIES: Air (given): \( v = 16.7 \times 10^{-6} \text{ m}^2 / \text{s} \); Air-water vapor (given):
\( D_{AB} = 0.26 \times 10^{-4} \text{ m}^2 / \text{s} \); Table A-6, Water vapor (\( T_s = 305 \text{ K} \)): \( \nu_g = 29.74 \text{ m}^3 / \text{kg} \); (\( T_s = 310 \text{ K} \)), \( \nu_g = 22.93 \text{ m}^3 / \text{kg} \).

ANALYSIS: The maximum flight distance is
\[
X_{\text{max}} = V t_{\text{max}}
\]
where the time to deplete 50% of the initial water content \( \Delta M \) is
\[
t_{\text{max}} = \frac{\Delta M}{\dot{m}_{\text{evap}}} = \frac{\Delta M}{h_m A_s (\rho_{A,s} - \rho_{A,\infty})}.
\]
The mass transfer coefficient is
\[
\bar{h}_m = Sh_L \frac{D_{AB}}{L} = 0.034 \text{Re}_L^{4/5} \text{Sc}^{1/3} \frac{D_{AB}}{L}
\]
\( \text{Sc} = \frac{v}{D_{AB}} = 0.642, \quad L = (A_s)^{1/2} = 0.2 \text{ m} \)
\( \text{Re}_L = \frac{V L}{v} = \frac{30 \text{ m/s} \times 0.2 \text{ m}}{16.7 \times 10^{-6} \text{ m}^2 / \text{s}} = 3.59 \times 10^5 \)
\( \bar{h}_m = 0.034 \left( 3.59 \times 10^5 \right)^{4/5} \left( 0.642 \right)^{1/3} \left( 0.26 \times 10^{-4} \text{ m}^2 / \text{s} / 0.2 \text{ m} \right) = 0.106 \text{ m/s} \).

Hence,
\[
t_{\text{max}} = \frac{0.025 \text{ kg}}{0.106 \text{ m/s} \left( 0.04 \text{ m}^2 \right) \left[ (29.74)^{-1} - 0.25 (22.93)^{-1} \right] \text{ kg/m}^3} = 259 \text{ s}
\]
\[
X_{\text{max}} = 30 \text{ m/s} (259 \text{ s}) = 7785 \text{ m} = 7.78 \text{ km}.
\]

COMMENTS: Evaporative heat loss is balanced by convection heat transfer from air. Hence, \( T_s < T_{\infty} \).
**PROBLEM 6.66**

**KNOWN:** Water-soaked paper towel experiences simultaneous heat and mass transfer while subjected to parallel flow of air, irradiation from a radiant lamp bank, and radiation exchange with surroundings. Average convection coefficient estimated as \( h = 28.7 \text{ W/m}^2\cdot\text{K} \).

**FIND:** (a) Rate at which water evaporates from the towel, \( n_A \) (kg/s), and (b) The net rate of radiation transfer, \( q_{rad} \) (W), to the towel. Determine the irradiation \( G \) (W/m\(^2\)).

**SCHEMATIC:**

**ASSUMPTIONS:**

1. Steady-state conditions,
2. Vapor behaves as an ideal gas,
3. Constant properties,
4. Towel experiences radiation exchange with the large surroundings as well as irradiation from the lamps,
5. Negligible heat transfer from the bottom side of the towel, and
6. Applicability of the heat-mass transfer analogy.

**PROPERTIES:**

- *Table A.4*, Air (\( T_f = 300 \text{ K} \)): \( \rho = 1.1614 \text{ kg/m}^3, c_p = 1007 \text{ J/kg} \cdot \text{K}, \alpha = 22.5 \times 10^{-6} \text{ m}^2/\text{s} \);
- *Table A.6*, Water (310 K): \( \rho_{A,s} = \rho_g = 1/\nu_g = 1/22.93 = 0.0436 \text{ kg/m}^3, h_{fg} = 2414 \text{ kJ/kg} \).

**ANALYSIS:**

(a) The evaporation rate from the towel is

\[
 n_A = \bar{h}_m A_s (\rho_{A,s} - \rho_{A,\infty})
\]

where \( \bar{h}_m \) can be determined from the heat-mass transfer analogy, Eq. 6.92, with \( n = 1/3 \),

\[
\frac{h}{\bar{h}_m} = \frac{\rho c_p L e^{2/3}}{h_{AB}} = \frac{\rho c_p \left( \frac{\alpha}{D_{AB}} \right)^{2/3}}{h_{AB}} = \frac{1.614 \text{ kg/m}^3 \times 1007 \text{ J/kg} \cdot \text{K} \left( \frac{22.5 \times 10^{-6}}{0.26 \times 10^{-4}} \right)^{2/3}}{1062 \text{ J/m}^3 \cdot \text{K}} = 1062 \text{ J/m}^3 \cdot \text{K}
\]

\[
 h_{AB} = 28.7 \text{ W/m}^2 \cdot \text{K}/1062 \text{ J/m}^3 \cdot \text{K} = 0.0270 \text{ m/s}
\]

The evaporation rate is

\[
 n_A = 0.0270 \text{ m/s} \times (0.0925 \times 0.0925) \text{ m}^2 \times (0.0436 - 0) \text{ kg/m}^3 = 1.00 \times 10^{-5} \text{ kg/s}
\]

(b) Performing an energy balance on the towel considering processes of evaporation, convection and radiation, find

\[
 \dot{E}_{in} = \dot{E}_{out} = q_{conv} - q_{evap} + q_{rad} = 0
\]

\[
 \bar{h}A_s (T_\infty - T_s) - n_A h_{fg} + q_{rad} = 0
\]

\[
 q_{rad} = 1.00 \times 10^{-5} \text{ kg/s} \times 2414 \times 10^3 \text{ J/kg} - 27.8 \text{ W/m}^2 \times (0.0925 \text{ m})^2 \times (290 - 310) \text{ K}
\]

\[
 q_{rad} = 2414 \text{ W} + 4.76 \text{ W} = 28.9 \text{ W}
\]

Continued...
PROBLEM 6.66 (Cont.)

The net radiation heat transfer to the towel is comprised of the absorbed irradiation and the net exchange between the surroundings and the towel,

\[ q_{\text{rad}} = \alpha G A_s + \varepsilon A_s \sigma \left( T_{\text{sur}}^4 - T_s^4 \right) \]

\[ 28.9 \text{ W} = 0.96 G (0.0925 \text{ m})^2 + 0.96 \times (0.0925 \text{ m})^2 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left( 300^4 - 310^4 \right) \text{K}^4 \]

Solving, find the irradiation from the lamps,

\[ G = 3583 \text{ W/m}^2. \]

COMMENTS: (1) From the energy balance in Part (b), note that the heat rate by convection is considerably smaller than that by evaporation.

(2) As we’ll learn in Chapter 12, the lamp irradiation found in Part (c) is nearly 3 times that of solar irradiation to the earth’s surface.
PROBLEM 6.67

KNOWN: Thin layer of water on concrete surface experiences evaporation, convection with ambient air, and radiation exchange with the sky. Average convection coefficient estimated as $h = 53 \text{ W/m}^2\cdot\text{K}$.

FIND: (a) Heat fluxes associated with convection, $q_{\text{conv}}^\prime\prime$, evaporation, $q_{\text{evap}}^\prime\prime$, and radiation exchange with the sky, $q_{\text{rad}}^\prime\prime$, (b) Use results to explain why the concrete is wet instead of dry, and (c) Direction of heat flow and the heat flux by conduction into or out of the concrete.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Vapor behaves as an ideal gas, (3) Constant properties, (4) Water surface is small compared to large, isothermal surroundings (sky), and (4) Applicability of the heat-mass transfer analogy.

PROPERTIES: Table A.4, Air ($T_i = (T_\infty + T_s)/2 = 282.5 \text{ K}$): $\rho = 1.243 \text{ kg/m}^3$, $c_p = 1007 \text{ J/kg} \cdot \text{K}$, $\alpha = 2.019 \times 10^5 \text{ m}^2/\text{s}$; Table A.8, Water-air ($T_i = 282.5 \text{ K}$): $D_{\text{AB}} = 0.26 \times 10^{-4} \text{ m}^2/\text{s} (282.5/298)^{3/2} = 0.24 \times 10^{-4} \text{ m}^2/\text{s}$; Table A.6, Water ($T_s = 275 \text{ K}$): $\rho_{A,s} = \rho_g = 1/\nu_g = 1/181.7 = 0.0055 \text{ kg/m}^3$, $h_{fg} = 2497 \text{ kJ/kg}$; Table A.6, Water ($T_\infty = 290 \text{ K}$): $\rho_{A,s} = 1/69.7 = 0.0143 \text{ kg/m}^3$.

ANALYSIS: (a) The heat fluxes associated with the processes shown on the schematic are

Convection:

$$q_{\text{conv}}^\prime\prime = h (T_\infty - T_s) = 53 \text{ W/m}^2 \cdot \text{K} (290 - 275) \text{ K} = +795 \text{ W/m}^2$$

Radiation Exchange:

$$q_{\text{rad}}^\prime\prime = e\sigma (T_s^4 - T_{\text{sky}}^4) = 0.96 \times 5.76 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (275^4 - 240^4) \text{ K}^4 = +131 \text{ W/m}^2$$

Evaporation:

$$q_{\text{evap}}^\prime\prime = n_A^\prime\prime h_{fg} = -2.255 \times 10^{-4} \text{ kg/s} \cdot \text{m}^2 \times 2497 \times 10^3 \text{ J/kg} = -563.1 \text{ W/m}^2$$

where the evaporation rate from the surface is

$$n_A^\prime\prime = \bar{n}_m \left( \rho_{A,s} - \rho_{A,\infty} \right) = 0.050 \text{ m/s} (0.0055 - 0.7 \times 0.0143) \text{ kg/m}^3 = -2.255 \times 10^{-4} \text{ kg/s} \cdot \text{m}^2$$

Continued...
and where the mass transfer coefficient is evaluated from the heat-mass transfer analogy, Eq. 6.92, with $n = 1/3$,

$$\frac{\bar{h}}{h_m} = \rho c_p L e^{2/3} = \rho c_p \left( \frac{\alpha}{D_{AB}} \right)^{2/3} = 1.243 \text{kg/m}^3 \times 1007 \text{J/kg} \cdot \text{K} \times \left( \frac{2.019 \times 10^{-5}}{0.26 \times 10^{-4}} \right)^{2/3}$$

$$\frac{\bar{h}}{h_m} = 1058 \text{J/m}^3 \cdot \text{K}$$

$$h_m = 53 \text{W/m}^2 \cdot \text{K} / 1058 \text{J/m}^3 \cdot \text{K} = 0.050 \text{m/s}$$

(b) From the foregoing evaporation calculations, note that water vapor from the air is condensing on the liquid water layer. That is, vapor is being transported to the surface, explaining why the concrete surface is wet, even without rain.

(c) From an overall energy balance on the water film considering conduction in the concrete as shown in the schematic,

$$\dot{E}_{in} - \dot{E}_{out} = 0$$

$$q_{conv} - q_{evap} - q_{rad} - q_{cond} = 0$$

$$q_{cond} = q_{conv} - q_{evap} - q_{rad}$$

$$q_{cond} = 1795 \text{W/m}^3 - (-563.1 \text{W/m}^2) - (+131 \text{W/m}^2) = 1227 \text{W/m}^2$$

The heat flux by conduction is into the concrete.
**PROBLEM 6.68**

**KNOWN:** Heater power required to maintain wetted (water) plate at 27°C, and average convection coefficient for specified dry air temperature, case (a).

**FIND:** Heater power required to maintain the plate at 37°C for the same dry air temperature if the convection coefficients remain unchanged, case (b).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Convection coefficients unchanged for different plate temperatures, (3) Air stream is dry at atmospheric pressure, and (4) Negligible heat transfer from the bottom side of the plate.

**PROPERTIES:** Table A-6, Water (T_{s,a} = 27°C = 300 K): $\rho_{A,s} = 1/\gamma_g = 0.02556$ kg/m$^3$, $h_{fg} = 2.438 \times 10^6$ J/kg; Water (T_{s,b} = 37°C = 310 K): $\rho_{A,s} = 1/\gamma_g = 0.04361$ kg/m$^3$, $h_{fg} = 2.414 \times 10^6$ J/kg.

**ANALYSIS:** For case (a) with $T_s = 27°C$ and $P_e = 432$ W, perform an energy balance on the plate to determine the mass transfer coefficient $h_m$.

$$E_{in} - E_{out} = 0$$

$$P_{e,a} - (q_{evap}^a + q_{cv}^a)A_s = 0$$

Substituting the rate equations and appropriate properties,

$$P_{e,a} - \left[ h_m \left( \rho_{A,s} - \rho_{A,\infty} \right) h_{fg} + h \left( T_{s,a} - T_{\infty} \right) \right] A_s = 0$$

$$432 \text{ W} + \left[ h_m \left( 0.0256 \text{ kg/m}^3 - 0 \right) \times 2.438 \times 10^6 \text{ J/kg} + 20 \text{ W/m}^2 \cdot \text{K} (27 - 32) \text{ K} \right] \times 0.2 \text{ m}^2 = 0$$

where $\rho_{A,s}$ and $h_{fg}$ are evaluated at $T_s = 27°C = 300$ K. Find,

$$h_m = 0.0363 \text{ m/s}$$

For case (b), with $T_s = 37°C$ and the same values for $h$ and $h_m$, perform an energy balance to determine the heater power required to maintain this condition.

$$P_{e,b} - \left[ h_m \left( \rho_{A,s} - 0 \right) h_{fg} + h \left( T_{s,b} - T_{\infty} \right) \right] A_s = 0$$

$$P_{e,b} - \left[ 0.0363 \text{ m/s} (0.04361 - 0) \text{ kg/m}^3 \times 2.414 \times 10^6 \text{ J/kg} + 20 \text{ W/m}^2 \cdot \text{K} (37 - 32) \right] \times 0.2 \text{ m}^2 = 0$$

$$P_{e,b} = 784 \text{ W}$$

where $\rho_{A,a}$ and $h_{fg}$ are evaluated at $T_s = 37°C = 310$ K.
PROBLEM 6.69

KNOWN: Dry air at 32°C flows over a wetted plate of width 1 m maintained at a surface temperature of 27°C by an embedded heater supplying 432 W.

FIND: (a) The evaporation rate of water from the plate, \( n_A \) (kg/h) and (b) The plate temperature \( T_s \) when all the water is evaporated, but the heater power remains the same.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Vapor behaves as an ideal gas, (3) Constant properties, and (4) Applicability of the heat-mass transfer analogy.

PROPERTIES: Table A.4, Air \((T_f = (32 + 27)°C/2 = 302.5 \text{ K})\): \( \rho = 1.153 \text{ kg/m}^3, c_p = 1007 \text{ J/kg} \cdot \text{K}, \alpha = 2.287 \times 10^5 \text{ m}^2/\text{s}; \) Table A.8, Water-air \((T_f = 300 \text{ K})\): \( D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}; \) Table A.6, Water \((T_s = 27°C = 300 \text{ K})\): \( \rho_A = 1/\nu_A = 1/39.13 = 0.0256 \text{ kg/m}^3, h_{fg} = 2438 \text{ kJ/kg}. \)

ANALYSIS: (a) Perform an energy balance on the wetted plate to obtain the evaporation rate, \( n_A \).

\[
\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0 \quad \Rightarrow \quad P_e + q_{\text{conv}} - q_{\text{evap}} = 0
\]

In order to find \( \overline{h} \), invoke the heat-mass transfer analogy, Eq. (6.92) with \( n = 1/3, \)

\[
\frac{\overline{h}}{h_m} = \rho c_p L e^{2/3} = \rho c_p \left( \frac{\alpha}{D_{AB}} \right)^{2/3} = 1.153 \text{ kg/m}^3 \times 1007 \text{ J/kg} \cdot \text{K} \left( \frac{2.287 \times 10^{-5}}{0.26 \times 10^{-4}} \right)^{2/3} = 1066 \text{ J/m}^3 \cdot \text{K} \quad (2)
\]

The evaporation rate equation

\[
n_A = \frac{\overline{h} m A_s}{(\rho_{A,s} - \rho_{A,\infty})}
\]

Substituting Eqs. (2) and (3) into Eq. (1), find \( \overline{h}_m \)

\[
P_e + \left(1066 J/\text{m}^3 \cdot \text{K} \cdot h_m \right) A_s (T_s - T_\infty) - h_m A_s (\rho_{A,s} - \rho_{A,\infty}) h_{fg} = 0
\]

\[
432 W + \left[ \frac{1066 J/\text{m}^3 \cdot \text{K} \cdot (32 - 27)}{0.0256 - 0} \text{ kg/} \text{m}^3 \times 2438 \times 10^3 \text{ J/kg} \right] (0.200 \times 1) \text{ m}^2 \cdot h_m = 0
\]

\[
h_m = 0.0378 \text{ m/s}
\]

Using Eq. (3), find

\[
n_A = 0.0378 \text{ m/s} (0.200 \times 1) \text{ m}^2 (0.0256 - 0) \text{ kg/} \text{m}^3 = 1.94 \times 10^{-4} \text{ kg/s} = 0.70 \text{ kg/h}
\]

(b) When the plate is dry, all the power must be removed by convection,

\[
P_e = q_{\text{conv}} = \overline{h} A_s (T_s - T_\infty)
\]

Assuming \( \overline{h} \) is the same as for conditions with the wetted plate,

\[
T_s = T_\infty + P_e / \overline{h} A_s = T_\infty + P_e / (1066 h_m) A_s
\]

\[
T_s = 32°C + 432 W / \left( 1066 \times 0.0378 \text{ W/} \text{m}^2 \cdot \text{K} \times 0.200 \text{ m}^2 \right) = 85.6°C
\]
PROBLEM 6.70

**KNOWN:** Surface temperature of a 20-mm diameter sphere is 32°C when dissipating 2.51 W in a dry air stream at 22°C.

**FIND:** Power required by the imbedded heater to maintain the sphere at 32°C if its outer surface has a thin porous covering saturated with water for the same dry air temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Heat and mass transfer analogy is applicable, (3) Heat transfer convection coefficient is the same for the dry and wet condition, and (3) Properties of air and the diffusion coefficient of the air-water vapor mixture evaluated at 300 K.

**PROPERTIES:** *Table A-4*, Air (300 K, 1 atm): \( \rho = 1.1614 \text{ kg/m}^3 \), \( c_p = 1007 \text{ J/kg} \cdot \text{K} \), \( \alpha = 22.5 \times 10^{-6} \text{ m}^2/\text{s} \); *Table A-8*, Water-air mixture (300 K, 1 atm): \( D_{A-B} = 0.26 \times 10^{-4} \text{ m}^2/\text{s} \); *Table A-4*, Water (305 K, 1 atm): \( \rho_{A,s} = 1/\gamma_g = 0.03362 \text{ kg/m}^3 \), \( h_{fg} = 2.426 \times 10^6 \text{ J/kg} \).

**ANALYSIS:** For the **dry case** (d), perform an energy balance on the sphere and calculate the heat transfer convection coefficient.

\[
\dot{E}_{in} - \dot{E}_{out} = P_{e,d} - q_{cv} = 0 \\
2.51 \text{ W} - \bar{h} \pi (0.020 \text{ m})^2 (32 - 22) \text{ K} = 0 \\
\bar{h} = 200 \text{ W/m}^2 \cdot \text{K}
\]

Use the heat-mass analogy, Eq. (6.67) with \( n = 1/3 \), to determine \( \bar{h}_m \).

\[
\frac{\bar{h}}{\bar{h}_m} = \rho c_p \left( \frac{\alpha}{D_{AB}} \right)^{2/3}
\]

\[
\frac{200 \text{ W/m}^2 \cdot \text{K}}{\bar{h}_m} = 1.1614 \text{ kg/m}^3 \times 1007 \text{ J/kg} \cdot \text{K} \left( \frac{22.5 \times 10^6 \text{ m}^2/\text{s}}{0.26 \times 10^4 \text{ m}^2/\text{s}} \right)^{2/3}
\]

\[
\bar{h}_m = 0.188 \text{ m/s}
\]

For the **wet case** (w), perform an energy balance on the wetted sphere using values for \( \bar{h} \) and \( \bar{h}_m \) to determine the power required to maintain the same surface temperature.

\[
\dot{E}_{in} - \dot{E}_{out} = P_{e,w} - q_{cv} - q_{evap} = 0 \\
P_{e,w} - \left[ \bar{h} (T_s - T_{\infty}) + \bar{h}_m \left( \rho_{A,s} - \rho_{A,\infty} \right) h_{fg} \right] A_s = 0 \\
P_{e,w} - \left[ 200 \text{ W/m}^2 \cdot \text{K} (32 - 22) + 0.188 \text{ m/s} (0.03362 - 0) \text{ kg/m}^3 \times 2.426 \times 10^6 \text{ J/kg} \right] \pi (0.020 \text{ m})^2 = 0
\]

\[
P_{e,w} = 21.8 \text{ W}
\]

**COMMENTS:** Note that \( \rho_{A,s} \) and \( h_{fg} \) for the mass transfer rate equation are evaluated at \( T_s = 32^\circ \text{C} = 305 \text{ K} \), not 300 K. The effect of evaporation is to require nearly 8.5 times more power to maintain the same surface temperature.
PROBLEM 6.71

KNOWN: Operating temperature, ambient air conditions and make-up water requirements for a hot tub.

FIND: Heater power required to maintain prescribed conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Side wall and bottom are adiabatic, (2) Heat and mass transfer analogy is applicable.

PROPERTIES: Table A-4, Air \( T = 300K \), 1 atm: \( \rho = 1.161 \text{ kg/m}^3 \), \( c_p = 1007 \text{ J/kg} \cdot \text{K} \), \( \alpha = 22.5 \times 10^{-6} \text{ m}^2/\text{s} \); Table A-6, Sat. water vapor (\( T = 310K \)): \( h_{fg} = 2414 \text{ kJ/kg} \), \( \rho_{A,sat}(T) = 1/\nu_g = (22.93 \text{ m}^3/\text{kg})^{-1} = 0.0436 \text{ kg/m}^3 \); (\( T_{\infty} = 290K \)): \( \rho_{A,sat}(T_{\infty}) = 1/\nu_g = (69.7 \text{ m}^3/\text{kg})^{-1} = 0.0143 \text{ kg/m}^3 \); Table A-8, Air-water vapor (298K): \( D_{AB} = 26 \times 10^{-6} \text{ m}^2/\text{s} \).

ANALYSIS: Applying an energy balance to the control volume,

\[
q_{elec} = q_{conv} + q_{evap} = \overline{h} A \left( T - T_{\infty} \right) + \dot{m}_{evap} h_{fg} (T).
\]

Obtain \( \overline{h} A \) from Eq. 6.67 with \( n = 1/3 \),

\[
\frac{\overline{h}}{h_m} = \frac{\overline{h}_A}{h_{mA}} = \rho c_p Le^{2/3}
\]

\[
\overline{h}_A = \overline{h}_{mA} \rho c_p Le^{2/3} = \frac{\dot{m}_{evap}}{\rho_{A,sat}(T) - \phi_{\infty} \rho_{A,sat}(T_{\infty})} \rho c_p Le^{2/3}.
\]

Substituting numerical values,

\[
Le = \alpha/D_{AB} = \left( 22.5 \times 10^{-6} \text{ m}^2/\text{s} \right)/26 \times 10^{-6} \text{ m}^2/\text{s} = 0.865
\]

\[
\overline{h}_A = \frac{10^{-3} \text{ kg/s}}{0.0436 - 0.3 \times 0.0143} \text{ kg/m}^3 \times 1.161 \text{ kg/m}^3 \times 1007 \text{ J/kg} \cdot \text{K} \times 0.865^{2/3} = 27.0 \text{ W/K}.
\]

Hence, the required heater power is

\[
q_{elec} = 27.0 \text{ W/K} \times (310 - 290) \text{ K} + 10^{-3} \text{ kg/s} \times 2414 \text{ kJ/kg} \times 1000 \text{ J/kJ}
\]

\[
q_{elec} = (540 + 2414) \text{ W} = 2954 \text{ W}.
\]

COMMENTS: The evaporative heat loss is dominant.
PROBLEM 6.72

KNOWN: Water freezing under conditions for which the air temperature exceeds 0°C.

FIND: (a) Lowest air temperature, $T_\infty$, before freezing occurs, neglecting evaporation, (b) The mass transfer coefficient, $h_m$, for the evaporation process, (c) Lowest air temperature, $T_\infty$, before freezing occurs, including evaporation.

SCHEMATIC:

No evaporation

With evaporation

ASSUMPTIONS: (1) Steady-state conditions, (2) Water insulated from ground, (3) Water surface has $\varepsilon = 1$, (4) Heat-mass transfer analogy applies, (5) Ambient air is dry.

PROPERTIES: Table A-4, Air ($T_f = 2.5^\circ C = 276 K$, 1 atm): $\rho = 1.2734 \text{ kg/m}^3$, $c_p = 1006 \text{ J/kg} \cdot \text{K}$, $\alpha = 19.3 \times 10^{-6} \text{ m}^2 / \text{s}$; Table A-6, Water vapor (273.15K): $h_{fg} = 2502 \text{ kJ/kg}$, $\rho_g = 1/\nu_g = 4.847 \times 10^{-3} \text{ kg/m}^3$; Table A-8, Water vapor - air (298K): $D_{AB} = 0.26 \times 10^{-4} \text{ m}^2 / \text{s}$.

ANALYSIS: (a) Neglecting evaporation and performing an energy balance,

$$h(T_\infty - T_s) - \varepsilon \sigma (T_s^4 - T_{sky}^4) = 0 \quad \text{or} \quad T_\infty = T_s + \left(\varepsilon \sigma / h\right) \left(T_s^4 - T_{sky}^4\right)$$

$$T_\infty = 0^\circ C + \frac{1 \times 5.667 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left[(0 + 273)^4 - (-30 + 273)^4\right]}{25 \text{ W/m}^2 \cdot \text{K}} = 4.69^\circ C.$$  

(b) Invoking the heat-mass transfer analogy in the form of Eq. 6.67 with $n = 1/3$,

$$\frac{h}{h_m} = \frac{\rho \cdot c_p \cdot \nu}{ \alpha / D_{AB}^{2/3}} \quad \text{or} \quad h_m = h / (\rho \cdot c_p \cdot \nu)^{2/3} \quad \text{where} \quad \nu = \alpha / D_{AB}^{2/3}$$

$$h_m = \left(\frac{25 \text{ W/m}^2 \cdot \text{K}}{1.273 \text{ kg/m}^3 \cdot (1006 \text{ J/kg} \cdot \text{K})} \left[\frac{19.3 \times 10^{-6} \text{ m}^2 / \text{s}}{0.26 \times 10^{-4} \text{ m}^2 / \text{s}}\right]^{2/3}\right) = 0.0238 \text{ m/s.}$$

(c) Including evaporation effects and performing an energy balance gives $q_{\text{conv}} - q_{\text{rad}} - q_{\text{evap}} = 0$

where $q_{\text{evap}} = \dot{m}^* h_{fg} = h_m \left(\rho_{A,s} - \rho_{A,\infty}\right) h_{fg}$, $\rho_{A,s} = \rho_g$ and $\rho_{A,\infty} = 0$. Hence,

$$T_\infty = T_s + \left(\varepsilon \sigma / h\right) \left(T_s^4 - T_{sky}^4\right) + \left(h_m / h\right) \left(\rho_g - 0\right) h_{fg}$$

$$T_\infty = 4.69^\circ C + \frac{0.0238 \text{ m/s}}{25 \text{ W/m}^2 \cdot \text{K}} \times 4.847 \times 10^{-3} \text{ kg/m}^3 \times 2.502 \times 10^6 \text{ J/kg}$$

$$T_\infty = 4.69^\circ C + 11.5^\circ C = 16.2^\circ C.$$
PROBLEM 6.73

KNOWN: Wet-bulb and dry-bulb temperature for water vapor-air mixture.

FIND: (a) Partial pressure, $p_A$, and relative humidity, $\phi$, using Carrier’s equation, (b) $p_A$ and $\phi$ using psychrometric chart, (c) Difference between air stream, $T_{\infty}$, and wet bulb temperatures based upon evaporative cooling considerations.

SCHEMATIC:

ASSUMPTIONS: (1) Evaporative cooling occurs at interface, (2) Heat-mass transfer analogy applies, (3) Species A and B are perfect gases.

PROPERTIES: Table A-6, Water vapor: $p_{A,sat} (21.1^\circ C) = 0.02512$ bar, $p_{A,sat} (37.8^\circ C) = 0.06603$ bar, $h_{fg} (21.1^\circ C) = 2451$ kJ/kg; Table A-4, Air ($T_{am} = [T_{WB} + T_{DB}]/2 \approx 300K, 1$ atm): $\alpha = 22.5 \times 10^{-6}$ m$^2$/s, $c_p = 1007$ J/kg$\cdot$K; Table A-8, Air-water vapor (298K): $D_{AB} = 0.26 \times 10^{-4}$ m$^2$/s.

ANALYSIS: (a) Carrier’s equation has the form

$$p_v = p_{gw} - \frac{(p - p_{gw}) \left(T_{DB} - T_{WB}\right)}{1810 - T_{WB}}$$

where $p_v$ = partial pressure of vapor in air stream, bar

$p_{gw} = \text{sat. pressure at } T_{WB} = 21.1^\circ C, 0.02512$ bar

$p = \text{total pressure of mixture, } 1.033 \text{ bar}$

$T_{DB} = \text{dry bulb temperature, } 37.8^\circ C$

$T_{WB} = \text{wet bulb temperature, } 21.1^\circ C$.

Hence,

$$p_v = 0.02512 \text{ bar} - \frac{(1.013 - 0.02512) \text{ bar} \times (37.8 - 21.1)^\circ \text{ C}}{1810 - (21.1 + 273.1) \text{ K}} = 0.0142 \text{ bar}.$$  

The relative humidity, $\phi$, is then

$$\phi \equiv \frac{p_A}{p_{A,sat}} = \frac{p_v}{p_A \left(37.8^\circ \text{ C}\right)} = \frac{0.0142 \text{ bar}}{0.06603 \text{ bar}} = 0.214.$$  

(b) Using a psychrometric chart

$$\begin{align*}
T_{WB} &= 21.1^\circ C = 70^\circ F \quad \phi \approx 0.225 < \\
T_{DB} &= 37.8^\circ C = 100^\circ F 
\end{align*}$$

$$p_v = \phi p_{sat} = 0.225 \times 0.06603 \text{ bar} = 0.0149 \text{ bar}.$$  

Continued ….
PROBLEM 6.73 (Cont.)

(c) An application of the heat-mass transfer analogy is the process of evaporative cooling which occurs when air flows over water. The change in temperature is estimated by Eq. 6.73.

\[
(T_\infty - T_s) = \frac{\left(\frac{M_A}{M_B}\right) h_{fg}}{c_p L_e^{2/3}} p_{A, sat} \left(\frac{T_s}{p}\right) - \frac{p_{A, \infty}}{p} \]

where \(c_p\) and \(L_e\) are evaluated at \(T_{am} = \frac{T_\infty + T_s}{2}\) and \(p_{A, \infty} = p_v\), as determined in Part (a). Substituting numerical values, using \(L_e = \frac{\alpha}{D_{AB}}\).

\[
(T_\infty - T_s) = \frac{(18 \text{ kg/kmol/29 kg/kmol}) \times 2451 \times 10^3 \text{ kg}^{-1}}{1007 \text{ J/kg} \cdot \text{K}} \left[\frac{22.5 \times 10^{-6} \text{m}^2/\text{s}}{0.26 \times 10^{-4} \text{m}^2/\text{s}}\right]^{2/3} \left[\frac{0.02491 \text{ bar}}{1.013 \text{ bar}} - \frac{0.0149 \text{ bar}}{1.013 \text{ bar}}\right]
\]

\[
(T_\infty - T_s) = 17.6^\circ \text{C}.
\]

Note that \(c_p\) and \(\alpha\) are associated with the air.

**COMMENTS:** The following table compares results from the two calculation methods.

**PROBLEM 6.74**

**KNOWN:** Wet and dry bulb temperatures.

**FIND:** Relative humidity of air.

**SCHEMATIC:**

```
Air

φ∞  
T∞ = 45°C

Wetted wick

Qconv

Qevap

Twb = 25°C
```

**ASSUMPTIONS:** (1) Perfect gas behavior for vapor, (2) Steady-state conditions, (3) Negligible radiation, (4) Negligible conduction along thermometer.

**PROPERTIES:** *Table A-4*, Air (308K, 1 atm): \( ρ = 1.135 \text{ kg/m}^3 \), \( c_p = 1007 \text{ J/kg} \cdot \text{K} \), \( α = 23.7 \times 10^{-6} \text{ m}^2/\text{s} \); *Table A-6*, Saturated water vapor (298K): \( v_g = 44.25 \text{ m}^3/\text{kg} \), \( h_f = 2443 \text{ kJ/kg} \); (318K): \( v_g = 15.52 \text{ m}^3/\text{kg} \); *Table A-8*, Air-vapor (1 atm, 298K): \( D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s} \), \( D_{AB} (308K) = 0.26 \times 10^{-4} \text{ m}^2/\text{s} \times (308/298)^{3/2} = 0.27 \times 10^{-4} \text{ m}^2/\text{s} \), \( Le = α/D_{AB} = 0.88 \).

**ANALYSIS:** From an energy balance on the wick, Eq. 6.71 follows from Eq. 6.68. Dividing Eq. 6.71 by \( ρ_{A,sat}(T_∞) \),

\[
\frac{T_∞ - T_s}{ρ_{A,sat}(T_∞)} = h_{fg} \left[ \frac{h_m}{h} \right] \left[ \frac{ρ_{A,sat}(T_s)}{ρ_{A,sat}(T_∞)} - \frac{ρ_{A,∞}}{ρ_{A,sat}(T_∞)} \right].
\]

With \( \left[ \frac{ρ_{A,∞}}{ρ_{A,sat}(T_∞)} \right] = φ∞ \) for a perfect gas and \( h/h_m \) given by Eq. 6.67,

\[
φ∞ = \frac{ρ_{A,sat}(T_s)}{ρ_{A,sat}(T_∞)} - \frac{ρ c_p}{Le^{2/3} ρ_{A,sat}(T_∞) h_{fg}} (T_∞ - T_s).
\]

Using the property values, evaluate

\[
\frac{ρ_{A,sat}(T_s)}{ρ_{A,sat}(T_∞)} = \frac{v_g T_∞}{v_g (T_s)} = \frac{15.52}{44.25} = 0.351
\]

\[
ρ_{A,sat}(T_∞) = \left(15.52 \text{ m}^3/\text{kg}\right)^{-1} = 0.064 \text{ kg/m}^3.
\]

Hence,

\[
φ∞ = 0.351 - \frac{1.135 \text{ kg/m}^3 \left(1007 \text{ J/kg} \cdot \text{K}\right)}{(0.88)^{2/3} 0.064 \text{ kg/m}^3 \left(2.443 \times 10^6 \text{ J/kg}\right) (45 - 25) \text{ K}} = 0.192.
\]

**COMMENTS:** Note that latent heat must be evaluated at the surface temperature (evaporation occurs at the surface).
PROBLEM 6.75

KNOWN: Heat transfer correlation for a contoured surface heated from below while experiencing air flow across it. Flow conditions and steady-state temperature when surface experiences evaporation from a thin water film.

FIND: (a) Heat transfer coefficient and convection heat rate, (b) Mass transfer coefficient and evaporation rate (kg/h) of the water, (c) Rate at which heat must be supplied to surface for these conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Heat-mass transfer analogy applies, (3) Correlation requires properties evaluated at \( T_f = (T_s + T_\infty)/2 \).

PROPERTIES: Table A-4, Air (\( T_f = (T_s + T_\infty)/2 = (290 + 310)K/2 = 300 K \), 1 atm): \( \nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}, k = 0.0263 \text{ W/m} \cdot \text{K}, \text{Pr} = 0.707; \) Table A-8, Air-water mixture (300 K, 1 atm): \( D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}; \) Table A-6, Sat. water (\( T_s = 310 K \)): \( \rho_{A,sat} = 1/\nu_g = 1/22.93 \text{ m}^3/\text{kg} = 0.04361 \text{ kg/m}^3, \ h_{fg} = 2414 \text{ kJ/kg}. \)

ANALYSIS: (a) To characterize the flow, evaluate \( \text{Re}_L \) at \( T_f \)
\[
\text{Re}_L = \frac{VL}{\nu} = \frac{10 \text{ m/s} \times 1 \text{ m}}{15.89 \times 10^{-6} \text{ m}^2/\text{s}} = 6.293 \times 10^5
\]
and substituting into the prescribed correlation for this surface, find
\[
\overline{\text{Nu}}_L = 0.43 \left( 6.293 \times 10^5 \right)^{0.58} (0.707)^{0.4} = 864.1
\]
\[
\overline{h}_L = \frac{\overline{\text{Nu}}_L \cdot k}{L} = \frac{864.1 \times 0.0263 \text{ W/m} \cdot \text{K}}{1 \text{ m}} = 22.7 \text{ W/m}^2 \cdot \text{K}.
\]
Hence, the convection heat rate is
\[
q_{\text{conv}} = \overline{h}_L A_S (T_s - T_\infty)
\]
\[
q_{\text{conv}} = 22.7 \text{ W/m}^2 \cdot \text{K} \times 1 \text{ m}^2 (310 - 290) \text{ K} = 454 \text{ W}
\]
(b) Invoking the heat-mass transfer analogy
\[
\overline{\text{Sh}}_L = \frac{\overline{h}_L}{D_{AB}} = 0.43 \text{Re}_L^{0.58} \text{Sc}^{0.4}
\]
where
\[
\text{Sc} = \frac{\nu}{D_{AB}} = \frac{15.89 \times 10^{-6} \text{ m}^2/\text{s}}{0.26 \times 10^{-4} \text{ m}^2/\text{s}} = 0.611
\]
and \( \nu \) is evaluated at \( T_f \). Substituting numerical values, find

Continued …..

Continued …..
PROBLEM 6.75 (Cont.)

\[
\overline{Sh}_L = 0.43 \left(6.293\times10^5\right)^{0.58} (0.611)^{0.4} = 815.2
\]

\[
\bar{h}_m = \frac{\overline{Sh}_L \cdot D_{AB}}{L} = \frac{815.2 \times 0.26 \times 10^{-4} \text{m}^2/\text{s}}{1 \text{ m}} = 2.12 \times 10^{-2} \text{ m/s.}
\]

The evaporation rate, with \( \rho_{A,s} = \rho_{A,\text{sat}} (T_s) \), is

\[
\dot{m} = \bar{h}_m A_s (\rho_{A,s} - \rho_{A,\infty})
\]

\[
\dot{m} = 2.12 \times 10^{-2} \text{ m/s} \times 1 \text{ m}^2 (0.04361 - 0) \text{ kg/m}^3
\]

\[
\dot{m} = 9.243 \times 10^{-4} \text{ kg/s} = 3.32 \text{ kg/h.}
\]

(c) The rate at which heat must be supplied to the plate to maintain these conditions follows from an energy balance.

\[
\dot{E}_{in} - \dot{E}_{out} = 0
\]

\[
\dot{q}_{in} - \dot{q}_{conv} - \dot{q}_{evap} = 0
\]

where \( \dot{q}_{in} \) is the heat supplied to sustain the losses by convection and evaporation.

\[
\dot{q}_{in} = \dot{q}_{conv} + \dot{q}_{evap}
\]

\[
\dot{q}_{in} = \bar{h}_L A_s (T_s - T_\infty) + \dot{m} h_f g
\]

\[
\dot{q}_{in} = 454 \text{ W} + 9.243 \times 10^{-4} \text{ kg/s} \times 2414 \times 10^3 \text{ J/kg}
\]

\[
\dot{q}_{in} = (254 + 2231) \text{ W} = 2685 \text{ W.}
\]

COMMENTS: Note that the loss from the surface by evaporation is nearly 5 times that due to convection.
PROBLEM 6.76

KNOWN: Thickness, temperature and evaporative flux of a water layer. Temperature of air flow and surroundings.

FIND: (a) Convection mass transfer coefficient and time to completely evaporate the water, (b) Convection heat transfer coefficient, (c) Heater power requirement per surface area, (d) Temperature of dry surface if heater power is maintained.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Applicability of heat and mass transfer analogy with n = 1/3, (3) Radiation exchange at surface of water may be approximated as exchange between a small surface and large surroundings, (4) Air is dry (\(\rho_{A,\infty} = 0\)), (5) Negligible heat transfer from unwetted surface of the plate.

PROPERTIES: Table A-6, Water (T\(_w\) = 340K): \(\rho_f = 979 \text{ kg/m}^3\), \(\rho_{A,sat} = v_g^{-1} = 0.174 \text{ kg/m}^3\), \(h_{fg} = 2342 \text{ kJ/kg}\). Prescribed, Air: \(\rho = 1.08 \text{ kg/m}^3\), \(c_p = 1008 \text{ J/kg} \cdot \text{K}\), \(k = 0.028 \text{ W/m} \cdot \text{K}\). Vapor/Air: \(D_{AB} = 0.29 \times 10^{-4} \text{ m}^2/\text{s}\). Water: \(\varepsilon_w = 0.95\). Plate: \(\varepsilon_p = 0.60\).

ANALYSIS: (a) The convection mass transfer coefficient may be determined from the rate equation

\[
\dot{n}_A^* = h_m \left( \rho_{A,s} - \rho_{A,\infty} \right), \quad \text{where} \quad \rho_{A,s} = \rho_{A,sat} \left( T_w \right) \text{ and } \rho_{A,\infty} = 0.
\]

Hence,

\[
h_m = \frac{\dot{n}_A^*}{\rho_{A,\text{sat}}} = \frac{0.03 \text{ kg/s} \cdot \text{m}^2}{0.174 \text{ kg/m}^3} = 0.172 \text{ m/s}
\]

The time required to completely evaporate the water is obtained from a mass balance of the form

\[
-n_A^* = \rho_f \frac{d\delta}{dt}, \quad \text{in which case}
\]

\[
t = \frac{\rho_f \delta_i}{\dot{n}_A^*} = \frac{979 \text{ kg/m}^3 \cdot (0.002 \text{ m})}{0.03 \text{ kg/s} \cdot \text{m}^2} = 65.3 \text{s}
\]

(b) With \(n = 1/3\) and \(Le = \alpha/D_{AB} = k/c_p D_{AB} = 0.028 \text{ W/m} \cdot \text{K}/(1.08 \text{ kg/m}^3 \times 1008 \text{ J/kg} \cdot \text{K} \times 0.29 \times 10^{-4} \text{ m}^2/\text{s}) = 0.887\), the heat and mass transfer analogy yields

\[
h = \frac{k h_m}{D_{AB}Le^{1/3}} = \frac{0.028 \text{ W/m} \cdot \text{K} \cdot (0.172 \text{ m/s})}{0.29 \times 10^{-4} \text{ m}^2/\text{s} \cdot (0.887)^{1/3}} = 173 \text{ W/m}^2 \cdot \text{K}
\]

The electrical power requirement per unit area corresponds to the rate of heat loss from the water. Hence,

Continued …..
PROBLEM 6.76 (Cont.)

\[ P^*_{\text{elec}} = q^*_{\text{evap}} + q^*_{\text{conv}} + q^*_{\text{rad}} = h_A \Delta h_{fg} + h(T_w - T_\infty) + \varepsilon_w \sigma \left( T_w^4 - T_{\text{sur}}^4 \right) \]

\[ P^*_{\text{elec}} = 0.03 \text{ kg} / \text{s} \cdot \text{m}^2 \left( 2.342 \times 10^6 \text{ J} / \text{kg} \right) + 173 \text{ W} / \text{m}^2 \cdot \text{K} \left( 40 \text{K} \right) \] \[ + 0.95 \times 5.67 \times 10^{-8} \text{ W} / \text{m}^2 \cdot \text{K}^4 \left( 340^4 - 300^4 \right) \]

\[ P^*_{\text{elec}} = 702,600 \text{ W} / \text{m}^2 + 6920 \text{ W} / \text{m}^2 + 284 \text{ W} / \text{m}^2 = 77,464 \text{ W} / \text{m}^2 \]

(c) After complete evaporation, the steady-state temperature of the plate is determined from the requirement that

\[ P^*_{\text{elec}} = h \left( T_p - T_\infty \right) + \varepsilon_p \sigma \left( T_p^4 - T_{\text{sur}}^4 \right) \]

\[ 77,464 \text{ W} / \text{m}^2 = 173 \text{ W} / \text{m}^2 \cdot \text{K} \left( T_p - 300 \right) + 0.60 \times 5.67 \times 10^{-8} \text{ W} / \text{m}^2 \cdot \text{K}^4 \left( T_p^4 - 300^4 \right) \]

\[ T_p = 702 \text{K} = 429^\circ \text{C} \]

COMMENTS: The evaporative heat flux is the dominant contributor to heat transfer from the water layer, with convection of sensible energy being an order of magnitude smaller and radiation exchange being negligible. Without evaporation (a dry surface), convection dominates and is approximately an order of magnitude larger than radiation.
**PROBLEM 6.77**

**KNOWN:** Heater power required to maintain water film at prescribed temperature in dry ambient air and evaporation rate.

**FIND:** (a) Average mass transfer convection coefficient \( \bar{h}_m \), (b) Average heat transfer convection coefficient \( \bar{h} \), (c) Whether values of \( \bar{h}_m \) and \( \bar{h} \) satisfy the heat-mass analogy, and (d) Effect on evaporation rate and disc temperature if relative humidity of the ambient air were increased from 0 to 0.5 but with heater power maintained at the same value.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Water film and disc are at same temperature; (2) Mass and heat transfer coefficient are independent of ambient air relative humidity, (3) Constant properties.

**PROPERTIES:** Table A-6, Saturated water (305 K): \( v_g = 29.74 \text{ m}^3/\text{kg}, h_{fg} = 2426 \times 10^3 \text{ J/kg}; 
Table A-4, Air (\( \bar{T} = 300 \text{ K}, 1 \text{ atm} \): \( k = 0.0263 \text{ W/m K}, \alpha = 22.5 \times 10^{-6} \text{ m}^2/\text{s}, 
Table A-8, Air-water vapor (300 K, 1 atm): \( D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}. 

**ANALYSIS:**

(a) Using the mass transfer convection rate equation,

\[
q_A = \bar{h}_m A_s \left( \rho_{A,s} - \rho_{A,\infty} \right) = \bar{h}_m A_s \rho_{A,sat} (1 - \phi_\infty)
\]

and evaluating \( \rho_{A,s} = \rho_{A,sat} (305 \text{ K}) = 1/v_g (305 \text{ K}) \) with \( \phi_\infty \sim \rho_{A,\infty} = 0 \), find

\[
\bar{h}_m = \frac{q_A}{A_s \left( \rho_{A,s} - \rho_{A,\infty} \right)}
\]

\[
\bar{h}_m = \frac{2.55 \times 10^{-4} \text{ kg/hr} \left( 3600 \text{ s/hr} \right)}{\pi \left( 0.020 \text{ m} \right)^2 / 4 \left( 1/29.74 - 0 \right) \text{ kg/m}^3} = 6.71 \times 10^{-3} \text{ m/s}. \]

(b) Perform an overall energy balance on the disc,

\[
q = q_{conv} + q_{evap} = \bar{h} A_s (T_s - T_\infty) + n_A h_{fg}
\]

and substituting numerical values with \( h_{fg} \) evaluated at \( T_s \), find \( \bar{h} \):

\[
200 \times 10^{-3} \text{ W} = \bar{h} \pi (0.020 \text{ m})^2 / 4(305 - 295) + 7.083 \times 10^{-8} \text{ kg/s} \times 2426 \times 10^3 \text{ J/kg}
\]

\[
\bar{h} = 8.97 \text{ W/m}^2 \cdot \text{K}. \]

Continued …..
(c) The heat-mass transfer analogy, Eq. 6.67, requires that

\[
\frac{\bar{h}}{h_m} = k \frac{D_{AB}}{D_{AB} \left( \frac{D_{AB}}{\alpha} \right)^{1/3}}.
\]

Evaluating \(k\) and \(D_{AB}\) at \(\bar{T} = \left( T_s + T_\infty \right) / 2 = 300 \text{ K}\) and substituting numerical values,

\[
\frac{8.97 \text{ W/m}^2 \cdot \text{K}}{6.71 \times 10^{-3} \text{ m/s}} = 1337 \neq \frac{0.0263 \text{ W/m} \cdot \text{K}}{0.26 \times 10^{-4} \text{ m}^2 / \text{s}} \left( \frac{0.26 \times 10^{-4} \text{ m}^2 / \text{s}}{22.5 \times 10^{-6} \text{ m}^2 / \text{s}} \right)^{1/3} = 1061
\]

Since the equality is not satisfied, we conclude that, for this situation, the analogy is only approximately met (\(\approx 30\%\)).

(d) If \(\phi_\infty = 0.5\) instead of 0.0 and \(q\) is unchanged, \(n_A\) will decrease by nearly a factor of two, as will \(n_A h_{fg} = q_{evap}\). Hence, since \(q_{conv}\) must increase and \(\bar{h}\) remains nearly constant, \(T_s - T_\infty\) must increase. Hence, \(T_s\) will increase.

**COMMENTS:** Note that in part (d), with an increase in \(T_s\), \(h_{fg}\) decreases, but only slightly, and \(\rho_{A,sat}\) increases. From a trial-and-error solution assuming constant values for \(\bar{h}_m\) and \(h\), the disc temperature is 315 K for \(\phi_\infty = 0.5\).
PROBLEM 6.78

KNOWN: Power-time history required to completely evaporate a droplet of fixed diameter maintained at 37°C.

FIND: (a) Average mass transfer convection coefficient when droplet, heater and dry ambient air are at 37°C and (b) Energy required to evaporate droplet if the dry ambient air temperature is 27°C.

SCHEMATIC:

ASSUMPTIONS: (1) Wetted surface area of droplet is of fixed diameter D, (2) Heat-mass transfer analogy is applicable, (3) Heater controlled to operate at constant temperature, \( T_s = 37°C \), (4) Mass of droplet same for part (a) and (b), (5) Mass transfer coefficients for parts (a) and (b) are the same.

PROPERTIES: *Table A-6*, Saturated water (37°C = 310 K): \( h_{fg} = 2414 \text{ kJ/kg}, \rho_{A,sat} = 1/\nu_g = 1/22.93 = 0.04361 \text{ kg/m}^3 \); *Table A-8*, Air-water vapor (\( T_s = 37°C = 310 \text{ K}, 1 \text{ atm} \)): \( D_{AB} = 0.26 \times 10^{-6} \text{ m}^2/\text{s}(310/289)^{3/2} = 0.276 \times 10^{-6} \text{ m}^2/\text{s} \); *Table A-4*, Air (\( T = (27 + 37)°C/2 = 305 \text{ K}, 1 \text{ atm} \)): \( \rho = 1.1448 \text{ kg/m}^3, c_p = 1008 \text{ J/kg} \cdot \text{K}, \nu = 16.39 \times 10^{-6} \text{ m}^2/\text{s}, Pr = 0.706 \).

ANALYSIS: (a) For the isothermal conditions (37°C), the electrical energy \( Q \) required to evaporate the droplet during the interval of time \( \Delta t = t_e \) follows from the area under the P-t curve above,

\[
Q = \int_0^{t_e} P \, dt = \left[ 20 \times 10^{-3} \text{ W} \times (50 \times 60) \text{ s} + 0.5 \times 20 \times 10^{-3} \text{ W} \times (100 - 50) \times 60 \text{ s} \right] = 90 \text{ J}.
\]

From an overall energy balance during the interval of time \( \Delta t = t_e \), the mass loss due to evaporation is

\[
Q = Mh_{fg} \quad \text{or} \quad M = \frac{Q}{h_{fg}}
\]

\[
M = 90 \text{ J}/2414 \times 10^3 \text{ J/kg} = 3.728 \times 10^{-5} \text{ kg}.
\]

To obtain the average mass transfer coefficient, write the rate equation for an interval of time \( \Delta t = t_e \),

\[
M = m \cdot t_e = \bar{h}_m A_S \left( \rho_{A,s} - \rho_{A,\infty} \right) \cdot t_e = \bar{h}_m A_S \rho_{A,s} \left( 1 - \phi_\infty \right) \cdot t_e
\]

Substituting numerical values with \( \phi_\infty = 0 \), find

\[
3.278 \times 10^{-5} \text{ kg} = \bar{h}_m \left( \pi \left( 0.004 \text{ m} \right)^2 / 4 \right) 0.04361 \text{ kg/m}^3 \times (100 \times 60) \text{ s}
\]

Continued …..
PROBLEM 6.78 (Cont.)

\( \bar{h}_m = 0.0113 \text{ m/s}. \)

(b) The energy required to evaporate the droplet of mass \( M = 3.728 \times 10^{-5} \text{ kg} \) follows from an overall energy balance,

\[
Q = M h_{fg} + \bar{h} A_S \left( T_e - T_\infty \right)
\]

where \( \bar{h} \) is obtained from the heat-mass transfer analogy, Eq. 6.67, using \( n = 1/3, \)

\[
\frac{\bar{h}}{h_m} = \frac{k}{D_{AB} L e^n} = \rho c_p L e^{2/3}
\]

where

\[
Sc = \frac{v}{D_{AB}} = \frac{16.39 \times 10^{-6} \text{ m}^2/\text{s}}{0.276 \times 10^{-4} \text{ m}^2/\text{s}} = 0.594
\]

\[
Le = \frac{Sc}{Pr} = \frac{0.594}{0.706} = 0.841.
\]

Hence,

\[
\bar{h} = 0.0113 \text{ m/s} \times 1.1448 \text{ kg/m}^3 \times 1008 \text{ J/kg} \cdot \text{K} \left( 0.841 \right)^{2/3} = 11.62 \text{ W/m}^2 \cdot \text{K}.
\]

and the energy requirement is

\[
Q = 3.728 \times 10^{-5} \text{ kg} \times 2414 \text{ kJ/kg} + 11.62 \text{ W/m}^2 \cdot \text{K} \left( \pi \left( 0.004 \text{ m} \right)^2 / 4 \right) \left( 37 - 27 \right) \degree \text{C}
\]

\[ Q = (90.00 + 0.00145) \text{J} = 90 \text{ J}. \]

The energy required to meet the convection heat loss is very small compared to that required to sustain the evaporative loss.
KNOWN: Initial plate temperature $T_p(0)$ and saturated air temperature ($T_\infty$) in a dishwasher at the start of the dry cycle. Thermal mass per unit area of the plate $Mc/A_s = 1600 \text{ J/m}^2\cdot\text{K}$.

FIND: (a) Differential equation to predict plate temperature as a function of time during the dry cycle and (b) Rate of change in plate temperature at the start of the dry cycle assuming the average convection heat transfer coefficient is $3.5 \text{ W/m}^2\cdot\text{K}$.

SCHEMATIC:

ASSUMPTIONS: (1) Plate is spacewise isothermal, (2) Negligible thermal resistance of water film on plate, (3) Heat-mass transfer analogy applies.

PROPERTIES: Table A-4, Air ($\bar{\mathbf{I}} = (55 + 65)^\circ\text{C}/2 = 333 \text{ K}, 1 \text{ atm}$): $\rho = 1.0516 \text{ kg/m}^3$, $c_p = 1008 \text{ J/kg}\cdot\text{K}$, $Pr = 0.703$, $\nu = 19.24 \times 10^{-6} \text{ m}^2/\text{s}$; Table A-6, Saturated water vapor, ($T_s = 65^\circ\text{C} = 338 \text{ K}$): $\rho_A = 0.1592 \text{ kg/m}^3$, $h_{fg} = 2347 \text{ kJ/kg}$; ($T_s = 55^\circ\text{C} = 328 \text{ K}$): $\rho_A = 0.1029 \text{ kg/m}^3$; Table A-8, Air-water vapor ($T_s = 65^\circ\text{C} = 338 \text{ K}, 1 \text{ atm}$): $D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}$ (338/298)$^{3/2}$ = $0.314 \times 10^{-4} \text{ m}^2/\text{s}$.

ANALYSIS: (a) Perform an energy balance on a rate basis on the plate, 
\[ \dot{E}_{in} - \dot{E}_{out} = \dot{E}_{st} \quad q_{conv} - q_{evap} = (Mc/A_s)(dT_p/dt). \]

Using the rate equations for the heat and mass transfer fluxes, find
\[ \bar{h}[T_\infty - T_p(t)] - \bar{h}_m[\rho_{A,s}(T_s) - \rho_{A,\infty}(T_\infty)]h_{fg} = (Mc/A_s)(dT_p/dt). \]

(b) To evaluate the change in plate temperature at $t = 0$, the start of the drying process when $T_p(0) = 65^\circ\text{C}$ and $T_\infty = 55^\circ\text{C}$, evaluate $\bar{h}_m$ from knowledge of $\bar{h} = 3.5 \text{ W/m}^2\cdot\text{K}$ using the heat-mass transfer analogy, Eq. 6.67, with $n = 1/3$,
\[ \frac{\bar{h}}{\bar{h}_m} = \rho \cdot c_p \cdot Le^{2/3} = \rho \cdot c_p \left( \frac{Sc}{Pr} \right)^{2/3} = \rho \cdot c_p \left( \frac{v / D_{AB}}{Pr} \right)^{2/3} \]
and evaluating thermophysical properties at their appropriate temperatures, find
\[ \frac{3.5 \text{ W/m}^2\cdot\text{K}}{\bar{h}_m} = 1.0516 \text{ kg/m}^3 \times 1008 \text{ J/kg}\cdot\text{K} \left( \frac{19.24 \times 10^{-6} \text{ m}^2/\text{s}}{0.703 \times 0.314 \times 10^{-4} \text{ m}^2/\text{s}} \right)^{2/3} \]
\[ \bar{h}_m = 3.619 \times 10^{-3} \text{ m/s}. \]

Substituting numerical values into the conservation expression of part (a), find
\[ dT_p/dt = -[35.0 + 478.2] \text{ W/m}^2\cdot\text{K}/1600 \text{ J/m}^2\cdot\text{K} = -0.32 \text{ K/s}. \]

COMMENTS: This rate of temperature change will not be sustained for long, since, as the plate cools, the rate of evaporation (which dominates the cooling process) will diminish.
**PROBLEM 7.1**

**KNOWN:** Temperature and velocity of fluids in parallel flow over a flat plate.

**FIND:** (a) Velocity and thermal boundary layer thicknesses at a prescribed distance from the leading edge, and (b) For each fluid plot the boundary layer thicknesses as a function of distance.

**SCHEMATIC:**

![Fluid diagram](image)

**ASSUMPTIONS:** (1) Transition Reynolds number is $5 \times 10^5$.

**PROPERTIES:** Table A.4, Air (300 K, 1 atm): $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$, $Pr = 0.707$; Table A.6, Water (300 K): $\nu = \mu/\rho = 855 \times 10^{-6} \text{ N} \cdot \text{s/m}^2/997 \text{ kg/m}^3 = 0.858 \times 10^{-6} \text{ m}^2/\text{s}$, $Pr = 5.83$; Table A.5, Engine Oil (300 K): $\nu = 550 \times 10^{-6} \text{ m}^2/\text{s}$, $Pr = 6400$; Table A.5, Mercury (300 K): $\nu = 0.113 \times 10^{-6} \text{ m}^2/\text{s}$, $Pr = 0.0248$.

**ANALYSIS:** (a) If the flow is laminar, the following expressions may be used to compute $\delta$ and $\delta_t$, respectively,

$$\delta = \frac{5x}{Re_x^{1/2}}$$

$$\delta_t = \frac{\delta}{Pr^{1/3}}$$

where

$$Re_x = \frac{u_\infty x}{\nu}$$

$$Re_x = \frac{1 \text{ m/s}(0.04 \text{ m})}{\nu} = \frac{0.04 \text{ m}^2/\text{s}}{\nu}$$

(b) Using IHT with the foregoing equations, the boundary layer thicknesses are plotted as a function of distance from the leading edge, $x$.

![Bl thickness plots](image)

**COMMENTS:** (1) Note that $\delta \approx \delta_t$ for air, $\delta > \delta_t$ for water, $\delta >> \delta_t$ for oil, and $\delta < \delta_t$ for mercury. As expected, the boundary layer thicknesses increase with increasing distance from the leading edge.

(2) The value of $\delta_t$ for mercury should be viewed as a rough approximation since the expression for $\delta/\delta_t$ was derived subject to the approximation that $Pr > 0.6$. 

**PROBLEM 7.2**

**KNOWN:** Temperature and velocity of engine oil. Temperature and length of flat plate.

**FIND:** (a) Velocity and thermal boundary layer thickness at trailing edge, (b) Heat flux and surface shear stress at trailing edge, (c) Total drag force and heat transfer per unit plate width, and (d) Plot the boundary layer thickness and local values of the shear stress, convection coefficient, and heat flux as a function of $x$ for $0 \leq x \leq 1$ m.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Critical Reynolds number is $5 \times 10^5$, (2) Flow over top and bottom surfaces.

**PROPERTIES:** Table A.5, Engine Oil ($T_f = 333$ K): $\rho = 864$ kg/m$^3$, $v = 86.1 \times 10^{-6}$ m$^2$/s, $k = 0.140$ W/m·K, $Pr = 1081$.

**ANALYSIS:** (a) Calculate the Reynolds number to determine nature of the flow,

$$Re_L = \frac{u_\infty L}{v} = \frac{0.1 \text{ m/s} \times 1 \text{ m}}{86.1 \times 10^{-6} \text{ m}^2/\text{s}} = 1161$$

Hence the flow is laminar at $x = L$, from Eqs. 7.19 and 7.24, and

$$\delta = 5L \left[ \frac{Re_L}{1161} \right]^{1/2} = 5(1 \text{ m})(1161)^{-1/2} = 0.147 \text{ m}$$

$$\delta_t = \delta Pr^{-1/3} = 0.147 \text{ m}(1081)^{-1/3} = 0.0143 \text{ m}$$

(b) The local convection coefficient, Eq. 7.23, and heat flux at $x = L$ are

$$h_L = \frac{k}{L} \left( \frac{Re_L}{1161} \right)^{1/2} Pr^{1/3} = \frac{0.140 \text{ W/m·K}}{1 \text{ m}} \left( \frac{0.332(1161)^{1/2}}{1081} \right)^{1/3} = 16.25 \text{ W/m}^2 \cdot \text{K}$$

$$q_x^* = h_L (T_S - T_\infty) = 16.25 \text{ W/m}^2 \cdot \text{K} (20 - 100) \times 9 = -1300 \text{ W/m}^2$$

Also, the local shear stress is, from Eq. 7.20,

$$\tau_{s,L} = \frac{\rho u_\infty^2}{2} \left( \frac{Re_L}{1161} \right)^{-1/2} = \frac{864 \text{ kg/m}^3}{2} \left( 0.1 \text{ m/s} \right)^2 \left( \frac{0.332}{1081} \right)^{-1/2}$$

$$\tau_{s,L} = 0.0842 \text{ kg/m·s}^2 = 0.0842 \text{ N/m}^2$$

(c) With the drag force per unit width given by $D' = 2L \overline{\tau}_{s,L}$ where the factor of 2 is included to account for both sides of the plate, it follows that

$$D' = 2L \left( \frac{\rho u_\infty^2}{2} \right) 1.328 \left[ \frac{Re_L}{1161} \right]^{-1/2} = (1 \text{ m}) \frac{864 \text{ kg/m}^3}{2} \left( 0.1 \text{ m/s} \right)^2 / 2 \times 1.328 \left( \frac{1161}{1081} \right)^{-1/2} = 0.337 \text{ N/m}$$

For laminar flow, the average value $\overline{h_L}$ over the distance 0 to L is twice the local value, $h_L$.

$$\overline{h_L} = 2h_L = 32.5 \text{ W/m}^2 \cdot \text{K}$$

The total heat transfer rate per unit width of the plate is

$$q' = 2L \overline{h_L} (T_S - T_\infty) = 2(1 \text{ m}) 32.5 \text{ W/m}^2 \cdot \text{K} (20 - 100) \times 9 = -5200 \text{ W/m}$$

Continued...
(c) Using IHT with the foregoing equations, the boundary layer thickness, and local values of the convection coefficient and heat flux were calculated and plotted as a function of $x$.

![Graph showing boundary layer thickness, convection coefficient, and heat flux as a function of distance from the leading edge.]

**COMMENTS:**

1. Note that since $Pr \gg 1$, $\delta >> \delta_t$. That is, for the high Prandtl liquids, the velocity boundary layer will be much thicker than the thermal boundary layer.

2. A copy of the *IHT Workspace* used to generate the above plot is shown below.

```plaintext
// Boundary layer thickness, delta
delta = 5 * x * Rex ^ -0.5
delta_mm = delta * 1000
delta_plot = delta_mm * 10 // Scaling parameter for convenience in plotting

// Convection coefficient and heat flux, $q''x$
q''x = hx * (Ts - Tinf)
Nux = 0.332 * Rex ^ 0.5 * Pr ^ (1/3)
Nux = hx * x / k
hx_plot = 100 * hx // Scaling parameter for convenience in plotting
q''x_plot = (-1) * q''x // Scaling parameter for convenience in plotting

// Reynolds number
Rex = uinf * x / nu

// Properties Tool: Engine Oil
// Engine Oil property functions : From Table A.5
// Units: T(K)
rho = rho_T("Engine Oil", Tf) // Density, kg/m^3
cp = cp_T("Engine Oil", Tf) // Specific heat, J/kg·K
nu = nu_T("Engine Oil", Tf) // Kinematic viscosity, m^2/s
k = k_T("Engine Oil", Tf) // Thermal conductivity, W/m·K
Pr = Pr_T("Engine Oil", Tf) // Prandtl number

// Assigned variables
Tf = (Ts + Tinf) / 2 // Film temperature, K
Tinf = 100 + 273 // Freestream temperature, K
Ts = 20 + 273 // Surface temperature, K
uinf = 0.1 // Freestream velocity, m/s
x = 1 // Plate length, m
```
PROBLEM 7.3

KNOWN: Velocity and temperature of air in parallel flow over a flat plate.

FIND: (a) Velocity boundary layer thickness at selected stations. Distance at which boundary layers merge for plates separated by $H = 3 \text{ mm}$. (b) Surface shear stress and $v(\delta)$ at selected stations.

SCHEMATIC:

ASSUMPTIONS: (1) Steady flow, (2) Boundary layer approximations are valid, (3) Flow is laminar.

PROPERTIES: *Table A-4*, Air ($300 \text{ K}, 1 \text{ atm}$): $\rho = 1.161 \text{ kg/m}^3$, $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$.

ANALYSIS: (a) For laminar flow,

$$\delta = \frac{5x}{Re_x^{1/2}} = \frac{5}{(u_\infty / \nu)^{1/2} x^{1/2}} \left( \frac{25 \text{ m/s} / 15.89 \times 10^{-6} \text{ m}^2/\text{s}}{x^{1/2}} \right) = 3.99 \times 10^{-3} \text{ m}^{1/2}.$$  

|x (m)| 0.001 | 0.01 | 0.1 |
|δ (mm) | 0.126 | 0.399 | 1.262 |

Boundary layer merger occurs at $x = x_m$ when $\delta = 1.5 \text{ mm}$. Hence

$$\frac{x_m^{1/2}}{3.99 \times 10^{-3} \text{ m}^{1/2}} = 0.376 \text{ m}^{1/2} \quad x_m = 141 \text{ mm}.$$  

(b) The shear stress is

$$\tau_{s,x} = 0.664 \frac{\rho u_\infty^2}{Re_x^{1/2}} = \frac{\rho u_\infty^2}{(u_\infty / \nu)^{1/2} x^{1/2}} \left( \frac{25 \text{ m/s} / 15.89 \times 10^{-6} \text{ m}^2/\text{s}}{x^{1/2}} \right)^{1/2} = 0.192 \left( \frac{\text{N/m}^2}{x^{1/2}} \right).$$  

|x (m)| 0.001 | 0.01 | 0.1 |
|τ_{s,x} (N/m^2) | 6.07 | 1.92 | 0.61 |

The velocity distribution in the boundary layer is $v = (1/2) \left( \frac{\nu u_\infty}{x} \right)^{1/2} (\eta df/d\eta - f)$. At $y = \delta$, $\eta \approx 5.0$, $f \approx 3.24$, $df/d\eta \approx 0.991$.

$$v = \frac{0.5}{x^{1/2}} \left( 15.89 \times 10^{-6} \text{ m}^2/\text{s} \times 25 \text{ m/s} \right)^{1/2} \left( 5.0 \times 0.991 - 3.28 \right) = \left( 0.0167/\eta^{1/2} \right) \text{ m/s}.$$  

|x (m)| 0.001 | 0.01 | 0.1 |
|v (m/s) | 0.528 | 0.167 | 0.053 |

COMMENTS: (1) $v \ll u_\infty$ and $\delta \ll x$ are consistent with BL approximations. Note, $v \rightarrow \infty$ as $x \rightarrow 0$ and approximations breakdown very close to the leading edge. (2) Since $Re_{x_m} = 2.22 \times 10^5$, laminar BL model is valid. (3) Above expressions are approximations for flow between parallel plates, since $du_\infty/dx > 0$ and $dp/dx < 0$.  

PROBLEM 7.4

KNOWN: Liquid metal in parallel flow over a flat plate.

FIND: An expression for the local Nusselt number.

SCHEMATIC:

ASSUMPTIONS: (1) Steady, incompressible flow, (2) \( \delta \ll \delta_t \), hence \( u(y) = u_\infty \), (3) Boundary layer approximations are valid, (4) Constant properties.

ANALYSIS: The boundary layer energy equation is

\[
u \frac{\partial T}{\partial x} + \nu \frac{\partial T}{\partial y} = \alpha \frac{\partial^2 T}{\partial y^2}.
\]

Assuming \( u(y) = u_\infty \), it follows that \( v = 0 \) and the energy equation becomes

\[
u_\infty \frac{\partial T}{\partial x} = \alpha \frac{\partial^2 T}{\partial y^2} \quad \text{or} \quad \frac{\partial T}{\partial x} = \frac{\alpha}{u_\infty} \frac{\partial^2 T}{\partial y^2}.
\]

**Boundary Conditions:** \( T(x,0) = T_s, T(x,\infty) = T_\infty \).

**Initial Condition:** \( T(0,y) = T_\infty \).

The differential equation is analogous to that for transient one-dimensional conduction in a plane wall, and the conditions are analogous to those of Fig. 5.7, Case (1). Hence the solution is given by Eqs. 5.57 and 5.58. Substituting \( y \) for \( x \), \( x \) for \( t \), \( T_\infty \) for \( T_i \), and \( \alpha/u_\infty \) for \( \alpha \), the boundary layer temperature and the surface heat flux become

\[
\frac{T(x,y) - T_s}{T_\infty - T_s} = \text{erf} \left[ \frac{y}{2(\alpha x/u_\infty)^{1/2}} \right]
\]

\[
q_s^* = \frac{k(T_s - T_\infty)}{(\pi \alpha x/u_\infty)^{1/2}}.
\]

Hence, with

\[
\text{Nu}_x \equiv \frac{h x}{k} = \frac{q_s^* x}{(T_s - T_\infty) k}
\]

find

\[
\text{Nu}_x = \frac{x}{(\pi \alpha x/u_\infty)^{1/2}} = \frac{(x u_\infty)^{1/2}}{\pi^{1/2}} \left( \frac{k}{\rho c_p} \frac{\mu c_p H}{k} \right)^{1/2} = \frac{1}{\pi} \left( \frac{\rho u_\infty x}{\mu c_p H} \right)^{1/2} k^{1/2}
\]

\[
\text{Nu}_x = 0.564 \left( \text{Re}_x \text{Pr} \right)^{1/2} = 0.564 \text{Pe}^{1/2}
\]

where \( \text{Pe} = \text{Re} \cdot \text{Pr} \) is the Peclet number.

**COMMENTS:** Because \( k \) is very large, axial conduction effects may not be negligible. That is, the \( \alpha \frac{\partial^2 T}{\partial x^2} \) term of the energy equation may be important.
PROBLEM 7.5

KNOWN: Form of velocity profile for flow over a flat plate.

FIND: (a) Expression for profile in terms of \( u_\infty \) and \( \delta \), (b) Expression for \( \delta(x) \), (c) Expression for \( C_{f,x} \).

SCHEMATIC:

\[
\begin{align*}
&\text{Schematic of flow over a flat plate with velocity profile } u(y) = C_1 + C_2 y \\
&\text{Boundary layer approximations are valid.}
\end{align*}
\]

ASSUMPTIONS: (1) Steady state conditions, (2) Constant properties, (3) Incompressible flow, (4) Boundary layer approximations are valid.

ANALYSIS: (a) From the boundary conditions

\[
\begin{align*}
&\frac{d}{dx} \left[ \int_0^\delta (u_\infty - u) \, dy \right] = \frac{\tau_s}{\rho} \\
&\frac{d^2 u_\infty}{dx^2} \int_0^\delta \left( 1 - \frac{u}{u_\infty} \right) \frac{u}{u_\infty} \, dy = \frac{\mu}{\rho} \frac{\partial u}{\partial y} \bigg|_{y=0} = \frac{v}{\delta} \\
&\frac{d^2 u_\infty}{dx^2} \left[ \frac{y^2}{2\delta} - \frac{y^3}{3\delta^2} \right] \bigg|_0^\delta = \frac{\mu u_\infty}{\delta} \quad \text{or} \quad \frac{u_\infty}{6} \frac{d\delta}{dx} = \frac{v}{\delta}.
\end{align*}
\]

Separating and integrating, find

\[
\delta^2 \left[ \frac{y^2}{2\delta} - \frac{y^3}{3\delta^2} \right] \bigg|_0^\delta = \left( \frac{12 v x}{u_\infty} \right)^{1/2} \left( \frac{v}{u_\infty x} \right)^{1/2} = 3.46 \times \left( \frac{v}{u_\infty x} \right)^{1/2} = 3.46 \times Re_x^{1/2}.
\]

(b) The shear stress at the wall is

\[
\tau_s = \frac{\mu}{\rho} \frac{\partial u}{\partial y} \bigg|_{y=0} = \frac{\mu u_\infty}{3.46} \times Re_x^{1/2}
\]

and the friction coefficient is

\[
C_{f,x} = \frac{\tau_s}{\rho \frac{u_\infty^2}{2}} = \frac{\mu}{\rho u_\infty x} \frac{2}{3.46} Re_x^{1/2} = 0.578 \times Re_x^{-1/2}.
\]

COMMENTS: The foregoing results underpredict those associated with the exact solution

\[
(\delta = 4.96 \times Re_x^{-1/2}, \ C_{f,x} = 0.664 \ Re_x^{-1/2}) \quad \text{and the cubic profile} \quad (\delta = 4.64 \times Re_x^{-1/2}, \ C_{f,x} = 0.646 \ Re_x^{-1/2}).
\]
PROBLEM 7.6

KNOWN: Velocity and temperature profiles and shear stress-boundary layer thickness relation for turbulent flow over a flat plate.

FIND: (a) Expressions for hydrodynamic boundary layer thickness and average friction coefficient, (b) Expressions for local and average Nusselt numbers.

SCHEMATIC:

ASSUMPTIONS: (1) Steady flow, (2) Constant properties, (3) Fully turbulent boundary layer, (4) Incompressible flow, (5) Isothermal plate, (6) Negligible viscous dissipation, (7) \( \delta \approx \delta_t \).

ANALYSIS: (a) The momentum integral equation is

\[
\rho \, u_\infty^2 \frac{d}{dx} \int_0^\delta \left(1 - \frac{u}{u_\infty}\right) \frac{dy}{u_\infty} = \tau_s.
\]

Substituting the expression for the wall shear stress

\[
\frac{d}{dx} \int_0^\delta \left(\frac{y^{1/7}}{\delta} - \left(\frac{y}{\delta}\right)^{2/7}\right) \frac{dy}{\delta} = \frac{d}{dx} \left(\frac{7}{8} \frac{y^{1/7}}{\delta} - \frac{7}{9} \frac{y^{9/7}}{\delta^{2/7}}\right) |_0^\delta
\]

\[
\frac{7}{72} \frac{d\delta}{dx} = 0.0228 \left(\frac{u_\infty \delta}{v}\right)^{-1/4}
\]

Knowing \( \delta \), it follows

\[
\tau_s = 0.0228 \rho u_\infty^2 \left(\frac{u_\infty}{v}\right)^{-1/4} \left[0.376 x \left(\frac{v}{u_\infty}\right)^{-1/5}\right]^{-1/4}
\]

\[
\frac{C_{f,x}}{\rho u_\infty^2/2} = 0.0456 \left[0.376 \frac{u_\infty}{v} \left(\frac{u_\infty}{v}\right)^{-1/5} \times x^{-1/5}\right]^{-1/4} = 0.0592 \left(\frac{v}{u_\infty}\right)^{-1/5}.
\]

Continued …..
PROBLEM 7.6 (Cont.)

The average friction coefficient is then

$$\bar{C}_{f,x} = \frac{1}{x} \int_0^x C_{f,x} \, dx = \frac{1}{x} \, 0.0592 \, \left( \frac{u_\infty}{v} \right)^{-1/5} \int_0^x x^{-1/5} \, dx$$

$$\bar{C}_{f,x} = \frac{1}{x} \, 0.0592 \, \left( \frac{u_\infty}{v} \right)^{-1/5} x^{4/5} \left( \frac{5}{4} \right) = 0.074 \, \text{Re}_x^{-1/5}. \quad <$$

(b) The energy integral equation for turbulent flow is

$$\frac{d}{dx} \int_0^{\delta_t} u \left( T_\infty - T \right) dy = \frac{q_s^*}{\rho \, c_p} = -\frac{h}{\rho \, c_p} \left( T_s - T_\infty \right).$$

Hence,

$$u_\infty \frac{d}{dx} \int_0^{\delta_t} \frac{u}{T_\infty} \frac{T - T_\infty}{T_s - T_\infty} \, dy = u_\infty \frac{d}{dx} \int_0^{\delta_t} \left( \frac{y}{\delta_t} \right)^{1/7} \left[ 1 - \left( \frac{y}{\delta_t} \right)^{1/7} \right] \, dy = \frac{h}{\rho \, c_p}$$

or, with $\xi = \delta_t / \delta$,

$$u_\infty \frac{d}{dx} \left[ \frac{7}{8} \delta_t^{8/7} - \frac{7}{9} \delta_t^{8/7} \right] = \frac{h}{\rho \, c_p} \quad u_\infty \frac{d}{dx} \left[ \frac{7}{72} \delta_t^{8/7} \right] = \frac{h}{\rho \, c_p}.$$  

Hence, with $\xi = 1$ and $\delta/x = 0.376 \, \text{Re}_x^{-1/5}$,

$$\frac{7}{72} \, u_\infty (0.376) \left( \frac{u_\infty}{v} \right)^{-1/5} \frac{d}{dx} \left( x^{4/5} \right) = \frac{h}{\rho \, c_p}$$

$$h = 0.0292 \, \rho \, c_p u_\infty \text{Re}_x^{-1/5} = 0.0292 \, \frac{k}{x} \, \frac{u_\infty}{\alpha} \, \frac{u_\infty x}{v} \, \text{Re}_x^{-1/5}$$

$$\text{Nu}_x = \frac{hx}{k} = 0.0292 \, \text{Re}_x^{4/5} \, \text{Pr}. \quad <$$

Hence,

$$\bar{h}_x = \frac{1}{x} \int_0^x \! \! h \, dx = \frac{0.0292 \, \text{Pr}}{x} \, k \left( \frac{u_\infty}{v} \right)^{4/5} \int_0^x x^{-1/5} \, dx = 0.0292 \, \frac{k}{x} \, \text{Pr} \left( \frac{u_\infty x}{v} \right)^{4/5} \left( \frac{5}{4} \right)$$

$$\bar{\text{Nu}}_x = \frac{\bar{h}_x x}{k} = 0.037 \, \text{Re}_x^{4/5} \, \text{Pr}. \quad <$$

COMMENTS: (1) The foregoing results are in excellent agreement with empirical correlations, except that use of Pr$^{1/3}$ instead of Pr, would be more appropriate.

(2) Note that the $1/7$ profile breaks down at the surface. For example,

$$\frac{\partial \left( u/u_\infty \right)}{\partial y} \bigg|_{y=0} = \frac{1}{7} \, \delta^{-1/7} \, y^{-6/7} = \infty$$

or $\tau_s = \infty$. Despite this unrealistic characteristic of the profile, its use with integral methods provides excellent results.
**PROBLEM 7.7**

**KNOWN:** Parallel flow over a flat plate and two locations representing a short span $x_1$ to $x_2$ where $(x_2 - x_1) \ll L$.

**FIND:** Three different expressions for the average heat transfer coefficient over the short span $x_1$ to $x_2$, $\overline{h}_{1-2}$.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Parallel flow over a flat plate.

**ANALYSIS:** The heat rate per unit width for the span can be written as

$$q_{1-2} = \overline{h}_{1-2} (x_2 - x_1)(T_s - T_\infty)$$

where $\overline{h}_{1-2}$ is the average heat transfer coefficient over the span and can be evaluated in either of the following three ways:

(a) **Local coefficient at** $\bar{x} = (x_1 + x_2)/2$. If the span is very short, it is reasonable to assume that

$$\overline{h}_{1-2} = h_{\bar{x}}$$

where $h_{\bar{x}}$ is the local convection coefficient at the mid-point of the span.

(b) **Local coefficients at** $x_1$ and $x_2$. If the span is very short it is reasonable to assume that $\overline{h}_{1-2}$ is the average of the local values at the ends of the span,

$$\overline{h}_{1-2} \approx \left[ h_{x1} + h_{x2} \right]/2.$$  

(c) **Average coefficients for** $x_1$ and $x_2$. The heat rate for the span can also be written as

$$q_{1-2} = q_{0-2} - q_{0-1}$$

where the rate $q_{0-x}$ denotes the heat rate for the plate over the distance from 0 to $x$. In terms of heat transfer coefficients, find

$$\overline{h}_{1-2} \cdot (x_2 - x_1) = \overline{h}_2 \cdot x_2 - \overline{h}_1 \cdot x_1$$

$$\overline{h}_{1-2} = \frac{\overline{h}_2}{x_2 - x_1} \cdot x_2 - \frac{\overline{h}_1}{x_2 - x_1} \cdot x_1$$

where $\overline{h}_1$ and $\overline{h}_2$ are the average coefficients from 0 to $x_1$ and $x_2$, respectively.

**COMMENTS:** Eqs. (2) and (3) are approximate and work better when the span is small and the flow is turbulent rather than laminar ($h_x \sim x^{-0.2}$ vs $h_x \sim x^{-0.5}$). Of course, we require that $x_c < x_1$, $x_2$ or $x_c > x_1$, $x_2$; that is, the approximations are inappropriate around the transition region. Eq. (5) is an exact relationship, which applies under any conditions.
**PROBLEM 7.8**

**KNOWN:** Flat plate comprised of rectangular modules of surface temperature $T_s$, thickness $a$ and length $b$ cooled by air at 25°C and a velocity of 30 m/s. Prescribed thermophysical properties of the module material.

**FIND:** (a) Required power generation for the module positioned 700 mm from the leading edge of the plate and (b) Maximum temperature in this module.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Laminar flow at leading edge of plate, (2) Transition Reynolds number of $5 \times 10^5$, (3) Heat transfer is one-dimensional in y-direction within each module, (4) $\dot{q}$ is uniform within module, (5) Negligible radiation heat transfer.

**PROPERTIES:** Module material (given): $k = 5.2$ W/m·K, $c_p = 320$ J/kg·K, $\rho = 2300$ kg/m$^3$; Table A-4, Air ($T_f = (T_s + T_\infty) / 2 = 360$ K, 1 atm): $k = 0.0308$ W/m·K, $\nu = 22.02 \times 10^{-6}$ m$^2$/s, $Pr = 0.698$.

**ANALYSIS:** (a) The module power generation follows from an energy balance on the module surface,

$$ q_{\text{conv}} = q_{\text{gen}} $$

$$ \overline{h} (T_s - T_\infty) = \dot{q} \cdot a \quad \text{or} \quad \dot{q} = \frac{\overline{h} (T_s - T_\infty)}{a} . $$

To select a convection correlation for estimating $\overline{h}$, first find the Reynolds numbers at $x = L$.

$$ Re_L = \frac{u_\infty L}{\nu} = \frac{30 \text{ m/s} \times 0.70 \text{ m}}{22.02 \times 10^{-6} \text{ m}^2/\text{s}} = 9.537 \times 10^5. $$

Since the flow is turbulent over the module, the approximation $\overline{h} \approx h_x (L + b/2)$ is appropriate, with

$$ Re_{L+b/2} = \frac{30 \text{ m/s} \times (0.700 + 0.050/2) \text{ m}}{22.02 \times 10^{-6} \text{ m}^2/\text{s}} = 9.877 \times 10^5. $$

Using the turbulent flow correlation with $x = L + b/2 = 0.725$ m,

$$ Nu_x = \frac{h_x x}{k} = 0.0296 \left( \frac{Re_x}{Pr} \right)^{4/3} $$

$$ Nu_x = 0.0296 \left( \frac{9.877 \times 10^5}{0.698} \right)^{4/3} (0.698)^{1/3} = 1640 $$

$$ \overline{h} \approx h_x = \frac{Nu_x k}{x} = \frac{1640 \times 0.0308 \text{ W/m·K}}{0.725} = 69.7 \text{ W/m}^2 \cdot \text{K}. $$

Continued …..
Hence,

\[
\dot{q} = \frac{69.7 \text{ W/m}^2 \cdot \text{K}(150 - 25) \text{ K}}{0.010 \text{ m}} = 8.713 \times 10^5 \text{ W/m}^3. \tag{<}
\]

(b) The maximum temperature within the module occurs at the surface next to the insulation (y = 0). For one-dimensional conduction with thermal energy generation, use Eq. 3.42 to obtain

\[
T(0) = \frac{\dot{q}a^2}{2k} + T_s = \frac{8.713 \times 10^5 \text{ W/m}^3 \times (0.010 \text{ m})^2}{2 \times 5.2 \text{ W/m} \cdot \text{K}} + 150^\circ \text{C} = 158.4^\circ \text{C}. \tag{<}
\]

**COMMENTS:** An alternative approach for estimating the average heat transfer coefficient for the module follows from the relation

\[
\frac{q_{\text{module}}}{q_0} = L_b \frac{\ln(1 + b)}{L_b} \quad \text{or} \quad h = \frac{L + b}{b} \frac{h_{L+b}}{h_L}.
\]

Recognizing that laminar and turbulent flow conditions exist, the appropriate correlation is

\[
\overline{Nu}_x = \left(0.037 \text{Re}_x^{4/5} - 871\right) \text{Pr}^{1/3}
\]

With \( x = L + b \) and \( x = L \), find

\[
\overline{h}_{L+b} = 54.81 \text{ W/m}^2 \cdot \text{K} \quad \text{and} \quad \overline{h}_L = 53.73 \text{ W/m}^2 \cdot \text{K}.
\]

Hence,

\[
\overline{h} = \left[ \frac{54.81 \times 0.750 - 53.73 \times 0.700}{0.050} \right] \text{ W/m}^2 \cdot \text{K} = 69.9 \text{ W/m}^2 \cdot \text{K}.
\]

which is in excellent agreement with the approximate result employed in part (a).
**PROBLEM 7.9**

**KNOWN:** Dimensions and surface temperature of electrically heated strips. Temperature and velocity of air in parallel flow.

**FIND:** (a) Rate of convection heat transfer from first, fifth and tenth strips as well as from all the strips, (b) For air velocities of 2, 5 and 10 m/s, determine the convection heat rates for all the locations of part (a), and (c) Repeat the calculations of part (b), but under conditions for which the flow is fully turbulent over the entire array of strips.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Top surface is smooth, (2) Bottom surface is adiabatic, (3) Critical Reynolds number is $5 \times 10^5$, (4) Negligible radiation.

**PROPERTIES:** *Table A.4, Air (T_f = 535 K, 1 atm):* $v = 43.54 \times 10^6$ m$^2$/s, $k = 0.0429$ W/m-K, Pr = 0.683.

**ANALYSIS:**

(a) The location of transition is determined from

$$x_c = 5 \times 10^5 \frac{v}{u_\infty} = 5 \times 10^5 \frac{43.54 \times 10^6}{2} = 10.9 \text{ m}$$

Since $x_c > > L = 0.25 \text{ m}$, the air flow is laminar over the entire heater. For the first strip, $q_1 = \bar{h}_1 (\Delta L \times w)(T_s - T_\infty)$ where $\bar{h}_1$ is obtained from

$$\bar{h}_1 = \frac{k}{\Delta L} 0.664 \text{Re}^{1/2} \text{Pr}^{1/3}$$

$$\bar{h}_1 = \frac{0.0429 \text{ W/m-K}}{0.01 \text{ m}} \times 0.664 \left( \frac{2 \text{ m/s} \times 0.01 \text{ m}}{43.54 \times 10^6 \text{ m}^2/\text{s}} \right)^{1/2} (0.683)^{1/3} = 53.8 \text{ W/m}^2 \cdot \text{K}$$

$$q_1 = 53.8 \text{ W/m}^2 \cdot \text{K} (0.01 \text{ m} \times 0.2 \text{ m}) (500 - 25) ^\circ \text{C} = 51.1 \text{ W}$$

For the fifth strip, $q_5 = q_{0-5} - q_{0-4}$.

$$q_5 = h_{0-5} (5\Delta L \times w)(T_s - T_\infty) - h_{0-4} (4\Delta L \times w)(T_s - T_\infty)$$

$$q_5 = (5h_{0-5} - 4h_{0-4})(\Delta L \times w)(T_s - T_\infty)$$

Hence, with $x_5 = 5\Delta L = 0.05 \text{ m}$ and $x_4 = 4\Delta L = 0.04 \text{ m}$, it follows that $h_{0-5} = 24.1 \text{ W/m}^2 \cdot \text{K}$ and $h_{0-4} = 26.9 \text{ W/m}^2 \cdot \text{K}$ and

$$q_5 = (5 \times 24.1 - 4 \times 26.9) \text{ W/m}^2 \cdot \text{K} (0.01 \times 0.2) \text{ m}^2 (500 - 25) \text{ K} = 12.2 \text{ W}$$

Similarly, where $h_{0-10} = 17.00 \text{ W/m}^2 \cdot \text{K}$ and $h_{0-9} = 17.92 \text{ W/m}^2 \cdot \text{K}$.

$$q_{10} = (10h_{0-10} - 9h_{0-9})(\Delta L \times w)(T_s - T_\infty)$$

$$q_{10} = (10 \times 17.00 - 9 \times 17.92) \text{ W/m}^2 \cdot \text{K} (0.01 \times 0.2) \text{ m}^2 (500 - 25) \text{ K} = 8.3 \text{ W}$$

Continued...
PROBLEM 7.9 (Cont.)

For the entire heater,

\[
\bar{h}_{0-25} = \frac{k}{L} 0.664 \operatorname{Re}^{1/2} \operatorname{Pr}^{1/3} = \frac{0.0429}{0.25} \times 0.664 \left( \frac{2 \times 0.25}{43.54 \times 10^{-6}} \right)^{1/2} \left(0.683\right)^{1/3} = 10.75 \text{ W/m}^2 \cdot \text{K}
\]

and the heat rate over all 25 strips is

\[
q_{0-25} = \bar{h}_{0-25} (L \times w) (T_s - T_\infty) = 10.75 \text{ W/m}^2 \cdot \text{K} (0.25 \times 0.2) \text{ m}^2 (500 - 25) \text{ C} = 255.3 \text{ W}
\]

(b,c) Using the IHT Correlations Tool, External Flow, for Laminar or Mixed Flow Conditions, and following the same method of solution as above, the heat rates for the first, fifth, tenth and all the strips were calculated for air velocities of 2, 5 and 10 m/s. To evaluate the heat rates for fully turbulent conditions, the analysis was performed setting \( \text{Re}_{x,c} = 1 \times 10^6 \). The results are tabulated below.

</table>

COMMENTS: (1) An alternative approach to evaluating the heat loss from a single strip, for example, strip 5, would take the form \( q_5 = \bar{h}_5 (\Delta L \times w) (T_s - T_\infty) \), where \( \bar{h}_5 = h_{x=x=4.5\Delta L} \) or \( \bar{h}_5 = (h_{x=x=5\Delta L} + h_{x=x=4\Delta L})/2 \).

(2) From the tabulated results, note that for both flow conditions, the heat rate for each strip and the entire heater, increases with increasing air velocity. For both flow conditions and for any specified velocity, the strip heat rates decrease with increasing distance from the leading edge.

(3) The effect of flow conditions, laminar vs. fully turbulent flow, on strip heat rates shows some unexpected behavior. For the \( u_\text{in} = 5 \text{ m/s} \) condition, the effect of turbulent flow is to increase the heat rates for the entire heater and the tenth and fifth strips. For the \( u_\text{in} = 10 \text{ m/s} \), the effect of turbulent flow is to increase the heat rates at all locations. This behavior is a consequence of low Reynolds number (\( \text{Re}_x = 2.3 \times 10^4 \)) at \( x = 0.25 \text{ m} \) with \( u_\text{in} = 10 \text{ m/s} \).

(4) To more fully appreciate the effects due to laminar vs. turbulent flow conditions and air velocity, it is useful to examine the local coefficient as a function of distance from the leading edge. How would you use the results plotted below to explain heat rate behavior evident in the summary table above?

[Graph showing local coefficient vs. distance from the leading edge]
**PROBLEM 7.10**

**KNOWN:** Speed and temperature of atmospheric air flowing over a flat plate of prescribed length and temperature.

**FIND:** Rate of heat transfer corresponding to $\text{Re}_{x,c} = 10^5$, $5 \times 10^5$ and $10^6$.

**SCHEMATIC:**

![Schematic](image)

**ASSUMPTIONS:** (1) Flow over top and bottom surfaces.

**PROPERTIES:** Table A-4, Air ($T_f = 348K$, 1 atm): $\rho = 1.00 \text{ kg/m}^3$, $\nu = 20.72 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 0.0299 \text{ W/mK}$, $Pr = 0.700$.

**ANALYSIS:** With

$$\text{Re}_L = \frac{u_\infty L}{\nu} = \frac{25 \text{ m/s} \times 1 \text{ m}}{20.72 \times 10^{-6} \text{ m}^2/\text{s}} = 1.21 \times 10^6$$

the flow becomes turbulent for each of the three values of $\text{Re}_{x,c}$. Hence,

$$\overline{\text{Nu}}_L = \left(0.037 \text{ Re}^{4/5}_L - A \right) Pr^{1/3}$$

$$A = 0.037 \text{ Re}^{4/5}_{x,c} - 0.664 \text{ Re}^{1/2}_{x,c}$$

<table>

</table>

where $q' = 2 \overline{h}_L (T_s - T_\infty)$ is the total heat loss per unit width of plate.

**COMMENTS:** Note that $\overline{h}_L$ decreases with increasing $\text{Re}_{x,c}$, as more of the surface becomes covered with a laminar boundary layer.
PROBLEM 7.11

KNOWN: Velocity and temperature of air in parallel flow over a flat plate of 1-m length.

FIND: (a) Calculate and plot the variation of the local convection coefficient, \( h(x) \), with distance for flow conditions corresponding to transition Reynolds numbers of \( 5 \times 10^5 \), \( 2.5 \times 10^5 \) and 0 (fully turbulent), (b) Plot the variation of the average convection coefficient, \( \overline{h_x} \), for the three flow conditions of part (a), and (c) Determine the average convection coefficients for the entire plate, \( \overline{h_L} \), for the three flow conditions of part (a).

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant surface temperature, and (3) Critical Reynolds depends upon prescribed flow conditions.

PROPERTIES: Table A.4, Air (\( T_f = 300 \) K, 1 atm): \( \nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s} \), \( k = 0.0263 \text{ W/m} \cdot \text{K} \), \( Pr = 0.707 \).

ANALYSIS: (a) The Reynolds number for the plate (\( L = 1 \) m) is
\[
Re_L = \frac{u_\infty L}{\nu} = \frac{10 \text{ m/s} \times 1 \text{ m}}{15.89 \times 10^{-6} \text{ m}^2/\text{s}} = 6.29 \times 10^5.
\]

Hence, the boundary layer conditions are mixed with \( Re_{x,c} = 5 \times 10^5 \),
\[
x_c = L \left( \frac{Re_{x,c}}{Re_L} \right) = 1 \text{ m} \times \frac{5 \times 10^5}{6.29 \times 10^5} = 0.795 \text{ m}
\]

Using the IHT Correlation Tool, External Flow, Local coefficients for Laminar or Turbulent Flow, \( h(x) \) was evaluated and plotted with critical Reynolds numbers of \( 5 \times 10^5 \), \( 2.5 \times 10^5 \) and 0 (fully turbulent). Note the location of the laminar-turbulent transition for the first two flow conditions.

Continued...
PROBLEM 7.11 (Cont.)

(b) Using the IHT Correlation Tool, External Flow, Average coefficient for Laminar or Mixed Flow, \( \overline{h}_X (x) \) was evaluated and plotted for the three flow conditions. Note that the change in \( \overline{h}_X (x) \) at the critical length, \( x_c \), is rather gradual, compared to the abrupt change for the local coefficient, \( h_x(x) \).

![Graph showing \( \overline{h}_L \) vs \( x \) for different flow conditions]

(c) The average convection coefficients for the plate can be determined from the above plot since \( \overline{h}_L = \overline{h}_X (L) \). The values for the three flow conditions are, respectively,

\[
\overline{h}_L = 17.4, 27.5 \text{ and } 37.8 \text{ W/}m^2\cdot\text{K} 
\]

COMMENTS: A copy of the IHT Workspace used to generate the above plots is shown below.

```
// Method of Solution: Use the Correlation Tools, External Flow, Flat Plate, for (i) Local, laminar or turbulent flow and (ii) Average, laminar or mixed flow, to evaluate the local and average convection coefficients as a function of position on the plate. ```
**PROBLEM 7.13**

**KNOWN:** Two plates of length L and 2L experience parallel flow with a critical Reynolds number of $5 \times 10^5$.

**FIND:** Reynolds numbers for which the total heat transfer rate is independent of orientation.

**SCHEMATIC:**

![Schematic](image)

**ASSUMPTIONS:** (1) Plate temperatures and flow conditions are equivalent.

**ANALYSIS:** The total heat transfer rate would be the same ($q_L = q_{2L}$), if the convection coefficients were equal, $\bar{h}_L = \bar{h}_{2L}$. Conditions for which such an equality is possible may be inferred from a sketch of $\bar{h}_L$ versus $Re_L$.

For laminar flow ($Re_L < Re_{x,c}$), $\bar{h}_L \propto L^{-1/2}$, and for mixed laminar and turbulent flow ($Re_L > Re_{x,c}$), $\bar{h}_L = C_1 L^{-1/5} - C_2 L^{-1}$. Hence $\bar{h}_L$ varies with $Re_L$ as shown, and two possibilities are suggested.

**Case (a):** Laminar flow exists on the shorter plate, while mixed flow conditions exist on the longer plate.

**Case (b):** Mixed boundary layer conditions exist on both plates.

In both cases, it is required that $\bar{h}_L = \bar{h}_{2L}$ and $Re_{2L} = 2 Re_L$. 

Continued …..
PROBLEM 7.13 (Cont.)

Case (a): From expressions for $h_L$ in laminar and mixed flow

\[
0.664 \frac{k}{L} \frac{Re^{1/2}}{Pr^{1/3}} = \frac{k}{2L} \left( 0.037 Re^{4/5}_L - 871 \right) Pr^{1/3}
\]

\[
0.664 Re^{1/2}_L = 0.032 Re^{4/5}_L - 435.
\]

Since $Re_L < 5 \times 10^5$ and $Re_{2L} = 2 Re_L > 5 \times 10^5$, the required value of $Re_L$ may be narrowed to the range

\[
2.5 \times 10^5 < Re_L < 5 \times 10^5.
\]

From a trial-and-error solution, it follows that

\[
Re_L \approx 3.2 \times 10^5.
\]

Case (b): For mixed flow on both plates

\[
\frac{k}{L} \left( 0.037 Re^{4/5}_L - 871 \right) Pr^{1/3} = \frac{k}{2L} \left( 0.037 Re^{4/5}_{2L} - 871 \right) Pr^{1/3}
\]

or

\[
0.037 Re^{4/5}_L - 871 = 0.032 Re^{4/5}_L - 435
\]

\[
0.005 Re^{4/5}_L = 436
\]

\[
Re_L = 1.50 \times 10^6.
\]

COMMENTS: (1) Note that it is impossible to satisfy the requirement that $h_L = h_{2L}$ if $Re_L < 0.25 \times 10^5$ (laminar flow for both plates).

(2) The results are independent of the nature of the fluid.
PROBLEM 7.14

KNOWN: Water flowing over a flat plate under specified conditions.

FIND: (a) Heat transfer rate per unit width, \( q' (W/m) \), evaluating properties at \( T_f = (T_s + T_\infty)/2 \), (b) Error in \( q' \) resulting from evaluating properties at \( T_\infty \), (c) Heat transfer rate, \( q' \), if flow is assumed turbulent at leading edge, \( x = 0 \).

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions.

PROPERTIES: Table A-6. Water (\( T_\infty = 4^\circ C = 277K \)): \( \rho_f = 1000 \text{ kg/m}^3 \), \( \mu_f = 1560 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 \), \( \nu_f = \mu_f/\rho_f = 1.560 \times 10^{-6} \text{ m}^2/\text{s} \), \( k_f = 0.577 \text{ W/m-K} \), \( Pr = 11.44 \); Water (\( T_f = 295K \)): \( \nu = 0.961 \times 10^{-6} \text{ m}^2/\text{s} \), \( k = 0.606 \text{ W/m-K} \), \( Pr = 6.62 \); Water (\( T_s = 40^\circ C = 313K \)): \( \mu = 657 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 \).

ANALYSIS: (a) The heat rate is given as \( q' = \bar{h}L(T_s - T_\infty) \), and \( \bar{h} \) must be estimated by the proper correlation. Using properties evaluated at \( T_f \), the Reynolds number is
\[
Re_L = \frac{u_\infty L}{\nu} = \frac{0.6 \text{ m/s} \times 1.5 \text{ m}}{0.961 \times 10^{-6} \text{ m}^2/\text{s}} = 9.365 \times 10^5.
\]
Hence flow is mixed and the appropriate correlation and convection coefficient are
\[
\overline{Nu}_L = \left[ 0.037 \left( \frac{Re}{L} \right)^{4/5} - 871 \right] Pr^{1/3} = \left[ 0.037 \left( 9.365 \times 10^5 \right)^{4/5} - 871 \right] 6.62^{1/3} = 2522
\]
\[
\bar{h}_L \equiv \frac{\overline{Nu}_L k}{L} = \frac{2522 \times 0.606 \text{ W/m-K}}{1.5 \text{ m}} = 1019 \text{ W/m}^2 \cdot \text{K}.
\]
The heat rate is then
\[
q' = 1019 \text{ W/m}^2 \cdot \text{K} \times 1.5 \text{ m} \times (40 - 4)^\circ \text{C} = 55.0 \text{ kW/m}.
\]

(b) Evaluating properties at the free stream temperature, \( T_\infty \),
\[
Re_L = \frac{0.6 \text{ m/s} \times 1.5 \text{ m}}{1.560 \times 10^{-6} \text{ m}^2/\text{s}} = 5.769 \times 10^5
\]
The flow is still mixed, giving
\[
\overline{Nu}_L = \left[ 0.037 \left( 5.769 \times 10^5 \right)^{4/5} - 871 \right] 11.44^{1/3} = 1424
\]
\[
\bar{h}_L = 1424 \times 0.577 \text{ W/m-K} \times \frac{1}{1.5 \text{ m}} = 575 \text{ W/m-K}
\]
\[
q' = 575 \text{ W/m-K} \times 1.5 \text{ m} \times (40 - 4)^\circ \text{C} = 31.1 \text{ kW/m}.
\]

Continued …..
(c) If flow were tripped at the leading edge, the flow would be turbulent over the full length of the plate, in which case,

\[
\begin{align*}
\bar{Nu}_L &= 0.037 \left( \frac{Re}{Pr} \right)^{4/5} = 0.037 \left( \frac{9.365 \times 10^5}{1.35 \times 10^5} \right)^{4/5} = 4157 \\
\bar{h}_L &= \bar{Nu}_L \frac{k}{L} = 4157 \times 0.606 \text{ W/m} \cdot \text{K} / 1.5 \text{ m} = 1679 \text{ W/m}^2 \cdot \text{K}
\end{align*}
\]

\[q' = \bar{h}_L (T_s - T_\infty) = 1679 \text{ W/m}^2 \cdot \text{K} \times 1.5 \text{ m} \times (40 - 4) \degree \text{C} = 90.7 \text{ kW/m}.\]

**COMMENTS:** Comparing results:

The heat rate is significantly underpredicted if the properties are incorrectly evaluated at \(T_\infty\) instead of \(T_f\).
PROBLEM 7.15

KNOWN: Temperature, pressure and Reynolds number for air flow over a flat plate of uniform surface temperature.

FIND: (a) Rate of heat transfer from the plate, (b) Rate of heat transfer if air velocity is doubled and pressure is increased to 10 atm.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform surface temperature, (3) Negligible radiation, (4) \( \text{Re}_c = 5 \times 10^5 \).

PROPERTIES: Table A-4, Air \( (T_f = 348\,\text{K}, \, 1\,\text{atm}) \): \( k = 0.0299\,\text{W/m}\cdot\text{K}, \, \text{Pr} = 0.70 \).

ANALYSIS: (a) The heat rate is

\[
q = \overline{h}_L (w \times L) \, (T_s - T_\infty).
\]

Since the flow is laminar over the entire plate for \( \text{Re}_L = 4 \times 10^4 \), it follows that

\[
\overline{\text{Nu}}_L = \frac{\overline{h}_L L}{k} = 0.664 \frac{\text{Re}_L^{1/2}}{\text{Pr}^{1/3}} = 0.664 \left(\frac{40,000}{(0.70)^{1/3}}\right) = 117.9.
\]

Hence

\[
\overline{h}_L = 117.9 \frac{k}{L} = 117.9 \frac{0.0299\,\text{W/m}\cdot\text{K}}{0.2\,\text{m}} = 17.6\,\text{W/m}^2\cdot\text{K}
\]

and

\[
q = 17.6 \frac{W}{m^2\cdot K} (0.1\,m \times 0.2\,m) \, (100 - 50)\,\text{C} = 17.6\,\text{W}.
\]

(b) With \( p_2 = 10\, p_1 \), it follows that \( \rho_2 = 10\, \rho_1 \) and \( \nu_2 = \nu_1/10 \). Hence

\[
\text{Re}_{L2} = \left(\frac{u_{\infty L}}{\nu}\right)_2 = 2 \times 10 \left(\frac{u_{\infty L}}{\nu}\right)_1 = 20\,\text{Re}_{L1} = 8 \times 10^5
\]

and mixed boundary layer conditions exist on the plate. Hence

\[
\overline{\text{Nu}}_L = \frac{\overline{h}_L L}{k} = \left(0.037\,\text{Re}_L^{4/5} - 871\right) \frac{(0.70)^{1/3}}{ \text{Pr}^{1/3}} = \left[0.037 \times \left(8 \times 10^5\right)^{4/5} - 871\right] (0.70)^{1/3}
\]

\[
\overline{\text{Nu}}_L = 961.
\]

Hence,

\[
\overline{h}_L = 961 \frac{0.0299\,\text{W/m}\cdot\text{K}}{0.2\,\text{m}} = 143.6\,\text{W/m}^2\cdot\text{K}
\]

\[
q = 143.6 \frac{W}{m^2\cdot K} (0.1\,m \times 0.2\,m) \, (100 - 50)\,\text{C} = 143.6\,\text{W}.
\]

COMMENTS: Note that, in calculating \( \text{Re}_{L2} \), ideal gas behavior has been assumed. It has also been assumed that \( k, \mu \), and \( \text{Pr} \) are independent of pressure over the range considered.
**PROBLEM 7.16**

**KNOWN:** Length and surface temperature of a rectangular fin.

**FIND:** (a) Heat removal per unit width, \( q' \), when air at a prescribed temperature and velocity is in parallel, turbulent flow over the fin, and (b) Calculate and plot \( q' \) for motorcycle speeds ranging from 10 to 100 km/h.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible radiation, (3) Turbulent flow over entire surface.

**PROPERTIES:** Table A.4, Air (412 K, 1 atm): \( \nu = 27.85 \times 10^{-6} \text{ m}^2/\text{s}, k = 0.0346 \text{ W/m-K}, \text{ Pr} = 0.69. \)

**ANALYSIS:** (a) The heat loss per unit width is
\[
q' = 2 \times \left[ \frac{hL(T_S - T_\infty)}{L} \right]
\]
where \( h \) is obtained from the correlation, Eq. 7.41 but with turbulent flow over the entire surface,

\[
\bar{Nu}_L = 0.037 \text{Re}_L^{4/5} \text{ Pr}^{1/3} = 0.037 \left[ \frac{80 \text{ km/h} \times 1000 \text{ m/km} \times 1/3600 \text{ h/s} \times 0.15 \text{ m}}{27.85 \times 10^{-6} \text{ m}^2/\text{s}} \right]^{4/5} (0.69)^{1/3} = 378
\]

Hence,
\[
\bar{h}_L = \frac{k}{\text{Nu}_L} = \frac{0.0346 \text{ W/m-K}}{0.15 \text{ m}} 378 = 87 \text{ W/m}^2 \cdot \text{K}
\]

\[
q' = 2 \times \left[ 87 \text{ W/m}^2 \cdot \text{K} \times 0.15 \text{ m} (523 - 300) \text{ K} \right] = 5826 \text{ W/m}.
\]

(b) Using the foregoing equations in the IHT Workspace, \( q' \) as a function of speed was calculated and is plotted as shown.

**COMMENTS:** (1) Radiation emission from the fin is not negligible. With an assumed emissivity of \( \varepsilon = 1 \), the rate of emission per unit width at 80 km/h would be \( q' = (\sigma T_s^4)2L = 1273 \text{ W/m.} \) If the fin received negligible radiation from its surroundings, its loss by radiation would then be approximately 20% of that by convection.

(2) From the correlation and heat rate expression, it follows that \( q' \sim u_\infty^{4/5} \). That is, \( q' \) vs. \( u_\infty \) is nearly linear as evident from the above plot.
PROBLEM 7.17

KNOWN: Wall of a metal building experiences a 10 mph (4.47 m/s) breeze with air temperature of 90°F (32.2°C) and solar insolation of 400 W/m². The length of the wall in the wind direction is 10 m and the emissivity is 0.93.

FIND: Estimate the average wall temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) The solar absorptivity of the wall is unity, (3) Sky irradiation is negligible, (4) Wall is isothermal at the average temperature T_s, (5) Flow is fully turbulent over the wall, and (6) Negligible heat transfer into the building.

PROPERTIES: Table A-4, Air (assume T_f = 305 K, 1 atm): \( \nu = 16.27 \times 10^6 \text{ m}^2/\text{s} \), \( k = 0.02658 \text{ W/m·K} \), Pr = 0.707.

ANALYSIS: Perform an energy balance on the wall surface considering convection, absorbed irradiation and emission. On a per unit width,

\[
\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0 \\
-\dot{q}_{\text{cv}} + (\alpha_S G_S - E_S) L = 0 \\
-h_L L (T_s - T_\infty) + (\alpha_S G_S - \varepsilon \sigma T_s^4) L = 0
\]

The average convection coefficient is estimated using Eq. 7.41 assuming fully turbulent flow over the length of the wall in the direction of the breeze.

\[
\frac{\bar{h}_L}{k} = \frac{Nu_L L}{k} = 0.037 \left( \frac{Re_L^{4/5}}{Pr^{1/3}} \right)
\]

\[
Re_L = \frac{u_\infty L}{\nu} = 4.47 \text{ m/s} \times 10 \text{ m} / 16.27 \times 10^6 \text{ m}^2/\text{s} = 2.748 \times 10^6
\]

\[
\bar{h}_L = \left( 0.02658 \text{ W/m·K/10 m} \right) \times 0.037 \left( 2.748 \times 10^6 \right)^{4/5} (0.707)^{1/3} = 12.4 \text{ W/m}^2·\text{K}
\]

Substituting numerical values into Eq. (1), find T_s.

\[
-12.4 \text{ W/m}^2 \times 10 \text{ m} \left[ T_s - (32.2 + 273) \right] \text{K} \\
+ \left[ 1.0 \times 400 \text{ W/m}^2 - 0.93 \times 5.67 \times 10^{-8} \text{ W/m}^2·\text{K}^4 \right] \times 10 \text{ m} = 0
\]

\[
T_s = 302.2 \text{ K} = 29°C < 304 \text{ K}
\]

COMMENTS: (1) The properties for the correlation should be evaluated at \( T_f = (T_s + T_\infty)/2 = 304 \text{ K} \). The assumption of 305 K was reasonable.

(2) Is the heat transfer by the emission process significant? Would application of a low emissive coating be effective in reducing the wall temperature, assuming \( \alpha_S \) remained unchanged? Or, should a low solar absorbing coating be considered?
PROBLEM 7.18

KNOWN: Square solar panel with an area of 0.09 m$^2$ has solar-to-electrical power conversion efficiency of 12%, solar absorptivity of 0.85, and emissivity of 0.90. Panel experiences a 4 m/s breeze with an air temperature of 25°C and solar insolation of 700 W/m$^2$.

FIND: Estimate the temperature of the solar panel for: (a) The operating condition (on) described above when the panel is producing power, and (b) The off condition when the solar array is inoperative. Will the panel temperature increase, remain the same or decrease, all other conditions remaining the same?

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) The backside of the panel experiences no heat transfer, (3) Sky irradiation is negligible, and (4) Wind is in parallel, fully turbulent flow over the panel.

PROPERTIES: Table A-4, Air (Assume $T_f = 300$ K, 1 atm): $\nu = 15.89 \times 10^{-6}$ m$^2$/s, $k = 0.0263$ W/m·K, $Pr = 0.707$.

ANALYSIS: (a) Perform an energy balance on the panel as represented in the schematic above considering convection, absorbed insolation, emission and generated electrical power.

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_{gen} = 0$$

$$-q_{cv} + \left[ \alpha S G_S - \varepsilon \sigma T_s^4 \right] A_S - P_{elec} = 0$$

(1)

Using the convection rate equation and power conversion efficiency,

$$q_{cv} = h_L A_S (T_s - T_\infty)$$

$$P_{elec} = \eta_e \alpha S G_S A_S$$

(2,3)

The average convection coefficient for fully turbulent conditions is

$$Nu_L = \frac{h_L}{k} = 0.037 \text{ Re}_L^{4/5} Pr^{1/3}$$

$$Re_L = u_\infty L / \nu = 4 \text{ m/s} \times 0.3 \text{ m} / 15.89 \times 10^{-6} \text{ m}^2/\text{s} = 7.49 \times 10^4$$

$$h_L = \left(0.0263 \text{ W/m-K} / 0.3 \text{ m}\right) \times 0.037 \times \left(7.49 \times 10^4\right)^{4/5} (0.707)^{1/3}$$

$$h_L = 23.0 \text{ W/m}^2\cdot\text{K}$$

Substituting numerical values in Eq. (1) using Eqs. (2 and 3) and dividing through by $A_S$, find $T_s$.

Continued …..
PROBLEM 7.18 (Cont.)

\[ 23 \text{ W/m}^2 \cdot K (T_s - 298) + 0.85 \times 700 \text{ W/m}^2 - 0.90 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot K^4 T_s^4 \\
-0.12 \left[ 0.85 \times 700 \text{ W/m}^2 \right] = 0 \]

\[ T_s = 302.2 \text{ K} = 29.2^\circ \text{C} \]  \( < \)

(b) If the solar array becomes inoperable (off) for reason of wire bond failures or the electrical circuit to the battery is opened, the \( P_{\text{elec}} \) term in the energy balance of Eq. (1) is zero. Using Eq. (4) with \( \eta_e = 0 \), find

\[ T_s = 31.7^\circ \text{C} \]  \( < \)

COMMENTS: (1) Note how the electrical power \( P_{\text{elec}} \) is represented by the \( \dot{E}_{\text{gen}} \) term in the energy balance. Recall from Section 1.2 that \( \dot{E}_{\text{gen}} \) is associated with conversion from some form of energy to thermal energy. Hence, the solar-to-electrical power conversion \( (P_{\text{elec}}) \) will have a negative sign in Eq. (1).

(2) It follows that when the solar array is on, a fraction \( (\eta_e) \) of the absorbed solar power (thermal energy) is converted to electrical energy. As such, the array surface temperature will be higher in the off condition than in the on condition.

(3) Note that the assumed value for \( T_f \) at which to evaluate the properties was reasonable.
PROBLEM 7.19

KNOWN: Ambient air conditions and absorbed solar flux for an aircraft wing of prescribed length and speed.

FIND: (a) Steady-state temperature of wing and (b) Calculate and plot the steady-state temperature for plane speeds 100 to 250 m/s.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform wing temperature, (3) Negligible radiation emission from surface.

PROPERTIES: Table A.4, Air ($T_f \approx 270$ K, $p = 0.7$ bar): $k = 0.0239$ W/m-K, $Pr = 0.715$, $\nu = 13.22 \times 10^{-6}$ m$^2$/s ($1.0133$ bar/$0.7$ bar) = $19.14 \times 10^{-6}$ m$^2$/s.

ANALYSIS: From an energy balance on the airfoil

$$q_{S,abs}A_s = 2q_{conv} = 2\bar{h}_L A_s (T_s - T_\infty^\prime)$$

$$T_s = T_\infty^\prime + q_{S,abs}^\prime / 2\bar{h}_L$$

(1,2)

Since

$$Re_L = u_\infty L / \nu = (100 \text{ m/s}) 2.5 \text{ m} / 19.14 \times 10^{-6} \text{ m}^2 / \text{s} = 1.31 \times 10^7$$

(3)

and $Re_{x,c} = 5 \times 10^5$, the flow may be approximated as turbulent over the entire plate. Hence, from Eq. 7.41,

$$\text{Nu}_L = 0.037 Re_L^{4/5} Pr^{1/3} = 0.037 \left(1.31 \times 10^7\right)^{4/5} (0.715)^{1/3} = 1.63 \times 10^4$$

(4)

$$\bar{h}_L = \frac{\text{Nu}_L k}{L} = \frac{1.63 \times 10^4 \left(0.0239 \text{ W/m-K}\right)}{2.5 \text{ m}} = 156 \text{ W/m}^2 \cdot \text{K}$$

(5)

Hence, from the energy balance

$$T_s = 263 \text{ K} + 800 \text{ W/m}^2 / 2 \times 156 \text{ W/m}^2 \cdot \text{K} = 266 \text{ K}$$

(b) Using the energy balance relation for $T_s$, Eq. (1), and the IHT Correlations Tool, External Flow, Average coefficient for Laminar or Turbulent Flow, $T_s$ as a function of $u_\infty$ was evaluated.

COMMENTS: (1) Radiation emission from the wing surface would decrease $T_s$, while radiation incident from the earth’s surface and the sky would act to increase $T_s$. The net effect on $T_s$ is likely to be small.

(2) How do you explain that the effect of aircraft speed on $T_s$ appears to be only slight? How does $\bar{h}_L$ dependent upon $u_\infty$? What is the limit of $T_s$ with increasing speed?
**PROBLEM 7.20**

**KNOWN:** Material properties, inner surface temperature and dimensions of roof of refrigerated truck compartment. Truck speed and ambient temperature. Solar irradiation.

**FIND:** (a) Outer surface temperature of roof and rate of heat transfer to compartment, (b) Effect of changing radiative properties of outer surface, (c) Effect of eliminating insulation.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible irradiation from the sky, (2) Turbulent flow over entire outer surface, (3) Average convection coefficient may be used to estimate average surface temperature, (4) Constant properties.

**PROPERTIES:** Table A-4, air (p = 1 atm, T_f ≈ 300K): ν = 15.89 × 10^{-6} m^2/s, k = 0.0263 W/m·K, Pr = 0.707.

**ANALYSIS:** (a) From an energy balance for the outer surface,

\[
\alpha S G_S + q^*_{\text{conv}} - E = q^*_{\text{cond}} = \frac{T_{S,o} - T_{S,i}}{R_{\text{tot}}}
\]

\[
\alpha S G_S + \bar{h} (T_{\infty} - T_{S,o}) - \varepsilon \sigma T^4_{S,o} = \frac{T_{S,o} - T_{S,i}}{2R_p^* + R_i^*}
\]

where \(R_p^* = \left( \frac{t_1}{k_p} \right) = 2.78 \times 10^{-5} \text{ m} \cdot \text{K} / \text{W}, \ R_i^* = \left( \frac{t_2}{k_i} \right) = 1.923 \text{ m}^2 \cdot \text{K} / \text{W}, \) and with \( \text{Re}_L = \frac{u_{\infty} L}{\nu} = 29.2 \text{ m/s} \times 10 \text{m} / 15.89 \times 10^{-6} \text{ m}^2 / \text{s} = 1.84 \times 10^7 \),

\[
\bar{h} = \frac{k}{L} \left( \frac{0.037}{10 \text{m}} \right) \left( \frac{0.0263}{10 \text{m} \cdot \text{K}} \right) \left( \frac{1.84 \times 10^7}{10 \text{m}} \right)^{4/5} (0.707)^{1/3} = 56.2 \text{ W/m}^2 \cdot \text{K}
\]

Hence,

\[
0.5 \left( \frac{750}{\text{W/m}^2 \cdot \text{K}} \right) + 56.2 \text{ W/m}^2 \cdot \text{K} \left( \frac{305 - T_{S,o}}{1.923 \text{m}^2 \cdot \text{K}} \right) - 0.5 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K} T^4_{S,o} = \frac{T_{S,o} - 263 \text{K}}{(5.56 \times 10^{-5} + 1.923) \text{m}^2 \cdot \text{K} / \text{W}}
\]

Solving, we obtain

\[
T_{S,o} = 306.8 \text{K} = 33.8^\circ \text{C}
\]

Hence, the heat load is

\[
q = (W \cdot L) q^*_{\text{cond}} = (3.5 \text{m} \times 10 \text{m}) \frac{(33.8 + 10)^\circ \text{C}}{1.923 \text{m}^2 \cdot \text{K} / \text{W}} = 797 \text{ W}
\]

(b) With the special surface finish \((\alpha_S = 0.15, \varepsilon = 0.8)\),

Continued …..
PROBLEM 7.20 (Cont.)

\[ T_{S,0} = 301.1K = 27.1°C \]

\[ q = 675.3W \]

(c) Without the insulation \((t_2 = 0)\) and with \(\alpha_S = \varepsilon = 0.5\),

\[ T_{S,0} = 263.1K = -9.9°C \]

\[ q = 90,630W \]

**COMMENTS:** (1) Use of the special surface finish reduces the solar input, while increasing radiation emission from the surface. The cumulative effect is to reduce the heat load by 15%. (2) The thermal resistance of the aluminum panels is negligible, and without the insulation, the heat load is enormous.
**PROBLEM 7.21**

**KNOWN:** Surface characteristics of a flat plate in an air stream.

**FIND:** Orientation which minimizes convection heat transfer.

**SCHEMATIC:**

![Diagram](image)

**ASSUMPTIONS:** (1) Surface B is sufficiently rough to trip the boundary layer when in the upstream position (Configuration 2).

**PROPERTIES:** Table A-4, Air ($T_f = 333K$, 1 atm): $v = 19.2 \times 10^{-6} m^2/s$, $k = 28.7 \times 10^{-3}$ W/mK, $Pr = 0.7$.

**ANALYSIS:** Since Configuration (2) results in a turbulent boundary layer over the entire surface, the lowest heat transfer is associated with Configuration (1). Find

$$Re_L = \frac{u_{\infty}L}{v} = \frac{20 \text{ m/s} \times 1 \text{ m}}{19.2 \times 10^{-6} \text{ m}^2/\text{s}} = 1.04 \times 10^6.$$ 

Hence in Configuration (1), transition will occur just before the rough surface ($x_c = 0.48m$). Note that

$$\overline{Nu}_{L,1} = \left[ 0.037 \left(1.04 \times 10^6 \right)^{4/5} - 871 \right] 0.7^{1/3} = 1366$$

$$\overline{Nu}_{L,2} = 0.037 \left(1.04 \times 10^6 \right)^{4/5} (0.7)^{1/3} = 2139 > \overline{Nu}_{L,1}.$$ 

For Configuration (1):

$$\frac{\overline{h}_{L,1}L}{k} = \overline{Nu}_{L,1} = 1366.$$ 

Hence

$$\overline{h}_{L,1} = 1366 \left(28.7 \times 10^{-3} \text{ W/m} \cdot \text{K} \right)/1 \text{ m} = 39.2 \text{ W/m}^2 \cdot \text{K}$$

and

$$q_L = \overline{h}_{L,1}A \left( T_s - T_{\infty} \right) = 39.2 \text{ W/m}^2 \cdot \text{K} \left( 0.5 \text{ m} \times 1 \text{ m} \right) \left( 100 - 20 \right) \text{K}$$

$$q_L = 1568 \text{ W}.$$
PROBLEM 7.22

KNOWN: Heat rate from and surface temperature of top surface of an oven under quiescent room air conditions (Case A).

FIND: (a) Heat rate when air at 15 m/s is blown across surface, (b) Surface temperature, $T_s$, achieved with the forced convection condition, and (c) Calculate and plot $T_s$ as a function of room air velocity for $5 \leq u_\infty \leq 30$ m/s.

SCHEMATIC:

ASSUMPTIONS: (1) Surface has uniform temperature under both conditions, (2) Negligible radiation effects, (3) Air is blown parallel to edge, and (4) Thermal resistance due to oven wall and internal convection are the same for both conditions.

PROPERTIES: Table A.4, Air ($T_f = (T_s + T_\infty)/2 \approx (37 + 17)/2 = 27$ °C = 300 K): $k = 0.0263$ W/m·K, $\nu = 15.89 \times 10^{-6}$ m$^2$/s, Pr = 0.707.

ANALYSIS: (a) For Case A, we can determine the thermal resistance due to the wall and internal convection as,

$$R_{t,i} = \frac{T_t - T_s}{q_A} = \frac{(150 - 47)\,^\circ C}{40\,W} = 2.575\,K/W$$

which remains constant for case B. Hence, for Case B with forced convection, the heat rate is

$$q_B = UA \left( T_t - T_\infty \right)$$

where

$$\left( UA \right)^{-1} = R_{t,i} + \left( \frac{1}{\bar{h}_o A_s} \right)$$

To estimate $\bar{h}_o$, find

$$Re_L = \frac{u_\infty L}{\nu} = \frac{20\,m/s \times 0.5\,m}{15.89 \times 10^{-6}\,m^2/s} = 6.293 \times 10^5.$$

Assuming $Re_{s,c} = 5 \times 10^5$, flow conditions are mixed; hence

$$Nu_L = \frac{\bar{h}_o L}{k} = \left( 0.037 \left( \frac{Re}{4.87} \right)^{1/3} \right) Pr^{1/3} = \left( \frac{0.037 \left( 6.293 \times 10^5 \right)^{0.8}}{4.87} \right) (0.707)^{1/3} = 660.0$$

$$\bar{h}_o = 660.0 \times 0.0263\,W/m \cdot K/0.5\,m = 34.7\,W/m^2 \cdot K.$$

Using Eq. (3) for $(UA)^{-1}$ and Eq. (2) for $q_B$, find

$$\left( UA \right)^{-1} = 2.575\,K/W + \left( \frac{1}{34.7\,W/m^2 \cdot K \cdot (0.5\,m)^2} \right) = (2.575 + 0.115) = 2.690\,K/W$$

Continued...
PROBLEM 7.22 (Cont.)

\[ q_B = \left( \frac{1}{2.690 \text{ K/W}} \right) \left( 150 - 17 \right) \text{ K} = 49.4 \text{ W}. \]

(b) From the rate equation at the surface,

\[ T_s = T_\infty + \frac{q}{\overline{h}_o} A_s \]  

\[ T_s = 17^\circ \text{ C} + 49.4 \text{ W} \sqrt{34.7 \text{ W/m}^2 \cdot \text{K} \times (0.5 \text{ m})^2} \]

\[ T_s = (17 + 5.7)^\circ \text{ C} = 22.7^\circ \text{ C} \]

(c) Using Eqs. (2), (3) and (4), and evaluating \( \overline{h}_o \) using IHT Correlations Tool, External Flow, Average coefficient for Laminar or Mixed Flow, the surface temperature was evaluated as a function of room air velocity and is plotted below.

![Surface temperature plot](image)

COMMENTS: (1) Note that in part (a), \( T_f = (T_s + T_\infty)/2 = (22.7 + 17)/2 = 19.8^\circ \text{ C} = 293 \text{ K} \) compared to the assumed value of 300 K. Performing an iterative solution with IHT, find \( T_f = 293 \) with \( T_s = 22.4^\circ \text{ C} \) suggesting the approximate value for \( T_f \) was satisfactory.

(2) From the plot, as expected, \( T_s \) decreases with increasing air velocity. What is the cause of the inflection in the curve at \( u_\infty = 15 \text{ m/s} \)? As \( u_\infty \) increases, what is the limit for \( T_s \)?
PROBLEM 7.23

KNOWN: Prevailing wind with prescribed speed blows past ten window panels, each of 1-m length, on a penthouse tower.

FIND: (a) Average convection coefficient for the first, third and tenth window panels when the wind speed is 5 m/s; evaluate thermophysical properties at 300 K, but determine suitability when ambient air temperature is in the range \(-15 \leq T_\infty \leq 38^\circ\text{C}\); (b) Compute and plot the average coefficients for the same panels with wind speeds for the range \(5 \leq u_\infty \leq 100\text{ km/h}\); explain features and relative magnitudes.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Wind over panels approximates parallel flow over a smooth flat plate, and (4) Transition Reynolds number is \(\text{Re}_{x,c} = 5 \times 10^5\).

PROPERTIES: \textit{Table A.4}, Air (\(T_f = 300\text{ K, 1 atm}\)): \(\nu = 15.89 \times 10^{-5}\text{ m}^2/\text{s}, k = 26.3 \times 10^{-3}\text{ W/m}\cdot\text{K}, \text{Pr} = 0.707\).

ANALYSIS: (a) The average convection coefficients for the first, third and tenth panels are

\[
\overline{h}_1, \quad \overline{h}_{2-3} = \frac{\overline{h}_3x_3 - \overline{h}_2x_2}{x_3 - x_2}, \quad \overline{h}_{9-10} = \frac{\overline{h}_{10}x_{10} - \overline{h}_9x_9}{x_{10} - x_9} \quad (1,2,3)
\]

where \(\overline{h}_2 = \overline{h}_2(x_2), \text{ etc.}\) If \(\text{Re}_{x,c} = 5 \times 10^5\), with properties evaluated at \(T_f = 300\text{ K}\), transition occurs at

\[
x_c = \frac{\nu}{u_\infty} \overline{\text{Re}}_{x,c} = \frac{15.89 \times 10^{-6}\text{ m}^2/\text{s}}{5\text{ m/s}} \times 5 \times 10^5 = 1.59\text{ m}
\]

The flow over the first panel is laminar, and \(\overline{h}_1\) can be estimated using Eq. (7.31).

\[
\overline{\text{Nu}}_{x1} = \frac{\overline{h}_1x_1}{k} = 0.664 \overline{\text{Re}}_{x}^{1/2} \text{Pr}^{1/3}
\]

\[
\overline{h}_1 = (0.0263\text{ W/m}\cdot\text{K} \times 0.664/\text{Im}) \left(5\text{ m/s} \times \text{Im}/15.89 \times 10^{-6}\text{ m}^2/\text{s}\right)^{1/2} (0.707)^{1/3} = 8.73\text{ W/m}^2\cdot\text{K}
\]

The flow over the third and tenth panels is mixed, and \(\overline{h}_2, \overline{h}_3, \overline{h}_9\) and \(\overline{h}_{10}\) can be estimated using Eq. (7.41). For the third panel with \(x_3 = 3\text{ m}\) and \(x_2 = 2\text{ m},\)

\[
\overline{\text{Nu}}_{x3} = \frac{\overline{h}_3x_3}{k} = \left(0.037 \overline{\text{Re}}_{x}^{4/5} - 871\right)\text{Pr}^{1/3}
\]

\[
\overline{h}_3 = (0.0263\text{ W/m}\cdot\text{K}/3\text{m}) \times \left[0.037 \left(5\text{ m/s} \times 3\text{ m}/15.89 \times 10^{-6}\text{ m}^2/\text{s}\right)^{4/5} - 871\right] (0.707)^{1/3} = 10.6\text{ W/m}^2\cdot\text{K}
\]

Continued...
PROBLEM 7.23 (Cont.)

\[
\bar{h}_2 = \left( \frac{0.0263 \text{W/m} \cdot \text{K}}{2\text{m}} \right) \times \left[ 0.037 \left( \frac{5 \text{m/s} \times 2\text{m}}{15.89 \times 10^{-6} \text{m}^2/\text{s}} \right)^{4/5} - 871 \right] (0.707)^{1/3} = 8.68 \text{W/m}^2 \cdot \text{K}
\]

From Eq. (2),

\[
\bar{h}_{2-3} = \frac{10.61 \text{W/m}^2 \cdot \text{K} \times 3\text{m} - 8.68 \text{W/m}^2 \cdot \text{K} \times 2\text{m}}{(3-2)\text{m}} = 14.5 \text{W/m}^2 \cdot \text{K}
\]

Following the same procedure for the tenth panel, find \( \bar{h}_{10} = 11.64 \text{W/m}^2 \cdot \text{K} \) and \( \bar{h}_9 = 11.71 \text{W/m}^2 \cdot \text{K} \), and

\[
\bar{h}_{9-10} = 11.1 \text{W/m}^2 \cdot \text{K}
\]

Assuming that the window panel temperature will always be close to room temperature, \( T_s = 23^\circ \text{C} = 296 \) K. If \( T_\infty \) ranges from -15 to 38°C, the film temperature, \( T_f = (T_s + T_\infty)/2 \), will vary from 275 to 310 K. We’ll explore the effect of \( T_f \) subsequently.

(b) Using the IHT Tool, Correlations, External Flow, Flat Plate, results were obtained for the average coefficients \( \bar{h} \). Using Eqs. (2) and (3), average coefficients for the panels as a function of wind speed were computed and plotted.

![Graph of average coefficients vs. wind speed](image)

**COMMENTS:** (1) The behavior of the panel average coefficients as a function of wind speed can be explained from the behavior of the local coefficient as a function of distance for different velocities as plotted below.

![Graph of local coefficients vs. distance](image)

Continued...
For low wind speeds, transition occurs near the mid-panel, making $h_1$ and $h_{9-10}$ nearly equal and very high because of leading-edge and turbulence effects, respectively. As the wind speed increases, transition occurs closer to the leading edge. Notice how $h_{2-3}$ increases rather abruptly, subsequently becoming greater than $h_{9-10}$. The abrupt increase in $h_1$ around 30 km/h is a consequence of transition occurring with $x < 1m$.

(2) Using the IHT code developed for the foregoing analysis with $u_\infty = 5$ m/s, the effect of $T_f$ is tabulated below

<table>
<thead>
<tr>
<th>$T_f$ (K)</th>
<th>275</th>
<th>300</th>
<th>310</th>
</tr>
</thead>
<tbody>
<tr>
<td>$h_1$ (W/m²·K)</td>
<td>8.72</td>
<td>8.73</td>
<td>8.70</td>
</tr>
<tr>
<td>$h_{2-3}$ (W/m²·K)</td>
<td>15.1</td>
<td>14.5</td>
<td>14.2</td>
</tr>
<tr>
<td>$h_{9-10}$ (W/m²·K)</td>
<td>11.6</td>
<td>11.1</td>
<td>10.8</td>
</tr>
</tbody>
</table>

The overall effect of $T_f$ on estimates for the average panel coefficient is slight, less than 5%.
**PROBLEM 7.24**

**KNOWN:** Design of an anemometer comprised of a thin metallic strip supported by stiff rods serving as electrodes for passage of heating current. Fine-wire thermocouple on trailing edge of strip.

**FIND:** (a) Relationship between electrical power dissipation per unit width of the strip in the transverse direction, \( P' \) (mW/mm), and airstream velocity \( u_\infty \) when maintained at constant strip temperature, \( T_s \); show the relationship graphically; (b) The uncertainty in the airstream velocity if the accuracy with which the strip temperature can be measured and maintained constant is \( \pm 0.2^\circ C \); (c) Relationship between strip temperature and airstream velocity \( u_\infty \) when the strip is provided with a constant power, \( P' = 30 \) mW/mm; show the relationship graphically. Also, find the uncertainty in the airstream velocity if the accuracy with which the strip temperature can be measured is \( \pm 0.2^\circ C \); (d) Compare features associated with each of the operating nodes.

**SCHEMATIC:**

![Schematic Diagram]

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties, (3) Strip has uniform temperature in the midspan region of the strip, (4) Negligible conduction in the transverse direction in the midspan region, and (5) Airstream over strip approximates parallel flow over two sides of a smooth flat plate.

**ANALYSIS:** (a) In the midspan region of uniform temperature \( T_s \) with no conduction in the transverse direction, all the dissipated electrical power is transferred by convection to the airstream,

\[
P' = 2h_L L (T_s - T_\infty)
\]

where \( P' \) is the power per unit width (transverse direction). Using the *IHT Correlation Tool for External Flow-Flat Plate* the power as a function of airstream velocity was determined and is plotted below. The IHT tool uses the flat plate correlation, Eq. 7.31 since the flow is laminar over this velocity range.
PROBLEM 7.24 (Cont.)

(b) By differentiation of Eq. (1), the relative uncertainties of the convection coefficient and strip temperature are, assuming the power remains constant,

\[ \frac{\Delta \hat{h}_L}{\hat{h}} = - \frac{\Delta T_s}{T_s - T_\infty} \]  

(2)

Since the flow was laminar for the range of airstream velocities, Eq. 7.31,

\[ \bar{h}_L \sim u^{1/2} \quad \text{or} \quad \frac{\Delta \bar{h}_L}{\bar{h}_L} = 0.5 \frac{\Delta u_\infty}{u_\infty} \]  

(3)

Hence, the relative uncertainty in the air velocity due to uncertainty in \( T_s \), \( \Delta T_s = \pm 0.2^\circ C \)

\[ \frac{\Delta u_\infty}{u_\infty} = 2 \frac{\Delta T_s}{T_s - T_\infty} = 2 \frac{\pm 0.2^\circ C}{(35 - 25)^\circ C} = \pm 4\% \]  

(4)

(c) Using the IHT workspace setting \( P' = 30 \text{ mW/mm} \), the strip temperature \( T_s \) as a function of the airstream velocity was determined and plotted. Note that the slope of the \( T_s \) vs. \( u_\infty \) curve is steep for low velocities and relatively flat for high velocities. That is, the technique is more sensitive at lower velocities. Using Eq. (4), but with \( T_s \) dependent upon \( u_\infty \), the relative uncertainty in \( u_\infty \) can be determined.

(d) For the constant power mode of operation, part (a), the uncertainty in \( u_\infty \) due to uncertainty in temperature measurement was found as 4\%, independent of the magnitude \( u_\infty \). For the constant-temperature mode of operation, the uncertainty in \( u_\infty \) is less than 4\% for velocities less than 30 m/s, with a value of 1\% around 2 m/s. However, in the upper velocity range, the error increases to 5\%. 
**PROBLEM 7.25**

**KNOWN:** Plate dimensions and initial temperature. Velocity and temperature of air in parallel flow over plates.

**FIND:** Initial rate of heat transfer from plate. Rate of change of plate temperature.

**SCHEMATIC:**

![Schematic Diagram]

**ASSUMPTIONS:** (1) Negligible radiation, (2) Negligible effect of conveyor velocity on boundary layer development, (3) Plates are isothermal, (4) Negligible heat transfer from sides of plate, (5) $Re_{x,c} = 5 \times 10^5$. (6) Constant properties.

**PROPERTIES:**
- Table A-1, AISI 1010 steel (573K): $k_p = 49.2 \text{ W/m} \cdot \text{K}$, $c = 549 \text{ J/kg} \cdot \text{K}$, $\rho = 7832 \text{ kg/m}^3$.
- Table A-4, Air (p = 1 atm, $T_f = 433\text{K}$): $\nu = 30.4 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 0.0361 \text{ W/m} \cdot \text{K}$, $Pr = 0.688$.

**ANALYSIS:** The initial rate of heat transfer from a plate is

$$q = 2 \overline{h} A_s (T_i - T_\infty) = 2 \overline{h} L^2 (T_i - T_\infty)$$

With $Re_L = u_\infty L / \nu = 10 \text{ m/s} \times 1 \text{m} / 30.4 \times 10^{-6} \text{ m}^2 / \text{s} = 3.29 \times 10^5$, flow is laminar over the entire surface and

$$\overline{Nu}_L = 0.664 Re_L^{1/2} Pr^{1/3} = 0.664 \left(3.29 \times 10^5\right)^{1/2} (0.688)^{1/3} = 336$$

$$\overline{h} = (k / L) \overline{Nu}_L = (0.0361 \text{ W/m} \cdot \text{K} / \text{m}) 336 = 12.1 \text{ W/m}^2 \cdot \text{K}$$

Hence,

$$q = 2 \times 12.1 \text{ W/m}^2 \cdot \text{K} \left(300 - 20\right)\text{K} = 6780 \text{ W}$$

Performing an energy balance at an instant of time for a control surface about the plate, $-\dot{E}_{out} = \dot{E}_{st}$, we obtain (Eq. 5.2),

$$\rho \delta L^2 c \left. \frac{dT}{dt} \right|_i = -\overline{h} L^2 (T_i - T_\infty)$$

$$\left. \frac{dT}{dt} \right|_i = -\frac{2 \left(12.1 \text{ W/m}^2 \cdot \text{K}\right) \left(300 - 20\right)\text{K}}{7832 \text{ kg/m}^3 \times 0.006 \text{m} \times 549 \text{ J/kg} \cdot \text{K}} = -0.26 \text{ K/s}$$

**COMMENTS:** (1) With $Bi = \overline{h} (\delta / 2) / k_p = 7.4 \times 10^{-4}$, use of the lumped capacitance method is appropriate. (2) Despite the large plate temperature and the small convection coefficient, if adjoining plates are in close proximity, radiation exchange with the surroundings will be small and the assumption of negligible radiation is justifiable.
PROBLEM 7.26

KNOWN: Velocity, initial temperature, and dimensions of aluminum strip on a production line. Velocity and temperature of air in counter flow over top surface of strip.

FIND: (a) Differential equation governing temperature distribution along the strip and expression for outlet temperature, (b) Value of outlet temperature for prescribed conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible variation of sheet temperature across its thickness, (2) Negligible effect of conduction along length (x) of sheet, (3) Negligible radiation, (4) Turbulent flow over entire top surface, (5) Negligible effect of sheet velocity on boundary layer development, (6) Negligible heat transfer from bottom surface and sides, (7) Constant properties.

PROPERTIES: Table A-1, Aluminum, 2024-T6 ($T_{Al} = 500K$): $\rho = 2770$ kg/m$^3$, $c_p = 983$ J/kg·K, $k=186$ W/m·K. Table A-4, Air ($p=1$ atm, $T_f = 400K$): $\nu = 26.4 \times 10^{-6}$ m$^2$/s, $k = 0.0338$ W/m·K, $Pr = 0.69$

ANALYSIS: (a) Applying conservation of energy to a stationary control surface, through which the sheet moves, steady-state conditions exist and $\dot{E}_{in} - \dot{E}_{out} = 0$. Hence, with inflow due to advection and outflow due to advection and convection,

$$\rho V A_c c_p (T + dT) - \rho V A_c c_p T - dq = 0$$

$$+ \rho V \delta W c_p dT - h_x (dx \cdot W) (T - T_\infty) = 0$$

$$\frac{dT}{dx} = \frac{h_x}{\rho V \delta c_p} (T - T_\infty)$$  \hspace{1cm} (1)

Alternatively, if the control surface is fixed to the sheet, conditions are transient and the energy balance is of the form, $-\dot{E}_{out} = \dot{E}_{st}$, or

$$-h_x (dx \cdot W)(T - T_\infty) = \rho (dx \cdot W \cdot \delta) c_p \frac{dT}{dt}$$

$$\frac{dT}{dt} = -\frac{h_x}{\rho \delta c_p} (T - T_\infty)$$

Dividing the left- and right-hand sides of the equation by $dx/dt$ and $dx/dt = -V$, respectively, equation (1) is obtained. The equation may be integrated from $x = 0$ to $x = L$ to obtain

$$\int_{T_i}^{T_o} \frac{dT}{T - T_\infty} = \frac{L}{\rho V \delta c_p} \left[ \frac{1}{L} \int_0^L h_x \, dx \right]$$

Continued …..
where \( h_x = (k / \chi)0.0296 \Re_{x}^{4/5} \Pr^{1/3} \) and the bracketed term on the right-hand side of the equation reduces to \( \bar{h}_L = (k / L)0.037 \Re_{L}^{4/5} \Pr^{1/3} \).

Hence,

\[
\ln \left( \frac{T_i - T_{\infty}}{T_o - T_{\infty}} \right) = \frac{L \bar{h}_L}{\rho V \delta c_p} \\
\frac{T_o - T_{\infty}}{T_i - T_{\infty}} = \exp \left( -\frac{L \bar{h}_L}{\rho V \delta c_p} \right)
\]

(b) For the prescribed conditions, \( \Re_{L} = u_{\infty}L / \nu = 20 \text{ m/s} \times 5 \text{ m} / 26.4 \times 10^{-6} \text{ m}^2 / \text{s} = 3.79 \times 10^6 \) and

\[
\bar{h}_L = \left( \frac{0.0338 \text{ W/m} \cdot \text{K}}{5 \text{ m}} \right)0.037 \left(3.79 \times 10^6\right)^{4/5} (0.69)^{1/3} = 40.5 \text{ W/m}^2 \cdot \text{K}
\]

\[
T_o = 20^\circ \text{C} + (280^\circ \text{C}) \exp \left( -\frac{5 \text{ m} \times 40.5 \text{ W/m}^2 \cdot \text{K}}{2770 \text{ kg/m}^3 \times 0.1 \text{ m/s} \times 0.002 \text{ m} \times 983 \text{ J/kg} \cdot \text{K}} \right) = 213^\circ \text{C}
\]

**COMMENTS:**

(1) With \( T_o = 213^\circ \text{C} \), \( T_A = 530^\circ \text{K} \) and \( T_r = 411^\circ \text{K} \), are close to values used to determine the material properties, and iteration is not needed. (2) For a representative emissivity of \( \varepsilon = 0.2 \) and \( T_{\text{sur}} = T_{\infty} \), the maximum value of the radiation coefficient is

\[
h_r = \varepsilon \sigma (T_i + T_{\text{sur}}) \left( T_i^2 + T_{\text{sur}}^2 \right) = 4.1 \text{ W/m}^2 \cdot \text{K} \ll \bar{h}_L. \] Hence, the assumption of negligible radiation is appropriate.
PROBLEM 7.27

KNOWN: Velocity, initial temperature, properties and dimensions of steel strip on a production line. Velocity and temperature of air in cross flow over top and bottom surfaces of strip. Temperature of surroundings.

FIND: (a) Differential equation governing temperature distribution along the strip, (b) Exact solution for negligible radiation and corresponding value of outlet temperature for prescribed conditions, (c) Effect of radiation on outlet temperature, and parametric effect of sheet velocity on temperature distribution.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible variation of sheet temperature across its width and thickness, (2) Negligible effect of conduction along length (x) of sheet, (3) Constant properties, (4) Radiation exchange between small surface (both sides of sheet) and large surroundings, (5) Turbulent flow over top and bottom surfaces of sheet, (6) Motion of sheet has a negligible effect on the convection coefficient, (V << u∞), (7) Negligible heat transfer from sides of sheet.

PROPERTIES: Prescribed. Steel: ρ = 7850 kg/m³, c_p = 620 J/kg·K, ε = 0.70. Air: k = 0.044 W/m·K, ν = 4.5 × 10⁻⁵ m²/s, Pr = 0.68.

ANALYSIS: (a) Applying conservation of energy to a stationary differential control surface, through which the sheet passes, conditions are steady and \( \dot{E}_{in} - \dot{E}_{out} = 0 \). Hence, with inflow due to advection and outflow due to advection, convection and radiation

\[
\rho V A_c c_p T - \rho V A_c c_p (T + dT) - 2 dq = 0
\]

\[-\rho V \delta W c_p dT - 2(Wdx) \left[ \bar{h}_W (T - T_\infty) + \varepsilon \sigma (T^4 - T_{sur}^4) \right] = 0 \]

\[
\frac{dT}{dx} = -\frac{2}{\rho V \delta c_p} \left[ \bar{h}_W (T - T_\infty) + \varepsilon \sigma (T^4 - T_{sur}^4) \right]
\]

(1) <

Alternatively, if the control surface is fixed to the sheet, conditions are transient and the energy balance is of the form, \( -\dot{E}_{out} = \dot{E}_{st} \), or

\[-2(Wdx) \left[ \bar{h}_W (T - T_\infty) + \varepsilon \sigma (T^4 - T_{sur}^4) \right] = \rho (W \delta dx) c_p \frac{dT}{dt} \]

\[
\frac{dT}{dt} = -\frac{2}{\rho \delta c_p} \left[ \bar{h}_W (T - T_\infty) + \varepsilon \sigma (T^4 - T_{sur}^4) \right]
\]

Dividing the left- and right-hand sides of the equation by dx/dt and V = dx/dt, respectively, Eq. (1) is obtained.

(b) Neglecting radiation, separating variables and integrating, Eq. (1) becomes

\[
\int_{T_i}^{T} \frac{dT}{T - T_\infty} = -\frac{2 \bar{h}_W}{\rho V \delta c_p} \int_{0}^{x} dx
\]

Continued ….
PROBLEM 7.27 (Cont.)

\[
\ln \left( \frac{T - T_\infty}{T_i - T_\infty} \right) = -\frac{2\bar{h}_W x}{\rho V \delta c_p} \\
T = T_\infty + (T_i - T_\infty) \exp \left( -\frac{2\bar{h}_W x}{\rho V \delta c_p} \right) 
\]

(2) <

With \( Re_W = u_\infty W / \nu = 20 \text{ m/s} \times 1 \text{ m} / 4 \times 10^{-5} \text{ m}^2 / \text{s} = 5 \times 10^5 \), the correlation for turbulent flow over a flat plate yields

\[
\overline{Nu}_W = 0.037 \text{Re}_W^{4/5} \text{Pr}^{1/3} = 0.037 \left(5 \times 10^5\right)^{4/5} \left(0.68\right)^{1/3} = 1179
\]

\[
\bar{h}_W = \frac{k}{W} \overline{Nu}_W = \frac{0.044 \text{ W/m} \cdot \text{K}}{1 \text{ m}} 1179 = 51.9 \text{ W/m}^2 \cdot \text{K}
\]

Hence, applying Eq. (2) at \( x = L = 10 \text{m} \),

\[
T_o = 20^\circ\text{C} + (480^\circ\text{C}) \exp \left( -\frac{2 \times 51.9 \text{ W/m}^2 \cdot \text{K} \times 10 \text{m}}{7850 \text{ kg/m}^3 \times 0.1 \text{m/s} \times 0.003 \text{m} \times 620 \text{ J/kg} \cdot \text{K}} \right) = 256^\circ\text{C}
\]

(c) Using the DER function of IHT, Eq. (1) may be numerically integrated from \( x = 0 \) to \( x = L = 10 \text{m} \) to obtain

\[
T_o = 210^\circ\text{C}
\]

Contrasting this result with that of Part (b), it’s clear that radiation makes a discernable contribution to cooling of the sheet. IHT was also used to determine the effect of the sheet velocity on the temperature distribution.

The sheet velocity has a significant influence on the temperature distribution. The temperature decay decreases with increasing \( V \) due to the increasing effect of advection on energy transfer in the \( x \) direction.

COMMENTS: (1) A critical parameter in the production process is the coiling temperature, that is, the temperature at which the wire may be safely coiled for subsequent storage or shipment. The larger the production rate \( (V) \), the longer the cooling distance needed to achieve a desired coiling temperature. (2) Cooling may be enhanced by increasing the cross stream velocity \( u_\infty \).
PROBLEM 7.28

KNOWN: Length, thickness, speed and temperature of steel strip.

FIND: Rate of change of strip temperature 1 m from leading edge and at trailing edge. Location of minimum cooling rate.

SCHEMATIC:

ASSUMPTIONS: (1) Constant properties, (2) Negligible radiation, (3) Negligible longitudinal conduction in strip, (4) Critical Reynolds number is \(5 \times 10^5\).

PROPERTIES: Steel (given): \(\rho = 7900 \text{ kg/m}^3\), \(c_p = 640 \text{ J/kg} \cdot \text{K}\). Table A-4, Air \((\bar{T} = 750\text{K}, 1 \text{ atm})\): \(v = 76.4 \times 10^{-6} \text{ m}^2/\text{s}\), \(k = 0.0549 \text{ W/m} \cdot \text{K}\), \(Pr = 0.702\).

ANALYSIS: Performing an energy balance for a control mass of unit surface area \(A_s\) riding with the strip,

\[-\dot{E}_{\text{out}} = \frac{dE_{\text{st}}}{dt}\]

\[-2h_x A_s (T - T_\infty) = \rho \delta A_s c_p \left(\frac{dT}{dt}\right)\]

\[
\frac{dT}{dt} = -\frac{2h_x (T - T_\infty)}{\rho \delta c_p} = -\frac{2(900\text{K})h_x}{7900 \text{ kg/m}^3 (0.003 \text{ m}) 640 \text{ J/kg} \cdot \text{K}} = -0.119h_x \left(\text{K/s}\right).
\]

At \(x = 1 \text{ m}\),

\[
Re_x = \frac{V x}{v} = \frac{20 \text{ m/s} (1 \text{ m})}{76.4 \times 10^{-6} \text{ m}^2/\text{s}} = 2.62 \times 10^5 < Re_{x,c}.
\]

Hence,

\[
h_x = (k/x) 0.332Re_x^{1/2}Pr^{1/3} = \frac{0.0549 \text{ W/m} \cdot \text{K}}{1 \text{ m}} \left(0.332\right) \left(2.62 \times 10^5\right)^{1/2} \left(0.702\right)^{1/3} = 8.29 \text{ W/m}^2 \cdot \text{K}
\]

and at \(x = 1 \text{ m}\), \(dT/dt) = -0.987 \text{ K/s}\).

At the trailing edge, \(Re_x = 2.62 \times 10^7 > Re_{x,c}\). Hence

\[
h_x = (k/x) 0.0296Re_x^{4/5}Pr^{1/3} = \frac{0.0549 \text{ W/m} \cdot \text{K}}{100 \text{ m}} \left(0.0296\right) \left(2.62 \times 10^7\right)^{4/5} \left(0.702\right)^{1/3} = 12.4 \text{ W/m}^2 \cdot \text{K}
\]

and at \(x = 100 \text{ m}\), \(dT/dt) = -1.47 \text{ K/s}\).

The minimum cooling rate occurs just before transition; hence, for \(Re_{x,c} = 5 \times 10^5\)

\[
x_c = 5 \times 10^5 \frac{(v/V)}{20 \text{ m/s}} = 5 \times 10^5 \times \frac{76.4 \times 10^{-6} \text{ m}^2/\text{s}}{20 \text{ m/s}} = 1.91 \text{ m}
\]

COMMENTS: The cooling rates are very low and would remain low even if radiation were considered. For this reason, hot strip metals are quenched by water and not by air.
PROBLEM 7.29

KNOWN: Finned heat sink used to cool a power diode.

FIND: (a) Operating temperature $T_d$ of the diode for prescribed conditions, (b) Options for reducing $T_d$.

SCHEMATIC:

ASSUMPTIONS: (1) All diode power is rejected from the four fins, (2) Diode behaves as an isothermal disk on a semi-infinite medium, (3) Fin tips are adiabatic, (4) Fins behave as flat plates with regard to forced convection (boundary layer thickness between fins is less than 1.5 mm/2), (5) Negligible heat loss from fin edges and prime (exposed base) surfaces.

PROPERTIES: Table A-1, Aluminum alloy 2024 ($\bar{T} = 300$ K): $k = 177$ W/m·K; Table A-4, Air ($T_f = (T_s + T_\infty)/2 = 300$ K, 1 atm): $\nu = 15.89 \times 10^{-6}$ m$^2$/s, $k = 0.0263$ W/m·K.

ANALYSIS: (a) From the thermal circuit for the system, $T_d = T_\infty + qR_{tot}$ where

\[ R_{tot} = R_{t,i} + R_{t,c} + R_{t,s} + R_{t,o}. \]

Thermal contact resistance, $R_{t,c}$:

\[ R_{t,c} = R_{t,c}^* / A_d = 10^{-5} \text{ m}^2 \cdot ^\circ \text{C}/\text{W} / (\pi/4)(0.005 \text{ m})^2 = 0.509 \text{ ^\circ C}/\text{W}. \]

Spreading thermal resistance, $R_{t,s}$: This resistance is due to conduction between the diode (an isothermal disk) and the heat sink (semi-infinite medium). From Table 4.1, the conduction shape factor is $S = 2D$. Hence,

\[ R_{t,s} = 1/k (2D) = 1/177 \text{ W/m·K} (2 \times 0.005 \text{ m}) = 0.565 \text{ ^\circ C}/\text{W}. \]

Thermal resistance of the fin array, $R_{t,o}$: From Table 3.4 for the fin with insulated tip,

\[ R_{t,f} = \frac{\theta_b}{q_f} = \frac{1}{M^* \cdot \tanh (mL_f)} \]

where

\[ m^2 = \left( hP/kA_c \right), \quad M^* = \left( hP/kA_c \right)^{1/2}. \]

To estimate the average heat transfer coefficient, consider the fin as a flat plate in parallel flow along the length, $L_p = 20$ mm. The Reynolds number is

\[ Re_L = \frac{u_\infty L_p}{v} = \frac{10 \text{ m/s} \times 0.020 \text{ m}}{15.89 \times 10^{-6} \text{ m}^2/\text{s}} = 1.259 \times 10^4. \]

Continued...
PROBLEM 7.29 (Cont.)

The flow is laminar, in which case

\[ \frac{\overline{h} L}{k} = 0.664 \frac{Re^{1/2}}{Pr^{1/3}} \]

\[ \overline{h} = \frac{0.0263 \text{ W/m} \cdot \text{K}}{0.020 \text{ m}} \times 0.664 \left(1.259 \times 10^4\right)^{1/2} (0.707)^{1/3} = 87.3 \text{ W/m}^2 \cdot \text{K} \]

With \( P = (2t + 2L_p) = 0.046 \) and \( A_c = tL_p = 3 \times 10^{-5} \text{ m}^2 \),

\[ m = \left[ \frac{87.3 \text{ W/m}^2 \cdot \text{K} \times 0.046 \text{ m} / 177 \text{ W/m} \cdot \text{K} \times 3 \times 10^{-5} \text{ m}^2} \right]^{1/2} = 27.52 \text{ m}^{-1} \]

\[ M^* = \left[ \frac{87.3 \text{ W/m}^2 \cdot \text{K} \times 0.046 \text{ m} / 177 \text{ W/m} \cdot \text{K} \times 3 \times 10^{-5} \text{ m}^2} \right]^{1/2} = 0.146 \text{ W/K} \]

Hence, with \( L_f = 10 \text{ mm} \),

\[ R_{t,f} = 1/0.146 \text{ W/K} \times \tanh \left(27.52 \text{ m}^{-1} \times 0.010 \text{ m} \right) = 25.51 \text{ºC/W} \]

With \( R_{t,o} \approx R_{t,f} / 4 \), the diode temperature is

\[ T_d = 17 \text{ºC} + 5 \text{ W} \left[ 0.80 + 0.509 + 0.565 + 0.25 \times 27.3 \right] ^0 \text{C/W} = 58 \text{oC} \]

(b) The IHT Extended Surfaces Model for an Array of Straight, Rectangular Fins was used with the External Flow, Flat Plate option from the Correlations Tool Pad to assess the effects of varying \( u_\infty \) and \( L_f \).

![Graph 1: Diode temperature vs Freestream velocity](image1)

![Graph 2: Diode temperature vs Fin length](image2)

Clearly, there are benefits to increasing both quantities, with \( T_d \) reduced from approximately 58ºC (\( u_\infty = 10 \text{ m/s}, L_f = 10 \text{ mm} \)) to 47.2ºC (\( u_\infty = 25 \text{ m/s}, L_f = 10 \text{ mm} \)) to 38.5ºC (\( u_\infty = 25 \text{ m/s}, L_f = 20 \text{ mm} \)). For \( u_\infty = 25 \text{ m/s} \) and \( L_f = 20 \text{ mm} \), the fin efficiency remains large (\( \eta_f = 0.87 \)), suggesting that, air flow and space limitations permitting, significant reduction, in \( T_d \) could still be gained by going to even larger values of \( L_f \).

Subject to the constraint that the spacing between fins between remain at or larger than 1.5 mm, there is no advantage to reducing the fin thickness. For a thickness of 0.5 mm, it would be possible to add only one more fin (\( N = 5 \)), yielding \( T_d = 44.4\text{oC} \) for \( u_\infty = 25 \text{ m/s} \) and \( L_f = 20 \text{ mm} \).

**COMMENTS:** Note that the fin resistance makes the dominant contribution to the total resistance. Hence, efforts to reduce the total resistance should focus on reducing the fin resistance.
PROBLEM 7.30

KNOWN: Dimensions of aluminum heat sink. Temperature and velocity of coolant (water) flow through the heat sink. Power dissipation of electronic package attached to the heat sink.

FIND: Base temperature of heat sink.

SCHEMATIC:

ASSUMPTIONS: (1) Average convection coefficient association with flow over fin surfaces may be approximated as that for a flat plate in parallel flow, (2) All of the electric power is dissipated by the heat sink, (3) Transition Reynolds number of $Re_{x,c} = 5 \times 10^5$, (4) Constant properties.

PROPERTIES: Given. Aluminum: $k_{hs} = 180 \text{ W/m}\cdot\text{K}$. Water: $k_w = 0.62 \text{ W/m}\cdot\text{K}$, $\nu = 7.73 \times 10^{-7} \text{ m}^2/\text{s}$, $Pr = 5.2$.

ANALYSIS: From the thermal circuit,

$$q = P_{elec} = \frac{T_b - T_\infty}{R_b + R_{t,o}}$$

where $R_b = L_b / k_{hs} (w_1 \times w_2) = 0.02\text{m} / 180\text{ W/m}\cdot\text{K} \cdot (0.11\text{m})^2 = 9.18 \times 10^{-3} \text{ K/W}$ and, from Eqs. 3.102 and 3.103,

$$R_{t,o} = \left( \frac{\bar{h} A_t}{1 - \frac{NA_f}{A_t} (1 - \eta_f)} \right)^{-1}$$

The fin and total surface area of the array are $A_f = 2w_2 (L_f + t/2) = 0.22\text{m} (0.065\text{m}) = 0.0143\text{m}^2$ and $A_t = NA_f + A_b = NA_f + (N-1)(S-t)w_2 = 6 \times 0.0143\text{m}^2 + 5(0.01\text{m})0.11\text{m} = (0.0858 + 0.0055) = 0.0913\text{m}^2$.

With $Re_{w_2} = u_{\infty}w_2 / \nu = 3 \text{ m/s} \times 0.11\text{m} / 7.73 \times 10^{-7} \text{ m}^2/\text{s} = 4.27 \times 10^5$, laminar flow may be assumed over the entire surface. Hence

$$\bar{h} = \left( \frac{k_w}{w_2} \right) \left( \frac{0.664 \text{Re}_{w_2}^{1/2} Pr^{1/3}}{0.664 \text{Re}_{w_2}^{1/2} Pr^{1/3}} \right) \left( \frac{0.62 \text{ W/m}\cdot\text{K}}{0.11\text{m}} \right) \left( \frac{4.27 \times 10^5}{5.2} \right)^{1/3} = 4236 \text{ W/m}^2 \cdot \text{K}$$

With $m = (2\bar{h} / k_{hs} t)^{1/2} = \left( \frac{8472 \text{ W/m}^2 \cdot \text{K}/180 \text{ W/m} \cdot \text{K}}{0.01\text{m}} \right)^{1/2} = 68.6 \text{ m}^{-1}$, $mL_c = 68.6 \text{ m}^{-1}$, $m(0.065\text{m}) = 4.46$ and $\tanh mL_c = 0.9997$, Eq. 3.89 yields

$$\eta_f = \frac{\tanh mL_c}{mL_c} = \frac{0.9997}{4.46} = 0.224$$

Continued …..
Hence,

\[
R_{t,o} = \left\{ \frac{4236 \text{ W/m}^2 \cdot \text{K}}{0.0913 \text{ m}^2} \left[ 1 - \frac{0.0858 \text{ m}^2}{0.0913 \text{ m}^2} (0.776) \right] \right\}^{-1} = 9.55 \times 10^{-3} \text{ K/W}
\]

and

\[
T_b = T_\infty + P_{\text{elec}} (R_b + R_{t,o}) = 17^\circ \text{C} + 1200 \text{ W} (0.0187 \text{ K/W}) = 39.5^\circ \text{C}
\]

**COMMENTS:**

1. The boundary layer thickness at the trailing edge of the fin is

\[
\delta = \frac{5 w_2}{\left( \text{Re}_{w_2} \right)^{1/2}} = 0.84 \text{ mm} << (S - 1).
\]

Hence, the assumption of parallel flow over a flat plate is reasonable. 

2. If a finned heat sink is not employed and heat transfer is simply by convection from the base surface, the corresponding convection resistance would be 0.0195 K/W, which is only twice the resistance associated with the fin array. The small enhancement by the array is attributable to the large value of $\eta$ and the correspondingly small value of $\eta_f$. Were a fluid such as air or a dielectric liquid used as the coolant, the much smaller thermal conductivity would yield a smaller $\eta$, a larger $\eta_f$ and hence a larger effectiveness for the array.
PROBLEM 7.31

KNOWN: Plate dimensions and freestream conditions. Maximum allowable plate temperature.

FIND: (a) Maximum allowable power dissipation for electrical components attached to bottom of plate, (b) Effect of air velocity and fins on maximum allowable power dissipation.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Negligible heat loss from sides and bottom, (4) Transition Reynolds number is $5 \times 10^5$, (5) Isothermal plate.

PROPERTIES: Table A.1, Aluminum ($T \approx 350$ K): $k \approx 240 \text{ W/m} \cdot \text{K}$; Table A.4, Air ($T_i = 325$ K, 1 atm): $\nu = 18.4 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 0.028 \text{ W/m} \cdot \text{K}$, $Pr = 0.70$.

ANALYSIS: (a) The heat transfer from the plate by convection is

$$q = P_{elec} = \frac{h A_s}{h A_s} (T_s - T_\infty).$$

For $u_\infty = 15 \text{ m/s}$,

$$Re_L = \frac{u_\infty L}{\nu} = \frac{15 \text{ m/s} \times 1.2 \text{ m}}{18.41 \times 10^{-6} \text{ m}^2/\text{s}} = 9.78 \times 10^5 > Re_{x,c}.$$

Hence, transition occurs on the plate and

$$Nu_L = \left(0.037 \left( \frac{Re_L}{5} \right)^{4/5} - 871\right)Pr^{1/3} = \left[0.037 \left(9.78 \times 10^5\right)^{4/5} - 871\right](0.70)^{1/3} = 1263$$

$$\frac{h}{L} = \frac{k}{L} = 1263 \frac{0.028 \text{ W/m} \cdot \text{K}}{1.2 \text{ m}} = 29.7 \text{ W/m}^2 \cdot \text{K}$$

The heat rate is

$$q = 29.7 \text{ W/m}^2 \cdot \text{K}(1.2 \text{ m})^2 (350 - 300) \text{ K} = 2137 \text{ W}.$$ (b) The effect of the freestream velocity was considered by combining the Correlations Toolpad for the average coefficient associated with flow over a flat plate with the Explore and Graph options of IHT.
The effect of increasing $u_\infty$ is significant, particularly following transition at $u_\infty \approx 7.7$ m/s. A maximum heat rate of $q = 3876$ W is obtained for $u_\infty = 25$ m/s, which corresponds to $h = 54$ W/m$^2$K and $Re_L = 1.63 \times 10^5$.

The *Extended Surfaces* Model for an *Array of Straight Rectangular Fins* was used with the *Correlations* Toolpad to determine the effect of adding fins, and a copy of the program is appended. With $L_f = 25$ mm, $w = 1.2$ m, $t = 0.005$ m, $S = 0.015$ m, $N = 80$ and $u_\infty = 25$ m/s, the solution yields

$$q = 16,480 \text{ W}$$

which is more than a four-fold increase relative to the unfinned case.

**COMMENTS:**

(1) With a fin efficiency of $\eta_f = 0.978$, there is significant latitude for yet further enhancement in heat transfer, as, for example, by increasing the fin length, $L_f$.

(2) The *IHT* code below includes the model for the *Extended Surface, Array of Straight Fins* and the *Correlation* for the convection coefficient of a flat plate with mixed flow conditions.

```plaintext

PROBLEM 7.32

KNOWN: Operating power of electrical components attached to one side of copper plate. Contact resistance. Velocity and temperature of water flow on opposite side.

FIND: (a) Plate temperature, (b) Component temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Negligible heat loss from sides and bottom, (4) Turbulent flow throughout.

PROPERTIES: Water (given): \( \nu = 0.96 \times 10^{-6} \text{ m}^2/\text{s} \), \( k = 0.620 \text{ W/m K} \), \( Pr = 5.2 \).

ANALYSIS: (a) From the convection rate equation,

\[
T_s = T_\infty + \frac{q}{\overline{h} A}
\]

where \( q = Nq_c = 2500 \text{ W} \) and \( A = L^2 = 0.04 \text{ m}^2 \). The convection coefficient is given by the turbulent flow correlation

\[
\overline{h} = Nu_{L} \left( \frac{k}{L} \right) = 0.037Re_{L}^{4/5} Pr^{1/3} \left( \frac{k}{L} \right)
\]

where

\[
Re_{L} = \left( \frac{u_\infty L}{\nu} \right) = \left( 2 \text{ m/s} \times 0.2 \text{ m} \right)/0.96 \times 10^{-6} \text{ m}^2/\text{s} = 4.17 \times 10^5
\]

and hence

\[
\overline{h} = 0.037 \left( 4.17 \times 10^5 \right)^{4/5} \left( 5.2 \right)^{1/3} \left( 0.62 \text{ W/m} \cdot \text{K}/0.2 \text{ m} \right) = 6228 \text{ W/m}^2 \cdot \text{K}.
\]

The plate temperature is then

\[
T_s = 17^\circ \text{C} + 2500 \text{ W} / \left( 6228 \text{ W/m}^2 \cdot \text{K} \right) \left( 0.20 \text{ m} \right)^2 = 27^\circ \text{C}.
\]

(b) For an individual component, a rate equation involving the component’s contact resistance can be used to find its temperature,

\[
q_c = \left( T_c - T_s \right) / R_{t,c} = \left( T_c - T_s \right) / \left( R_{t,c}^* / A_c \right)
\]

\[
T_c = T_s + q_c R_{t,c}^* / A_c = 27^\circ \text{C} + 25 \text{ W} \left( 2 \times 10^{-4} \text{ m}^2 \cdot \text{K}/\text{W} \right) / 10^{-4} \text{ m}^2
\]

\[
T_c = 77^\circ \text{C}.
\]

COMMENTS: With \( Re_{L} = 4.17 \times 10^5 \), the boundary layer would be laminar over the entire plate without the boundary layer trip, causing \( T_s \) and \( T_c \) to be appreciably larger.
PROBLEM 7.33

KNOWN: Air at 27°C with velocity of 10 m/s flows turbulently over a series of electronic devices, each having dimensions of 4 mm × 4 mm and dissipating 40 mW.

FIND: (a) Surface temperature $T_s$ of the fourth device located 15 mm from the leading edge, (b) Compute and plot the surface temperatures of the first four devices for the range $5 \leq u_\infty \leq 15$ m/s, and (c) Minimum free stream velocity $u_\infty$ if the surface temperature of the hottest device is not to exceed 80°C.

SCHEMATIC:

ASSUMPTIONS: (1) Turbulent flow, (2) Heat from devices leaving through top surface by convection only, (3) Device surface is isothermal, and (4) The average coefficient for the devices is equal to the local value at the mid position, i.e. $\bar{h}_4 = h_x (L)$.

PROPERTIES: Table A.4, Air (assume $T_s = 330$ K, $\bar{T} = (T_s + T_\infty)/2 = 315$ K, 1 atm): $k = 0.0274$ W/m·K, $\nu = 17.40 \times 10^{-6}$ m²/s, $\alpha = 24.7 \times 10^{-6}$ m²/s, $Pr = 0.705$.

ANALYSIS: (a) From Newton’s law of cooling,

$$T_s = T_\infty + \frac{q_{\text{conv}}}{\bar{h}_4 A_s}$$

where $\bar{h}_4$ is the average heat transfer coefficient over the 4th device. Since flow is turbulent, it is reasonable and convenient to assume that

$$\bar{h}_4 = h_x (L = 15 \text{ mm}).$$

To estimate $h_x$, use the turbulent correlation evaluating thermophysical properties at $T_f = 315$ K (assume $T_s = 330$ K),

$$Nu_x = 0.0296 \text{Re}_x^{4/5} Pr^{1/3}$$

where

$$\text{Re}_x = \frac{u_\infty L}{\nu} = \frac{10 \text{ m/s} \times 0.015 \text{ m}}{17.4 \times 10^{-6} \text{ m}^2/\text{s}} = 8621$$

giving

$$Nu_x = \frac{h_x L}{k} = 0.0296 (8621)^{4/5} (0.705)^{1/3} = 37.1$$

$$\bar{h}_4 = h_x = \frac{Nu_x k}{L} = \frac{37.1 \times 0.0274 \text{ W/m·K}}{0.015 \text{ m}} = 67.8 \text{ W/m}^2 \cdot \text{K}$$

Hence, with $A_s = 4 \text{ mm} \times 4 \text{ mm}$, the surface temperature is

$$T_s = 300 \text{ K} + \frac{40 \times 10^{-3} \text{ W}}{67.8 \text{ W/m}^2 \cdot \text{K} \times (4 \times 10^{-3} \text{ m})^2} = 337 \text{ K} = 64°C.$$
PROBLEM 7.33 (Cont.)

(b) The surface temperature for each of the four devices \((i = 1, 2, 3, 4)\) follows from Eq. (1),

\[
T_{s,i} = T_\infty + \frac{q_{\text{conv}}}{\overline{h}_i} A_S
\]  

For devices 2, 3 and 4, \(\overline{h}_i\) is evaluated as the local coefficient at the mid-positions, Eq. (2), \(x_2 = 6.5\) mm, \(x_3 = 10.75\) mm and \(x_4 = 15\) mm. For device 1, \(\overline{h}_1\) is the average value 0 to \(x_1\), where evaluated \(x_1 = L_1 = 4.25\) mm. Using Eq. (3) in the IHT Workspace along with the Correlations Tool, External Flow, Local Coefficient for Laminar or Turbulent Flow, the surface temperatures \(T_{s,i}\) are determined as a function of the free stream velocity.

![Graph showing surface temperature vs. free stream velocity](image)

(c) Using the Explore option on the Plot Window associated with the IHT code of part (b), the minimum free stream velocity of \(u_\infty = 6.6\) m/s will maintain device 4, the hottest of the devices, at a temperature \(T_{s,4} = 80^\circ\)C.

COMMENTS:  (1) Note that the thermophysical properties were evaluated at a reasonable assumed film temperature in part (a).

(2) From the \(T_{s,i}\) vs. \(u_\infty\) plots, note that, as expected, the surface temperatures of the devices increase with distance from the leading edge.
PROBLEM 7.34

KNOWN: Convection correlation for irregular surface due to electronic elements mounted on a circuit board experiencing forced air cooling with prescribed temperature and velocity

FIND: Surface temperature when heat dissipation rate is 30 mW for chip of prescribed area located a specific distance from the leading edge.

SCHEMATIC:

ASSUMPTIONS: (1) Situation approximates parallel flow over a flat plate with prescribed correlation, (2) Heat rate is from top surface of chip.

PROPERTIES: Table A-4. Air (assume $T_s = 45^\circ$C, then $\overline{T} = (45 + 25)^\circ$C/2 = 310 K, 1 atm): $k = 0.027$ W/m$\cdot$K, $\nu = 16.90 \times 10^{-6}$ m$^2$/s, Pr = 0.706.

ANALYSIS: For the chip upper surface, the heat rate is

$$q_{\text{chip}} = \bar{h}_{\text{chip}} A_s (T_s - T_\infty) \quad \text{or} \quad T_s = T_\infty + q_{\text{chip}} / \bar{h}_{\text{chip}} A_s$$

Assuming the average convection coefficient over the chip length to be equal to the local value at the center of the chip ($x = x_o$), $ar{h}_{\text{chip}} = h_x (x_o)$, where

$$Nu_x = 0.04 \text{Re}_x^{0.85} \text{Pr}^{0.33}$$

$$h_x = \frac{Nu_x k}{x_o} = \frac{473.4 \times 0.027 \text{ W/m} \cdot \text{K}}{0.120 \text{ m}} = 107 \text{ W/m}^2 \cdot \text{K}$$

Hence,

$$T_s = 25^\circ \text{C} + 30 \times 10^{-3} \text{ W/107 W/m}^2 \cdot \text{K} \times \left(4 \times 10^{-3} \text{ m} \right)^2 = \left(25 + 17.5\right)^\circ \text{C} = 42.5^\circ \text{C}. \,<$$

COMMENTS: (1) Note that the assumed value of $\frac{\overline{\text{T}}}{\overline{\text{T}}}$ used to evaluate the thermophysical properties was reasonable. (2) We could have evaluated $\bar{h}_{\text{chip}}$ by two other approaches. In one case the average coefficient is approximated as the arithmetic mean of local values at the leading and trailing edges of the chip.

$$\bar{h}_{\text{chip}} \approx \left[ h_x (x_2) + h_x (x_1) \right] / 2 = 107 \text{ W/m}^2 \cdot \text{K}.$$  

The exact approach is of the form

$$\bar{h}_{\text{chip}} \cdot \ell = \bar{h}_{\text{chip}} (x_2) - \bar{h}_{\text{chip}} (x_1)$$

Recognizing that $h_x \sim x^{-0.15}$, it follows that

$$\bar{h}_x = \frac{1}{x} \int_0^x h_x \cdot \text{d} x \approx 1.176 h_x$$

and $\bar{h}_{\text{chip}} = 108 \text{ W/m}^2 \cdot \text{K}$. Why do results for the two approximate methods and the exact method compare so favorably?
PROBLEM 7.35

KNOWN: Air at atmospheric pressure and a temperature of 25°C in parallel flow at a velocity of 5 m/s over a 1-m long flat plate with a uniform heat flux of 1250 W/m².

FIND: (a) Plate surface temperature, \( T_s(L) \), and local convection coefficient, \( h_x(L) \), at the trailing edge, \( x = L \), (b) Average temperature of the plate surface, \( \overline{T_s} \), (c) Plot the variation of the plate surface temperature, \( T_s(x) \), and the convection coefficient, \( h_x(x) \), with distance on the same graph; explain key features of these distributions.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Flow is fully turbulent, and (3) Constant properties.

PROPERTIES: Table A-4, Air (assume \( T_f = 325 \) K, 1 atm): \( \nu = 18.76 \times 10^{-6} \text{ m}^2/\text{s} \); \( k = 0.0284 \text{ W/m} \cdot \text{K} \); \( Pr = 0.703 \)

ANALYSIS: (a) At the trailing edge, \( x = L \), the convection rate equation is

\[
q_s' = q_{cv} = h_x(L)[T_s(L) - T_\infty]
\]

(1)

where the local convection coefficient, assuming turbulent flow, follows from Eq. 7.51.

\[
Nu_x = \frac{h_x}{k} = 0.0308 \frac{Re_x^{4/5} Pr^{1/3}}{k}
\]

(2)

With \( x = L = 1 \text{ m} \), find

\[
Re_x = u_\infty L / \nu = 5 \text{ m/s} \times 1 \text{ m} / 18.76 \times 10^{-6} \text{ m}^2/\text{s} = 2.67 \times 10^5
\]

\[
h_x(L) = (0.0284 \text{ W/m} \cdot \text{K} / 1 \text{ m}) \times 0.0308 \left(2.67 \times 10^5\right)^{4/5} (0.703)^{1/3} = 17.1 \text{ W/m}^2 \cdot \text{K}
\]

Substituting numerical values into Eq. (1),

\[
T_s(L) = 25^\circ\text{C} + 1250 \text{ W/m}^2 / 17.1 \text{ W/m}^2 \cdot \text{K} = 98.3^\circ\text{C}
\]

(b) The average surface temperature \( \overline{T_s} \) follows from the expression

\[
\overline{T_s} - T_\infty = \frac{1}{L} \int_0^L (T_s - T_\infty) \, dx = \frac{q_s'}{L} \int_0^L \frac{x}{k Nu_x} \, dx
\]

(3)

where \( Nu_x \) is given by Eq. (2). Using the Integral function in IHT as described in Comment (3) find \( \overline{T_s} = 86.1^\circ\text{C} \).

(c) The variation of the plate surface temperature \( T_s(x) \) and convection coefficient, \( h_x(x) \), shown in the graph are calculated using Eqs. (1) and (2).

Continued …..
COMMENTS: (1) To avoid performing the integration of part (b), it is reasonable to use the approximate, simpler Eqs. 7.53a and integrating Eq. 7.51,

\[ \bar{\text{Nu}}_L = 0.0385 \text{Re}_L^{4/5} \text{Pr}^{1/3} = 0.0385 \left(2.67 \times 10^5\right)^{4/5} (0.703)^{1/3} = 751 \]

\[ \bar{h}_L = \bar{\text{Nu}}_L k / L = 751 \times 0.0284 \text{ W/m/K} / 1 \text{ m} = 213 \text{ W/m}^2\cdot\text{K} \]

\[ \bar{T}_S = T_\infty + \frac{q'' s''}{k \bar{\text{Nu}}_L} = 83.6^\circ\text{C}. \]

(2) The properties for the correlation should be evaluated at \( T_f = \left( \bar{T}_S + T_\infty \right) / 2 \). From the foregoing analyses, \( T_f = (86.1 + 25) / 2 = 55.5^\circ\text{C} = 329 \text{ K} \). Hence, the assumed value of 325 K was reasonable.

(3) The IHT code, excluding the input variables and air property functions, used to evaluate the integral of Eq. (3) and generate the graphs in part (c) is shown below.

```c
/* Programming note: when using the INTEGRAL function, the value of the independent variable must not be specified as an input variable. If done so, this error message will appear:
"Redefinition of a constant variable." */

// Turbulent flow correlation, Eq. 7.50, local values
Nu_x = 0.0308 * Re_x * 0.8 * Pr*0.333
Nu_x = h_x * x / k
Re_x = uinf * x / nu

// Plate temperatures
// Local
Ts_x = Tinf + q's / h_x
// Average
Ts_avg = Tinf + q's / L * INTEGRAL (y,x)
delT_avg = Ts_avg - Tinf
y = x / (k * Nu_x)
```
PROBLEM 7.36

KNOWN: Conditions for airflow over isothermal plate with optional unheated starting length.

FIND: (a) local coefficient, $h_x$, at leading and trailing edges with and without an unheated starting length, $\xi = 1$ m.

SCHEMATIC:

![Diagram of airflow](image)

PROPERTIES: Table A.4, Air ($T_f = 325$ K, 1 atm): $\nu = 18.4 \times 10^{-6}$ m$^2$/s, Pr = 0.703, $k = 0.0282$ W/m·K.

ANALYSIS: (a) The Reynolds number at $\xi = 1$ m is

$$Re_\xi = \frac{u_\infty \xi}{\nu} = \frac{2 \text{ m/s} \times 1 \text{ m}}{18.4 \times 10^{-6} \text{ m}^2/\text{s}} = 1.087 \times 10^5$$

If $Re_\infty = 5 \times 10^5$, flow is laminar over the entire plate (with or without the starting length). In general,

$$Nu_x = \frac{0.332 Re_x^{1/2} Pr^{1/3}}{\left[1 - (\xi/x)^{3/4}\right]^{1/3}}$$

$$h_x = \frac{0.332 k Pr^{1/3} Re_x^{1/2}}{x \left[1 - (\xi/x)^{3/4}\right]^{1/3}} = 0.00832 \text{ W/m·K} \frac{Re_x^{1/2}}{x \left[1 - (\xi/x)^{3/4}\right]^{1/3}}.$$

With Unheated Starting Length: Leading edge (x = 1 m): $Re_x = Re_\xi$, $\xi/x = 1$, $h_x = \infty$

Trailing Edge (x = 2 m): $Re_x = 2 Re_\xi = 2.17 \times 10^5$, $\xi/x = 0.5$

$$h_x = 0.00832 \text{ W/m·K} \frac{\left(2.17 \times 10^5\right)^{1/2}}{2 \text{ m} \left[1 - (0.5)^{3/4}\right]^{1/3}} = 2.61 \text{ W/m}^2 \cdot \text{K}$$

Without Unheated Starting Length: Leading edge (x = 0): $h_x = \infty$

Trailing edge (x = 1 m): $Re_x = 1.087 \times 10^5$

$$h_x = 0.00832 \text{ W/m·K} \frac{\left(1.087 \times 10^5\right)^{1/2}}{1 \text{ m}} = 2.74 \text{ W/m}^2 \cdot \text{K}$$

(b) The average convection coefficient $\overline{h_L}$ for the two cases in the schematic are, from Eq. 6.6.

Continued...
\[ \bar{h}_L = \frac{1}{L} \int_{\xi=0}^{L} h_x(x) \, dx \]  

(2)

where \( L \) is the x location at the end of the heated section. Substituting Eq. (1) into Eq. (2) and numerically integrate, the results are tabulated below:

<table>
<thead>
<tr>
<th>( \xi ) (m)</th>
<th>( h_x(L)(W/m^2\cdot K) )</th>
<th>( \bar{h}_L ) (W/m^2\cdot K)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>2.74</td>
<td>5.41</td>
</tr>
<tr>
<td>1</td>
<td>2.61</td>
<td>4.22</td>
</tr>
</tbody>
</table>

(c) The variation of the local convection coefficient over the plate, with and without the unheated starting length, using Eq. (1) is shown below. The abscissa is \( x - \xi \).

**COMMENTS:**

(1) When the velocity and thermal boundary layers grow simultaneously (without starting length), we expect the local and average coefficients to be larger than when the velocity boundary layer is thicker (with starting length).

(2) When \( \xi = 0 \), \( \bar{h}_L = 2h_x \), when \( \xi = 1 \), \( \bar{h}_L < 2h_x \). From Eq. (7.49), \( \bar{h}_L = 4.25 \text{ W/m}^2 \cdot \text{K} \).

(3) The numerical integration of Eq. (2) was performed using the INTEGRAL \((f,x)\) operation in IHT as shown in the Workspace below.

```plaintext
// Average Coefficient:
hbarL = 1 / (L - zeta) * INTEGRAL (hx,x)

// Local Coefficient With Unheated Starting Length:
hx = ( k / x) * 0.332 * Rex^0.5 * Pr^0.3333 / ( 1 - (zeta / x)^3/4 )^(1/3)
Rex = uinf * x / nu

// Properties Tool - Air:
// Air property functions : From Table A.4
// Units: T(K); 1 atm pressure
nu = nu_T("Air",Tf) // Kinematic viscosity, m^2/s
k = k_T("Air",Tf) // Thermal conductivity, W/m·K
Pr = Pr_T("Air",Tf) // Prandtl number
Tf = 325 // Film temperature, K

// Assigned Variables:
uinf = 2 // Airstream velocity, m/s
x = 1 // Distance from leading edge, m
L = 2 // Full length of plate, m
zeta = 1 // Starting length, m
xzeta = x - zeta // Difference
```
PROBLEM 7.37

KNOWN: Cover plate dimensions and temperature for flat plate solar collector. Air flow conditions.

FIND: (a) Heat loss with simultaneous velocity and thermal boundary layer development, (b) Heat loss with unheated starting length.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible radiation, (3) Boundary layer is not disturbed by roof-plate interface, (4) \( \text{Re}_{x,c} = 5 \times 10^5 \).

PROPERTIES: Table A-4, Air (\( T_f = 285.5 \text{K}, 1 \text{ atm} \)): \( \nu = 14.6 \times 10^{-6} \text{m}^2/\text{s}, k = 0.0251 \text{W/m}\cdot\text{K}, \text{Pr} = 0.71 \).

ANALYSIS: (a) The Reynolds number for the plate of \( L = 1 \text{m} \) is

\[
\text{Re}_L = \frac{u_{\infty} L}{\nu} = \frac{2 \text{ m/s} \times 1 \text{ m}}{14.6 \times 10^{-6} \text{ m}^2/\text{s}} = 1.37 \times 10^5 < \text{Re}_{x,c}.
\]

For laminar flow

\[
\overline{\text{Nu}}_L = 0.664 \text{Re}_L^{1/2} \text{Pr}^{1/3} = 0.664 \left(1.37 \times 10^5\right)^{1/2} (0.71)^{1/3} = 219.2
\]

\[
q = \frac{k \overline{\text{Nu}}_L A_s (T_s - T_{\infty})}{L} = \frac{0.0251 \text{W/m}\cdot\text{K}}{1 \text{m}} \times 219.2 \left(2 \text{ m}^2\right) 5^\circ \text{C} = 55 \text{ W}.
\]

(b) The Reynolds number for the roof and collector of length \( L = 3 \text{m} \) is

\[
\text{Re}_L = \frac{2 \text{ m/s} \times 3 \text{m}}{14.6 \times 10^{-6} \text{ m}^2/\text{s}} = 4.11 \times 10^5 < \text{Re}_{x,c}.
\]

Hence, laminar boundary layer conditions exist throughout and the heat rate is

\[
q = \int_{T_s}^{T_{\infty}} q'' dA = (T_s - T_{\infty})0.332 \left(\frac{u_{\infty}}{\nu}\right)^{1/2} \text{Pr}^{1/3} \text{kW} \int_{\xi}^{L} \frac{x^{-1/2} dx}{\left(1 - (\xi / x)^{3/4}\right)^{1/3}}
\]

\[
q = (5^\circ \text{C})0.332 \left(\frac{2 \text{ m/s}}{14.6 \times 10^{-6} \text{ m}^2/\text{s}}\right)^{1/2} (0.71)^{1/3} 0.0251 \left(\frac{\text{W}}{\text{m}\cdot\text{K}}\right) \int_{\xi}^{L} \frac{x^{-1/2} dx}{\left(1 - (\xi / x)^{3/4}\right)^{1/3}}
\]

Using a numerical technique to evaluate the integral,

\[
q = 27.50 \int_{2}^{3} \frac{x^{-1/2} dx}{\left[1 - (2.0/x)^{3/4}\right]^{1/3}} = 27.50 \times 1.417 = 39 \text{ W}
\]

COMMENTS: Values of \( \overline{\text{h}} \) with and without the unheated starting length are 3.9 and 5.5 W/m\(^2\cdot\text{K}\). Prior development of the velocity boundary layer decreases \( \overline{\text{h}} \).
**PROBLEM 7.38**

**KNOWN:** Surface dimensions for an array of 10 silicon chips. Maximum allowable chip temperature. Air flow conditions.

**FIND:** Maximum allowable chip electrical power (a) without and (b) with a turbulence promoter at the leading edge.

**SCHEMATIC:**

![Schematic Image]

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Film temperature of 52°C, (3) Negligible radiation, (4) Negligible heat loss through insulation, (5) Uniform heat flux at chip interface with air, (6) \( \text{Re}_{x,c} = 5 \times 10^5 \).

**PROPERTIES:** Table A-4, Air (\( T_f = 325 \text{K}, 1 \text{ atm} \)): \( \nu = 18.4 \times 10^{-6} \text{ m}^2/\text{s}, k = 0.0282 \text{ W/m K}, \text{Pr} = 0.703 \).

**ANALYSIS:** \( \text{Re}_L = \frac{u_\infty L}{\nu} = 40 \text{ m/s} \times 0.1 \text{ m}/18.4 \times 10^{-6} \text{ m}^2/\text{s} = 2.174 \times 10^5 \). Hence, flow is laminar over all chips without the promoter.

(a) For *laminar flow*, the minimum \( h_x \) exists on the last chip. Approximating the average coefficient for Chip 10 as the local coefficient at \( x = 95 \text{ mm} \), \( \bar{h}_{10} = h_x = 0.095 \text{ m} \cdot \text{K} \).

\[
\bar{h}_{10} = 0.453 \frac{k}{x} \frac{1}{2} \frac{P_r^{1/3}}{10} \quad \text{Re}_x = \frac{u_\infty x}{\nu} = \frac{40 \text{ m/s} \times 0.095 \text{ m}}{18.4 \times 10^{-6} \text{ m}^2/\text{s}} = 2.065 \times 10^5 \\
\bar{h}_{10} = 0.453 \frac{0.0282 \text{ W/m K}}{0.095} \left( \frac{2.065 \times 10^5}{1/2} \right) \left( 0.703 \right)^{1/3} = 54.3 \text{ W/m}^2 \cdot \text{K} \\
q_{10} = \bar{h}_{10} A \left( T_s - T_\infty \right) = 54.3 \frac{W}{\text{m}^2 \cdot \text{K}} \left( 0.01 \text{ m} \right)^2 \left( 80 - 24 \right) \degree \text{C} = 0.30 \text{ W}.
\]

Hence, if all chips are to dissipate the same power and \( T_s \) is not to exceed 80°C.

\[ q_{\text{max}} = 0.30 \text{ W}. \]

(b) For *turbulent flow*,

\[
\bar{h}_{10} = 0.0308 \frac{k}{x} \frac{\text{Re}_x^{1/5}}{P_r^{1/3}} = 0.308 \frac{0.0282 \text{ W/m K}}{0.095 \text{ m}} \left( 2.065 \times 10^5 \right)^{1/5} \left( 0.703 \right)^{1/3} = 145 \text{ W/m}^2 \cdot \text{K} \\
q_{10} = \bar{h}_{10} A \left( T_s - T_\infty \right) = 1452 \frac{W}{\text{m}^2 \cdot \text{K}} \left( 0.01 \text{ m} \right)^2 \left( 80 - 24 \right) \degree \text{C} = 0.81 \text{ W}.
\]

Hence,

\[ q_{\text{max}} = 0.81 \text{ W}. \]

**COMMENTS:** It is far better to orient array normal to the air flow. Since \( \bar{h}_1 > \bar{h}_{10} \), more heat could be dissipated per chip, and the same heat could be dissipated from each chip.
**PROBLEM 7.39**

**KNOWN:** Dimensions and maximum allowable temperature of a silicon chip. Air flow conditions.

**FIND:** Maximum allowable power with or without unheated starting length.

**SCHEMATIC:**

![Diagram of air flow and silicon chip](image)

**ASSUMPTIONS:** (1) Steady-state conditions, (2) \( T_f = 52^\circ C \), (3) Negligible radiation, (4) Negligible heat loss through insulation, (5) Uniform heat flux at chip-air interface, (6) \( \text{Re}_{x,c} = 5 \times 10^5 \).

**PROPERTIES:** Table A-4, Air \((T_f = 325K, 1 \text{ atm})\): \( \nu = 18.41 \times 10^{-6} \text{ m}^2/\text{s} \), \( k = 0.0282 \text{ W/m} \cdot \text{K} \), \( \text{Pr} = 0.703 \).

**ANALYSIS:** For uniform heat flux, maximum \( T_s \) corresponds to minimum \( h_x \). Without unheated starting length,

\[
\text{Re}_L = \frac{u_\infty L}{v} = \frac{20 \text{ m/s} \times 0.01 \text{ m}}{18.41 \times 10^{-6} \text{ m}^2/\text{s}} = 10,864.
\]

With the unheated starting length, \( L = 0.03 \text{ m} \), \( \text{Re}_L = 32,591 \). Hence, the flow is laminar in both cases and the minimum \( h_x \) occurs at the trailing edge \((x = L)\).

**Without unheated starting length,**

\[
h_L = \frac{k}{L} \left( \frac{\text{Re}_L^{1/2} \text{Pr}^{1/3}}{v} \right) = \frac{0.0282 \text{ W/m} \cdot \text{K}}{0.01 \text{ m}} \left( 10,864 \right)^{1/2} \left( 0.703 \right)^{1/3} \leq 118 \text{ W/m}^2 \cdot \text{K}
\]

\[
q^* (L) = h_L \left( T_s - T_\infty \right) = 118 \text{ W/m}^2 \cdot \text{K} \left( 80 - 24 \right)^\circ \text{C} = 6630 \text{ W/m}^2
\]

\[
q_{max} = A_s q^* = \left( 10^{-2} \text{m} \right)^2 6630 \text{ W/m}^2 = 0.66 \text{ W}.
\]

**With the unheated starting length,**

\[
h_L = \frac{k}{L} \left( \frac{\text{Re}_L^{1/2} \text{Pr}^{1/3}}{v} \right) \left[ 1 - \left( \frac{\xi}{L} \right)^{3/4} \right]^{1/3} = \frac{0.0282 \text{ W/m} \cdot \text{K}}{0.03 \text{ m}} \left( 32,951 \right)^{1/2} \left( 0.703 \right)^{1/3} \left[ 1 - \left( 0.02/0.03 \right)^{3/4} \right]^{1/3}
\]

\[
h_L = 107 \text{ W/m}^2 \cdot \text{K}
\]

\[
q^* (L) = h_L \left( T_s - T_\infty \right) = 107 \text{ W/m}^2 \cdot \text{K} \left( 80 - 24 \right)^\circ \text{C} = 6013 \text{ W/m}^2
\]

\[
q_{max} = A_s q^* = \times 6013 \text{ W/m}^2 = 0.60 \text{ W}.
\]

**COMMENTS:** Prior velocity boundary layer development on the unheated starting section decreases \( h_x \), although the effect diminishes with increasing \( x \).
**PROBLEM 7.40**

**KNOWN:** Experimental apparatus providing nearly uniform airstream over a flat *test plate*. Temperature history of the pre-heated plate for airstream velocities of 3 and 9 m/s were fitted to a fourth-order polynomial.

**FIND:** (a) Convection coefficient for the two cases assuming the plate behaves as a spacewise isothermal object and (b) Coefficients $C$ and $m$ for a correlation of the form $Nu_L = CRe^m Pr^{1/3}$; compare result with a standard-plate correlation and comment on the goodness of the comparison; explain any differences.

**SCHEMATIC:**

![Test plate diagram]

<table>
<thead>

</tbody>
</table>

**ASSUMPTIONS:** (1) Airstream over the *test plate* approximates parallel flow over a flat plate, (2) Plate is spacewise isothermal, (3) Negligible radiation exchange between plate and surroundings, (4) Constant properties, and (5) Negligible heat loss from the bottom surface or edges of the test plate.

**PROPERTIES:** *Table A.4*, Air ($T_f = (T_s - T_\infty)/2 \approx 310$ K, 1atm): $k_a = 0.0269$ W/m·K, $\nu = 1.669 \times 10^{-5}$ m²/s, $Pr = 0.706$. Test plate (Given): $\rho = 2770$ kg/m³, $c_p = 875$ J/kg·K, $k = 177$ W/m·K.

**ANALYSIS:** (a) Using the lumped-capacitance method, the energy balance on the plate is

$$-\bar{h}_L A_s \left[T_s(t) - T_\infty\right] = \rho Vc_p \frac{dT}{dt} \tag{1}$$

and the average convection coefficient can be determined from the temperature history, $T_s(t)$,

$$\bar{h}_L = \frac{\rho Vc_p}{A_s} \frac{dT}{dt} \tag{2}$$

where the temperature-time derivative is

$$\frac{dT_s}{dt} = b + 2ct + 3dt^2 + 4et^3 \tag{3}$$

The temperature time history plotted below shows the experimental behavior of the observed data.

![Temperature history graph]

Continued...
Problem 7.40 (Cont.)

Consider now the integrated form of the energy balance, Eq. (5.6), expressed as

\[
\ln \left( \frac{T_s(t) - T_\infty}{T_i - T_\infty} \right) = -\left( \frac{h_L A_s}{\rho V c} \right) t
\]

If we were to plot the LHS vs t, the slope of the curve would be proportional to \( h_L \). Using IHT, plots were generated of \( h_L \) vs. \( T_s \), Eq. (1), and \( \ln \left( \frac{T_s(t) - T_\infty}{(T_i - T_\infty)} \right) \) vs. t, Eq. (4). From the latter plot, recognize that the regions where the slope is constant corresponds to early times (\( \leq 100 \) s when \( u_\infty = 3 \) m/s and \( \leq 50 \) s when \( u_\infty = 5 \) m/s).

Selecting two elapsed times at which to evaluate \( h_L \), the following results were obtained

<table>
<thead>
<tr>
<th>( u_\infty ) (m/s)</th>
<th>t (s)</th>
<th>( T_s ) (°C)</th>
<th>( h_L ) (W/m²·K)</th>
<th>( \overline{Nu}_L )</th>
<th>( \overline{Re}_L )</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>100</td>
<td>44.77</td>
<td>30.81</td>
<td>152.4</td>
<td>2.39 \times 10^4</td>
</tr>
<tr>
<td>9</td>
<td>50</td>
<td>45.80</td>
<td>56.7</td>
<td>280.4</td>
<td>7.17 \times 10^4</td>
</tr>
</tbody>
</table>

where the dimensionless parameters are evaluated as

\[
\overline{Nu}_L = \frac{h_L L}{k_a} \quad \overline{Re}_L = \frac{u_\infty L}{\nu}
\]

where \( k_a, \nu \) are thermophysical properties of the airstream.

(b) Using the above pairs of \( \overline{Nu}_L \) and \( \overline{Re}_L \), \( C \) and \( m \) in the correlation can be evaluated,

\[
\overline{Nu}_L = C \overline{Re}_L^m Pr^{1/3}
\]

\[
152.4 = C(2.39 \times 10^4)^m (0.706)^{1/3} \]

\[
280.4 = C(7.17 \times 10^4)^m (0.706)^{1/3}
\]

Solving, find

\[
C = 0.633 \quad m = 0.555
\]
The plot below compares the experimental correlation \((C = 0.633, \ m = 0.555)\) with those for laminar flow \((C = 0.664, \ m = 0.5)\) and fully turbulent flow \((C = 0.037, \ m = 0.8)\). The experimental correlation yields \(\bar{\text{Nu}}_L\) values which are 25% higher than for the correlation. The most likely explanation for this unexpected trend is that the airstream reaching the plate is not parallel, but with a slight impingement effect and/or the flow is very highly turbulent at the leading edge.

**COMMENTS:** (1) A more extensive analysis of the experimental observations would involve determining \(\bar{\text{Nu}}_L\) for the full range of elapsed time (rather than at two selected times) and using a fitting routine to determine values for \(C\) and \(m\).
**PROBLEM 7.41**

**KNOWN:** Cylinder diameter and surface temperature. Temperature and velocity of fluids in cross flow.

**FIND:** (a) Rate of heat transfer per unit length for the fluids: atmospheric air and saturated water, and engine oil, for velocity \( V = 5 \) m/s, using the Churchill-Bernstein correlation, and (b) Compute and plot \( q' \) as a function of the fluid velocity \( 0.5 \leq V \leq 10 \) m/s.

**SCHEMATIC:**

```
Air, water, or oil
\( T_\infty = 20 \, ^\circ C \)
\( V = 5 \) m/s
\( T_s = 50 \, ^\circ C \)
\( D = 0.01 \) m
```

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Uniform cylinder surface temperature.

**PROPERTIES:** Table A.4, Air (\( T_i = 308 \) K, 1 atm): \( \nu = 16.69 \times 10^{-6} \) m\(^2\)/s, \( k = 0.0269 \) W/m K, \( Pr = 0.706 \); Table A.6, Saturated Water (\( T_i = 308 \) K): \( \rho = 994 \) kg/m\(^3\), \( \mu = 725 \times 10^{-6} \) N-s/m\(^2\), \( k = 0.625 \) W/m K, \( Pr = 4.85 \); Table A.5, Engine Oil (\( T_i = 308 \) K): \( \nu = 340 \times 10^{-6} \) m\(^2\)/s, \( k = 0.145 \) W/m K, \( Pr = 4000 \).

**ANALYSIS:** (a) For each fluid, calculate the Reynolds number and use the Churchill-Bernstein correlation, Eq. 7.57,

\[
\frac{\bar{h}D}{k} = 0.3 + \frac{0.62 \Re_D^{1/2} \Pr^{1/3}}{1 + (0.4/\Pr)^{2/3}} \left[ 1 + \left( \frac{\Re_D}{282,000} \right)^{5/8} \right]^{4/5}
\]

**Fluid: Atmospheric Air**

\[
\Re_D = \frac{VD}{\nu} = \frac{(5 \, \text{m/s})(0.01 \, \text{m})}{16.69 \times 10^{-6} \, \text{m}^2/\text{s}} = 2996
\]

\[
\bar{h} = \frac{k}{\bar{\nu}_D} = \frac{0.0269 \, \text{W/m.K}}{0.01 \, \text{m}} = 28.1 = 75.5 \, \text{W/m}^2 \cdot \text{K}
\]

\[
q' = \bar{h} \pi D (T_s - T_\infty) = 75.5 \, \text{W/m}^2 \cdot \text{K} \pi (0.01 \, \text{m})(50 - 20) \, ^\circ \text{C} = 71.1 \, \text{W/m}
\]

**Fluid: Saturated Water**

\[
\Re_D = \frac{VD}{\nu} = \frac{(5 \, \text{m/s})(0.01 \, \text{m})}{725 \times 10^{-6} \, \text{N.s/m}^2/994 \, \text{kg/m}^3} = 68,552
\]

\[
\bar{\nu}_D = 0.3 + \frac{0.62 (68,552)^{1/2} (4.85)^{1/3}}{1 + (0.4/4.85)^{2/3}} \left[ 1 + \left( \frac{68,552}{282,000} \right)^{5/8} \right]^{4/5} = 347
\]

Continued...
PROBLEM 7.41 (Cont.)

\[ h = \frac{k}{\text{D}} \frac{\text{Nu}_D}{0.625 \text{W/m} \cdot \text{K}} = \frac{347}{0.01 \text{m}} = 21,690 \text{W/m}^2 \cdot \text{K} \quad q' = 20,438 \text{W/m} \]

\[ \text{Fluid: Engine Oil} \]

\[ \text{Re}_D = \frac{V \text{D}}{\nu} = \frac{(5 \text{ m/s})0.01 \text{m}}{340 \times 10^{-6} \text{ m}^2 / \text{s}} = 147 \]

\[ \text{Nu}_D = 0.3 + \frac{0.62(147)^{1/2}(4000)^{1/3}}{1 + (0.4/4000)^{2/3}}^{1/4} \left[ 1 + \left( \frac{147}{282,000} \right)^{5/8} \right]^{4/5} = 120 \]

\[ h = \frac{k}{\text{D}} \frac{\text{Nu}_D}{0.145 \text{W/m} \cdot \text{K}} = \frac{120}{0.01 \text{m}} = 1740 \text{W/m}^2 \cdot \text{K} \quad q' = 1639 \text{W/m} \]

(b) Using the IHT Correlations Tool, External Flow, Cylinder, along with the Properties Tool for each of the fluids, the heat rates, \( q' \), were calculated for the range \( 0.5 \leq V \leq 10 \text{ m/s} \). Note the \( q' \) scale multipliers for the air and oil fluids which permit easy comparison of the three curves.

![Graph](image)

COMMENTS: (1) Note the inapplicability of the Zhukauskas relation, Eq. 7.56, since \( \text{Pr}_{\text{oil}} > 500 \).

(2) In the plot above, recognize that the heat rate for the water is more than 10 times that with oil and 300 times that with air. How do changes in the velocity affect the heat rates for each of the fluids?
PROBLEM 7.42

KNOWN: Conditions associated with air in cross flow over a pipe.

FIND: (a) Drag force per unit length of pipe, (b) Heat transfer per unit length of pipe.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform cylinder surface temperature, (3) Negligible radiation effects.

PROPERTIES: Table A-4, Air (T_f = 335 K, 1 atm): \( \nu = 19.31 \times 10^{-6} \text{ m}^2/\text{s}, \rho = 1.048 \text{ kg/m}^3, k = 0.0288 \text{ W/m} \cdot \text{K}, \text{Pr} = 0.702. \)

ANALYSIS: (a) From the definition of the drag coefficient with \( A_f = DL \), find

\[
F_D = C_D A_f \frac{\rho V^2 F_C A}{2},
\]

\[
F_D = C_D D \frac{\rho V^2}{2}.
\]

With

\[
Re_D = \frac{VD}{\nu} = \frac{15 \text{ m/s} \times (0.025 \text{ m})}{19.31 \times 10^{-6} \text{ m}^2/\text{s}} = 1.942 \times 10^4
\]

from Fig. 7.8, \( C_D \approx 1.1. \) Hence

\[
F_D = 1.1(0.025 \text{ m}) \times 1.048 \text{ kg/m}^3 \times (15 \text{ m/s})^2 / 2 = 3.24 \text{ N/m}.
\]

(b) Using Hilpert’s relation, with \( C = 0.193 \) and \( m = 0.618 \) from Table 7.2,

\[
\bar{h} = \frac{k}{D} C Re_D^m Pr^{1/3} = \frac{0.0288 \text{ W/m} \cdot \text{K}}{0.025 \text{ m}} \times 0.193 \left(1.942 \times 10^4\right)^{0.618} (0.702)^{1/3}
\]

\[
\bar{h} = 88 \text{ W/m}^2 \cdot \text{K}.
\]

Hence, the heat rate per unit length is

\[
q' = \bar{h} (\pi D) (T_S - T_\infty) = 88 \text{ W/m}^2 \cdot \text{K} (\pi \times 0.025 \text{ m}) \times (100 - 25) \text{°C} = 520 \text{ W/m}.
\]

COMMENTS: Using the Zhukauskas correlation and evaluating properties at \( T_\infty \) (\( v = 15.71 \times 10^{-6} \text{ m}^2/\text{s}, k = 0.0261 \text{ W/m} \cdot \text{K}, \text{Pr} = 0.707 \)), but with \( \text{Pr}_S = 0.695 \) at \( T_s \),

\[
\bar{h} = \frac{0.0261}{0.025} 0.26 \left( \frac{15 \times 0.025}{15.71 \times 10^{-6}} \right)^{0.6} (0.707)^{0.37} (0.707/0.695)^{1/4} = 102 \text{ W/m}^2 \cdot \text{K}.
\]

This result agrees with that obtained from Hilpert’s relation to within the uncertainty normally associated with convection correlations.
PROBLEM 7.43

KNOWN: Initial temperature, power dissipation, diameter, and properties of heating element. Velocity and temperature of air in cross flow.

FIND: (a) Steady-state temperature, (b) Time to come within 10°C of steady-state temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Uniform heater temperature, (2) Negligible radiation.

PROPERTIES: Table A.4, air (assume $T_i \approx 450$ K): $v = 32.39 \times 10^{-6}$ m$^2$/s, $k = 0.0373$ W/m·K, Pr = 0.686.

ANALYSIS: (a) Performing an energy balance for steady-state conditions, we obtain

$q'_{conv} = \bar{h}(\pi D)(T - T_\infty) = P_{elec} = 1000$ W/m

With

$$Re_D = \frac{VD}{\nu} = \frac{(10 \text{ m/s})0.01 \text{ m}}{32.39 \times 10^{-6} \text{ m}^2/\text{s}} = 3,087$$

the Churchill and Bernstein correlation, Eq. 7.57, yields

$$\frac{Nu_D}{0.3} = 0.62 \frac{Re_D^{1/2} Pr^{1/3}}{1 + (0.4/Pr)^{2/3}} \left[ 1 + \left( \frac{Re_D}{282,000} \right)^{5/8} \right]^{4/5}$$

$$\frac{Nu_D}{0.3} = 0.62 \frac{(3087)^{1/2} (0.686)^{1/3}}{1 + (0.4/0.686)^{2/3}} \left[ 1 + \left( \frac{3087}{282,000} \right)^{5/8} \right]^{4/5} = 28.2$$

$$\bar{h} = \frac{k}{D} Nu_D = \frac{0.0373 \text{ W/m} \cdot \text{K}}{0.010 \text{ m}} \cdot 28.2 = 105.2 \text{ W/m}^2 \cdot \text{K}$$

Hence, the steady-state temperature is

$$T = T_\infty + \frac{P_{elec}}{\pi D \bar{h}} = 300 \text{ K} + \frac{1000 \text{ W/m}}{\pi (0.01 \text{ m})105.2 \text{ W/m}^2 \cdot \text{K}} = 603 \text{ K}$$

(b) With Bi = $\frac{\bar{h}r_i}{k} = 105.2 \text{ W/m}^2 \cdot \text{K}(0.005 \text{ m})/240 \text{ W/m} \cdot \text{K} = 0.0022$, a lumped capacitance analysis may be performed. The time response of the heater is given by Eq. 5.25, which, for $T_i = T_\infty$, reduces to

$$T = T_\infty + (b/a) \left[ 1 - \exp(-at) \right]$$

Continued...
where \( a = \frac{4 h}{D \rho c_p} = \frac{(4 \times 105.2 \text{ W/m}^2 \cdot \text{K})}{(0.01 \text{ m} \times 2700 \text{ kg/m}^3 \times 900 \text{ J/kg} \cdot \text{K})} = 0.0173 \text{ s}^{-1} \) and \( b/a = \frac{P_{\text{elec}}}{\pi D \bar{h}} = 1000 \text{ W/m/} \pi \left( \frac{0.01 \text{ m} \times 105.2 \text{ W/m}^2 \cdot \text{K}}{\pi} \right) = 302.6 \text{ K}. \) Hence,

\[
\left[ 1 - \exp\left( -0.0173t \right) \right] = \frac{(593 - 300) \text{K}}{302.6 \text{K}} = 0.968
\]

\( t \approx 200 \text{s} \)

**COMMENTS:**

(1) For \( T = 603 \text{ K} \) and a representative emissivity of \( \varepsilon = 0.8, \) net radiation exchange between the heater and surroundings at \( T_{\text{sur}} = T_m = 300 \text{ K} \) would be

\[
q_{\text{rad}}' = \varepsilon \sigma \cdot \pi D \left( T^4 - T_{\text{sur}}^4 \right) = 0.8 \times 5.67 \times 10^{-8} \text{ W/m}^2 \text{K}^4 (\pi \times 0.01 \text{ m})(603^4 - 300^4)\text{K}^4 = 177 \text{ W/m}. \]

Hence, although small, radiation exchange is not negligible. The effects of radiation are considered in Problem 7.46.

(2) The assumed value of \( T_f \) is very close to the actual value, rendering the selected air properties accurate.
PROBLEM 7.44

KNOWN: Initial temperature, power dissipation, diameter, and properties of a heating element. Velocity and temperature of air in cross flow. Temperature of surroundings.

FIND: (a) Steady-state temperature, (b) Time to come within 10°C of steady-state temperature, (c) Variation of power dissipation required to maintain a fixed heater temperature of 275°C over a range of velocities.

SCHEMATIC:

ASSUMPTIONS: Uniform heater surface temperature.

ANALYSIS: (a) Performing an energy balance for steady-state conditions, we obtain

\[ q'_{\text{conv}} + q'_{\text{rad}} = P'_{\text{elec}} \]

\[ \bar{h}(\pi D)(T - T_\infty) + \varepsilon\sigma(\pi D)(T^4 - T_{\text{sur}}^4) = P'_{\text{elec}} \]

\[ \bar{h}(\pi \times 0.01\text{m})(T - 300\text{K}) + 0.8 \times 5.67 \times 10^{-8}\text{ W/m}^2\text{.K} \left(T^4 - 300^4\right) \text{K}^4 = 1000\text{ W/m} \]

Using the IHT Energy Balance Model for an Isothermal Solid Cylinder with the Correlations Tool Pad for a Cylinder in Crossflow and the Properties Tool Pad for Air, we obtain

\[ T = 562.4\text{ K} \]

where \( \bar{h} = 105.4\text{ W/m}^2\text{.K} \), \( h_r = 15.9\text{ W/m}^2\text{.K} \), \( q'_{\text{conv}} = 868.8\text{ W/m} \), and \( q'_{\text{rad}} = 131.2\text{ W/m} \).

(b) With \( \text{Bi} = \left(\bar{h} + h_r\right)\frac{r_0}{k} = (121.3\text{ W/m}^2\text{.K})\times0.005\text{ m}/240\text{ W/m}^2\text{.K} = 0.0025 \), the transient behavior may be analyzed using the lumped capacitance method. Using the IHT Lumped Capacitance Model to perform the numerical integration, the following temperature histories were obtained.
The agreement between predictions with and without radiation for $t < 50s$ implies negligible radiation. However, as the heater temperature increases with time, radiation becomes significant, yielding a reduced heater temperature. Steady-state temperatures correspond to 562.4 K and 602.8 K, with and without radiation, respectively. The time required for the heater to reach 552.4 K (with radiation) is $t \approx 155s$.

(c) If the heater temperature is to be maintained at a fixed value in the face of velocity excursions, provision must be made for adjusting the heater power. Using the Explore and Graph options of IHT with the model of part (a), the following results were obtained.

![Graph of power dissipation vs. freestream velocity](image)

For $T = 275^\circ C = 548$ K, the controller would compensate for velocity reductions from 10 to 5 m/s by reducing the power from approximately 935 to 690 W/m.

**COMMENTS:** Although convection heat transfer substantially exceeds radiation heat transfer, radiation is not negligible and should be included in the analysis. If it is neglected, $T = 603$ K would be predicted for $P'_{\text{elec}} = 1000$ W/m, in contrast 562 K from the results of part (a).
PROBLEM 7.45

KNOWN: Pin fin of 10 mm diameter dissipates 30 W by forced convection in cross-flow of air with \( \text{Re}_D = 4000 \).

FIND: Fin heat rate if diameter is doubled while all conditions remain the same.

SCHEMATIC:

\[ q_{\text{conv}} = 30 \text{W} \]

ASSUMPTIONS: (1) Pin behaves as infinitely long fin, (2) Conditions of flow, as well as base and air temperatures, remain the same for both situations, (3) Negligible radiation heat transfer.

ANALYSIS: For an infinitely long pin fin, the fin heat rate is

\[ q_f = q_{\text{conv}} = \left( \frac{\bar{h} P k A_c}{A_{\text{c}}} \right)^{1/2} \theta_b \]

where \( P = \pi D \) and \( A_c = \pi D^2 / 4 \). Hence,

\[ q_{\text{conv}} \sim \left( \bar{h} \cdot D \cdot D^2 \right)^{1/2} \cdot \cdot \cdot \]

For forced convection cross-flow over a cylinder, an appropriate correlation for estimating the dependence of \( \bar{h} \) on the diameter is

\[ \bar{N}_u_D = \frac{\bar{h} D}{k} = C \text{Re}_D^m \text{Pr}^{1/3} = C \left( \frac{VD}{v} \right)^m \text{Pr}^{1/3} \cdot \cdot \cdot \]

From Table 7.2 for \( \text{Re}_D = 4000 \), find \( m = 0.466 \) and

\[ \bar{h} \sim D^{-1}(D)^{0.466} = D^{-0.534} \cdot \cdot \cdot \]

It follows that

\[ q_{\text{conv}} \sim \left( D^{-0.534} \cdot D \cdot D^2 \right)^{1/2} = D^{1.23} \cdot \cdot \cdot \]

Hence, with \( q_1 \rightarrow D_1 \) (10 mm) and \( q_2 \rightarrow D_2 \) (20 mm), find

\[ q_2 = q_1 \left( \frac{D_2}{D_1} \right)^{1.23} = 30 \text{W} \left( \frac{20}{10} \right)^{1.23} = 70.4 \text{W}. \]

COMMENTS: The effect of doubling the diameter, with all other conditions remaining the same, is to increase the fin heat rate by a factor of 2.35. The effect is nearly linear, with enhancements due to the increase in surface and cross-sectional areas (\( D^{1.5} \)) exceeding the attenuation due to a decrease in the heat transfer coefficient (\( D^{-0.267} \)). Note that, with increasing Reynolds number, the exponent \( m \) increases and there is greater heat transfer enhancement due to increasing the diameter.
PROBLEM 7.46

KNOWN: Pin fin installed on a surface with prescribed heat rate and temperature.

FIND: (a) Maximum heat removal rate possible, (b) Length of the fin, (c) Effectiveness, $\varepsilon_f$, (d) Percentage increase in heat rate from surface due to fin.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Conditions over $A_s$ are uniform for both situations, (3) Conditions over fin length are uniform, (4) Flow over pin fin approximates cross-flow.

PROPERTIES: *Table A-4*, Air ($T_f = (T_\infty + T_s)/2 = (27 + 127)^\circ C/2 = 350$ K): $v = 20.92 \times 10^{-6}$ m$^2$/s, $k = 30.0 \times 10^{-3}$ W/m$\cdot$K, Pr = 0.700. *Table A-1*, SS AISI304 ($T_f = T_s = 350$ K): $k = 15.8$ W/m$\cdot$K.

ANALYSIS: (a) Maximum heat rate from fin occurs when fin is infinitely long,

$$q_f = M = \left(\frac{hP}{kA_c}\right)^{1/2} \theta_b$$

from Eq. 3.80. Estimate convection heat transfer coefficient for cross-flow over cylinder,

$$Re_D = \frac{VD}{v} = 5 \text{ m/s} \times 0.005 \text{ m} / 20.92 \times 10^{-6} \text{ m}^2 / \text{s} = 1195.$$  

Using the Hilpert correlation, Eq. 7.55, with Table 7.2, find

$$h = \frac{k}{D} \frac{CReD}{Pr^{0.466}}$$

From Eq. (1), with $P = \pi D$, $A_c = \pi D^2 / 4$, and $\theta_b = T_s - T_\infty$, find

$$q_f = \left(98.9 \text{ W/m}^2 \cdot \text{K} \times \pi \left(0.005 \text{ m}\right) \times 15.8 \text{ W/m} \cdot \text{K} \times \pi \left(0.005 \text{ m}^2 / 4\right) / 4 \right)^{1/2} (127 - 27) \text{ K} = 2.20 \text{ W}.$$  

(b) From Example 3.8, $L \approx L_\infty = 2.65(kA_c/hP)^{1/2}$. Hence,

$$L \approx L_\infty = 2.65 \left[15.8 \text{ W/m} \cdot \text{K} \times \pi \left(0.005 \text{ m}^2 / 4 / 98.9 \text{ W/m}^2 \cdot \text{K} \times \pi \left(0.005 \text{ m}^2 / 4\right) / 4 \right)^{1/2} = 37.4 \text{ mm}.\right.$$  

(c) From Eq. 3.81, with $h_s$ used for the base area $A_s$, the effectiveness is

$$\varepsilon_f = \frac{q_f}{h_s A_{c,b} \theta_b} = \frac{q_f A_s}{q_{wo} A_{c,b}} = \frac{2.2 \text{ W}}{0.5 \text{ W}} \left(0.020 \times 0.020\right) \left(0.005 \text{ m}^2 / 4\right) / \pi = 89.6$$

where $h_s = q_{wo} / A_{s,\theta_b}$.

(d) The percentage increase in heat rate with the installed fin (w) is

$$\frac{q_w - q_{wo}}{q_{wo}} \times 100 = \left[q_f + h_s \left(A_s - \pi D^2 / 4\right)(T_s - T_\infty) - q_{wo}\right] \times 100 / q_{wo}$$

$$\Delta q/q = \left[2.2 \text{ W} + 12.5 \text{ W/m}^2 \cdot \text{K} \left[0.02 \text{ m}^2 - (\pi / 4)(0.005 \text{ m})^2\right](100 \text{ K} - 0.5 \text{ W})\right] \times 100 / 0.5 \text{ W}$$

$$\Delta q/q = 435\%.$$
**PROBLEM 7.47**

**KNOWN:** Dimensions of chip and pin fin. Chip temperature. Free stream velocity and temperature of air coolant.

**FIND:** (a) Average pin convection coefficient, (b) Pin heat transfer rate, (c) Total heat rate, (d) Effect of velocity and pin diameter on total heat rate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional conduction in pin, (3) Constant properties, (4) Convection coefficients on pin surface (tip and side) and chip surface correspond to single cylinder in cross flow, (5) Negligible radiation.

**PROPERTIES:** Table A.1, Copper (350 K): \( k = 399 \, \text{W/m-K} \); Table A.4, Air \((T_f \approx 325 \, \text{K}, 1 \, \text{atm})\): \( \nu = 18.41 \times 10^{-6} \, \text{m}^2/\text{s}, k = 0.0282 \, \text{W/m-K}, \text{Pr} = 0.704 \).

**ANALYSIS:**

(a) With \( V = 10 \, \text{m/s} \) and \( D = 0.002 \, \text{m} \),

\[
\text{Re}_D = \frac{VD}{v} = \frac{10 \, \text{m/s} \times 0.002 \, \text{m}}{18.41 \times 10^{-6} \, \text{m}^2/\text{s}} = 1087
\]

Using the Churchill and Bernstein correlations, Eq. (7.57),

\[
\overline{\text{Nu}}_D = 0.3 + \frac{0.62 \text{Re}_D^{1/2} \text{Pr}^{1/3}}{[1 + (0.4/\text{Pr})^{2/3}]^{1/4}} \left[ 1 + \left( \frac{\text{Re}_D}{282,000} \right)^{5/8} \right]^{4/5} = 16.7
\]

\[
\bar{h} = \left( \overline{\text{Nu}}_D k / D \right) = (16.7 \times 0.0282 \, \text{W/m-K}/0.002 \, \text{m}) = 235 \, \text{W/ m}^2 \cdot \text{K}
\]

(b) For the fin with tip convection and

\[
\text{M} = \left( \bar{h} \pi D \pi D^2 / 4 \right)^{1/2} \quad \theta_b = \left( \pi / 2 \right) \left[ 235 \, \text{W/ m}^2 \cdot \text{K} \times (0.002 \, \text{m}) \times 399 \, \text{W/m-K} \right]^{1/2} = 50 \, \text{K} = 2.15 \, \text{W}
\]

\[
m = (\bar{h} P / k A_c)^{1/2} = \left( 4 \times 235 \, \text{W/ m}^2 \cdot \text{K} / 399 \, \text{W/m-K} \times 0.002 \, \text{m} \right)^{1/2} = 34.3 \, \text{m}^{-1}
\]

\[
\text{mL} = 34.3 \, \text{m}^{-1} (0.012 \, \text{m}) = 0.412
\]

\[
\left( \bar{h} / mk \right) = \left( 235 \, \text{W/ m}^2 \cdot \text{K} / 34.3 \, \text{m}^{-1} \times 399 \, \text{W/m-K} \right) = 0.0172.
\]

The fin heat rate is

\[
q_f = M \frac{\sinh mL + \left( \bar{h} / mk \right) \cosh mL}{\cosh mL + \left( \bar{h} / mk \right) \sinh mL} = 0.868 \, \text{W}.
\]

Continued...
(c) The total heat rate is that from the base and through the fin,
\[ q = q_b + q_f = \hat{h} \left( W^2 - \pi D^2 / 4 \right) \theta_b + q_f = (0.151 + 0.868) W = 1.019 W. \]

(d) Using the IHT Extended Surface Model for a Pin Fin with the Correlations Tool Pad for a Cylinder in crossflow and Properties Tool Pad for Air, the following results were generated.

Clearly, there is significant benefit associated with increasing \( V \) which increases the convection coefficient and the total heat rate. Although the convection coefficient decreases with increasing \( D \), the increase in the total heat transfer surface area is sufficient to yield an increase in \( q \) with increasing \( D \). The maximum heat rate is \( q = 2.77 \) W for \( V = 40 \) m/s and \( D = 4 \) mm.

**COMMENTS:** Radiation effects should be negligible, although tip and base convection coefficients will differ from those calculated in parts (a) and (d).
**PROBLEM 7.48**

**KNOWN:** Diameter, resistivity, thermal conductivity and emissivity of Nichrome wire. Electrical current. Temperature of air flow and surroundings. Velocity of air flow.

**FIND:** (a) Surface and centerline temperatures of the wire, (b) Effect of flow velocity and electric current on temperatures.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Radiation exchange with large surroundings, (3) Constant Nichrome properties, (4) Uniform surface temperature.

**PROPERTIES:** Prescribed, Nichrome: \( k = 25 \, \text{W/m-K}, \rho_e = 10^{-6} \, \Omega \cdot \text{m}, \epsilon = 0.2, \) Table A-4, air \((T_f = 800 \, \text{K} : k_a = 0.057 \, \text{W/m-K}, v = 8.5 \times 10^{-5} \, \text{m/s}, Pr = 0.71).\)

**ANALYSIS:** (a) The surface temperature may be obtained from Eq. 3.55, with \( \bar{h} = \bar{h}_c + h_r \) and

\[
\dot{q} = I^2 \rho_c / \pi = I^2 \rho_c / A_c = I^2 \rho_c / \left( \pi D^2 / 4 \right) = 1.013 \times 10^9 \, \text{W/m}^3.
\]

\[
T_s = T_\infty + \frac{\dot{q} (D/2)}{2 (\bar{h}_c + h_r)} \tag{1}
\]

The convection coefficient is obtained from the Churchill and Bernstein correlation

\[
\bar{h}_c = \frac{k_a}{D} \left\{ 0.3 + \frac{0.62 \text{Re}_D^{1/2} \text{Pr}^{1/3}}{1 + (0.4 / \text{Pr})^{2/3}} \left[ 1 + \left( \frac{\text{Re}_D}{282,000} \right)^{5/8} \right]^{4/5} \right\} = 230 \, \text{W/m}^2 \cdot \text{K}
\]

where \( \text{Re}_D = VD / \nu = 58.8 \) and the radiation coefficient is obtained from Eq. 1.9

\[
h_r = \epsilon \sigma (T_s + T_{\text{sur}}) \left( T_s^2 + T_{\text{sur}}^2 \right) \tag{2}
\]

From an iterative solution of Eqs. (1) and (2), we obtain

\[
T_s = 1285 \, \text{K} = 1012 \, ^\circ \text{C}
\]

From Eq. 3.53, the centerline temperature is

\[
T_0 = \frac{\dot{q} (D/2)^2}{4k} + T_s = \frac{1.013 \times 10^9 \, \text{W/m}^3 (0.0005 \, \text{m})^2}{100 \, \text{W/m-K}} + 1012 \, ^\circ \text{C} = 1014 \, ^\circ \text{C}
\]

The centerline temperature is only approximately 2°C larger than the surface temperature, and the wire may be assumed to be isothermal.

Continued ….
PROBLEM 7.48 (Cont.)

(b) Over the range $1 \leq V < 100 \text{ m/s}$ for $I = 25 \text{A}$, $\overline{h}_c$ varies from approximately $114 \text{ W/m}^2 \cdot \text{K}$ to $1050 \text{ W/m}^2 \cdot \text{K}$, while $h_f$ varies from approximately $69 \text{ W/m}^2 \cdot \text{K}$ to $4 \text{ W/m}^2 \cdot \text{K}$. The effect on the surface temperature is shown below.

![Graph showing surface temperature vs. air velocity](image)

Maximum and minimum values of $T_s = 1433^\circ \text{C}$ and $T_s = 290^\circ \text{C}$ are associated with the smallest and largest velocities respectively, while the difference between the centerline and surface temperatures remains at $(T_0 - T_s) = 2^\circ \text{C}$.

For $V = 5 \text{ m/s}$, the effect on $T_s$ of varying the current over the range from 1 to 30A is shown below.

![Graph showing surface temperature vs. electric current](image)

From a value of $T_s = 52^\circ \text{C}$ at 1A, $T_s$ increases to $1320^\circ \text{C}$ at 30A. Over this range the temperature difference $(T_0 - T_s)$ increases from approximately $0.01^\circ \text{C}$ to $3^\circ \text{C}$.

**COMMENTS:**

1. The radiation coefficient for the conditions of Part (a) is $h_f = 32 \text{ W/m}^2 \cdot \text{K}$, which is approximately 1/8 of the total coefficient $\overline{h}$. Hence, except for small values of $V$ less than approximately 5 m/s, radiation is negligible compared with convection.
2. The small wire diameter and large thermal conductivity are responsible for maintaining nearly isothermal conditions within the wire.
3. The calculations of Part (b) were performed using the IHT solver with the function $T_f = T_{\text{fluid avg}}(T_s, T_{\text{inf}})$ used to account for the effect of temperature on the air properties.
**PROBLEM 7.49**

**KNOWN:** Temperature and heat dissipation in a wire of diameter D.

**FIND:** (a) Expression for flow velocity over wire, (b) Velocity of airstream for prescribed conditions.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Uniform wire temperature, (3) Negligible radiation.

**PROPERTIES:** Table A-4, Air (T<sub>∞</sub> = 298 K, 1 atm): ν = 15.8 × 10<sup>-6</sup> m<sup>2</sup>/s, k = 0.0262 W/mK, Pr = 0.71; (T<sub>s</sub> = 313 K, 1 atm): Pr = 0.705.

**ANALYSIS:** (a) The rate of heat transfer per unit cylinder length is

\[ q' = \left( \frac{q}{L} \right) = \bar{h} (\pi D) \left( T_s - T_\infty \right) \]

where, from the Zhukauskas relation, with Pr ≈ Pr<sub>s</sub>,

\[ \bar{h} = \frac{k}{D} \frac{C}{C} \frac{\text{Re}^m}{D} \frac{\text{Pr}^n}{D} = \frac{k}{D} \frac{C}{C} \left( \frac{VD}{\nu} \right)^m \text{Pr}^n \]

Hence,

\[ V = \left[ \frac{q'}{\left( k/D \right) C \text{Pr}^n (\pi D) \left( T_s - T_\infty \right)} \right]^{1/m} \left( \frac{\nu}{D} \right). \]

(b) Assuming (10<sup>3</sup> < Re<sub>D</sub> < 2 × 10<sup>5</sup>), C = 0.26, m = 0.6 from Table 7.3. Hence,

\[ V = \left[ \frac{35 \text{ W/m}}{0.0262 \text{ W/m·K} \times 0.26(0.71)^{0.37} \pi (40 - 25) \text{ °C}} \right]^{1/0.6} \left( \frac{15.8 \times 10^{-6} \text{ m}^2 / \text{s}}{5 \times 10^{-4} \text{ m}} \right) \]

\[ V = 97 \text{ m/s}. \]

To verify the assumption of the Reynolds number range, calculate

\[ \text{Re}_D = \frac{VD}{\nu} = \frac{97 \text{ m/s} \left( 5 \times 10^{-4} \text{ m} \right)}{15.8 \times 10^{-6} \text{ m}^2 / \text{s}} = 3074. \]

Hence the assumption was correct.

**COMMENTS:** The major uncertainty associated with using this method to determine V is that associated with use of the correlation for Nu<sub>D</sub>. 
PROBLEM 7.50

KNOWN: Platinum wire maintained at a constant temperature in an airstream to be used for determining air velocity changes.

FIND: (a) Relationship between fractional changes in current to maintain constant wire temperature and fractional changes in air velocity and (b) Current required when air velocity is 10 m/s.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Cross-flow of air on wire with $40 < \text{Re}_D < 1000$, (3) Radiation effects negligible, (4) Wire is isothermal.

PROPERTIES: Platinum wire (given): Electrical resistivity, $\rho_e = 17.1 \times 10^{-5}$ Ohm-m; Table A-4, Air ($T_\infty = 27^\circ C = 300 \text{ K}, 1 \text{ atm}$): $\nu = 15.89 \times 10^{-6}$ m$^2$/s, $k = 0.0263$ W/m-K, $Pr = 0.707$; ($T_s = 77^\circ C = 350 \text{ K}, 1 \text{ atm}$): $Pr_s = 0.700$.

ANALYSIS: (a) From an energy balance on a unit length of the platinum wire,

$$q_{\text{elec}} - q_{\text{conv}} = I^2 R_e - \bar{h} P (T_s - T_\infty) = 0$$  \hspace{1cm} (1)

where the electrical resistance per unit length is $R_e = \rho_e / A_c$, $P = \pi D$, and $A_c = \pi D^2/4$. Hence,

$$I = \left[ \frac{\bar{h}PA_e}{\rho_e} (T_s - T_\infty) \right]^{1/2} = \left[ \frac{\pi^2 h D^3}{4 \rho_e} (T_s - T_\infty) \right]^{1/2}$$ \hspace{1cm} (2)

For the range $40 < \text{Re}_D < 1000$, using the Zhukauskas correlation for cross-flow over a cylinder with $C = 0.51$ and $m = 0.5$,

$$\bar{Nu}_D = \frac{\bar{h}D}{k} = 0.51 \text{Re}_D^{0.5} Pr^{0.37} \left( \frac{Pr}{Pr_s} \right)^{1/4} = 0.51 \left( \frac{VD}{v} \right)^{0.5} Pr^{0.37} \left( \frac{Pr}{Pr_s} \right)^{1/4}$$ \hspace{1cm} (3)

note that $\bar{h} \sim \nu^{0.5}$, which, when substituted into Eq. (2) yields

$$I \sim \bar{h}^{1/2} = \left( \nu^{0.5} \right)^{1/2} = \nu^{1/4}.$$

Differentiating the proportionality and dividing the result by the proportionality, it follows that

$$\frac{\Delta I}{I} \approx \frac{1}{4} \frac{\Delta V}{V}.$$  \hspace{1cm} (4)

(b) For air at $T_\infty = 27^\circ C$ and $V = 10$ m/s, the current required to maintain the wire of $D = 0.5$ mm at $T_s = 77^\circ C$ follows from Eq. (2) with $\bar{h}$ evaluated by Eq. (3)

Continued …..
where \( \text{Re}_D = 315 \). Hence the required current is

\[
I = \left[ \frac{\pi^2 \times 420 \text{ W/m}^2 \cdot \text{K} (0.0005 \text{ m})^3}{4 \times 17.1 \times 10^{-5} \Omega \cdot \text{m}} \right]^{1/2} (77 - 27) \text{K} = 195 \text{ mA.} \tag{5}
\]

**COMMENTS:**

(1) To measure 1% fractional velocity change, a 0.25% fractional change in current must be measured according to Eq. (4). From Eq. (5), this implies that \( \Delta I = 0.0025I = 0.0025 \times 195 \text{ mA} = 488 \mu\text{A.} \) An electronic circuit with such measurement sensitivity requires care in its design.

(2) Instruments built on this principle to measure air velocities are called *hot-wire anemometers.* Generally, the wire diameters are much smaller (3 to 30 \( \mu\text{m} \) vs 500 \( \mu\text{m} \) of this problem) in order to have faster response times.

(3) What effect would the presence of radiation exchange between the wire and its surroundings have?
**PROBLEM 7.51**

**KNOWN:** Temperature sensor of 12.5 mm diameter experiences cross-flow of water at 80°C and velocity, $0.005 < V < 0.20$ m/s. Sensor temperature may vary over the range $20 < T_s < 80$°C.

**FIND:** Expression for convection heat transfer coefficient as a function of $T_s$ and $V$.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Sensor-water flow approximates a cylinder in cross-flow, (3) Prandtl number varies linearly with temperature over the range of interest.

**PROPERTIES:** *Table A-6, Sat. water ($T_\infty = 80$°C = 353 K):* $k = 0.670$ W/mK, $\nu = \mu\nu_f = 352 \times 10^{-6}$ N⋅s/m$^2 \times 1.029 \times 10^{-3}$ m$^3$/kg = $3.621 \times 10^{-7}$ m$^2$/s; $Pr_s$ values for $20 \leq T_s \leq 80$°C:

<table>
<thead>
<tr>
<th>$T$ (K)</th>
<th>293</th>
<th>300</th>
<th>325</th>
<th>350</th>
<th>353</th>
</tr>
</thead>
<tbody>
<tr>
<td>$Pr$</td>
<td>7.00</td>
<td>5.83</td>
<td>3.42</td>
<td>2.29</td>
<td>2.20</td>
</tr>
</tbody>
</table>

**ANALYSIS:** Using the Zhukauskus correlation for the range $40 < Re_D < 4000$ with $C = 0.51$ and $m = 0.5$,

$$\frac{hD}{k} = 0.51 Re_D^{0.5} Pr^{0.37} \left(\frac{Pr}{Pr_s}\right)^{1/4}.$$

with $Re_D = VD/\nu$, the thermophysical properties of interest are $k$, $\nu$ and $Pr$, which are evaluated at $T_\infty = 80$°C, and $Pr_s$ which varies markedly with $T_s$ for the range $20 < T_s < 80$°C. Assuming $Pr_s$ to vary linearly with $T_s$ and using the extreme values to find the relation,

$$Pr_s = 7.00 + \frac{(2.20 - 7.00)}{(353 - 293)}(T_s - 293)K = 7.00 - 0.0800(T_s - 293)$$

where the units of $T_s$ are [K]. Substituting numerical values, find

$$h(T_s) = \frac{0.670W/m\cdot K}{0.0125m} \left(\frac{V \times 0.0125m}{3.621 \times 10^{-7}m^2/s}\right)^{0.5} \left(\frac{2.20}{7.00 - 0.080(T_s - 293)}\right)^{0.37} \left[3.182 - 0.0364(T_s - 293)\right]^{-1/4}.$$

**COMMENTS:** (1) From the $Pr_s$ vs $T_s$ graph above, a linear fit is seen to be poor for this temperature range. However, because the $Pr_s$ dependence is to the $\frac{1}{4}$ power, the discrepancy may be acceptable.
**PROBLEM 7.52**

**KNOWN:** Diameter, electrical resistance and current for a high tension line. Velocity and temperature of ambient air.

**FIND:** (a) Surface and (b) Centerline temperatures of the wire, (c) Effect of air velocity on surface temperature.

**SCHEMATIC:**

![Diagram](Diagram.png)

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties, (3) One-dimensional radial conduction.

**PROPERTIES:** Table A.4, Air (T_f ≈ 300 K, 1 atm): \( \nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}, k = 0.0263 \text{ W/m} \cdot \text{K}, \text{Pr} = 0.707; \) Table A.1, Copper (T = 300 K): \( k = 400 \text{ W/m} \cdot \text{K} \).

**ANALYSIS:** (a) Applying conservation of energy to a control volume of unit length,

\[
\dot{E}_g = I^2 R' = q' = \bar{h} \pi D (T_s - T_\infty)
\]

With
\[
\text{Re}_D = \frac{VD}{\nu} = \frac{10 \text{ m/s} (0.025 \text{ m})}{15.89 \times 10^{-6} \text{ m}^2/\text{s}} = 15,733
\]

the Churchill and Bernstein correlation, yields

\[
\frac{\text{Nu}_D}{\text{Re}_D} = 0.3 + \frac{0.62 \text{Re}_D^{1/2} \text{Pr}^{1/3}}{1 + (0.4/\text{Pr})^{2/3}}^{1/4} \left[ 1 + \left( \frac{\text{Re}_D}{282,000} \right)^{5/8} \right]^{4/5} = 69.0
\]

Hence,

\[
\bar{h} = \frac{\text{Nu}_D}{D} \frac{k}{\pi D} = 69.0 \frac{0.0263 \text{ W/m} \cdot \text{K}}{0.025 \text{ m}} = 72.6 \text{ W/m}^2 \cdot \text{K}
\]

and

\[
T_s = T_\infty + \frac{I^2 R' \pi}{\bar{h} \pi D} = 10^\circ \text{C} + \frac{(1000 \text{ A})^2 (10^{-4} \text{ W/m})}{72.6 \text{ W/m}^2 \cdot \text{K} \pi (0.025 \text{ m})} = 10^\circ \text{C} + 17.6^\circ \text{C} = 27.6^\circ \text{C}
\]

(b) With \( \dot{q} = \dot{E}_g / (\pi D^2 / 4) = 4 (1000 \text{ A})^2 (10^{-4} \text{ W/m}) / \pi (0.025 \text{ m})^2 = 2.04 \times 10^5 \text{ W/m}^3 \), Equation 3.53 yields

\[
T(0) = \frac{\dot{q} R' \pi}{4k} + T_s = \frac{2.041 \times 10^5 \text{ W/m}^3 (0.0125 \text{ m})^2}{1600 \text{ W/m} \cdot \text{K}} + 27.6^\circ \text{C} = 0.02^\circ \text{C} + 27.6^\circ \text{C} \approx 27.6^\circ \text{C}
\]

Continued...
PROBLEM 7.52 (Cont.)

(c) The effect of V on the surface temperature was determined using the *Correlations* and *Properties* Tool Pads of IHT.

![Graph showing relationship between Freestream velocity (V) and Surface temperature (T_s).](image)

The effect is significant, with a surface temperature of $T_s \approx 70^\circ C$ corresponding to $V = 1$ m/s. For velocities of 1 and 10 m/s, respectively, convection coefficients are 21.1 and 72.8 W/m$^2$K and film temperatures are 313.2 and 291.7 K.

**COMMENTS:** The small values of $\dot{q}$ and $r_o$ and the large value of $k$ render the wire approximately isothermal.
PROBLEM 7.53

KNOWN: Aluminum transmission line with a diameter of 20 mm having an electrical resistance of \( R' = 2.636 \times 10^{-4} \text{ ohm/m} \) carrying a current of 700 A subjected to severe cross winds. To reduce potential fire hazard when adjacent lines make contact and spark, insulation is to be applied.

FIND: (a) The bare conductor temperature when the air temperature is 20°C and the line is subjected to cross flow with a velocity of 10 m/s; (b) The conductor temperature for the same conditions, but with an insulation covering of 2 mm thickness and thermal conductivity of 0.15 W/m-K; and (c) Plot the conductor temperatures of the bare and insulated conductors for wind velocities in the range of 2 to 20 m/s. Comment on the features of the curves and the effect that wind velocity has on the conductor operating temperatures.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform surface temperatures, (3) Negligible solar irradiation and radiation exchange, and (4) Constant properties.

PROPERTIES: Table A-4, Air \( (T_f = (T_s + T_\infty)/2, \text{ 1 atm}) \): evaluated using the IHT Properties library with a Correlation function; see Comment 2.

ANALYSIS: (a) For the bare conductor the energy balance per unit length is

\[
\dot{E}_\text{in} - \dot{E}_\text{out} + \dot{E}_\text{gen} = 0
\]

\[0 - q_{cv} + \dot{q} A_c = 0\]  

(1)

where the cross-sectional area of the conductor is \( A_c = \pi D^2/4 \) and the generation rate is

\[
\dot{q} = I^2 R' / A_c = \left(700 A \right)^2 \times 2.636 \times 10^{-4} \Omega / m / \left(\pi (0.020 m)^2 / 4 \right)
\]

\[
\dot{q} = 4.111 \times 10^5 \text{ W/m}^3
\]

The convection rate equation can be expressed as

\[
\dot{q}_{cv} = \left( T_{c,bare} - T_\infty \right) / R'_c
\]

\[R'_c = 1 / \left( \bar{h} D \times \pi D \right)\]

and the convection coefficient is estimated using the Churchill-Bernstein correlation, Eq. 7.57, with \( \text{Re}_D = V D / \nu \),

\[
\bar{Nu}_L = \frac{\bar{h} D}{k} = 0.3 + \frac{0.62 \text{ Re}_D^{1/2} \text{ Pr}^{1/3}}{1 + \left(0.4 / \text{Pr}\right)^{2/3}} \left[1 + \left( \frac{\text{Re}_D}{282,000} \right)^{5/8} \right]^{4/5}
\]

(4)

(b) For the conductor with insulation thickness \( t = 2 \text{ mm} \), the energy balance per unit length is

\[
\dot{E}_\text{in} - \dot{E}_\text{out} + \dot{E}_\text{gen} = 0
\]

\[0 - \left( T_{c,ins} - T_\infty \right) / R'_c + \dot{I}^2 R'_c / A_c = 0\]  

(5)

Continued …..
PROBLEM 7.53 (Cont.)

where $R'_t$ is the sum of the insulation conduction and convection process thermal resistances,

$$
R'_t = \ln\left(\frac{(D+2t)}{D}\right)/(2\pi k) + 1/\left[\bar{h}_{D+2t}(0+2t)\right]
$$

(6)

The results of the analysis using $IHT$ are tabulated below.

<table>
<thead>
<tr>

</tbody>
</table>

(c) Using the $IHT$ code with the foregoing relations, the conductor temperatures $T_{c,\text{base}}$ and $T_{c,\text{ins}}$ for the bare and insulated conditions are calculated and plotted for the wind velocity range of 2 to 20 m/s.

**COMMENTS:**

1. The effect of the 2-mm thickness insulation is to increase the conductor operating temperature by $(68.3 - 46.1)°C = 22°C$. While we didn’t account for an increase in the electrical resistivity with increasing temperature, the adverse effect is to increase the $I^2R$ loss, which represents a loss of revenue to the power provider. From the graph, note that the conductor temperature increases markedly with decreasing wind velocity, and the effect of insulation is still around $+20°C$.

2. Because of the tediousness of hand calculations required in using the convection correlation without fore-knowledge of $T_f$ at which to evaluate properties, we used the $IHT$ Correlation function treating $T_f$ as one of the unknowns in the system of equations. Salient portions of the $IHT$ code and property values are provided below.

Continued .....
PROBLEM 7.53 (Cont.)

// Forced convection, cross flow, cylinder
NuDbar = NuD_bar_EF_CY(ReD,Pr)     // Eq 7.57
NuDbar = hDbar * Do / k
ReD = V * Do / nu  // Outer diameter; bare or with insulation

// Evaluate properties at the film temperature, Tf.
Tf = Tfluid_avg (Tinf,Ts)      // Ts is the outer surface temperature
/* Correlation description: External cross flow (EF) over cylinder (CY), average coefficient, 
ReD*Pr>0.2, Churchill-Bernstein correlation, Eq 7.57. See Table 7.9. */

// Air property functions : From Table A.4
// Units: T(K); 1 atm pressure
nu = nu_T("Air",Tf)  // Kinematic viscosity, m^2/s
k = k_T("Air",Tf)  // Thermal conductivity, W/m·K
Pr = Pr_T("Air",Tf)  // Prandtl number

(3) Is the temperature gradient within the conductor significant?
PROBLEM 7.54

KNOWN: Diameter and length of a copper rod, with fixed end temperatures, inserted in an airstream of prescribed velocity and temperature.

FIND: (a) Midplane temperature of rod, (b) Rate of heat transfer from the rod.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in rod, (3) Negligible contact resistance, (4) Negligible radiation, (5) Constant properties.

PROPERTIES: Table A-1, Copper (T≈ 80°C = 353 K): k = 398 W/m·K; Table A-4, Air (T∞ = 25°C = 300K, 1 atm): v = 15.8 × 10^{-6} m^2/s, k = 0.0263 W/m·K, Pr = 0.707; Table A-4, Air (T∞ = 80°C = 350K, 1 atm): Prs = 0.700.

ANALYSIS: (a) For case B of Table 3.4, \( \frac{\theta}{\theta_b} = \frac{\cosh (L - x)}{\cosh (mL)} = \frac{T - T∞}{T_b - T∞} \) where

\[
m = \left( \frac{hP_A}{kA_C} \right)^{1/2} = \left( 4\frac{h}{kD} \right)^{1/2}.
\]

Using the Zhukauskas correlation with n = 0.37,

\[
\begin{align*}
\bar{Nu}_D &= C Re_{D}^{1/4} Pr^{n} (Pr/Pr_s)^{1/4} \\
Re_{D} &= \frac{VD}{\nu} = \frac{25 \text{ m/s} \times 0.01 \text{ m}}{15.8 \times 10^{-6} \text{ m}^2/\text{s}} = 15,823
\end{align*}
\]

and C = 0.26, m = 0.6 from Table 7-4. Hence

\[
\begin{align*}
\bar{Nu}_D &= 0.26 \times 15,823^{0.6} (0.707)^{0.37} (0.707/0.700)^{1/4} = 75.8 \\
\bar{h} &= \frac{k}{\bar{Nu}_D} = 0.0263 \text{ W/m·K} \times (75.8) = 199 \text{ W/m}^2 \cdot \text{K} \\
m &= \left( \frac{4 \times 199 \text{ W/m}^2 \cdot \text{K}}{398 \text{ W/m} \cdot \text{K} \times 0.01 \text{ m}} \right)^{1/2} = 14.2 \text{ m}^{-1}.
\end{align*}
\]

Hence,

\[
\begin{align*}
\frac{T(L) - T∞}{T_b - T∞} &= \frac{\cosh (0)}{\cosh (14.2 \text{ m}^{-1} \times 0.05 \text{ m})} = \frac{1}{1.26} = 0.79
\end{align*}
\]

\[
T(L) = 25^\circ \text{C} + 0.79(90 - 25) = 76.6^\circ \text{C}.
\]

(b) From Eq. 3.76, q = 2qf = 2M tanh mL,

\[
M = \left( \frac{hP_A}{kA_C} \right)^{1/2} \theta_b = \left[ 199 \frac{W}{\text{m}^2 \cdot \text{K}} \times (\pi \times 0.01 \text{ m}) \left( 398 \frac{W}{\text{m} \cdot \text{K}} \right) \frac{\pi}{4} (0.01 \text{ m})^2 \right]^{1/2} \text{ at } 65^\circ \text{C}
\]

\[
M = 28.7 \text{ W} \quad q = 2(28.7 \text{ W}) \tanh \left( 14.2 \text{ m}^{-1} \times 0.05 \text{ m} \right) = 35 \text{ W}.
\]

COMMENTS: Note adiabatic condition associated with symmetry about midplane.
PROBLEM 7.55

FIND: (a) Cost of daily heat loss from an uninsulated pipe, (b) Savings associated with insulating the pipe.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Negligible convection resistance for water flow, (3) Negligible contact resistance between insulation and pipe, (4) Negligible radiation.

PROPERTIES: Table A-4, air \( p = 1 \) atm, \( T_f = 300 \) K: \( k_a = 0.0263 \text{ W/m}\cdot\text{K} \).

\[ \nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}, \text{ Pr} = 0.707. \]

ANALYSIS: (a) With \( \text{Re}_D = \frac{VD_o}{\nu} = 3 \text{ m/s} \times 0.1 \text{ m} / 15.89 \times 10^{-6} \text{ m}^2/\text{s} = 18,880 \), application of the Churchill-Bernstein correlation yields

\[
\overline{\text{Nu}}_D = 0.3 + \frac{0.62 (18,800)^{1/2} (0.707)^{1/3}}{1 + (0.4/0.707)^{2/3}} = 76.6
\]

\[
\overline{h} = \left( \frac{k_a}{D_o} \right) \overline{\text{Nu}}_D = \frac{0.0263 \text{ W/m}\cdot\text{K}}{0.1 \text{ m}} (76.6) = 20.1 \text{ W/m}^2\cdot\text{K}
\]

Without the insulation, the total thermal resistance and heat loss per length of pipe are then

\[
R'_{\text{tot(wo)}} = \frac{\ln(D_o/D_t) + \frac{1}{\pi D_o h}}{2\pi k_p} = \frac{\ln(100/84)}{2\pi \times 60 \text{ W/m}\cdot\text{K}} + \frac{1}{\pi (0.1 \text{ m}) 20.1 \text{ W/m}^2\cdot\text{K}} = 4.63 \times 10^{-4} + 0.158 \text{ m} \cdot \text{K/W} = 0.159 \text{ m} \cdot \text{K/W}
\]

\[
q'_{\text{wo}} = \frac{\Delta T}{R'_{\text{tot(wo)}}} = \frac{55 \circ\text{C}}{0.159 \text{ m} \cdot \text{K/W}} = 346 \text{ W/m} = 0.346 \text{ kW/m}
\]

The corresponding daily energy loss is

\[
Q'_{\text{wo}} = 0.346 \text{ kW/m} \times 24 \text{ h/day} = 8.3 \text{ kW} \cdot \text{h/m} \cdot \text{d}
\]

and the associated cost is

\[
C'_{\text{wo}} = (8.3 \text{ kW} \cdot \text{h/m} \cdot \text{d}) (0.05 \text{ kW} \cdot \text{h}) = $0.415 / \text{m} \cdot \text{d}
\]

(b) The conduction resistance of the insulation is

Continued ...
PROPERTY 7.55 (Cont.)

\[ R_{\text{end}}' = \frac{\ln \left( D_0 / D_1 \right)}{2\pi k_i} = \frac{\ln(120/100)}{2\pi \left( 0.026 \text{ W} / \text{m} \cdot \text{K} \right)} = 1.116 \text{ m} \cdot \text{K} / \text{W} \]

Using the Churchill-Bernstein correlation with an outside diameter of \( D_0 = 0.12 \text{ m} \), \( \text{Re}_D = 22,660 \),
\( \overline{\text{Nu}}_D = 83.9 \) and \( \overline{\text{T}} = 18.4 \text{ W} / \text{m}^2 \cdot \text{K} \). The convection resistance is then

\[ R_{\text{con}}' = \frac{1}{\pi D_0 h} = \frac{1}{\pi \left( 0.12 \text{ m} \right) 18.4 \text{ W} / \text{m}^2 \cdot \text{K}} = 0.144 \text{ m} \cdot \text{K} / \text{W} \]

and the total resistance is

\[ R_{\text{tot}}'(w) = \left( 4.63 \times 10^{-4} + 1.116 + 0.144 \right) \text{m} \cdot \text{K} / \text{W} = 1.261 \text{ m} \cdot \text{K} / \text{W} \]

The heat loss and cost are then

\[ q'_w = \frac{T - T_\infty}{R_{\text{tot}}'(w)} = \frac{55^\circ \text{C}}{1.261 \text{ m} \cdot \text{K} / \text{W}} = 43.6 \text{ W} / \text{m} = 0.0436 \text{ kW} / \text{m} \]

\[ C'_w = 0.0436 \text{ kW} / \text{m} \times 24 \text{ h} / \text{d} \times 0.05 / \text{kW} \cdot \text{h} = 0.052 / \text{m} \cdot \text{d} \]

The daily savings is then

\[ S' = C'_{w_0} - C'_w = 0.363 / \text{m} \cdot \text{d} \]

**COMMENTS:**
1. The savings are significant, and the pipe should be insulated.
2. Assuming a negligible temperature drop across the pipe wall, a pipe emissivity of \( \varepsilon_p = 0.6 \) and surroundings at \( T_{\text{sur}} = 268 \text{K} \), the radiation coefficient associated with the uninsulated pipe is \( h_r = \varepsilon \sigma (T + T_{\text{sur}}) \left( T^2 + T_{\text{sur}}^2 \right) = 0.6 \times 5.67 \times 10^{-8} \text{ W} / \text{m}^2 \cdot \text{K}^4 \left( 591^2 + 268^2 \right) K^2 = 3.5 \text{ W} / \text{m}^2 \cdot \text{K} \). Accordingly, radiation increases the heat loss estimate of Part (a) by approximately 17%.
PROBLEM 7.56

KNOWN: Diameter and surface temperature of an uninsulated steam pipe. Velocity and temperature of air in cross flow.

FIND: (a) Heat loss per unit length, (b) Effect of insulation thickness on heat loss.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform surface temperature, (3) Negligible radiation.

PROPERTIES: Table A.4, Air ($T_f \approx 350$ K, 1 atm): $v = 20.9 \times 10^{-6}$ m$^2$/s, $k = 0.030$ W/m·K, $Pr = 0.70$.

ANALYSIS: (a) Without the insulation, the heat loss per unit length is

$$q' = \hbar \pi D (T_{s,i} - T_\infty)$$

where $\hbar$ may be obtained from the Churchill-Bernstein relation. With

$$Re_D = \frac{VD}{v} = \frac{5 \text{m/s} \times 0.5 \text{m}}{20.9 \times 10^{-6} \text{m}^2/\text{s}} = 1.196 \times 10^5$$

$$\overline{Nu_D} = 0.3 + \frac{0.62 Re_D^{1/2} Pr^{1/3}}{1 + (0.4/Pr)^{2/3}} \left[1 + \left(\frac{Re_D}{282,000}\right)^{5/8}\right]^{4/5} = 242$$

$$\overline{h} = \frac{\overline{Nu_D} k}{D} = 242 \frac{0.030 \text{W/m·K}}{0.5 \text{m}} = 14.5 \text{W/m²·K}$$

The heat rate is then

$$q' = 14.5 \text{W/m²·K} \pi (0.5 \text{m})(150 - (-10)) \degree C = 3644 \text{W/m}.$$  \(<

(b) With the insulation, the heat loss may be expressed as

$$q' = U_i \pi D (T_{s,i} - T_\infty)$$

where, from Eq. 3.31,

$$U_i = \left[\frac{(D/2)}{k_i} \ln \overline{\tau} + \frac{1}{\overline{h}}\right]^{-1}$$

and $\overline{\tau} \equiv (D/2 + \delta)/(D/2)$. The outer diameter, $D_o = D + 2\delta$, as well as the film temperature, $T_f = (T_{s,o} + T_\infty)/2$, must now be used to evaluate the convection coefficient, where

Continued...
PROBLEM 7.56 (Cont.)

\[
\frac{T_{s,i} - T_{s,o}}{T_{s,i} - T_\infty} = \frac{\frac{R'_\text{cond}}{R'_\text{tot}}}{\frac{(\ln \bar{r})/k_i}{(\ln \bar{r})/k_i + 1/(D/2)\bar{r}h}}
\]

Using the IHT Correlations and Properties Tool Pads to evaluate \( \bar{h} \), the following results were obtained.

The insulation is extremely effective, with a thickness of only 10 mm yielding a 7-fold reduction in heat loss and decreasing the outer surface temperature from 150 to 10°C. For \( \delta = 50 \) mm, \( U_i = 0.56 \) W/m\(^2\)-K, \( q' = 140 \) W/m and \( T_{s,o} = -5.2°C \).

**COMMENTS:** The dominant contribution to the total thermal resistance is made by the insulation.
**PROBLEM 7.57**

**KNOWN:** Person, approximated as a cylinder, is subjected to prescribed convection conditions.

**FIND:** Heat rate from body for prescribed temperatures.

**SCHEMATIC:**

![Schematic of a cylinder with air flow](image)

**ASSUMPTIONS:** 
1. Steady-state conditions, 
2. Person can be approximated by cylindrical form having uniform surface temperature, 
3. Negligible heat loss from cylinder top and bottom surfaces, 
4. Negligible radiation effects.

**PROPERTIES:** Table A-4, Air ($T_\infty = 268$ K, 1 atm): $\nu = 1.304 \times 10^{-6}$ m$^2$/s, $k = 23.74 \times 10^{-3}$ W/m·K, $Pr = 0.725$; (TS = 297 K, 1 atm): $Pr = 0.707$.

**ANALYSIS:** The heat transfer rate from the cylinder, approximating the person, is given as

$$q = \bar{h} A_s (T_s - T_\infty)$$

where $A_s = \pi D l$ and $\bar{h}$ must be estimated from a correlation appropriate to cross-flow over a cylinder. Use the Zhukauskas relation,

$$\overline{Nu} = \frac{\bar{h} D}{k} = C \frac{Re^m Pr^n}{(Pr_{Pr})^{1/4}}$$

and calculate the Reynold’s number,

$$Re_D = \frac{VD}{\nu} = \frac{15 \text{ m/s} \times 0.3 \text{ m}}{1.304 \times 10^{-6} \text{ m}^2/\text{s}} = 345,092.$$ 

From Table 7-4, find $C = 0.076$ and $m = 0.7$. Since $Pr < 10$, $n = 0.37$, giving

$$\overline{Nu} = 0.076 (345,092)^{0.7} 0.725^{0.37} \left(\frac{0.725}{0.707}\right)^{1/4} = 511$$

$$\bar{h} = \frac{\overline{Nu}}{D} \frac{k}{D} = \frac{511 \times 23.74 \times 10^{-3} \text{ W/m} \cdot \text{K}}{0.3 \text{ m}} = 40.4 \text{ W/m}^2 \cdot \text{K}.$$

The heat transfer rate is

$$q = 40.4 \text{ W/m}^2 \cdot \text{K} \left(\pi \times 0.3 \text{ m} \times 1.8 \text{ m}\right) \left(24 - (-5)\right)^\circ \text{C} = 1988 \text{ W.}$$

**COMMENTS:** Note the temperatures at which properties are evaluated for the Zhukauskas correlation.
**PROBLEM 7.58**

**KNOWN:** Dimensions and thermal conductivity of a thermocouple well. Temperatures at well tip and base. Air velocity.

**FIND:** Air temperature.

**SCHEMATIC:**

![Schematic of thermocouple well](image)

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties, (3) One-dimensional conduction along well, (4) Uniform convection coefficient, (5) Negligible radiation.

**PROPERTIES:** Steel (given): \( k = 35 \text{ W/m} \cdot \text{K} \); Air (given): \( \rho = 0.774 \text{ kg/m}^3, \mu = 251 \times 10^{-7} \text{ N} \cdot \text{s/m}^2 \), \( k = 0.0373 \text{ W/m} \cdot \text{K} \), \( Pr = 0.686 \).

**ANALYSIS:** Applying Equation 3.70 at the well tip \((x = L)\), where \( T = T_1 \),

\[
\frac{T_1 - T_\infty}{T_2 - T_\infty} = \left[ \cosh mL + \left( \frac{h}{mk} \right) \sinh mL \right]^{-1}
\]

\[
m = \left( \frac{hP}{kA_c} \right)^{1/2}, \quad P = \pi D_o = \pi (0.010 \text{ m}) = 0.0314 \text{ m}
\]

\[
A_c = \left( \frac{\pi}{4} \right) \left( D_o^2 - D_i^2 \right) = \left( \frac{\pi}{4} \right) (0.010^2 - 0.005^2) \text{ m}^2 = 5.89 \times 10^{-5} \text{ m}^2.
\]

With \( \text{Re}_D = \frac{D o V D}{\mu} = \frac{0.744 \text{ kg/m}^3 \cdot (3 \text{ m/s}) \cdot 0.01 \text{ m}}{251 \times 10^{-7} \text{ N} \cdot \text{s/m}^2} = 925 \),

\( C = 0.51, \quad m = 0.5, \quad n = 0.37 \) and the Zhukauskas correlation yields

\[
\overline{Nu}_D = 0.51 \text{Re}_C^{0.5} Pr^{0.37} (Pr/Pr_C)^{1/4} = 0.51 (925)^{0.5} (0.686)^{0.37} \times 1 = 13.5
\]

\[
\bar{h} = \overline{Nu}_D \frac{k}{D_o} = 13.5 \frac{0.0373 \text{ W/m} \cdot \text{K}}{0.01 \text{ m}} = 50.4 \text{ W/m}^2 \cdot \text{K}.
\]

Hence

\[
m = \left[ \frac{50.4 \text{ W/m}^2 \cdot \text{K}}{(35 \text{ W/m} \cdot \text{K}) \cdot 5.89 \times 10^{-5} \text{ m}^2} \right]^{1/2} = 27.7 \text{ m}^{-1} \quad \text{mL} = \left( 27.7 \text{ m}^{-1} \right) 0.15 \text{ m} = 4.15.
\]

With

\[
\frac{h}{mk} = \left( \frac{50.4 \text{ W/m}^2 \cdot \text{K}}{27.7 \text{ m}^{-1}} \right) \left( 35 \text{ W/m} \cdot \text{K} \right) = 0.0519
\]

find

\[
\frac{T_1 - T_\infty}{T_2 - T_\infty} = \left[ 32.62 + (0.0519) 32.61 \right]^{-1} = 0.0291 \quad T_\infty = 452.2 \text{ K}.
\]

**COMMENTS:** Heat conduction along the wall to the base at 375 K is balanced by convection from the air.
**PROBLEM 7.59**

**KNOWN:** Mercury-in-glass thermometer mounted on duct wall used to measure air temperature.

**FIND:** (a) Relationship for the immersion error, \( \Delta T_i = T(L) - T_\infty \) as a function of air velocity, thermometer diameter and length, (b) Length of insertion if \( \Delta T_i \) is not to exceed 0.25°C when the air velocity is 10 m/s, (c) For the length of part (b), calculate and plot \( \Delta T_i \) as a function of air velocity for 2 to 20 m/s, and (d) For a given insertion length, will \( \Delta T_i \) increase or decrease with thermometer diameter increase; is \( \Delta T_i \) more sensitive to diameter or velocity changes?

**SCHEMATIC:**

![Schematic](image)

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Thermometer approximates a one-dimensional (glass) fin with an adiabatic tip, (3) Convection coefficient is uniform over length of thermometer.

**PROPERTIES:** Table A.3, Glass (300 K): \( k_g = 1.4 \text{ W/m-K} \); Table A.4, Air (\( T_f = (15 + 77)\text{°C}/2 = 320 \text{ K}, 1 \text{ atm}) \): \( k = 0.0278 \text{ W/m-K}, \nu = 17.90 \times 10^{-6} \text{ m/s}, \text{Pr} = 0.704 \).

**ANALYSIS:** (a) From the analysis of a one-dimensional fin, see Table 3.4,

\[
\frac{T_L - T_\infty}{T_b - T_\infty} = \frac{1}{\cosh(mL)} \quad m^2 = \frac{\bar{h}P}{k_gA_c} = \frac{4\bar{h}}{k_gD}
\]  

(1)  

where \( P = \pi D \) and \( A_c = \pi D^2/4 \). Hence, the immersion error is

\[
\Delta T_i = T(L) - T_\infty = (T_b - T_\infty)/\cosh(mL).
\]  

(2)  

Using the Hilpert correlation for the circular cylinder in cross flow,

\[
\bar{h} = \frac{k}{D} C \text{Re}_D^{m} \text{Pr}^{1/3} = \frac{k}{D} C \left( \frac{VD}{\nu} \right)^m \text{Pr}^{1/3} = \frac{k \text{Pr}^{1/3}}{\nu^m} C \cdot V^m \cdot D^{m-1}
\]  

(3)  

\[
\bar{h} = N \cdot V^m \cdot D^{m-1} \quad \text{where} \quad N = \frac{k \text{Pr}^{1/3}}{\nu^m} C
\]  

(4,5)  

Substituting into Eq. (2), the immersion error is

\[
\Delta T_i (V, D, L) = (T_b - T_\infty)/\cosh \left\{ \left[ \left( \frac{4}{k_g} \right) N \cdot V^m \cdot D^{m-2} \right]^{1/2} L \right\}
\]  

(6)  

where \( k_g \) is the thermal conductivity of the glass thermometer.

(b) When the air velocity is 10 m/s, find

\[
\text{Re}_D = \frac{VD}{\nu} = \frac{10 \text{ m/s} \times 0.004 \text{ m}}{17.9 \times 10^{-6} \text{ m}^2/\text{s}^2} = 2235
\]

Continued...
with \( C = 0.683 \) and \( m = 0.466 \) from Table 7.2 for the range \( 40 < \text{Re}_D < 4000 \). From Eqs. (5) and (6),

\[
N = \frac{0.0278 \text{ W/m} \cdot \text{K} (0.704)^{1/3}}{(17.9 \times 10^{-6} \text{ m/s}^2)^{0.466}} \times 0.683 = 2.753
\]

\[
\Delta T_i = (15 - 77) \frac{K}{\cosh \left( \frac{4}{1.4 \text{ W/m} \cdot \text{K}} \times 2.753 (10 \text{ m/s})^{0.466} (0.004 \text{ m})^{0.466 - 2} \right) L^{1/2}}
\]

and when \( \Delta T_i = -0.25^\circ \text{C} \), find

\[
L = 18.7 \text{ mm}
\]

(c) For the air velocity range 2 to 20 m/s, find 447 ≤ \( \text{Re}_D \) ≤ 4470 for which the previous values of \( C \) and \( m \) of the Hilpert correlation are appropriate. Hence, the immersion error for an insertion length of \( L = 18.7 \text{ mm} \), part (b), find

\[
\Delta T_i = (15 - 77) \frac{K}{\cosh \left( \frac{4}{1.4 \text{ W/m} \cdot \text{K}} \times 2.753 \times V^{0.466} (0.004 \text{ m})^{-1.534} \right) 0.0187}
\]

\[
\Delta T_i = -62^\circ \text{C} \left/ \cosh \left( 3.629 V^{0.233} \right) \right.
\]

where the units of \( V \) are [m/s]. Entering the above equation into the IHT Workspace the plot shown below was generated.

(d) For a given insertion length, the immersion error will increase if the diameter of the thermometer were increased. This follows from Eq. (6) written as

\[
\Delta T_i \sim \frac{1}{\cosh \left( A \cdot D^{(m-2)/2} \right)}
\]

where \( A \) is a constant depending on variables other than \( D \). For a given insertion length and air velocity, from Eq. (6)

\[
\Delta T_i \sim \frac{1}{\cosh \left( B \cdot V^{m/2} \right)}
\]

where \( B \) is a constant. From Eq. (7) we see \( \Delta T_i \) relates to change in diameter as \( D^{0.707} \) and to change in velocity as \( V^{0.233} \). That is, to reduce the immersion error decrease \( D \) and increase \( V \) (both cause \( h \) to increase!). Based upon the exponents of each parameter, however, diameter change is the more influential.
PROBLEM 7.60

KNOWN: Hot film sensor on a quartz rod maintained at $T_s = 50^\circ C$.

FIND: (a) Compute and plot the convection coefficient as a function of velocity for water, $0.5 \leq V_w \leq 5$ m/s, and air, $1 \leq V_a \leq 20$ m/s with $T_\infty = 20^\circ C$ and (b) Suitability of using the hot film sensor for the two fluids based upon Biot number considerations.

SCHEMATIC:

ASSUMPTIONS: (1) Cross-flow over a smooth cylinder, (2) Steady-state conditions, (3) Uniform surface temperature.

PROPERTIES: Table A.6, Water ($T_f = 308$ K, sat liquid); Table A.4, Air ($T_f = 308$ K, 1 atm).

ANALYSIS: (a) Using the IHT Tool, Correlations, Cylinder, along with the Properties Tool for Air and Water, results were obtained for the convection coefficients as a function of velocity.

(b) The Biot number, $hD/2k$, is the ratio of the internal to external thermal resistances. When $Bi >> 1$, the thin film is thermally coupled well to the fluid. When $Bi \leq 1$, significant power from the heater is dissipated axially by conduction in the rod. The Biot numbers for the fluids as a function of velocity are shown below.

We conclude that the sensor is well suited for use with water, but not so for use with air.

Continued...
PROBLEM 7.60 (Cont.)

COMMENTS: A copy of the IHT workspace developed to generate the above plots is shown below.

// Problem 7.61

// Correlation Tool: External Flow, Cylinder
/* Correlation description: External cross flow (EF) over cylinder (CY), average coefficient, ReD*Pr>0.2, Churchill-Bernstein correlation, Eq 7.57. See Table 7.9. */

Ts = 30 + 273 // Surface temperature, K
Tinf = 20 + 273 // Fluid temperature, K

/* Solve, Explore and Graph: After solving, separate Explore sweeps for 1 <= Va <= 20 and 0.5 <= Vw <= 5 m/s were performed saving results in different Data Sets. Four separate plot windows were generated. */
PROBLEM 7.61

FIND: (a) Fluid velocity, (b) Heat flux if sensor is coated by a deposit.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Constant properties, (3) Thickness of hot film sensor is negligible, (4) Applicability of Churchill-Bernstein correlation for uniform surface heat flux, (5) \( \text{Re}_D \leq 282,000 \), (6) Deposit may be approximated as a plane layer.

PROPERTIES: Table A-6, water \( (T_f = 292.5 \text{K}) \): \( k = 0.602 \text{ W} / \text{m} \cdot \text{K}, \nu = 1.02 \times 10^{-6} \text{ m}^2 / \text{s}, \text{Pr} = 7.09 \).

ANALYSIS: (a) With \( \text{Re}_D \ll 282,000 \) and \( \overline{h} = q_{hf} / (T_{s,hf} - T_{\infty}) \), Eq. (7.57) reduces to

\[
\overline{Nu}_D = \frac{q_{\ast,hf}D}{k(T_{s,hf} - T_{\infty})} = 0.3 + \frac{0.62 \text{Re}_D^{1/2} \text{Pr}^{1/3}}{\left[1 + (0.4/\text{Pr})^{2/3}\right]^{1/4}}
\]

Substituting for \( D \), \( T_{s,hf} - T_{\infty} \), \( k \) and \( \text{Pr} \),

\[
4.98 \times 10^{-4} q_{\ast,hf} = 0.3 + 1.15 \text{Re}_D^{1/2}
\]

or, with \( \text{Re}_D^{1/2} = (D/\nu)^{1/2} \nu^{1/2} = 38.3 \nu^{1/2} \),

\[
4.98 \times 10^{-4} q_{\ast,hf} = 0.3 + 44.1 \nu^{1/2}
\]

Substituting for \( q_{\ast,hf} \),

\[
\nu = 0.20 \text{ m/s}
\]

(b) For a fixed value of \( T_{s,hf} \), the thermal resistance of the deposit reduces \( q_{\ast,hf} \). From the thermal circuit,

\[
q_{\ast,hf} = \frac{T_{s,hf} - T_{\infty}}{(1/\overline{h}) + (\delta/k_d)}
\]

Using Eq. (1) to evaluate \( \overline{h} \),

Continued …..
\[
\bar{h} \approx \frac{k}{(D + \delta)} \left\{ 0.3 + \frac{0.62 \text{Re}^{1/2} \text{Pr}^{1/3}}{\left[ 1 + (0.4/\text{Pr})^{2/3} \right]^{1/4}} \right\}
\]

where, with \( V = 0.20 \text{ m/s}, \) \( \text{Re}_D = V (D + \delta)/\nu = 314, \) we obtain

\[
\bar{h} \approx \frac{0.602 \text{ W} / \text{m} \cdot \text{K}}{0.0016 \text{ m}} \{20.7\} = 7,780 \text{ W} / \text{m}^2 \cdot \text{K}
\]

Hence,

\[
q_{\text{hf}} = \frac{5^\circ \text{C}}{(1.285 \times 10^{-4} + 0.5 \times 10^{-4}) \text{m}^2 \cdot \text{K} / \text{W}} = 2.80 \times 10^4 \text{ W} / \text{m}^2
\]

With the foregoing heat flux applied to the sensor and use of the model for Part (a), the sensor would indicate a velocity predicted from Eq. (2), or

\[
V = \left[ \left( 4.98 \times 10^{-4} \times 2.80 \times 10^4 - 0.3 \right) / 44.1 \right]^2 = 0.096 \text{ m/s}
\]

The error in the velocity measurement is therefore

\[
\% \text{ Error} = \frac{V_{(a)} - V_{(b)}}{V_{(a)}} (100\%) = \frac{0.20 - 0.096}{0.20} \times 100 = 52\%
\]

**COMMENTS:** (1) The accuracy of the hot-film sensor is strongly influenced by the deposit, and in any such application it is important to maintain a clean surface. (2) The Reynolds numbers are much less than 282,000 and assumption 5 is valid.
PROBLEM 7.62

KNOWN: Long coated plastic, 20-mm diameter rod, initially at a uniform temperature of $T_i = 25\, ^\circ C$, is suddenly exposed to the cross-flow of air at $T_\infty = 350\, ^\circ C$ and $V = 50\, m/s$.

FIND: (a) Time for the surface of the rod to reach $175\, ^\circ C$, the temperature above which the special coating cures, and (b) Compute and plot the time-to-reach $175\, ^\circ C$ as a function of air velocity for $5 \leq V \leq 50\, m/s$.

SCHEMATIC:

ASSUMPTIONS: (a) One-dimensional, transient conduction in the rod, (2) Constant properties, and (3) Evaluate thermophysical properties at $T_f = [(T_s + T_i)/2 + T_\infty] = [(175 + 25)/2 + 350] \, ^\circ C = 225\, ^\circ C = 500\, K$.

PROPERTIES: Rod (Given): $\rho = 2200\, kg/m^3$, $c = 800\, J/kg\cdot K$, $k = 1\, W/m\cdot K$, $\alpha = k/\rho c = 5.68 \times 10^{-7}\, m^2/s$; Table A.4, Air ($T_\infty \approx 500\, K$, 1 atm): $\nu = 38.79 \times 10^{-6}\, m^2/s$, $k = 0.0407\, W/m\cdot K$, $Pr = 0.684$.

ANALYSIS: (a) To determine whether the lumped capacitance method is valid, determine the Biot number

$$Bilc = \frac{\bar{h}(r_0/2)}{k} \quad (1)$$

The convection coefficient can be estimated using the Churchill-Bernstein correlation, Eq. 7.57,

$$\frac{\bar{h}D}{k} = 0.3 + \frac{0.63 \text{Re}_D^{1/2} \text{Pr}^{1/3}}{1 + (0.4/\text{Pr})^{2/3}} \left[1 + \left(\frac{\text{Re}_D}{282,000}\right)^{5/8}\right]^{4/5}$$

$$\text{Re}_D = \frac{VD}{\nu} = 50\, m/s \times 0.020\, m/38.79 \times 10^{-6}\, m^2/s = 25,780$$

$$\bar{h} = \frac{0.0407\, W/m\cdot K}{0.020\, m} \left[0.3 + \frac{0.63(25,780)^{1/2}(0.684)^{1/3}}{1 + (0.4/0.684)^{2/3}} \left[1 + \left(\frac{25,780}{282,000}\right)^{5/8}\right]^{4/5}\right] = 184\, W/m^2\cdot K$$

Substituting for $\bar{h}$ from Eq. (2) into Eq. (1), find

$$Bilc = 184\, W/m^2\cdot K / (0.010\, m/2) / 1\, W/m\cdot K = 0.92 \gg 0.1$$

Hence, the lumped capacitance method is inappropriate. Using the one-term series approximation, Section 5.6.2, Eqs. 5.49 with Table 5.1,

$$\theta^* = C_1 \exp \left(-\frac{r^*}{\zeta_1}\right) = \frac{r^*}{r_0} = 1$$

$$\theta^* = \frac{T(r_0, t) - T_\infty}{T_i - T_\infty} = \frac{(175 - 350)\, ^\circ C}{(25 - 350)\, ^\circ C} = 0.54$$

$$\text{Bi} = \bar{h}r_0/k = 1.84 \quad \zeta_1 = 1.5308\, rad \quad C_1 = 1.3384$$

Continued...
0.54 = 1.3384exp\[-(1.5308\text{rad})^2\text{Fo}]J_o(1.5308 \times 1)

Using Table B.4 to evaluate $J_o(1.5308) = 0.4944$, find $\text{Fo} = 0.0863$ where

$$\text{Fo} = \frac{\alpha t_o \times 5.68 \times 10^{-7}}{r_0^2} \left(\frac{\text{m}^2}{\text{s} \times t_o}\right) = 5.68 \times 10^{-3} t_o$$  \hspace{1cm} (6)

$$t_o = 15.2\text{s}$$

(b) Using the *IHT Model, Transient Conduction, Cylinder*, and the *Tool, Correlations, External Flow, Cylinder*, results for the time-to-reach a surface temperature of 175°C as a function of air velocity $V$ are plotted below.

![Graph](image)

**COMMENTS:**

(1) Using the *IHT Tool, Correlations, External Flow, Cylinder*, the effect of the film temperature $T_f$ on the estimated convection coefficient with $V = 50 \text{ m/s}$ can be readily evaluated.

<table>
<thead>
<tr>
<th>$T_f (\text{K})$</th>
<th>460</th>
<th>500</th>
<th>623</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\text{h (W/m}^2\cdot\text{K)}$</td>
<td>187</td>
<td>184</td>
<td>176</td>
</tr>
</tbody>
</table>

At early times, $\text{h} = 184 \text{ W/m}^2\cdot\text{K}$ is a good estimate, while as the cylinder temperature approaches the airstream temperature, the effect starts to be noticeable (10% decrease).

(2) The IHT analysis performed for part (b) was developed in two parts. Using a known value for $\text{h}$, the *Transient Conduction, Cylinder Model* was tested. Separately, the *Correlation Tools* was assembled and tested. Then, the two files were merged to give the workspace for determining the time-to-reach 175°C as a function of velocity $V$. 
**PROBLEM 7.63**

**KNOWN:** Velocity, diameter, initial temperature and properties of extruded wire. Temperature and velocity of air. Temperature of surroundings.

**FIND:** (a) Differential equation for temperature distribution \( T(x) \), (b) Exact solution for negligible radiation and corresponding value of temperature at prescribed length of wire, (c) Effect of radiation on temperature of wire at prescribed length. Effect of wire velocity and emissivity on temperature distribution.

**SCHEMATIC:**

![Diagram showing temperature distribution and heat transfer](image)

**ASSUMPTIONS:** (1) Negligible variation of wire temperature in radial direction, (2) Negligible effect of axial conduction along the wire, (3) Constant properties, (4) Radiation exchange between small surface and large enclosure, (5) Motion of wire has a negligible effect on the convection coefficient \( V_c \ll V \).

**PROPERTIES:** Prescribed. Copper: \( \rho = 8900 \text{ kg/m}^3, c_p = 400 \text{ J/kg K}, \varepsilon = 0.55 \). Air:

\( k = 0.037 \text{ W/m K}, \nu = 3 \times 10^{-5} \text{ m}^2/\text{s}, \text{Pr} = 0.69 \).

**ANALYSIS:** (a) Applying conservation of energy to a stationary control surface, through which the wire moves, steady-state conditions exist and \( \dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0 \). Hence, with inflow due to advection and outflow due to advection, convection and radiation,

\[
\rho V_c A c_p T - \rho V_e A c_p (T + dT) - dq_{\text{conv}} - dq_{\text{rad}} = 0
\]

\[
-\rho V_c \left( \pi D^2 / 4 \right) c_p dT - \pi D dx \left[ \bar{h}(T - T_{\infty}) + \varepsilon \sigma \left( T^4 - T_{\text{sur}}^4 \right) \right] = 0
\]

\[
\frac{dT}{dx} = -\frac{4}{\rho V_e D c_p} \left[ \bar{h}(T - T_{\infty}) + \varepsilon \sigma \left( T^4 - T_{\text{sur}}^4 \right) \right] \tag{1}
\]

Alternatively, if the control surface is fixed to the wire, conditions are transient and the energy balance is of the form, \( -\dot{E}_{\text{out}} = \dot{E}_{\text{st}} \), or

\[
-\pi D dx \left[ \bar{h}(T - T_{\infty}) + \varepsilon \sigma \left( T^4 - T_{\text{sur}}^4 \right) \right] = \rho \left( \frac{\pi D^2}{4} \right) c_p \frac{dT}{dt}
\]

\[
\frac{dT}{dt} = -\frac{4}{\rho D c_p} \left[ \bar{h}(T - T_{\infty}) + \varepsilon \sigma \left( T^4 - T_{\text{sur}}^4 \right) \right]
\]

Dividing the left- and right-hand sides of the equation by \( dx/dt \) and \( V_c = dx/dt \) respectively, Eq. (1) is obtained.

(b) Neglecting radiation, separating variables and integrating, Eq. (1) becomes

\[
\int_{T_i}^{T} \frac{dT}{T - T_{\infty}} = -\frac{4\bar{h}}{\rho V_e D c_p} \int_{0}^{x} dx
\]

Continued .....
PROBLEM 7.63 (Cont.)

\[
\ln \left( \frac{T - T_\infty}{T_i - T_\infty} \right) = -\frac{4h x}{\rho V_e D c_p}
\]

\[
T = T_\infty + (T_i - T_\infty) \exp \left( -\frac{4h x}{\rho V_e D c_p} \right)
\]  \(\text{(2)}\)

With \( Re_D = \frac{V D}{\nu} = 5 \text{ m/s} \times 0.005 \text{ m} / 3 \times 10^{-5} \text{ m}^2 / \text{s} = 833 \), the Churchill-Bernstein correlation yields

\[
\overline{Nu}_D = 0.3 + \frac{0.62(833)^{1/2}(0.69)^{1/3}}{1+(0.4/0.69)^{2/3}} \left[ 1+\left( \frac{833}{282,000} \right) \right]^{5/8}^{4/5} = 14.4
\]

\[
\overline{h} = \frac{k}{\overline{Nu}_D} = \frac{0.037 \text{ W/m K}}{0.005 \text{ m}} = 107 \text{ W/m}^2 \cdot \text{K}
\]

Hence, applying Eq. (2) at \( x = L \),

\[
T_0 = 25^\circ C + (575^\circ C) \exp \left( -\frac{4 \times 107 \text{ W/m}^2 \cdot \text{K} \times 5 \text{ m}}{8900 \text{ kg/m}^3 \times 0.2 \text{ m/s} \times 0.005 \text{ m} \times 400 \text{ J/kg K}} \right)
\]

\[
T_0 = 340^\circ C
\]
(c) Using the DER function of IHT, Eq. (1) may be numerically integrated from \( x = 0 \) to \( x = L = 5.0 \text{ m} \) to obtain

\[
T_0 = 309^\circ C
\]

Hence, radiation makes a discernable contribution to cooling of the wire. IHT was also used to obtain the following distributions.

The speed with which the wire is drawn from the extruder has a significant influence on the temperature distribution. The temperature decay decreases with increasing \( V_e \) due to the increasing effect of advection on energy transfer in the \( x \) direction. The effect of the surface emissivity is less pronounced, although, as expected, the temperature decay becomes more pronounced with increasing \( \varepsilon \).

**COMMENTS:**
1. A critical parameter in wire extrusion processes is the *coiling temperature*, that is, the temperature at which the wire may be safely coiled for subsequent storage or shipment. The larger the production rate \( (V_e) \), the longer the cooling distance needed to achieve a desired coiling temperature.
2. Cooling may be enhanced by increasing the cross-flow velocity, and the specific effect of \( V \) may also be explored.
**PROBLEM 7.64**

**KNOWN:** Experimental apparatus comprised of a flat plate subjected to an airstream in parallel flow. Electrical patch heater on backside dissipates 15.5 W for all conditions. Pin fins fabricated from brass with prescribed diameter and length can be firmly attached to the plate. Fin tip and base temperatures observed for five different configurations (N, number of fins).

**FIND:** (a) The thermal resistance between the plate and airstream for the five configurations, (b) Model of the plate-fin system using appropriate convection correlations to predict the thermal resistances for the five configurations; compare predictions and observations; explain differences, and (b) Predict thermal resistances when the airstream velocity is doubled.

**SCHEMATIC:**

![Schematic Diagram](image)

**Experimental observations:**

<table>
<thead>
<tr>
<th>N</th>
<th>T_{tip} (°C)</th>
<th>T_s (°C)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>--</td>
<td>70.2</td>
</tr>
<tr>
<td>1</td>
<td>40.6</td>
<td>67.4</td>
</tr>
<tr>
<td>2</td>
<td>39.5</td>
<td>64.7</td>
</tr>
<tr>
<td>5</td>
<td>36.4</td>
<td>57.4</td>
</tr>
<tr>
<td>8</td>
<td>34.2</td>
<td>52.1</td>
</tr>
</tbody>
</table>

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible effect of flow interactions between pins, (3) Negligible radiation exchange with surroundings, (4) All heater power is transferred to airstream, and (5) Constant properties.

**PROPERTIES:** *Table A.4*, Air (T_f = 310 K, 1 atm): k = 0.0270 W/m·K, ν = 1.69 × 10^{-5} m²/s, Pr = 0.706; *Table A.1*, Brass (T = 300 K): k = 110 W/m·K.

**ANALYSIS:** (a) The thermal resistance between the plate and the airstream is defined as

\[ R_{tot} = \frac{T_s - T_\infty}{q} \]  \hspace{1cm} (1)

The heat rate is 15.6 W for all configurations and using T_s values from the above table with T_\infty = 20°C, find

Continued...
(b) The thermal resistance of the plate-fin system can be expressed as

\[ R_{\text{tot}} = \left[ \frac{1}{R_{\text{base}}} + \frac{N}{R_{\text{fin}}} \right]^{-1} \] (2)

where the thermal resistance of the exposed portion of the base, \( A_b \), is

\[ R_{\text{base}} = \frac{1}{\overline{h}_b A_b} \] (3)

\[ A_b = A_s - N A_c \] (4)

where the \( A_c \) is the cross-sectional area of a fin and \( A_s \) is the plate surface area. Approximating the airstream over the plate as parallel flow over a plate, use the IHT Correlation Tool, External Flow, Flat Plate assuming the flow is turbulated by the leading edge, to find

\[ \overline{h}_b = 51 \text{ W/m}^2 \cdot \text{K}. \]

From the experimental observation with no fins (\( N = 0 \)), the convection coefficient was measured as

\[ \overline{h}_{b, \text{exp}} = \frac{q}{A_s (T_s - T_\infty)} = \frac{15.5 \text{ W}}{(0.0259 \text{ m})^2 (70.2 - 20) \degree \text{C}} = 460 \text{ W/m}^2 \cdot \text{K} \]

Since the predicted coefficient is nearly an order of magnitude lower, we chose to use the experimental value in our subsequent analyses to predict overall system thermal resistance.

Approximating the airstream over a pin fin as cross-flow over a cylinder, use the IHT Correlation Tool, External Flow, Cylinder to find

\[ \overline{h}_{\text{fin}} = 118 \text{ W/m}^2 \cdot \text{K}. \]

Using the IHT Extended Surface Model for the Rectangular Pin Fin (Temperature Distribution and Heat Rate) with a convection tip condition, the following fin thermal resistance was found as

\[ R_{\text{fin}} = 25.4 \text{ K/W} \]

Using the foregoing values for \( R_{\text{fin}} \) and \( \overline{h}_b \), the thermal resistances of the plate-fin system are tabulated below.

<table>
<thead>
<tr>
<th>( N )</th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>4</th>
<th>8</th>
</tr>
</thead>
<tbody>
<tr>
<td>( R_{\text{base}} ) (K/W)</td>
<td>3.241</td>
<td>3.331</td>
<td>3.426</td>
<td>3.746</td>
<td>4.133</td>
</tr>
<tr>
<td>( R_{\text{fin}} ) (K/W)</td>
<td>--</td>
<td>25.4</td>
<td>12.7</td>
<td>5.08</td>
<td>3.18</td>
</tr>
<tr>
<td>( R_{\text{tot}} ) (K/W)</td>
<td>3.24</td>
<td>2.95</td>
<td>2.70</td>
<td>2.16</td>
<td>1.80</td>
</tr>
</tbody>
</table>

By comparison with the experimental results of part (a), note that we assured agreement for the \( N = 0 \) condition by using the measured rather than estimated (correlation) convection coefficient. The predicted thermal resistances are systematically lower than the experimental values, with the worst case (\( N = 8 \)) being 13% lower.
PROBLEM 7.64 (Cont.)

(c) The effect of doubling the velocity, from \( u_\infty = 6 \) to \( 12 \) m/s, will cause the fin convection coefficient to increase from \( \bar{h}_{\text{fin}} = 118 \) to \( 169 \) W/m\(^2\)-K. For the base convection coefficient, we’ll assume the flow is fully turbulent so that \( \bar{h} \sim (u_\infty)^{0.8} \) according to Eq. 7.41, hence

\[
\bar{h}_{b}(12 \text{ m/s}) = \bar{h}_{b}(6 \text{ m/s}) \left( \frac{12}{6} \right)^{0.8} = 460 \text{ W/m}^2 \cdot \text{K}(2)^{0.8} = 800 \text{ W/m}^2 \cdot \text{K}
\]

Using the same procedure as above, find

<table>
<thead>
<tr>
<th>N</th>
<th>( R_{\text{base}} ) (K/W)</th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>4</th>
<th>8</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>R_{\text{fin}} (K/W)</td>
<td>--</td>
<td>18.96</td>
<td>9.480</td>
<td>4.740</td>
<td>2.370</td>
</tr>
<tr>
<td>2</td>
<td>R_{\text{tot}} (K/W)</td>
<td>1.86</td>
<td>1.74</td>
<td>1.63</td>
<td>1.48</td>
<td>1.19</td>
</tr>
</tbody>
</table>

The effect of doubling the airstream velocity is to reduce the thermal resistance by approximately 35%.
**PROBLEM 7.65**

**KNOWN:** Temperature and velocity of water flowing over a sphere of prescribed temperature and diameter.

**FIND:** (a) Drag force, (b) Rate of heat transfer.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Uniform surface temperature.

**PROPERTIES:** Table A-6, Saturated Water ($T_\infty = 293K$): $\rho = 998 \text{ kg/m}^3$, $\mu = 1007 \times 10^{-6} \text{ Ns/m}^2$, $k = 0.603 \text{ W/mK}$, $Pr = 7.00$; ($T_s = 333K$): $\mu = 467 \times 10^{-6} \text{ Ns/m}^2$; ($T_f = 313K$): $\rho = 992 \text{ kg/m}^3$, $\mu = 657 \times 10^{-6} \text{ Ns/m}^2$.

**ANALYSIS:** (a) Evaluating $\mu$ and $\rho$ at the film temperature,

$$Re_D = \frac{\rho V D}{\mu} = \frac{(992 \text{ kg/m}^3) 5 \text{ m/s} (0.02 \text{ m})}{657 \times 10^{-6} \text{ Ns/m}^2} = 1.51 \times 10^5$$

and from Fig. 7.8, $C_D = 0.42$. Hence

$$F_D = C_D \frac{\pi D^2 \rho V^2}{4} = 0.42 \frac{\pi (0.02 \text{ m})^2}{4} 992 \text{ kg/m}^3 \frac{(5 \text{ m/s})^2}{2} = 1.64 \text{ N.}$$  

(b) With the Reynolds number evaluated at the free stream temperature,

$$Re_D = \frac{\rho V D}{\mu} = \frac{998 \text{ kg/m}^3 (5 \text{ m/s}) (0.02 \text{ m})}{1007 \times 10^{-6} \text{ Ns/m}^2} = 9.91 \times 10^4$$

it follows from the Whitaker relation that

$$\overline{Nu}_D = 2 + \left[ 0.4 (9.91 \times 10^4)^{1/2} + 0.06 (9.91 \times 10^4)^{2/3} \right] (7.0)^{0.4} \left( \frac{1007}{467} \right)^{1/4} = 673.$$  

Hence, the convection coefficient and heat rate are

$$\overline{h} = \frac{k}{D} \overline{Nu}_D = \frac{0.603 \text{ W/m} \cdot \text{K}}{0.02 \text{ m}} 673 = 20,300 \text{ W/m}^2 \cdot \text{K}$$

$$q = \overline{h} (\pi D^2) (T_s - T_\infty) = 20,300 \frac{W}{\text{m}^2} \pi (0.02 \text{ m})^2 (60 - 20) \degree \text{C} = 1020 \text{ W.}$$

**COMMENTS:** Compare the foregoing value of $\overline{h}$ with that obtained in the text example under similar conditions. The significant increase in $\overline{h}$ is due to the much larger value of $k$ and smaller value of $\nu$ for the water. Note that $Re_D$ is slightly beyond the range of the correlation.
PROBLEM 7.66

KNOWN: Temperature and velocity of air flow over a sphere of prescribed surface temperature and diameter.

FIND: (a) Drag force, (b) Heat transfer rate with air velocity of 25 m/s; and (c) Compute and plot the heat rate as a function of air velocity for the range 1 \( \leq V \leq 25 \) m/s.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform surface temperature, (3) Negligible radiation exchange with surroundings.

PROPERTIES: Table A.4, Air (\( T_w = 298 \) K, 1 atm): \( \mu = 184 \times 10^{-7} \) N \( \cdot \) s/m\(^2\); \( \nu = 15.71 \times 10^{-6} \) m\(^2\)/s, \( k = 0.0261 \) W/m \( \cdot \) K, \( Pr = 0.71\); (\( T_s = 348 \) K): \( \mu = 208 \times 10^{-7} \) N \( \cdot \) s/m\(^2\); \( T_f = 323 \) K): \( \nu = 18.2 \times 10^{-6} \) m\(^2\)/s, \( \rho = 1.085 \) kg/m\(^3\).

ANALYSIS: (a) Working with properties evaluated at \( T_f \)

\[
Re_D = \frac{VD}{\nu} = \frac{25 \text{ m/s}(0.01 \text{ m})}{18.2 \times 10^{-6} \text{ m}^2/\text{s}} = 1.37 \times 10^4
\]

and from Fig. 7.8, find \( C_D \approx 0.4 \). Hence

\[
F_D = C_D \left( \pi D^2/4 \right) \left( \rho V^2/2 \right) = 0.4 \left( \pi/4 \right)(0.01 \text{ m})^2 1.085 \text{ kg/m}^3 (25 \text{ m/s})^2/2 = 0.011 \text{ N}
\]

(b) With

\[
Re_D = \frac{VD}{\nu} = \frac{25 \text{ m/s}(0.01 \text{ m})}{15.71 \times 10^{-6} \text{ m}^2/\text{s}} = 1.59 \times 10^4
\]

it follows from the Whitaker relation that

\[
\overline{Nu}_D = 2 + \left[ 0.4 \left( 1.59 \times 10^4 \right)^{1/2} + 0.06 \left( 1.59 \times 10^4 \right)^{2/3} \right] Pr 0.4 \left( \frac{\mu}{\mu_s} \right)^{1/4}
\]

\[
\overline{Nu}_D = 2 + \left[ 0.4 \left( 1.59 \times 10^4 \right)^{1/2} + 0.06 \left( 1.59 \times 10^4 \right)^{2/3} \right] (0.71) 0.4 \left( \frac{184}{208} \right)^{1/4} = 76.7
\]

Hence, the convection coefficient and convection heat rate are

\[
\bar{h} = \overline{Nu}_D \frac{k}{D} = 76.7 \frac{0.0261 \text{ W/m} \cdot \text{K}}{0.01 \text{ m}} = 200 \text{ W/m}^2 \cdot \text{K}
\]

\[
q = \bar{h} \pi D^2 (T_s - T_\infty) = 200 \text{ W/m}^2 \cdot \text{K} \times \pi (0.01 \text{ m})^2 (75 - 25) \text{°C} = 3.14 \text{ W}
\]

Continued...
PROBLEM 7.66 (Cont.)

(c) Using the IHT Correlation Tool, External Flow, Sphere, the average coefficient and heat rate were calculated and are plotted below.

![Graph showing convection coefficient and heat rate vs. air velocity.]

**COMMENTS:** (1) A copy of the IHT Workspace used to generate the above plot is shown below.

```
// Correlation Tool - External Flow, Sphere:
NuDbar = NuL_bar_EF_SP(ReD,Pr,mu,mus) // Eq 7.58
NuDbar = hbar * D / k
ReD = V * D / nu
/* Evaluate properties at Tinf and the surface temperature, Ts. */

// Properties Tool - Air:
// Air property functions : From Table A.4
// Units: T(K); 1 atm pressure
mu = mu_T("Air",Tinf) // Viscosity, N·s/m^2
mus = mu_T("Air",Ts) // Viscosity, N·s/m^2
nu = nu_T("Air",Tinf) // Kinematic viscosity, m^2/s
k = k_T("Air",Tinf) // Thermal conductivity, W/m·K
Pr = Pr_T("Air",Tinf) // Prandtl number

// Heat Rate Equation:
q = hbar * pi * D^2 * (Ts - Tinf)

// Assigned Variables:
D = 0.01 // Sphere diameter, m
Ts = 75 + 273 // Surface temperature, K
V = 25 // Airstream velocity, m/s
Tinf = 25 + 273 // Airstream temperature, K
```
PROBLEM 7.67

KNOWN: Sphere with a diameter of 20 mm and a surface temperature of 60°C that is immersed in a fluid at a temperature of 30°C with a velocity of 2.5 m/s.

FIND: The drag force and the heat rate when the fluid is (a) water and (b) air at atmospheric pressure. Explain why the results for the two fluids are so different.

SCHEMATIC:

ASSUMPTIONS: (1) Flow over a smooth sphere, (2) Constant properties.

PROPERTIES: Table A-6, Water (T_∞ = 30°C = 303 K): \( \mu = 8.034 \times 10^{-4} \text{ N} \cdot \text{s/m}^2, \nu = 8.068 \times 10^{-7} \text{ m}^2/\text{s}, k = 0.6172 \text{ W/m-K}, Pr = 5.45; \) Water (T_s = 333 K): \( \mu_s = 4.674 \times 10^{-4} \text{ N} \cdot \text{s/m}^2; \) Table A-4, Air (T_∞ = 30°C = 303 K, 1 atm): \( \mu = 1.86 \times 10^{-5} \text{ N} \cdot \text{s/m}^2, \nu = 1.619 \times 10^{-5} \text{ m}^2/\text{s}, k = 0.0265 \text{ W/m-K}, Pr = 0.707; \) Air (T_∞ = 333 K): \( \mu_s = 2.002 \times 10^{-5} \text{ N} \cdot \text{s/m}^2. \)

ANALYSIS: The drag force, \( F_D \), for the sphere is determined from the drag coefficient, Eq. 7.54,

\[
C_D = \frac{F_D}{A_f \left( \rho V^2 / 2 \right)}
\]

where \( A_f = \pi D^2 / 4 \) is the frontal area. \( C_D \) is a function of the Reynolds number \( Re_D = VD / \nu \) as represented in Figure 7.8. For the convection rate equation,

\[
q = \overline{h_D} A_s (T_s - T_\infty)
\]

where \( A_s = \pi D^2 \) is the surface area and the convection coefficient is estimated using the Whitaker correlation, Eq. 7.59,

\[
\overline{Nu_D} = 2 + \left[ 0.4 \left( \frac{Re_D}{Pr} \right)^{1/4} + 0.06 \left( \frac{Re_D}{Pr} \right)^{2/3} \right] \left( \frac{\mu_s}{\mu} \right)^{1/2}
\]

where all properties except \( \mu_s \) are evaluated at \( T_\infty \). For convenience we will evaluate properties required for the drag force at \( T_\infty \). The results of the analyses for the two fluids are tabulated below.

<table>
<thead>
<tr>
<th>Fluid</th>
<th>Re_D</th>
<th>C_D</th>
<th>F_D (N)</th>
<th>\overline{Nu_D}</th>
<th>\overline{h_D} (W/m²·K)</th>
<th>q(W)</th>
</tr>
</thead>
<tbody>
<tr>
<td>water</td>
<td>6.198 × 10⁴</td>
<td>0.5</td>
<td>0.489</td>
<td>439</td>
<td>13,540</td>
<td>510</td>
</tr>
<tr>
<td>air</td>
<td>3.088 × 10³</td>
<td>0.4</td>
<td>0.452 × 10⁻³</td>
<td>31.9</td>
<td>42.3</td>
<td>1.59</td>
</tr>
</tbody>
</table>

The frontal and surface areas, respectively, are \( A_f = 3.142 \times 10^{-4} \text{ m}^2 \) and \( A_s = 1.257 \times 10^{-3} \text{ m}^2 \).

COMMENTS: The Reynolds number is the ratio of inertia to viscous forces. We associate higher viscous shear and heat transfer with larger Reynolds numbers. The drag force also depends upon the fluid density, which further explains why \( F_D \) for water is much larger, by a factor of 1000, than for air. \( \overline{Nu_D} \) is dependent upon \( Re_D^n \) where \( n = 1/2 \) to \( 2/3 \), and represents the dimensionless temperature gradient at the surface. Since the thermal conductivity of water is nearly 20 times that of air, we expect a significant difference between \( \overline{h_D} \) and \( q \) for the two fluids.
PROBLEM 7.68

KNOWN: Conditions associated with airflow over a spherical light bulb of prescribed diameter and surface temperature.

FIND: Heat loss by convection.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform surface temperature.

PROPERTIES: Table A-4, Air (T_f = 25°C, 1 atm): \( \nu = 15.71 \times 10^{-6} \, \text{m}^2/\text{s}, \) \( k = 0.0261 \, \text{W/m·K}, \) Pr = 0.71, \( \mu = 183.6 \times 10^{-7} \, \text{N} \cdot \text{s/m}^2; \) Table A-4, Air (T_s = 140°C, 1 atm): \( \mu = 235.5 \times 10^{-7} \, \text{N} \cdot \text{s/m}^2. \)

ANALYSIS: The heat rate by convection is

\[
q = \overline{h} \left( \frac{\pi D^2}{2} \right) (T_s - T_\infty)
\]

where \( \overline{h} \) may be estimated from the Whitaker relation

\[
\overline{h} = \frac{k}{D} \left[ 2 + \left( 0.4 \frac{\text{Re}_D^{1/2}}{D} + 0.06 \frac{\text{Re}_D^{2/3}}{D} \right) \frac{\text{Pr}^{0.4}}{\mu_s^{1/4}} \right]
\]

where

\[
\text{Re}_D = \frac{V D}{\nu} = \frac{0.5 \, \text{m/s} \times 0.05 \, \text{m}}{15.71 \times 10^{-6} \, \text{m}^2/\text{s}} = 1591.
\]

Hence,

\[
\overline{h} = \frac{0.0261 \, \text{W/m·K}}{0.05 \, \text{m}} \left\{ 2 + \left[ 0.4 (1591)^{1/2} + 0.06 (1591)^{2/3} \right] \left( \frac{0.71}{235.5} \right)^{1/4} \right\}
\]

\[
\overline{h} = 11.4 \, \text{W/m}^2 \cdot \text{K}
\]

and the heat rate is

\[
q = 11.4 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} \left( \frac{0.05 \, \text{m}}{2} \right)^2 \left( 140 - 25 \right) = 10.3 \, \text{W.}
\]

COMMENTS: (1) The low value of \( \overline{h} \) suggests that heat transfer by free convection may be significant and hence that the total loss by convection exceeds 10.3 W.

(2) The surface of the bulb also dissipates heat to the surrounding by radiation. Further, in an actual light bulb, there is also heat loss by conduction through the socket.
PROBLEM 7.69

KNOWN: Diameter, properties and initial temperature of niobium sphere. Velocity and temperature of nitrogen. Temperature of surroundings.

FIND: (a) Time for sphere to cool to prescribed temperature if radiation is neglected, (b) Cooling time if radiation is considered. Effect of flow velocity.

SCHEMATIC:

ASSUMPTIONS: (1) Lumped capacitance method is valid, (2) Constant properties, (3) Radiation exchange with large surroundings.

PROPERTIES: Table A-4, nitrogen (T∞ = 298K): ρ = 177×10⁻⁷ N·s²/m⁴, υ = 15.7×10⁻⁶ m²/s, k = 0.0257 W/m·K, Pr = 0.716. Table A-4, nitrogen (T∞ = 873K): ρ = 368×10⁻⁷ N·s²/m⁴.

ANALYSIS: (a) Neglecting radiation, the cooling time may be determined from Eq. (5.5),

\[
t = \frac{\rho \left( \frac{\pi D^3}{6} \right) c}{h \pi D^2} \ln \frac{\theta_i}{\theta} = \frac{\rho c D}{6h} \ln \frac{T_i - T_\infty}{T_f - T_\infty}
\]

The convection coefficient is obtained from the Whitaker correlation with Re_D = VD/υ = 5 m/s×0.01m/15.7×10⁻⁶ m²/s = 3185. Hence,

\[
\bar{N}u_D = \left( \frac{hD}{k} \right) = 2 + \left( 0.4 \text{Re}^{1/2}_D + 0.06 \text{Re}^{2/3}_D \right) \text{Pr}^{0.4} \left( \frac{\mu}{\mu_s} \right)^{1/4}
\]

\[
h = \frac{0.0257 \text{W/m·K}}{0.01 \text{m}} \left\{ 2 + \left[ 0.4 (3185)^{1/2} + 0.06 (3185)^{2/3} \right] (0.716)^{0.4} \left( \frac{177}{368} \right)^{0.25} \right\} = 71.8 \text{W/m·K}
\]

\[
t = \frac{8600 \text{kg/m}^3 \times 290 \text{J/kg·K} \times 0.01 \text{m} \times \ln \left( \frac{900 - 25}{300 - 25} \right)}{6 \times 71.8 \text{W/m·K} \times 67 \text{s}} <
\]

(b) If the effect of radiation is considered, the cooling time can be obtained by integrating Eq. (5.15). With \( \frac{A_s}{V} = \frac{\pi D^2}{\left( \frac{\pi D^3}{6} \right)} = 6/D \), the appropriate form of the equation is

\[
\frac{dT}{dt} = -\frac{6}{\rho c D} \left[ h(T - T_\infty) + \varepsilon \sigma (T^4 - T_{sur}^4) \right]
\]

Using the DER function of IHT to integrate this equation over the limits from \( T_i = 1173 \text{K} \) to \( T_f = 573 \text{K} \), we obtain

\[
t = 48 \text{s} <
\]

Continued …..
For $V = 1.0$ and $25.0 \text{ m/s}$, the cooling times are $t = 80$ and $24 \text{ s}$, respectively. Temperature histories for the three velocities are shown below.

**COMMENTS:** The cooling time is significantly affected by the flow velocity.
PROBLEM 7.70

KNOWN: An underwater instrument pod having a spherical shape with a diameter of 85 mm dissipating 300 W.

FIND: Estimate the surface temperature of the pod for these conditions: (a) when submersed in a bay where the water temperature is $15^\circ C$ and the current is 1 m/s, and (b) after being hauled out of the water without deactivating the power and suspended in the ambient where the air temperature is $15^\circ C$ and the wind speed is 3 m/s.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Flow over a smooth sphere, (3) Uniform surface temperatures, (4) Negligible radiation heat transfer for air (a) condition, and (5) Constant properties.

PROPERTIES: Table A-6, Water ($T_\infty = 15^\circ C = 288$ K): $\mu = 0.001053$ N-m/s$^2$, $\nu = 1.139 \times 10^{-6}$ m$^2$/s, $k = 0.5948$ W/m-K, $Pr = 8.06$; Table A-4, Air ($T_\infty = 288$ K, 1 atm): $\mu = 1.788 \times 10^{-5}$ N-m/s$^2$, $\nu = 1.482 \times 10^{-5}$ m$^2$/s, $k = 0.02534$ W/m-K; Air ($T_s = 945$ K): $\mu_s = 4.099 \times 10^{-5}$ N-m/s$^2$, $Pr = 0.710$.

ANALYSIS: The energy balance for the submersed-in-water (w) and suspended-in-air (a) conditions are represented in the schematics above and have the form

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_{gen} = -q_{cv} + P_e = 0$$

$$-\overline{h}_D A_s (T_s - T_\infty) + P_e = 0$$

where $A_s = \pi D^2$ and $\overline{h}_D$ is estimated using the Whitaker correlation, Eq. 7.59,

$$\overline{Nu}_D = 2 + \left[0.4 \frac{Re}{D}^{1/2} + 0.06 \frac{Re}{D}^{2/3}\right]Pr^{0.4} \left(\frac{\mu}{\mu_s}\right)^{1/4}$$

where all properties except $\mu_s$ are evaluated at $T_\infty$. The results are tabulated below.

<table>
<thead>
<tr>
<th>Condition</th>
<th>$Re_D$</th>
<th>$\overline{Nu}_D$</th>
<th>$\overline{h}_D$ (W/m$^2$K)</th>
<th>$T_s$ ($^\circ C$)</th>

<tr>
<td>(a) air</td>
<td>$1.72 \times 10^4$</td>
<td>67.5</td>
<td>20.1</td>
<td>672</td>
</tr>
</tbody>
</table>

COMMENTS: (1) While submerged and dissipating 300 W, the pod is safely operating at a temperature slightly above that of the water. When hauled from the water and suspended in air, the pod temperature increases to a destruction temperature (672$^\circ C$). The pod gets smoked!

(2) The assumption that $\mu/\mu_s \approx 1$ is appropriate for the water (w) condition. For the air (a) condition, $\mu/\mu_s = 0.436$ and the final term of the correlation is significant. Recognize that radiation exchange with the surroundings for the air condition should be considered for an improved estimate.

Continued .....
PROBLEM 7.70 (Cont.)

(3) Why such a difference in $T_s$ for the water (w) and air (a) conditions? From the results table note that the $Re_D$, $Nu_D$, and $h_D$ are, respectively, 4x, 7x and 170x times larger for water compared to air. Water, because of its thermophysical properties which drive the magnitude of $h_D$, is a much better coolant than air for similar flow conditions.

/* Comment: Because $T_s$ is much larger than $T_{inf}$ for the in-air operation, the ratio of $\mu / \mu_s$ exceeds the limits for the correlation. Hence, a warning message comes with the IHT solution. */

/* Results - operation in air

PROBLEM 7.71

KNOWN: Air cooling requirements for lead pellets in the molten slate.

FIND: Height of tower from which pellets must be dropped to convert from liquid to solid state.

SCHEMATIC:

ASSUMPTIONS: (1) Pellet remains at melting point temperature throughout process, (2) Density of lead, \( \rho_\ell \), remains constant (at density of molten lead) throughout process, (3) Radiation effects are negligible.

PROPERTIES: Table A-7, Lead (M.P. = \( T_s = 327.2^\circ C \)): \( \rho_\ell \approx 10,600 \text{ kg/m}^3 \); Handbook Chemistry and Physics: Latent heat of fusion, \( h_{sf} = 24.5 \text{ kJ/kg} \); Table A-4, Air (\( T_\infty = 15^\circ C \)): \( \rho_a = 1.22 \text{ kg/m}^3 \), \( \nu = 14.8 \times 10^{-6} \text{ m}^2/\text{s} \), \( k = 25.3 \times 10^{-3} \text{ W/mK} \), \( Pr = 0.71 \), \( \mu = 178.6 \times 10^{-7} \text{ N}\cdot\text{s/m}^2 \); (\( T_s = 327^\circ C \)): \( \mu_s = 306 \times 10^{-7} \text{ N}\cdot\text{s/m}^2 \).

ANALYSIS: Conservation of energy dictates that the energy released to solidification must be given off to the air by convection. Applying the conservation of energy requirement on a time interval basis,

\[
-E_{\text{out}} = \Delta E_{\text{st}} \quad \text{where} \quad E_{\text{out}} = q_{\text{conv}} \cdot t_s
\]

and \( t_s \) is the time required to completely solidify a pellet. Hence,

\[
-h \left( \pi D^2 \right) (T_s - T_\infty) \cdot t_s = -h_{sf} \rho_\ell \left( \pi D^3 / 6 \right).
\]

With the pellet moving at the terminal velocity, \( V \), the height of the tower must be

\[
H = V \cdot t_s = \frac{V h_{sf} \rho_\ell D}{6h(T_s - T_\infty)}
\]

The terminal velocity may be obtained from a force balance on the pellet. Equating the drag and gravity forces,

\[
F_g = F_D
\]

where \( F_g = \rho_\ell \left( \pi D^3 / 6 \right) g \) and \( F_D \) is obtained from the drag coefficient

\[
\rho_\ell \left( \pi D^3 / 6 \right) g = C_D \left( \pi D^2 / 4 \right) \left( \rho_a \nu^2 / 2 \right)
\]

\[
V = \left( \frac{4}{3} \frac{\rho_\ell}{\rho_a} \frac{gD}{C_D} \right)^{1/2} \left[ \frac{410,600 \text{ kg/m}^3 \left(9.8 \text{ m/s}^2 \right) \left(0.003 \text{ m} \right)}{3 \frac{1.22 \text{ kg/m}^3}{C_D}} \right]^{1/2}
\]

\[
V (\text{m/s}) = 18.5/C_{D}^{1/2}
\]

Continued …..
PROBLEM 7.71 (Cont.)

The drag coefficient may be obtained from Fig. 7.8 and knowledge of the Reynolds number, where

\[ \text{Re}_D = \frac{VD}{V} = \frac{V(0.003 \text{ m})}{14.8 \times 10^{-6} \text{ m}^2 / \text{s}} = 202.7 \text{ V (m/s)}. \]

In a trial-and-error procedure which involves guessing a value of V, calculating Re_D, obtaining C_D from Fig. 7.8, and computing V from Eq. (1), it was found that

\[ V \approx 29 \text{ m/s} \quad \text{Re}_D \approx 5900. \]

From the Whitaker correlation, it follows that

\[ \overline{\text{Nu}}_D = 2 + \left[ 0.4 \text{Re}^{1/2}_D + 0.06 \text{Re}^{2/3}_D \right] \text{Pr}^{0.4} \left( \frac{\mu}{\mu_s} \right)^{1/4} \]

\[ \overline{\text{Nu}}_D = 2 + \left[ 0.4(5900)^{1/2} + 0.06(5900)^{2/3} \right] (0.71)^{0.4} \left( \frac{178.6 \times 10^{-7}}{306 \times 10^{-7}} \right)^{1/4} = 40.4 \]

\[ \overline{h} = \overline{\text{Nu}}_D \left( \frac{k}{D} \right) = 40.4 \left( \frac{25.3 \times 10^{-3} \text{ W/m} \cdot \text{K}}{0.003 \text{ m}} \right) = 341 \text{ W/m}^2 \cdot \text{K}. \]

Accordingly,

\[ H = \frac{29 \text{ m/s} \times 24,500 \text{ J/kg} \times 10,600 \text{ kg/m}^3 \times 0.003 \text{ m}}{6 \times 341 \text{ W/m}^2 \cdot \text{K} \times (327.2 - 15)^\circ \text{C}} = 35 \text{ m}. \]

**COMMENTS:**

(1) In a free fall from such a height (H = 35 m), the pellet will not have sufficient time to reach the terminal velocity (its maximum velocity on impacting the water would be 28.7 m/s). Accordingly, V has been overestimated and the required value of H has been overpredicted. A more accurate treatment would involve applying the energy balance at successive times from the initiation of the fall, using the pellet velocity appropriate to each time.

(2) Accounting for radiation effects would further diminish the required value of H.

(3) The correlation has been used outside its range of applicability, since \( \mu/\mu_s < 1 \).
**PROBLEM 7.72**

**KNOWN:** A spherical workpiece of pure copper with a diameter of 15 mm and emissivity of 0.5 is suspended in a large furnace with walls at a uniform temperature of 600°C. The air flow over the workpiece has a temperature of 900°C with a velocity of 7.5 m/s.

**FIND:** (a) The steady-state temperature of the workpiece; (b) Estimate the time required for the workpiece to reach within 5°C of the steady-state temperature if its initial, uniform temperature is 25°C; (c) Estimate the steady-state temperature of the workpiece if the air velocity is doubled with all other conditions remaining the same; also, determine the time required for the workpiece to reach within 5°C of this value. Plot on the same graph the workpiece temperature histories for the two air velocity conditions.

**SCHEMATIC:**

![Schematic Diagram]

**ASSUMPTIONS:** (1) Flow over a smooth sphere, (2) Sphere behaves as spacewise isothermal object; lumped capacitance method is valid, (3) Sphere is small object in large, isothermal surroundings, and (4) Constant properties.

**PROPERTIES:** Table A-4, Air ($T_\infty = 1173$ K, 1 atm): $\mu = 4.665 \times 10^{-5}$ N⋅s/m$^2$, $\nu = 0.0001572$ m$^2$/s, $k = 0.075$ W/m⋅K, $Pr = 0.728$; Air ($T_s = 1010$ K, 1 atm): $\mu_s = 4.268 \times 10^{-5}$ N⋅s/m$^2$.

**ANALYSIS:** (a) The steady-state temperature is determined from the energy balance on the sphere as represented in the schematic above.

\[
\dot{E}_{in} - \dot{E}_{out} + \dot{E}_{gen} = 0 \quad -q_{cv} - q_{rad} + 0 = 0
\]

\[
-\dot{n}_D A_s (T_s - T_\infty) - \varepsilon A_s \sigma (T_s^4 - T_{s\text{sur}}^4) = 0
\]  \hspace{1cm} (1)

where $A_s = \pi D^2/4$. The convection coefficient can be estimated using the Whitaker correlation, Eq. 7.59, where all properties except $\mu_s$ are evaluated at $T_\infty$. Assume $T_s = 737°C = 1010$ K to evaluate $\mu_s$.

\[
\overline{Nu}_D = 2 + \left[ 0.4 \text{Re}_D^{1/2} + 0.06 \text{Re}_D^{2/3} \right] \text{Pr}^{0.4} \left( \mu / \mu_s \right)^{1/4}
\]  \hspace{1cm} (2)

See the table below for results of the correlation calculations. From the energy balance, canceling out $A_s$, with numerical values, find $T_s$.

\[
-79.8 \text{ W/m}^2 \cdot \text{K} (T_s - 1173) K - 0.5 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left( T_s^4 - 873^4 \right) K^4 = 0
\]

\[
T_s = 1010 \text{ K} = 737°C.
\]

(b) The time required for the sphere initially at $T_i = 25°C$ to reach within 5°C of the steady-state temperature can be determined from the energy balance for the transient condition.

Continued .....
PROBLEM 7.72 (Cont.)

\[
\dot{E}_{\text{in}} - \dot{E}_{\text{out}} + \dot{E}_{\text{gen}} = \dot{E}_{\text{st}}
\]

\[
-\overline{h}_D A_s (T_s - T_\infty) - \varepsilon A_s \sigma (T_s^4 - T_{\text{sur}}^4) = \rho c \left( \pi D^3 / 6 \right) \frac{dT}{dt}
\]

(3)

Recognize that \(\overline{h}_D\) is not constant, but depends upon \(T_s(t)\). Using IHT to perform the integration, evaluate \(\overline{h}_D\), and provide pure copper properties \(\rho\) and \(c\) as a function of \(T_s\), the time \(t_o\) for \(T(t_o) = (737 - 5)°C = 732°C\) is

\[t_o = 274 \text{ s}\]

See Comments 1 and 2 for details on the IHT calculation method.

(c) Use Eq. (1) and (2) to find the steady-state temperature when the air velocity is doubled, \(V = 2 \times 7.5 \text{ ms} = 15 \text{ m/s}\). The results are tabulated below along with those from part (a).

<table>
<thead>
<tr>
<th>Part</th>
<th>(V) (m/s)</th>
<th>(\text{Re}_D)</th>

</table>

As expected, increasing the air velocity will cause the sphere temperature to increase toward \(T_\infty\). Note that \(\overline{h}_D\) increases by a factor of 1.4 as the air velocity is doubled. From correlation Eq. (2) note that \(\overline{h}_D\) is approximately proportional to \(V^n\) where \(n\) is in the range 1/2 to 2/3. Using the IHT code for the lumped capacitance analysis, the time for \(T(t_o) = (760 - 5)°C = 755°C\) is

\[t_o = 230 \text{ s}\]

The temperature histories for the two air velocity conditions are calculated using the foregoing transient analyses in the IHT workspace.

Continued.....
COMMENTS:  (1) The portion of the IHT code for performing the energy balance and evaluating the convection correlation function using the properties function follows.

```
// Convection correlation, sphere
NuDbar = NuL_bar_EF_SP(ReD,Pr,mu,mus)   // Eq 7.59
NuDbar = hbar * D / k
ReD = V * D / nu
/* All properties except mus are evaluated at Tinf. */
/* Correlation description: External flow (EF) over a sphere (SP), average coefficient,
3.5<ReD<7.6x10^4, 0.71<Pr<380, 1.0<(mu/mus)<3.2, Whitaker correlation, Eq 7.59. See Table 7.9. */

// Energy balance, steady-state temperature
-hbar * As * (Ts - Tinf) - eps * sigma * (Ts^4 - Tsur^4) * As = 0
As = pi * D^2
sigma = 5.67e-8

// Air property functions : From Table A.4
// Units: T(K); 1 atm pressure
mu = mu_T("Air",Tinf)   // Viscosity, N·s/m^2
mus = mu_T("Air",Ts)   // Viscosity, N·s/m^2
nu = nu_T("Air",Tinf)   // Kinematic viscosity, m^2/s
k = k_T("Air",Tinf)   // Thermal conductivity, W/m·K
Pr = Pr_T("Air",Tinf)   // Prandtl number

// Input variables
D = 0.015
eps = 0.5
V = 7.5
Tinf = 900 + 273
Tsur = 600 + 273
```

(2) Two modifications can be made to the code above to perform the lumped capacitance method for the transient analysis: (a) include the storage term in the energy balance and (b) provide the properties function for copper. The initial condition, T_i = 288 K, is entered as the initial condition when the solver performs the integration.

```
// Energy balance, steady-state; equilibrium temperature
-hbar * As * (Ts - Tinf) - eps * sigma * (Ts^4 - Tfur^4) * As = M * ccu * der(Ts,t)
As = pi * D^2
sigma = 5.67e-8
M = rhocu * pi * D^3 / 6

// Copper (pure) property functions : From Table A.1
// Units: T(K)
rhocu = rho_300K("Copper")   // Density, kg/m^3
kcu = k_T("Copper",Ts)   // Thermal conductivity, W/m·K
ccu = cp_T("Copper",Ts)   // Specific heat, J/kg·K
```

(3) Show that the lumped capacitance method is valid for this application.
PROBLEM 7.73

KNOWN: Diameter and initial and final temperatures of copper spheres quenched in a water bath.

FIND: (a) Terminal velocity in the bath, (b) Tank height.

SCHEMATIC:

ASSUMPTIONS: (1) Sphere descends at terminal velocity, (2) Uniform, but time varying surface, temperature.

PROPERTIES: Table A-1, Copper (350K): \( \rho = 8933 \text{ kg/m}^3 \), \( k = 398 \text{ W/mK} \), \( c_p = 387 \text{ J/kg} \cdot \text{K} \); Table A-6, Water (\( T_\infty = 280 \text{ K} \)): \( \rho = 1000 \text{ kg/m}^3 \), \( \mu = 1422 \times 10^{-6} \text{ N.s/m}^2 \), \( k = 0.582 \text{ W/mK} \), \( Pr = 10.26 \); \( T_s \approx 340 \text{ K} \): \( \mu_s = 420 \times 10^{-5} \text{ N.s/m}^2 \).

ANALYSIS: A force balance gives \( C_D \left( \frac{\pi D^2}{4} \right) \rho V^2 / 2 = (\rho_{cu} - \rho) g \frac{\pi D^3}{6} \),

\[
C_D \frac{V^2}{2} = \frac{4D}{3} \frac{\rho_{cu} - \rho}{\rho} g = \frac{4 \times 0.02 \text{ m}}{3} \frac{8933 - 1000}{1000} 9.8 \text{ m/s}^2 = 2.07 \text{ m}^2 / \text{s}^2.
\]

An iterative solution is needed, where \( C_D \) is obtained from Figure 7.8 with \( Re_D = \frac{VD}{\nu} = 0.02 \text{ m/V/1.42 \times 10^{-6} \text{ m}^2/\text{s} = 14,085 \text{ V (m/s)} \} \). Convergence is achieved with \( V \approx 2.1 \text{ m/s} \) for which \( Re_D = 29,580 \) and \( C_D \approx 0.46 \). Using the Whitaker expression

\[
\overline{h} = \overline{Nu}_D \frac{k}{D} = 439 \times 0.582 \text{ W/m.K}/0.02 \text{ m} = 12,775 \text{ W/m}^2 \cdot \text{K}.
\]

To determine applicability of lumped capacitance method, find \( Bi = \overline{h} \left( \frac{r_o}{3} / k_{cu} = 12,775 \text{ W/m}^2 \cdot \text{K} \right) \)

\( W/\text{m}^2 \cdot \text{K} \left( 0.01 \text{ m/3}/398 \text{ W/m.K} \right) = 0.11 \). Applicability is marginal. Use Heisler charts,

\[
\theta_o^* = \frac{T_o - T_\infty}{T_i - T_\infty} = \frac{320 - 280}{360 - 280} = 0.5, \quad Bi^{-1} = \frac{k}{h_{ro}} = 3.12, \quad Fo = 0.88 = \frac{\alpha_{t_f}}{r_o^2}.
\]

With \( \alpha_{cu} = k/\rho c_p = 398 \text{ W/m.K/(8933 kg/m}^3 \cdot \text{g)} (387 \text{ J/kg} \cdot \text{K}) = 1.15 \times 10^{-4} \text{ m}^2 / \text{s}, \) find

\[
t_f = 0.88 \left( 0.01 \text{ m} \right)^2 / 1.15 \times 10^{-4} \text{ m}^2 / \text{s} = 0.77 \text{ s}.
\]

Required tank height is

\( H = t_f \cdot V = 0.77 \text{ s} \times 2.1 \text{ m/s} = 1.6 \text{ m}. \)

COMMENTS: If \( t_f \) is evaluated from the approximate series solution, \( \theta_o^* = C_1 \exp \left( -\frac{\zeta_1^2}{2} \right) \), we obtain \( t_f = 0.76 \text{ s} \). Note that the terminal velocity is not reached immediately. Reduced \( V \) implies reduced \( \overline{h} \) and increased \( t_f \).
PROBLEM 7.74

KNOWN: Diameter and initial and final temperatures of copper spheres quenched in an oil bath.

FIND: (a) Terminal velocity in bath, (b) Bath height.

SCHEMATIC:

ASSUMPTIONS: (1) Sphere descends at terminal velocity, (2) Uniform, but time varying, surface temperature.

PROPERTIES: Table A-1, Copper (350K): \( \rho_{cu} = 8933 \text{ kg/m}^3, k = 398 \text{ W/m} \cdot \text{K}, c_p = 387 \text{ J/kg} \cdot \text{K}; \)

Table A-5, Oil (\( T_\infty = 300\text{K} \)): \( \rho = 884 \text{ kg/m}^3, \mu = 0.486 \text{ N} \cdot \text{s/m}^2, k = 0.145 \text{ W/m} \cdot \text{K}, Pr = 6400; (T_s = 340\text{K}): \mu = 0.0531 \text{ N} \cdot \text{s/m}^2. \)

ANALYSIS: (a) Force balance gives \( C_D \left( \frac{\pi D^2}{4} \right) \rho V^2 / 2 = (\rho_{cu} - \rho) g \pi D^3 / 6, \)

\[ C_D V^2 = \frac{4D}{3} \frac{\rho_{cu} - \rho}{\rho} g = \frac{4 \times 0.02 \text{ m}}{3} \frac{8933 - 884}{884} \frac{9.8 \text{ m/s}^2}{3} = 2.38 \text{ m}^2 / \text{s}^2. \]

An iterative solution is needed, where \( C_D \) is obtained from Fig. 7.8 with

\[ \text{Re}_D = \frac{V D}{\nu} = \frac{0.02 \text{ m}}{(0.486/884) \text{ m}^2 / \text{s}} = 36.4 \text{ V (m/s)}. \]

Convergence is achieved for \( V = 1.1 \text{ m/s} \) for which \( \text{Re}_D = 40 \) and \( C_D = 1.97. \) Using the Whitaker expression

\[ \overline{\text{Nu}}_D = 2 + \left( 0.4 \text{ Re}_D^{1/2} + 0.06 \text{ Re}_D^{2/3} \right) Pr^{0.4} (\mu / \mu_s)^{1/4} \]

\[ \overline{\text{Nu}}_D = 2 + \left( 0.4 \times 60^{1/2} + 0.06 \times 40^{2/3} \right) (6400)^{0.4} (0.486/0.0531)^{1/4} = 189.2 \]

\[ \overline{h} = \overline{\text{Nu}}_D \frac{k}{D} = 189.2 \times 0.145/0.02 = 1357 \text{ W/m}^2 \cdot \text{K}. \]

To determine applicability of the lumped capacitance method, find \( \text{Bi} = \overline{h} (t_0 / 3) / k_{cu} = 1357 \text{ W/m}^2 \cdot \text{K} (0.01 \text{ m}^3)/398 \text{ W/m} \cdot \text{K} = 0.011. \) Hence lumped capacitance method can be used; from Eq. 5.5,

\[ t_f = \frac{(\rho c)_m T^3 / 6}{\overline{h} \pi D^2} \left( \frac{\ln T_i - T_\infty}{T_f - T_\infty} \right) \]

\[ t_f = \frac{8933 \text{ kg/m}^3 \times 387 \text{ J/kg} \cdot \text{K} \times 0.02 \text{ m}}{1357 \text{ W/m}^2 \cdot \text{K}} \frac{60}{20} = 9.33 \text{ s}. \]

Required tank height is \( H = t_f \cdot V = 9.33 \text{ s} \times 1.1 \text{ m/s} = 10.3 \text{ m}. \)

COMMENTS: (1) Whitaker correlation has been used well beyond its limits (Pr >> 380). Hence estimate of \( \overline{h} \) is uncertain. (2) Since terminal velocity is not reached immediately, \( \overline{h} < 1357 \text{ W/m}^2 \cdot \text{K} \) and \( t_f > 9.33 \text{ s}. \)
**PROBLEM 7.75**

**KNOWN:** Velocity of plasma jet and initial particle velocity in a plasma spray coating process. Distance from particle injection to impact.

**FIND:** (a) Particle velocity and distance of travel as a function of time. Time-in-flight and particle impact velocity, (b) Convection heat transfer coefficient and time required to heat particle to melting point and to subsequently melt it.

**SCHEMATIC:**

- Alumina particle \( m_p, V_p, D_p = 50 \, \mu m \)
- \( T_m = 2318 \, K \), \( h_f = 3577 \, kJ/kg \)
- \( \rho_p = 3970 \, kg/m^3, k_p = 10.5 \, W/m-K \)
- \( c_p = 1560 \, J/kg \, K \)
- Plasma jet \( V = 400 \, m/s \)
- \( T_e = 10,000 \, K \)
- \( k = 0.671 \, W/m-K \), \( c_p = 1480 \, J/kg-K \)
- \( \mu = 2.70 \times 10^{-4} \, kg/s-m \)
- \( v = 5.6 \times 10^{-3} \, m^2/s \)

**ASSUMPTIONS:** (1) Applicability of Stokes’ law, (2) Constant particle and plasma properties, (3) Negligible influence of viscosity ratio in Whitaker correlation, (4) Negligible radiation effects, (5) Validity of lumped capacitance approximation.

**ANALYSIS:** (a) From Eqs. 7.54 and 7.58,

\[
C_D = \frac{F_D}{\frac{A_f}{\rho \overline{V}^2 / 2}} = \frac{24}{\text{Re}_D} = \frac{24}{\rho \overline{V} D_p / \mu}
\]

where \( \overline{V} = V - V_p \) is the relative velocity and \( A_f = \pi D_p^2 / 4 \). Hence, the drag force on the particle is

\[
F_D = 3\pi\mu D_p \overline{V} = m_p \left( \frac{dV_p}{dt} \right) = -m_p \left( \frac{d\overline{V}}{dt} \right)
\]

Separating variables and integrating from the nozzle exit, where \( V_p = 0, \overline{V} = V \) and \( t = 0 \),

\[
\int \overline{V} \, d\overline{V} = -\frac{3\pi\mu D_p}{m_p} \int_0^t dt
\]

\[
\ln \frac{\overline{V}}{V} = -\frac{3\pi\mu D_p t}{m_p}
\]

\[
\overline{V} = V \exp \left( -3\pi\mu D_p t / m_p \right) = V - V_p
\]

Hence,

\[
V_p(t) = V \left[ 1 - \exp \left( -3\pi\mu D_p t / m_p \right) \right]
\]

With \( V_p = dx_p / dt \), it follows that

\[
\int_0^L dx_p = \int_0^{t_f} V \left[ 1 - \exp \left( -3\pi\mu D_p t / m_p \right) \right] dt
\]

Continued...
PROBLEM 7.75 (Cont.)

\[ L = V_{tf} - \frac{V_{mp}}{3\pi \mu D_p} \left[ 1 - \exp \left( -3\pi \mu D_p t_f / m_p \right) \right] \]

Substituting the prescribed values of \( D_p, L, V \) and the material properties, the foregoing equations yield

\[ V_p = 166.7 \text{ m/s} \quad t_f = 0.0011 \text{ s} \]

(b) Assuming an average value of \( V = 315 \text{ m/s} \), the Reynolds number is

\[ Re_D = \frac{315 \text{ m/s} \times 50 \times 10^{-6} \text{ m}}{5.6 \times 10^{-3} \text{ m}^2/\text{s}} = 2.81 \]

From the Whitaker correlation,

\[ \overline{Nu_D} = 2 + \left( 0.4 \cdot Re_D^{1/2} + 0.06 \cdot Re_D^{2/3} \right) Pr^{0.4} \]

\[ \overline{Nu_D} = 2 + \left( 0.4 \times 2.81^{1/2} + 0.06 \times 2.81^{2/3} \right) (0.60)^{0.4} = 2.64 \]

\[ \overline{h} = 2.64 k / D_p = 2.64 \left( 0.671 \text{ W/m·K} \right) / 50 \times 10^{-6} \text{ m} = 35.400 \text{ W/m}^2 \cdot \text{K} \]

The two-step melting process involves (i) the time \( t_1 \) to heat the particle to its melting point and (ii) the time \( t_2 \) required to achieve complete melting. Hence, \( t_m = t_1 + t_2 \), where from Eq. 5.5,

\[ t_1 = \frac{\rho_p D_p C_p}{6h} \ln \frac{T_i - T_{\infty}}{T_{mp} - T_{\infty}} \]

\[ t_1 = \frac{3970 \text{ kg/m}^3 \left( 50 \times 10^{-6} \text{ m} \right) 1560 \text{ J/kg·K}}{6 \left( 35.400 \text{ W/m}^2 \cdot \text{K} \right)} \ln \frac{(300 - 10,000)}{(2318 - 10,000)} = 3.4 \times 10^{-4} \text{ s} \]

Performing an energy balance for the second step, we obtain

\[ \int_{t_1}^{t_m} q_{\text{conv}} \, dt = \Delta E_{st} = \rho_p \forall h_{sf} \]

Hence,

\[ t_2 = \frac{\rho_p D_p h_{sf}}{6h} \left( \frac{T_{\infty} - T_{mp}}{T_{mp} - T_{\infty}} \right) = \frac{3970 \text{ kg/m}^3 \left( 50 \times 10^{-6} \text{ m} \right) 3.577 \times 10^6 \text{ J/kg}}{6 \left( 35.400 \text{ W/m}^2 \cdot \text{K} \right) (10,000 - 2318) \text{ K}} = 4.4 \times 10^{-4} \text{ s} \]

Hence,

\[ t_m = \left( 3.4 \times 10^{-4} + 4.4 \times 10^{-4} \right) \text{s} = 7.8 \times 10^{-4} \text{ s} \]

and the prescribed value of \( L \) is sufficient to insure complete melting before impact.

COMMENTS: (1) Since \( Bi = \left( \overline{h} D_p / 3 \right) / k_p \approx 0.03 \), use of the lumped capacitance approach is appropriate.

(2) With \( Re_D = 2.81 \), conditions are slightly outside the ranges associated with Stokes’ law and the Whitaker correlation.
PROBLEM 7.76

KNOWN: Diameter, velocity, initial temperature and melting point of molten aluminum droplets. Temperature of helium atmosphere.

FIND: Maximum allowable separation between droplet injector and substrate.

SCHEMATIC:

Helium
T_{\infty} = 300 \text{ K}

Molten aluminum sphere
D = 5 \times 10^{-4} \text{ m}
T_i = 1100 \text{ K}, T_f \geq 933 \text{ K}
V = 3 \text{ m/s}

ASSUMPTIONS: (1) Lumped capacitance approximation is valid, (2) Constant properties, (3) Negligible radiation.

PROPERTIES: Table A-4. Helium (T_{\infty} = 300 \text{ K}): v = 122 \times 10^{-6} \text{ m}^2/\text{s}, \mu = 199 \times 10^{-7} \text{ N}\cdot\text{s}/\text{m}^2, k = 0.152 \text{ W/ m}\cdot\text{K}, \text{Pr} = 0.68. Helium (T_s = 1000 \text{ K}): \mu_s = 446 \times 10^{-7} \text{ N}\cdot\text{s}/\text{m}^2. Given, Aluminum: \rho = 2500 \text{ kg/ m}^3, c = 1200 \text{ J/ kg}\cdot\text{K}, k = 200 \text{ W/ m}\cdot\text{K}.

ANALYSIS: With \text{Re}_D = \frac{VD}{v} = 3 \text{ m/s} \left(5 \times 10^{-4} \text{ m}\right) / 122 \times 10^{-6} \text{ m}^2/\text{s} = 12.3, the Whitaker correlation yields

$$h = \frac{k}{D} \left[2 + \left(0.4 \text{Re}_D^{1/2} + 0.06 \text{Re}_D^{2/3}\right)\right] \text{Pr}^{0.4} \left(\frac{\mu}{\mu_s}\right)^{1/4}$$

$$h = \frac{0.152 \text{ W/ m}\cdot\text{K}}{0.0005 \text{m}} \left[2 + \left(0.4 (12.3)^{1/2} + 0.06 (12.3)^{2/3}\right) \left(0.68\right)^{0.4} \left(\frac{199}{446}\right)^{1/4}\right] = 975 \text{ W/ m}^2\cdot\text{K}$$

The time-of-flight for the droplet to cool from 1100K to 933K may be obtained from Eq. 5.5.

$$t = \frac{\rho c}{h A_s} \ln \frac{\theta_1}{\theta} = \frac{\rho c D}{6h} \ln \frac{T_i - T_{\infty}}{T_f - T_{\infty}}$$

$$t = \frac{\left(2500 \text{ kg/ m}^3\right)1200 \text{ J/ kg}\cdot\text{K} \left(0.0005 \text{m}\right)}{6 \times 975 \text{ W/ m}^2\cdot\text{K}} \ln \frac{800}{633} = 0.06 \text{s}$$

The maximum separation is therefore

$$L = V \times t = 3 \text{ m/s} \times 0.06 \text{s} = 0.18 \text{m} = 180 \text{ mm}$$

COMMENTS: (1) With Bi = \frac{h \left(D/6\right)}{k} = 4 \times 10^{-4}, the lumped capacitance approximation is excellent. (2) With the surroundings assumed to be at T_{sur} = T_{\infty} and a representative emissivity of \varepsilon = 0.1 for molten aluminum, \varepsilon \sigma \left(T_i + T_{\infty}\right) \left(T_i^2 + T_{\infty}^2\right) = 10 \text{ W/ m}^2\cdot\text{K} \ll h = 975 \text{ W/ m}^2\cdot\text{K}. Hence, radiation is, in fact, negligible.
PROBLEM 7.77

KNOWN: Diameter, initial temperature and properties of glass beads suspended in an airstream of prescribed temperature.

FIND: (a) Velocity of airstream, (b) Time required to cool the beads from 477 to 80°C.

SCHEMATIC:

ASSUMPTIONS: (1) Lumped capacitance approximation may be used, (2) Constant properties, (3) Radiation exchange is with large surroundings at $T_{sur} = T_{\infty}$.

PROPERTIES: Table A.4, Air ($T_{\infty} = 288$ K): $\rho = 1.21$ kg/m³, $\nu = 14.8 \times 10^{-6}$ m²/s, $\mu = 179 \times 10^{-7}$ N·s/m², $k = 0.0253$ W/m·K, $Pr = 0.71$.

ANALYSIS: (a) Using Eq. 7.44 with the force balance, $F_g = F_d$,

$$V = \left( \frac{4 \times D}{3 \rho} \frac{g \rho}{C_D} \right)^{1/2} = \left( \frac{4 \times 2200 \times 9.8 \text{ m/s}^2 \times 0.003 \text{ m}}{1.21 \cdot C_D} \right)^{1/2} = \frac{8.44}{C_D^{1/2}}$$

Also,

$$Re_D = \frac{VD}{\nu} = \frac{V(0.003 \text{ m})}{14.8 \times 10^{-6} \text{ m}^2/\text{s}} = 202.7 \text{ V}$$

From Fig. 7.8, the foregoing results yield $C_D = 0.4$, for which

$$V \approx 13.3 \text{ m/s}$$

and $Re_D \approx 2700$.

(b) Applying an energy balance to a control surface about the bead, Eq. 5.15 may be obtained, with $\dot{E}_g = 0$, $q_s^* = 0$, $A_{s(c,r)} = \pi D^2$, and $\forall = \pi D^3/6$. Hence,

$$\rho_c g \frac{dT}{dt} = -\left( \frac{6}{D} \right) \left[ \bar{h} (T - T_{\infty}) + \varepsilon_g \sigma \left( T^4 - T_{sur}^4 \right) \right]$$

where $\bar{h}$ is given by the Whitaker correlation,

$$Nu_D = 2 + \left( 0.4 Re_D^{1/2} + 0.06 Re_D^{2/3} \right) Pr^{0.4} \left( \mu / \mu_s \right)^{1/4}$$

Using the IHT Lumped Capacitance Model with the appropriate Correlations and Properties Tool Pads, the foregoing integration was evaluated numerically, and the following temperature history was obtained.

Continued...
The desired temperature of $T = 80^\circ\text{C} = 353 \text{ K}$ is obtained at $t = 7\text{s}$, and at $t = 20\text{s}$ the temperature is within $1.5^\circ\text{C}$ of ambient conditions.

COMMENTS: (1) With $\text{Bi} = \left(\overline{h} + h_{\text{rad}}\right)r_0/k = (218 + 30) \text{ W/m}^2\cdot\text{K}(0.0005 \text{ m})/1.4 \text{ W/m} \cdot \text{K} = 0.089$ at $T = 750 \text{ K}$, the lumped capacitance assumption is satisfactory and becomes increasingly better as $h_{\text{rad}}$ decreases with decreasing $T$.

(2) The small bead diameter and large velocity provide a large convection coefficient, which insures rapid cooling to the desired temperature. Even at the maximum temperature ($T = 750 \text{ K}$), $h_{\text{rad}} = 30 \text{ W/m}^2\cdot\text{K}$ makes a small contribution to the cooling process.
**PROBLEM 7.78**

**KNOWN:** Velocity and temperature of combustion gases. Diameter and emissivity of thermocouple junction. Combustor temperature.

**FIND:** (a) Time to achieve 98% of maximum thermocouple temperature rise, (b) Steady-state thermocouple temperature, (c) Effect of gas velocity and thermocouple emissivity on measurement error.

**SCHEMATIC:**

- $1 \leq V \leq 25 \text{ m/s}$
- $T_{\infty} = 1000 \text{ K}$
- $D = 0.001 \text{ m}$
- $T_c = 400 \text{ K}$

**ASSUMPTIONS:** (1) Validity of lumped capacitance analysis, (2) Constant properties, (3) Negligible conduction through lead wires, (4) Radiation exchange between small surface and a large enclosure (parts b and c).

**PROPERTIES:** Thermocouple (given): $0.1 \leq \varepsilon \leq 1.0$, $k = 100 \text{ W/m-K}$, $c = 385 \text{ J/kg-K}$, $\rho = 8920 \text{ kg/m}^3$;
Gases (given): $k = 0.05 \text{ W/m-K}$, $\nu = 50 \times 10^{-6} \text{ m}^2/\text{s}$, $Pr = 0.69$.

**ANALYSIS:** (a) If the lumped capacitance analysis may be used, it follows from Equation 5.5 that

$$t = \frac{\rho V c}{h A_s} \ln \frac{T_i - T_{\infty}}{T - T_{\infty}} = \frac{D \rho c}{6h} \ln (50).$$

Neglecting the viscosity ratio correlation for variable property effects, use of $V = 5 \text{ m/s}$ with the Whitaker correlation yields

$$\bar{h} = \frac{0.05 \text{ W/m-K}}{0.001 \text{ m}} \left[ 2 + \left( 0.4 \frac{100}{2} + 0.06 \left( \frac{100}{2} \right)^{2/3} \right) (0.69)^{0.4} \right] = 328 \text{ W/m}^2 \cdot \text{K}$$

Since $Bi = \frac{\bar{h} (r_b/3) / k}{5.5 \times 10^4}$, the lumped capacitance method may be used. Hence,

$$t = \frac{0.001 \text{ m} \left( 8920 \text{ kg/m}^3 \right) 385 \text{ J/kg-K}}{6 \times 328 \text{ W/m}^2 \cdot \text{K}} \ln (50) = 6.83 \text{s}$$

(b) Performing an energy balance on the junction and evaluating radiation exchange from Equation 1.7,

$$q_{\text{conv}} = q_{\text{rad}}.$$ Hence, with $\varepsilon = 0.5$,

$$\bar{h} A_s (T_{\infty} - T) = \varepsilon A_s \sigma \left( T^4 - T_c^4 \right)$$

$$1000 (T - T) = 0.5 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left[ T^4 - (400)^4 \right] K^4.$$

$$T = 936 \text{ K}$$

(c) Using the *IHT First Law Model for a Solid Sphere* with the appropriate *Correlation* for external flow from the Tool Pad, parametric calculations were performed to determine the effects of $V$ and $\varepsilon$, and the following results were obtained.

Continued...
Since the temperature recorded by the thermocouple junction increases with increasing V and decreasing ε, the measurement error, $T_\infty - T$, decreases with increasing V and decreasing ε. The error is due to net radiative transfer from the junction (which depresses T) and hence should decrease with decreasing ε. For a prescribed heat loss, the temperature difference ($T_\infty - T$) decreases with decreasing convection resistance, and hence with increasing $h(V)$.

**COMMENTS:** To infer the actual gas temperature (1000 K) from the measured result (936 K), correction would have to be made for radiation exchange with the cold surroundings.
**PROBLEM 7.79**

**KNOWN:** Diameter, emissivity and temperature of a thermocouple junction exposed to hot gases flowing through a duct of prescribed surface temperature.

**FIND:** (a) Relative magnitudes of gas and thermocouple temperatures if the duct surface temperature is less than the gas temperature, (b) Gas temperature for prescribed conditions, (c) Effect of Velocity and emissivity on measurement error.

**SCHEMATIC:**

![Diagram showing Thermocouple junction exposed to hot gases and a duct with surface temperature T_s = 175 °C.]

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Junction is diffuse-gray, (3) Duct forms a large enclosure about the junction, (4) Negligible heat transfer by conduction through the thermocouple leads, (5) Gas properties are those of atmospheric air.

**PROPERTIES:** Table A-4, Air (T_g = 650 K, 1 atm): \( \nu = 60.21 \times 10^{-6} \text{ m}^2/\text{s}, k = 0.0497 \text{ W/m-K}, \text{Pr} = 0.690, \mu = 322.5 \times 10^{-7} \text{ N-s/m}^2 \); Air (T_j = 593 K, 1 atm): \( \mu = 304 \times 10^{-7} \text{ N-s/m}^2 \).

**ANALYSIS:** (a) From an energy balance on the thermocouple junction, \( q_{\text{conv}} = q_{\text{rad}} \). Hence, \( \varepsilon \sigma A (T_g^4 - T_j^4) \) or \( T_g - T_j = \frac{\varepsilon}{h} \sigma (T_j^4 - T_s^4) \).

If \( T_s < T_j \), it follows that \( T_j < T_g \). 

(b) Neglecting the variable property correction, \( (\mu/\mu_s)^{1/4} = (322.5/304)^{1/4} = 1.01 \approx 1.00 \), and using

\[
\text{Re}_D = \frac{VD}{\nu} = \frac{3 \text{ m/s} (0.002 \text{ m})}{60.21 \times 10^{-6} \text{ m}^2/\text{s}} = 100
\]

the Whitaker correlation for a sphere gives

\[
\bar{h} = \frac{0.0497 \text{ W/m-K}}{0.002 \text{ m}} \left\{ 2 + \left[ 0.4 (100)^{1/2} + 0.06 (100)^{2/3} \right] (0.69)^{0.4} \right\} = 163 \text{ W/m}^2 \cdot \text{K}.
\]

Hence

\[
(T_g - 593 \text{ K}) = \frac{0.6}{163 \text{ W/m}^2 \cdot \text{K}} \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left[ (593 \text{ K})^4 - (448 \text{ K})^4 \right] = 17 \text{ K}
\]

\( T_g = 610 \text{ K} = 337^\circ \text{C}. \)

(c) With \( T_g \) fixed at 610 K, the IHT *First Law* Model was used with the *Correlations* and *Properties* Tool Pads to compute the measurement error as a function of \( V \) and \( \varepsilon \). 

Continued...
Since the convection resistance decreases with increasing \( V \), the junction temperature will approach the gas temperature and the measurement error will decrease. Since the depression in the junction temperature is due to radiation losses from the junction to the duct wall, a reduction in \( \varepsilon \) will reduce the measurement error.

**COMMENTS:** In part (b), calculations could be improved by evaluating properties at 610 K (instead of 650 K).
**PROBLEM 7.80**

**KNOWN:** Diameter and emissivity of a thermocouple junction exposed to hot gases of prescribed velocity and temperature flowing through a duct of prescribed surface temperature.

**FIND:** (a) Thermocouple reading for gas at atmospheric pressure, (b) Thermocouple reading when gas pressure is doubled.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Junction is diffuse-gray, (3) Duct forms a large enclosure about junction, (4) Negligible heat loss by conduction through thermocouple leads, (5) Gas properties are those of air, (6) Perfect gas behavior.

**PROPERTIES:** Table A-4, Air ($T_g = 773$ K, 1 atm): $v = 80.5 \times 10^{-6}$ m$^2$/s, $k = 0.0561$ W/m$\cdot$K, $Pr = 0.705$.

**ANALYSIS:** (a) Performing an energy balance on the junction

\[
q_{\text{conv}} = q_{\text{rad}} \quad (g \rightarrow j) \quad (j \rightarrow s)
\]

\[
\bar{h}A(T_g - T_j) = \varepsilon \sigma A (T_j^4 - T_s^4).
\]

Neglecting the variable property correction, $(\mu/\mu_s)^{1/4}$, and using

\[
Re_D = \frac{VD}{v} = \frac{3 \text{ m/s} \times 0.002 \text{ m}}{80.5 \times 10^{-6} \text{ m}^2/\text{s}} = 74.5
\]

the Whitaker correlation for a sphere gives,

\[
\bar{h} = \frac{0.0561 \text{ W/m} \cdot \text{K}}{0.002 \text{ m}} \left[2 + \left[0.4 \left(74.5\right)^{1/2} + 0.06 \left(74.5\right)^{2/3}\right] \left(0.705\right)^{0.4}\right] = 166 \text{ W/m}^2 \cdot \text{K.}
\]

\[
166\left(773 - T_j\right) = 0.6 \times 5.67 \times 10^{-8} \left[T_j^4 - (473)^4\right]
\]

and from a trial-and-error solution,

\[
T_j = 726 \text{ K.}
\]

(b) Assuming all properties other than $v$ to remain constant with a change in pressure, $\uparrow$ $p$ by 2 will $\downarrow$ $v$ by 2 and hence $\uparrow$ $Re_D$ by 2, giving $Re_D = 149$. Hence

\[
\bar{h} = \frac{0.0561}{0.002} \left[2 + \left[0.4 \left(149\right)^{1/2} + 0.06 \left(149\right)^{2/3}\right] \left(0.705\right)^{0.4}\right] = 216 \text{ W/m}^2 \cdot \text{K.}
\]

\[
216\left(773 - T_j\right) = 0.6 \times 5.67 \times 10^{-8} \left[T_j^4 - (473)^4\right]
\]

and from a trial-and-error solution

\[
T_j = 735 \text{ K.}
\]

**COMMENTS:** The thermocouple error will $\downarrow$ with $\uparrow$ $h$, which $\uparrow$ with $\uparrow$ $p$. 

<
PROBLEM 7.81

KNOWN: Velocity and temperature of helium flow over graphite coated uranium oxide pellets. Pellet and coating diameters and thermal conductivity. Surface temperature of coating.

FIND: (a) Rate of heat transfer, (b) Volumetric generation rate in pellet and pellet surface temperature, (c) Radial temperature distribution in pellet, (d) Effect of gas velocity on center and surface temperatures.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, steady conduction in the radial direction, (2) Uniform generation, (3) Constant properties, (4) Negligible radiation, (5) Negligible contact resistance.

PROPERTIES: Table A.4. Helium ($T_\infty = 500$ K, 1 atm): $\nu = 290 \times 10^{-6}$ m$^2$/s, $k = 0.22$ W/m·K, $Pr = 0.67$, $\mu = 283 \times 10^{-7}$ N·s/m$^2$; ($T_{s,o} = 1300$ K, with extrapolation): $\mu = 592 \times 10^{-7}$ N·s/m$^2$.

ANALYSIS: (a) The heat transfer rate is $q = \bar{h}A_s \left(T_{s,o} - T_\infty\right)$, where the convection coefficient can be estimated from $
abla \text{Nu}_D = 2 + \left(0.4 \text{Re}_D^{1/2} + 0.06 \text{Re}_D^{2/3}\right) Pr^{0.4} \left(\mu_{\infty}/\mu_s\right)^{1/4}$, where

\[
\text{Re}_D = \frac{VD_o}{\nu} = \frac{20 \text{ m/s} \times 0.012 \text{ m}}{290 \times 10^{-6} \text{ m}^2/\text{s}} = 828
\]

\[
\nabla \text{Nu}_D = 2 + \left[0.4 \left(828\right)^{1/2} + 0.06 \left(828\right)^{2/3}\right] \left(0.67\right)^{0.4} \left(283/592\right)^{1/4} = 13.9
\]

\[
\bar{h} = \frac{k}{D_o} \nabla \text{Nu}_D = \frac{0.22 \text{ W/m·K} \times 13.9}{0.012 \text{ m}} = 255 \text{ W/m}^2\cdot\text{K}.
\]

Hence, $q = 255 \text{ W/m}^2\cdot\text{K} \times \pi \left(0.012 \text{ m}\right)^2 \left(1300 - 500\right) \text{K} = 92.2 \text{ W}$.

(b) The volumetric heat rate in the pellet is

\[
\dot{q} = \frac{q}{\pi D_i^3/6} = \frac{6 \times 92.2 \text{ W}}{\pi \left(0.01 \text{ m}\right)^3} = 1.76 \times 10^8 \text{ W/m}^3
\]

The inner surface temperature of the coating is equal to the pellet surface temperature,

\[
T_{s,i} = T_{s,o} = q \frac{1}{4\pi k_g} \left(\frac{1}{\eta_i} - \frac{1}{\eta_o}\right) = \frac{92.2 \text{ W}}{4\pi \left(2 \text{ W/m·K}\right)} \left(\frac{1}{0.005 \text{ m}} - \frac{1}{0.006 \text{ m}}\right) = 122.3 \text{ K}
\]

\[
T_{s,i} = 1300 \text{ K} + 122.3 \text{ K} = 1422 \text{ K}.
\]

(c) The heat equation for the spherical pellet reduces to

\[
\frac{k_p}{r^2} \frac{d}{dr} \left(r^2 \frac{dT}{dr}\right) = -\dot{q}
\]

Integrating twice,

\[
r^2 \frac{dT}{dr} = -\frac{\dot{q}}{3k_p} r^3 + C_1 \quad \frac{dT}{dr} = -\frac{\dot{q}}{3k_p} r + C_1
\]

Continued...
PROBLEM 7.81 (Cont.)

\[ T = -\frac{q}{6k_p}r^2 - \frac{C_1}{r} + C_2. \]

Applying boundary conditions,

\[ r = 0: \quad \frac{dT}{dr}_{r=0} = 0 \quad \rightarrow \quad C_1 = 0 \]

\[ r = r_i: \quad T(r_i) = T_{s,i} \quad \rightarrow \quad C_2 = T_{s,i} + \left(\frac{q}{6k_p}\right)\eta_i^2. \]

Hence the temperature distribution is

\[ T(r) = T_{s,i} + \left(\frac{q}{6k_p}\right)\left(\eta_i^2 - r^2\right) = T(0) - \left(\frac{q}{6k_p}\right)r^2 \]

where the temperature at the pellet center is \( T(0) = T_{s,i} + \left(\frac{q}{6k_p}\right)\eta_i^2 \).

For the prescribed conditions,

\[ T(0) = 1422 \text{ K} + \left(1.76 \times 10^8 \text{ W/m}^3 / 6 \times 2 \text{ W/m} \cdot \text{K}(0.005 \text{ m})^2 \right) = 1789 \text{ K}. \]

(d) With \( q = 1.5 \times 10^8 \text{ W/m}^3 \), parametric calculations were performed using the IHT Model for One-Dimensional, Steady-State Conduction in a sphere, with the surface condition,

\[ q^* (\eta_i) = \left(T_{s,i} - T_\infty\right) / R_{t,i}, \]

where the total thermal resistance, \( R_{t,i} = R_{t,i}^c / 4\pi \eta_i^2 \), is

\[ R_{t,i} = R_{tcnd} + R_{tcnv} = \frac{1}{4\pi k_p} \left(\frac{1}{\eta_i} - \frac{1}{\eta_0}\right) + \frac{1}{4\pi \eta_i^2 h}. \]

The Correlations and Properties Tool Pads were used to evaluate the convection coefficient, and the following results were obtained.

As expected, all temperatures increase with decreasing \( V \), while fixed values of \( q \), and hence \( q(r_i) \), and \( R_{tcnd} \) provide fixed values of \( (T(0) - T_{s,i}) \) and \( (T_{s,i} - T_{s,o}) \), respectively.

COMMENTS: In a more detailed analysis, radiation heat transfer, which would decrease the temperatures, should be considered.
PROBLEM 7.82

KNOWN: Initial temperature, dimensions and properties of chip and solder connectors. Velocity, temperature and properties of liquid.

FIND: (a) Ratio of time constants (chip-to-solder), (b) Chip-to-solder temperature difference after 0.25s of heating.

SCHEMATIC:

ASSUMPTIONS: (1) Solder balls and chips are spatially isothermal, (2) Negligible heat transfer from sides of chip, (3) Top and bottom surfaces of chip act as flat plates in turbulent parallel flow, (4) Heat transfer from solder balls may be approximated as that from an isolated sphere, (5) Constant properties.

PROPERTIES: Given. Dielectric liquid: \( k = 0.064 \, \text{W/m} \cdot \text{K}, \nu = 10^{-6} \, \text{m}^2/\text{s}, \text{Pr} = 25 \). Silicon chip: \( k = 150 \, \text{W/m} \cdot \text{K}, \rho = 2300 \, \text{kg/m}^3, c_p = 700 \, \text{J/kg} \cdot \text{K} \); Solder ball: \( k = 40 \, \text{W/m} \cdot \text{K}, \rho = 10,000 \, \text{kg/m}^3, c_p = 150 \, \text{J/kg} \cdot \text{K} \).

ANALYSIS: (a) From Eq. 5.7, the thermal time constant is \( \tau = \left( \frac{\rho c}{k} \right) \frac{L^2}{A} \). Hence,

\[
\frac{\tau_{t,ch}}{\tau_{t,sld}} = \frac{1}{2} \frac{h_{ch}}{h_{sld}} \left( \frac{\pi D^2}{\pi D^2 / 6} \right) = 3 \frac{h_{sld}}{h_{ch}}
\]

The convection coefficient for the chip may be obtained from Eq. 7.44, with \( \text{Re}_L = \frac{VL}{\nu} = 0.2 \, \text{m/s} \times 0.01 \, \text{m} / 10^{-6} \, \text{m}^2/\text{s} = 2000 \).

\[
h_{ch} = \frac{0.064 \, \text{W/m} \cdot \text{K}}{0.01 \, \text{m}} (0.037)(2000)^{4/5} (25)^{1/3} = 302 \, \text{W/m}^2 \cdot \text{K}
\]

The convection coefficient for the solder may be obtained from Eq. 7.59, with \( \text{Re}_D = \frac{VD}{\nu} = 0.2 \, \text{m/s} \times 0.001 \, \text{m} / 10^{-6} \, \text{m}^2/\text{s} = 200 \). Neglecting the effect of the viscosity ratio,

\[
h_{sld} = \frac{0.064 \, \text{W/m} \cdot \text{K}}{0.01 \, \text{m}} \left\{ 2 + \left[ 0.4(200)^{1/2} + 0.06(200)^{2/3} \right] (25)^{0.4} \right\} = 1916 \, \text{W/m}^2 \cdot \text{K}
\]

Hence,

\[
\frac{\tau_{t,ch}}{\tau_{t,sld}} = 3 \left( \frac{2300 \, \text{kg/m}^3 \times 700 \, \text{J/kg} \cdot \text{K}}{10,000 \, \text{kg/m}^3 \times 150 \, \text{J/kg} \cdot \text{K}} \right) \frac{1916 \, \text{W/m}^2 \cdot \text{K}}{302 \, \text{W/m}^2 \cdot \text{K}} = 20.4
\]

Hence, the solder responds much more quickly to the convective heating.

(b) From Eq. 5.6, the chip-to-solder temperature difference may be expressed as

Continued …..
PROBLEM 7.82 (Cont.)

\[ T_{ch} - T_{sld} = (T_i - T_\infty) \left\{ \exp \left[ -\left( \frac{2h}{\rho c t} \right)_{ch} t \right] - \exp \left[ -\left( \frac{6h}{\rho c D} \right)_{sld} t \right] \right\} \]

\[ T_{ch} - T_{sld} = 60^\circ C \left\{ \exp \left[ -\frac{604 \text{ W/m}^2\cdot\text{K}}{1610 \text{ J/m}^2\cdot\text{K}} \cdot 0.25 \text{s} \right] - \exp \left[ -\frac{11,496 \text{ W/m}^2\cdot\text{K}}{1500 \text{ J/m}^2\cdot\text{K}} \cdot 0.25 \text{s} \right] \right\} \]

\[ T_{ch} - T_{sld} = 60^\circ C \{0.910 - 0.147\} = 45.8^\circ C \]

COMMENTS: (1) The foregoing process is used to subject soldered chip connections (a major reliability issue) to rapid and intense thermal stresses. (2) Some heat transfer by conduction will occur between the chip and solder balls, thereby reducing the temperature difference and thermal stress. (3) Constriction of flow between the chip and substrate will reduce \( \bar{h}_{sld} \), as well as \( \bar{h}_{ch} \) at the lower surface of the chip, relative to values predicted by the correlations. The corresponding time constants would be increased accordingly. (4) With \( Bi_{ch} = \frac{\bar{h}_{ch}}{k_{chip}} \left( t/2 \right) < 0.001 \) and \( Bi_{sld} = \frac{\bar{h}_{sld}}{k_{sld}} (D/6) < 0.008 \), the lumped capacitance analysis is appropriate for both components.
**PROBLEM 7.83**

**KNOWN:** Conditions associated with Example 7.6, but with reduced longitudinal and transverse pitches.

**FIND:** (a) Air side convection coefficient, (b) Tube bundle pressure drop, (c) Heat rate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Uniform tube surface temperature.

**PROPERTIES:** Table A-4. Atmospheric air ($T_\infty = 288$ K): $\rho = 1.217$ kg/m$^3$, $\nu = 14.82 \times 10^{-6}$ m$^2$/s, $k = 0.0253$ W/m·K, $Pr = 0.71$, $c_p = 100.7$ J/kg·K; ($T_s = 343$ K): $Pr = 0.701$.

**ANALYSIS:**

(a) From the tube pitches, find

$$S_D = \left[ \frac{S_T^2}{2} + \left( \frac{S_T}{2} \right)^2 \right]^{1/2} = \left[ \frac{(20.5)^2}{2} + \left( \frac{10.25}{2} \right)^2 \right]^{1/2} = 22.91 \text{ mm}$$

$$\left( \frac{S_T + D}{2} \right) = \left( \frac{20.5 + 16.4}{2} \right) = 18.45 \text{ mm}.$$  

Hence, the maximum velocity occurs on the transverse plane, and

$$V_{\text{max}} = \frac{S_T}{S_T - D} \cdot \frac{6 \text{ m/s}}{30 \text{ m/s}} = 6 \text{ m/s}.$$  

With $Re_{D,\text{max}} = \frac{V_{\text{max}} D}{\nu} = \frac{30 \text{ m/s}}{14.82 \times 10^{-6} \text{ m}^2/\text{s}} = 3.32 \times 10^4$

and $(S_T/S_L) = 1 < 2$, it follows from Table 7.7 that

$C = 0.35 \quad m = 0.60$.

Hence, from the Zhukauskas correlation and Table 7.8 ($C_2 = 0.95$),

$$\bar{Nu}_D = (0.95) 0.35 \cdot 0.6 \cdot \Re_{D,\text{max}} \cdot Pr^{0.36} \left( \frac{Pr}{Pr_s} \right)^{1/4} = 152 \quad \frac{k}{D} = 0.0253 \text{ W/m·K}.$$  

(b) From the Zhukauskas relation

$$\Delta p = N_L \chi \left( \frac{\rho V_{\text{max}}^2}{2} \right) f.$$  

With $Re_{D,\text{max}} = 3.32 \times 10^4$, $Pr = (S_T/D) = 1.25$ and $(Pr_s/Pr) = 1$, it follows from Fig. 7.14 that

$\chi \approx 1.02 \quad f \approx 0.38$.  

Continued …..
PROBLEM 7.83 (Cont.)

Hence

\[ \Delta p = 7 \times 1.02 \frac{1.217 \text{ kg/m}^3 (30 \text{ m/s})^2}{2} 0.38 = 1490 \text{ N/m}^2 \]

\[ \Delta p = 0.0149 \text{ bar.} \]

(c) The air outlet temperature is obtained from

\[ T_s - T_o = (T_s - T_i) \exp \left( -\frac{\pi DN_\bar{h}}{\rho VN_\bar{T} \bar{S}_t c_p} \right) \]

\[ T_s - T_o = 55^\circ \text{C} \exp \left\{ -\pi \left( 0.0164 \text{ m} \right) 56 \left( 234 \text{ W/m}^2 \cdot \text{K} \right) \right\} \]

\[ 1.217 \text{ kg/m}^3 \times 6 \text{ m/s} \times 8 \times 0.0205 \text{ m} \times 1007 \text{ J/kg} \cdot \text{K} \]

\[ T_s - T_o = 31.4^\circ \text{C} \]

\[ T_o = 38.5^\circ \text{C}. \]

The log mean temperature difference is

\[ \Delta T_{l/m} = \frac{\Delta T_i - \Delta T_o}{\ln (\Delta T_i / \Delta T_o)} = \frac{(55 - 31.4)^\circ \text{C}}{\ln (55/31.4)} = 42.1^\circ \text{C} \]

\[ q' = \frac{N_\bar{h} \pi D \Delta T_{l/m}}{56 \left( 234 \text{ W/m}^2 \cdot \text{K} \right) \pi (0.0164 \text{ m}) 42.1^\circ \text{C} \]

\[ q' = 28.4 \text{ kW/m}. \]

COMMENTS: Making the tube bank more compact has the desired effect of increasing the convection coefficient and therefore the heat transfer rate. However, it has the adverse effect of increasing the pressure drop and hence the fan power requirement. Note that the convection coefficient increases by a factor of \((234/135.6) = 1.73\), while the pressure drop increases by a factor of \((1490/246) = 6.1\). This disparity is a consequence of the fact that \( \bar{h} \sim V_{max}^{0.6} \), while \( \Delta p \sim V_{max}^2 \). Hence any increase in \( V_{max} \), which would result from a more closely spaced arrangement, would more adversely affect \( \Delta p \) than favorably affect \( \bar{h} \).
PROBLEM 7.84

KNOWN: Surface temperature and geometry of a tube bank. Velocity and temperature of air in cross flow.

FIND: (a) Total heat transfer, (b) Air flow pressure drop.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible radiation, (3) Uniform surface temperature.

PROPERTIES: Table A-4, Atmospheric air (T_{\infty} = 298 K): v = 15.8 \times 10^{-6} m^2/s, k = 0.0263 W/m\cdot K, Pr = 0.707, c_p = 1007 J/kg\cdot K, \rho = 1.17 kg/m^3; (T_s = 373 K): Pr = 0.695.

ANALYSIS: (a) The total heat transfer rate is

\[ q = \frac{\dot{h} \pi D L}{\ell n\left(\frac{T_s - T_i}{T_s - T_o}\right)} = \frac{\dot{h} \pi D L}{\ell n\left(\frac{T_s - T_i}{T_s - T_o}\right)} \]

With \( V_{\text{max}} = \frac{S_T}{S_T - D} \cdot \frac{15 \text{ mm}}{5 \text{ mm}} = 15 \text{ m/s} = 15 \text{ m/s}, \) \( \text{Re}_{D,\text{max}} = \frac{15 \text{ m/s} \cdot (0.01 \text{ m})}{15.8 \times 10^{-6} \text{ m}^2/\text{s}} = 9494. \) Tables 7.7 and 7.8 give C = 0.27, m = 0.63 and C_2 = 0.99. Hence, from the Zhukauskas correlation

\[ \overline{\text{Nu}} = 0.99 \times 0.27 (9494)^{0.63} (0.707)^{0.36} (0.707 / 0.695)^{1/4} = 75.9 \]

\[ \overline{\dot{h}} = \overline{\text{Nu}} \cdot k / D = 75.9 \times 0.0263 \text{ W/m} \cdot \text{K}/0.01 \text{ m} = 200 \text{ W/m}^2 \cdot \text{K} \]

\[ T_s - T_o = (T_s - T_i) \exp\left(-\frac{\pi D N\dot{h}}{\rho V N T_S T_c \rho}ight) \approx 75^\circ \text{C} \exp\left(-\frac{\pi \times 0.01 \text{ m} \times 196 \times 200 \text{ W/m}^2 \cdot \text{K}}{1.17 \text{ kg/m}^3 \times 5 \text{ m/s} \times 14 \times 0.015 \text{ m} \times 1007 \text{ J/kg} \cdot \text{K}}\right) \]

Hence

\[ T_s - T_o = 27.7^\circ \text{C} \]

Hence

\[ q = 200 \text{ W/m}^2 \cdot \text{K} \times 196\pi \left(0.01 \text{ m}\right) \frac{75^\circ \text{C} - 27.7^\circ \text{C}}{\ell n(75/27.7)} = 58.5 \text{ kW}. \]

(b) With \( \text{Re}_{D,\text{max}} = 9494, (P_T - 1)/(P_L - 1) = 1, \) Fig. 7.13 yields \( f = 0.32 \) and \( \chi = 1. \) Hence,

\[ \Delta p = N \chi \left(\rho V_{\text{max}}^2 / 2\right) f = 14 \times 1 \left(\frac{1.17 \text{ kg/m}^3 \left(15 \text{ m/s}\right)^2}{2}\right) 0.32 \]

\[ \Delta p = 590 \text{ N/m}^2 = 5.9 \times 10^{-3} \text{ bar}. \]

COMMENTS: The heat transfer rate would have been substantially overestimated (93.3 kW) if the inlet temperature difference \( (T_s - T_i) \) had been used in lieu of the log-mean temperature difference.
PROBLEM 7.85

KNOWN: Surface temperature and geometry of a tube bank. Inlet velocity and inlet and outlet temperatures of air in cross flow over the tubes.

FIND: Number of tube rows needed to achieve the prescribed outlet temperature and corresponding pressure of drop of air.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Negligible temperature drop across tube wall and uniform outer surface temperature, (3) Constant properties, (4) $C_2 \approx 1$.

PROPERTIES: Table A-4, Atmospheric air. ($\bar{T} = (T_i + T_o)/2 = 323K$): $\rho = 1.085 \text{ kg/m}^3$, $c_p = 1007 \text{ J/kg} \cdot \text{K}$, $\nu = 18.2 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 0.028 \text{ W/m} \cdot \text{K}$, $Pr = 0.707$; $(T_i = 298K)$: $\rho = 1.17 \text{ kg/m}^3$; $(T_k = 373K)$: $Pr = 0.695$.

ANALYSIS: The temperature difference $(T_s - T)$ decreases exponentially in the flow direction, and at the outlet

$$
\frac{T_s - T_o}{T_s - T_i} = \exp\left(-\frac{\pi DNL h}{\rho V S T c_p}\right)
$$

where $N_L = N / N_T$. Hence,

$$
N_L = -\frac{\rho V S T c_p}{\pi D h} \ln\left(\frac{T_s - T_o}{T_s - T_i}\right)
$$

With $V_{max} = \left[\frac{S_T}{(S_T - D)} \right] V = 15 \text{ m/s}$, $Re_{D,max} = V_{max}D/\nu = 8240$. Hence, with $S_T / S_L = 1 > 0.7$, $C = 0.27$ and $m = 0.63$ from Table 7.7, and the Zhukauskas correlation yields

$$
\bar{Nu}_D = C C_2 Re_{D,max}^{1/4} Pr^{0.36} \left(\frac{Pr}{Pr_T}\right)^{1/4} = 0.27 \times 1(8240)^{0.63} (0.707)^{0.36} (0.707 / 0.695)^{1/4} = 70.1
$$

$$
\frac{k}{D \bar{Nu}_D} = 0.028 \text{ W/m} \cdot \text{K} \quad 70.1 = 196.3 \text{ W/m}^2 \cdot \text{K}
$$

Hence,

$$
N_L = -\frac{1.17 \text{ kg/m}^3 (5 \text{ m/s}) 0.015 (1007 \text{ J/kg} \cdot \text{K})}{\pi (0.01m) 196.3 \text{ W/m}^2 \cdot \text{K} \ln\left(\frac{25}{75}\right)} = 15.7
$$

and 16 tube rows should be used $N_L = 16$.

With $Re_{D,max} = 8240$, $P_L = 1.5$ and $(P_T - 1)/(P_L - 1) = 1$, $f = 0.35$ and $\chi = 1$ from Fig. 7.13. Hence,

$$
\Delta p = N_L \chi \left(\frac{\rho V_{max}^2}{2}\right) f = 16 \left[\frac{1.085 \text{ kg/m}^3 \times (15 \text{ m/s})^2}{2}\right] 0.35 = 684 \text{ N/m}^2
$$

COMMENTS: (1) With $C_2 = 0.99$ for $N_L = 16$ from Table 7.8, assumption 4 is appropriate. (2) Note use of the density evaluated at $T_i = 298K$ in Eq. (1).
PROBLEM 7.86

KNOWN: Geometry, surface temperature, and air flow conditions associated with a tube bank.

FIND: Rate of heat transfer per unit length.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible radiation effects, (3) Gas properties are approximately those of air.

PROPERTIES: Table A-4, Air (300K, 1 atm): Pr = 0.707; Table A-4, Air (700K, 1 atm): ν = 68.1 × 10^{-6} m^2/s, k = 0.0524 W/m·K, Pr = 0.695, ρ = 0.498 kg/m^3, c_p = 1075 J/kg·K.

ANALYSIS: The rate of heat transfer per unit length of tubes is

\[ q' = \bar{h} \pi D \frac{T_S - T_t}{\ln[(T_S - T_t)/(T_S - T_0)]}. \]

With \( V_{\text{max}} = \frac{S_T}{S_T - D} = \frac{20}{10} = 2 \text{ m/s} \), \( \text{Re}_{D,\text{max}} = \frac{V_{\text{max}} D}{\nu} = \frac{10 \text{ m/s} \times 0.01 \text{ m}}{68.1 \times 10^{-6} \text{ m}^2/\text{s}} = 1468. \)

Tables 7.7 and 7.8 give \( C = 0.27, m = 0.63 \) and \( C_2 = 0.97. \) Hence from the Zhukauskas correlation,

\[ \frac{\overline{Nu_D}}{D} = \frac{C C_2 \text{Re}_{D,\text{max}}^{0.36} \left(Pr/Pr_S\right)^{1/4}}{0.26(1468)^{0.63}(0.695)^{0.36}(0.695/0.707)^{1/4}} = 22.4 \]

\[ \bar{h} = \frac{k}{D} \frac{\overline{Nu_D}}{D} = 0.0524 \text{ W/m·K} \times 22.4/0.01 \text{ m} = 117 \text{ W/m}^2·\text{K}. \]

Hence,

\[ (T_S - T_0) = (T_S - T_t) \exp \left( -\frac{\pi D \bar{h} \overline{Nu_D}}{\rho V N_T S_T c_p} \right) = -400 \text{K} \exp \left( -\frac{\pi \times 0.01 \text{ m} \times 500 \times 117 \text{ W/m}^2·\text{K}}{0.498 \text{ kg/m}^3 \times 50 \text{ (0.02 m)} \times 1075 \text{ J/kg·K}} \right) \]

\[ T_S - T_0 = -201.3 \text{K} \]

and the heat rate is

\[ q' = \left(117 \text{ W/m}^2·\text{K}\right)500\pi(0.01 \text{ m}) \left(\frac{-400 + 201.3}{\ln((-400)/(-201.3))}\right) = -532 \text{ kW/m} \]

COMMENTS: (1) There is a significant decrease in the gas temperature as it passes through the tube bank. Hence, the heat rate would have been substantially overestimated (- 768 kW) if the inlet temperature difference had been used in lieu of the log-mean temperature difference. (2) The negative sign implies heat transfer to the water. (3) If the temperature of the water increases substantially, the assumption of uniform T_S becomes poor. The extent to which the water temperature increases depends on the water flow rate.
PROBLEM 7.87

KNOWN: An air duct heater consists of an aligned arrangement of electrical heating elements with \( S_L = S_T = 24 \text{ mm} \), \( N_L = 3 \) and \( N_T = 4 \). Atmospheric air with an upstream velocity of 12 m/s and temperature of 25°C moves in cross flow over the elements with a diameter of 12 mm and length of 250 mm maintained at a surface temperature of 350°C.

FIND: (a) The total heat transfer to the air and the temperature of the air leaving the duct heater, (b) The pressure drop across the element bank and the fan power requirement, (c) Compare the average convection coefficient obtained in part (a) with the value for an isolated (single) element; explain the relative difference between the results; (d) What effect would increasing the longitudinal and transverse pitches to 30 mm have on the exit temperature of the air, the total heat rate, and the pressure drop?

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible radiation effects, (3) Negligible effect of change in air temperature across tube bank on air properties.

PROPERTIES: Table A-4, Air \((T_i = 298, 1 \text{ atm})\): \( \rho = 1.171 \text{ kg/m}^3 \), \( c_p = 1007 \text{ J/kg K} \); Air \((T_m = (T_i + T_o)/2 = 309 \text{ K}, 1 \text{ atm})\): \( \rho = 1.130 \text{ kg/m}^3 \), \( c_p = 1007 \text{ J/kg K} \), \( \mu = 1.89 \times 10^{-5} \text{ N s/m}^2 \), \( k = 0.02699 \text{ W/m K} \), \( Pr = 0.7057 \); Air \((T_s = 623 \text{ K}, 1 \text{ atm})\): \( Pr_s = 0.687 \); Air \((T_f = (T_i + T_o)/2 = 461 \text{ K}, 1 \text{ atm})\): \( \nu = 3.373 \times 10^{-5} \text{ m}^2/\text{s} \), \( k = 0.03801 \text{ W/m K} \), \( Pr = 0.686 \).

ANALYSIS: (a) The total heat transfer to the air is determined from the rate equation, Eq. 7.71,

\[
q = N \left( h_D \pi D \Delta T_{fm} \right)
\]

(1)

where the log mean temperature difference, Eq. 7.69, is

\[
\Delta T_{fm} = \frac{T_S - T_i}{T_S - T_o} \left( \frac{T_S - T_i}{T_S - T_o} \right)
\]

(2)

and from the overall energy balance, Eq. 7.70,

\[
\frac{T_S - T_o}{T_S - T_i} = \exp \left( \frac{\pi DN_D}{\rho VN_T S_T c_p} \right)
\]

(3)

The properties \( \rho \) and \( c_p \) in Eq. (3) are evaluated at the inlet temperature \( T_i \). The average convection coefficient using the Zhukaukus correlation, Eq. 7.67 and 7.68,

\[
\overline{Nu_D} = \frac{h_D}{k} = C \left( \frac{Re_{D,\text{max}}}{Pr} \right)^{0.36} \left( Pr_s \right)^{1/4}
\]

(4)

where \( C = 0.27 \), \( m = 0.63 \) are determined from Table 7.7 for the aligned configuration with \( S_T/S_L = 1 > 0.7 \) and \( 10^3 < Re_{D,\text{max}} \leq 10^5 \). All properties except \( Pr_s \) are evaluated at the arithmetic mean temperature \( T_m = (T_i + T_o)/2 \). The maximum Reynolds number, Eq. 7.62, is

Continued .....
PROBLEM 7.87 (Cont.)

\[ \text{Re}_{D,\text{max}} = \frac{\rho V_{\text{max}} D}{\mu} \tag{5} \]

where for the aligned arrangement, the maximum velocity occurs at the transverse plane, Eq. 7.65,

\[ V_{\text{max}} = \frac{S_T}{S_T - D} V \tag{6} \]

The results of the analyses for \( S_T = S_L = 24 \text{ mm} \) are tabulated below.

<table>
<thead>

</tbody>
</table>

(b) The pressure drop across the tube bundle follows from Eq. 7.72,

\[ \Delta p = N_L \chi \left( \frac{\rho V_{\text{max}}^2}{2} \right) f \tag{7} \]

where the friction factor, \( f \), and correction factor, \( \chi \), are determined from Fig. 7.13 using \( \text{Re}_{D,\text{max}} = 1.723 \times 10^4 \).

\( f = 0.2 \quad \chi = 1 \)

Substituting numerical values,

\[ \Delta p = 3 \times 1 \left[ 1.171 \text{ kg/m}^3 \times \left( 24 \text{ m/s} \right)^2 / 2 \right] \times 0.2 \]

\[ \Delta p = 195 \text{ N/m}^2 \]

The fan power requirement is

\[ P = \forall \Delta p = V N_T S_T L \Delta p \tag{8} \]

\[ P = 12 \text{ m/s} \times 4 \times 0.024 \text{ m} \times 0.250 \text{ m} \times 195 \text{ N/m}^2 \]

\[ P = 56 \text{ W} \]

where \( \forall \) is the volumetric flow rate. For this calculation, \( \rho \) in Eq. (7) was evaluated at \( T_m \).

(c) For a single element in cross flow, the average convection coefficient can be estimated using the Churchill-Bernstein correlation, Eq. 7.57,

\[ \overline{\text{Nu}}_D = \frac{\overline{h}_D D}{k} = 0.3 + \frac{0.62 \text{ Re}_D^{1/2} \text{ Pr}^{1/3}}{1 + (0.4 / \text{ Pr})^{2/3}} \left[ 1 + \left( \frac{\text{Re}_D}{282,000} \right)^{5/8} \right]^{4/5} \tag{9} \]

where all properties are evaluated at the film temperature, \( T_f = (T_i + T_o)/2 \). The results of the calculations are

\[ \text{Re}_D = 4269 \quad \overline{\text{Nu}}_{D,1} = 33.4 \quad \overline{h}_{D,1} = 106 \text{ W/m}^2 \cdot \text{K} \]

Continued …..
PROBLEM 7.87 (Cont.)

For the isolated element, \( \bar{h}_{D,1} = 106 \text{ W/m}^2 \cdot \text{K} \), compared to the average value for the array, \( \bar{h}_D = 216 \text{ W/m}^2 \cdot \text{K} \). Because the first row of the array acts as a turbulence grid, the heat transfer coefficient for the second and third rows will be larger than for the first row. Here, the array value is twice that for the isolated element.

(d) The effect of increasing the longitudinal and transverse pitches to 30 mm, should be to reduce the outlet temperature, heat rate, and pressure drop. The effect can be explained by recognizing that the maximum Reynolds number will be decreased, which in turn will result in lower values for the convection coefficient and pressure drop. Repeating the calculations of part (a) for \( S_L = S_T = 30 \text{ mm} \), find

\[
\begin{array}{ccccccc}
V_{\text{max}} & \text{Re}_{D,\text{max}} & \text{Nu}_D & \bar{h}_D & \Delta T_{\text{out}} & q & T_0 \\
(\text{m/s}) & & (\text{W/m}^2 \cdot \text{K}) & & (\text{°C}) & (\text{W}) & (\text{°C}) \\
12 & 1.46 \times 10^4 & 86.7 & 193 & 317 & 6925 & 41.3 \\
\end{array}
\]

and part (b) for the pressure drop and fan power, find

\[ f = 0.18 \quad \chi = 1 \quad \Delta p = 122 \text{ N/m}^2 \quad P = 44 \text{ W} \]
PROBLEM 7.88

KNOWN: Surface temperature and geometry of a tube bank. Velocity and temperature of air in cross-flow.

FIND: (a) Air outlet temperature, (b) Pressure drop and fan power requirements.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible radiation, (3) Air pressure is approximately one atmosphere, (4) Uniform surface temperature.

PROPERTIES: Table A-4. Air (300 K, 1 atm): \( \rho = 1.1614 \text{ kg/m}^3 \), \( c_p = 1007 \text{ J/kg} \cdot \text{K} \), \( v = 15.89 \times 10^{-6} \text{ m}^2/\text{s} \), \( k = 0.0263 \text{ W/m} \cdot \text{K} \), \( Pr = 0.707 \); (373K): \( Pr = 0.695 \).

ANALYSIS: (a) The air temperature increases exponentially, with

\[
T_T = T_s - (T_s - T_t) \exp \left( -\frac{\pi DN h}{\rho V N T_s c_p} \right)
\]

With \( V_{\text{max}} = \frac{S_T}{S_T - D} V = \frac{60}{30} = 2 \text{ m/s} \), \( \text{Re}_{D,\text{max}} = \frac{30 \text{ m/s} \times 0.03 \text{ m}}{15.89 \times 10^{-6} \text{ m}^2/\text{s}} = 56,639 \).

Tables 7.7 and 7.8 give \( C = 0.27 \), \( m = 0.63 \) and \( C_2 = 0.97 \). Hence from the Zhukauskas correlation,

\[
\bar{h} = \frac{\text{Nu}_D}{k/D} = 229 \times 0.0263 \text{ W/m} \cdot \text{K}/0.03 \text{ m} = 201 \text{ W/m}^2 \cdot \text{K}.
\]

Hence,

\[
T_T = 373K - (373 - 300)K \exp \left( -\frac{\pi \times 0.03 \text{ m} \times 70 \times 201 \text{ W/m}^2 \cdot \text{K}}{1.1614 \text{ kg/m}^3 \times 15 \text{ m/s} \times 7 \times 0.06 \text{ m} \times 1007 \text{ J/kg} \cdot \text{K}} \right)
\]

\[
T_T = 373K - 73K \times 0.835 = 312K = 39^\circ \text{C}.
\]

(b) With \( \text{Re}_{D,\text{max}} = 5.66 \times 10^4 \), \( P_L = 2 \), \( (P_T - 1)/(P_L - 1) = 1 \), Fig. 7.13 yields \( f \approx 0.19 \) and \( \chi \approx 1 \). Hence,

\[
\Delta p = N_L \chi \left( \frac{\rho V_{\text{max}}^2}{2} \right) = 10 \left( \frac{1.1614 \text{ kg/m}^3 \times (30 \text{ m/s})^2}{2} \right) 0.19 = 993 \text{ N/m}^2 = 0.00993 \text{ bar}.
\]

The fan power requirement is

\[
P = m_a \Delta p / \rho = \rho V N T_s T_L \Delta p / \rho = 15 \text{ m/s} \times 7 \times 0.06 \text{ m} \times 1 \text{ m} \times 993 \text{ N/m}^2 = 6.26 \text{ kW}.
\]

COMMENTS: The heat rate is

\[
q = \dot{m}_a c_p (T_T - T_t) = \rho V N T_s T_L c_p (T_T - T_t)
\]

\[
q = 1.1614 \text{ kg/m}^3 \times 15 \text{ m/s} \times 7 \times 0.06 \text{ m} \times 1 \text{ m} \times 1007 \text{ J/kg} \cdot \text{K} (312 - 300) \text{ K} = 88.4 \text{ kW}.
\]
PROBLEM 7.89

KNOWN: Characteristics of pin fin array used to enhance cooling of electronic components. Velocity and temperature of coolant air.

FIND: (a) Average convection coefficient for array, (b) Total heat rate and air outlet temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible radiation, (3) One-dimensional conduction in pins, (4) Uniform plate temperature, (5) Plates have a negligible effect on flow over pins, (6) Uniform convection coefficient over all surfaces, corresponding to average coefficient for flow over a tube bank.

PROPERTIES: Air (300 K, 1 atm): \( \rho = 1.1614 \text{ kg/m}^3 \), \( \text{Pr} = 0.707 \), \( c_p = 1007 \text{ J/kg} \cdot \text{K} \), \( \mu = 184.6 \times 10^{-7} \text{ kg/s} \cdot \text{m} \), \( k = 0.0263 \text{ W/m} \cdot \text{K} \). Aluminum (given): \( k = 240 \text{ W/m} \cdot \text{K} \).

ANALYSIS: (a) From the Zhukauskas relation

\[
\overline{Nu}_D = CRe^{m}_{D,\text{max}} \Pr^{0.36} (Pr_{\infty}/Pr_{\text{s}})^{1/4}
\]

\[
(Pr_{\infty}/Pr_{\text{s}})^{1/4} = 1 \quad V_{\text{max}} = \frac{S_T}{S_T - D} V = \frac{4}{4-2} 10 \text{ m/s} = 20 \text{ m/s}
\]

\[
Re_{D,\text{max}} = \frac{1.164 \text{ kg/m}^3 \times 20 \text{ m/s} \times 0.002 \text{ m}}{184.6 \times 10^{-7} \text{ kg/s} \cdot \text{m}} = 2517
\]

From Table 7.7 find \( C = 0.27 \) and \( m = 0.63 \), hence

\[
\overline{Nu}_D = 0.27 (2517)^{0.63} (0.707)^{0.36} = 33.1
\]

\[
\overline{h} = \frac{k}{\overline{Nu}_D} = 33.1 \times \frac{0.0263 \text{ W/m} \cdot \text{K}}{0.002 \text{ m}} = 435 \text{ W/m}^2 \cdot \text{K}.
\]

(b) If \( T_s = 350 \text{ K} \) is taken to be the temperature of all of the heat transfer surfaces, correction must be made for the actual temperature drop along the pins. This is done by introducing the overall surface efficiency \( \eta_o \) and replacing \( \overline{h}A \) by \( \overline{h}A\eta_o \). Hence, to obtain the air outlet temperature, we use

\[
\frac{T_s - T_\infty}{T_s - T_i} = \exp \left( -\frac{\overline{h}A\eta_o}{\text{mc}_p} \right)
\]

where

Continued …..
PROBLEM 7.89 (Cont.)

\[ A_t = N (\pi D L) + 2W^2 - 2N \left(\pi D^2 / 4\right) \]

\[ A_t = 625 \left(\pi \times 0.002 \text{ m} \times 0.1 \text{ m}\right) + 2(0.1 \text{ m})^2 - 2 \times 625\pi (0.002 \text{ m})^2 / 4 = 0.409 \text{ m}^2 \]

Also \( \eta_0 = 1 - \frac{A_t}{A_t} \left(1 - \eta_f\right) \) where \( \eta_f \) is given by Eq. (3.86). With symmetry about the midplane of the pin, \( q_f = M \tanh (mL/2) \). Hence

\[ \eta_f = \frac{q}{q_{\text{max}}} = \frac{\left(\frac{h\pi D k D^2 / 4}{\theta_b \tanh (mL/2)}\right)^{1/2}}{h\pi D (L/2) \theta_b} = \frac{\tanh (mL/2)}{(k/kD)^{1/2} L} \]

or, with \( m = \left[\frac{h\pi D / (k\pi D^2 / 4)}{k/kD}\right]^{1/2} = 2 (k/kD)^{1/2} \),

\[ m = 2 \left(\frac{435 \text{ W/m}^2 \cdot \text{K}}{240 \text{ W/m} \cdot \text{K} \times 0.002 \text{ m}}\right)^{1/2} = 60.2 \text{ m}^{-1} \]

\[ mL/2 = 60.2 \text{ m}^{-1} \times 0.05 \text{ m} = 3.01 \text{ m} \]

\[ \text{and} \quad \tanh (mL/2) = 0.995 \]

\[ \eta_f = \frac{0.995}{3.01} = 0.331. \]

Hence, \( \eta_0 = 1 - \frac{625 \times \pi (0.002 \text{ m})(0.1 \text{ m})}{0.409 \text{ m}^2} (1 - 0.331) = 0.357 \)

\[ \dot{m} = \rho V LN_{\text{T}S} = 1.1614 \text{ kg/m}^3(10 \text{ m/s})0.1 \text{ m}(25)(0.004 \text{ m}) = 0.116 \text{ kg/s}. \]

Now evaluating the air outlet temperature,

\[ \frac{T_o - T_o}{T_s - T_i} = \exp \left(\frac{-435 \text{ W/m}^2 \cdot \text{K} \times 0.409 \text{ m}^2 \times 0.357}{0.116 \text{ kg/s} \times 1007 \text{ J/kg} \cdot \text{K}}\right) = 0.581 \]

\[ T_o = T_s - 0.581(T_s - T_i) = 350 \text{ K} - 0.581(50 \text{ K}) \]

\[ T_o = 321 \text{ K}. \]

The total heat rate is

\[ q = \dot{m} c_p (T_o - T_i) = 0.116 \text{ kg/s} (1007 \text{ J/kg} \cdot \text{K}) 21 \text{ K} = 2453 \text{ W}. \]

**COMMENTS:**

1. The average surface heat flux which can be dissipated by the electronic components is \( q/2W^2 = 122,650 \text{ W/m}^2 \), or 12.3 W/cm\(^2\).  
2. To check the numerical results, compute

\[ \Delta T_{\text{f,m}} = \frac{\Delta T_o - \Delta T_i}{\ln (\Delta T_o / \Delta T_i)} = \frac{29 \text{ K} - 50 \text{ K}}{\ln (29/50)} = 38.6 \text{ K} \]

Hence \( q = hA_t \eta_0 \Delta T_{\text{f,m}} = 435 \text{ W/m}^2 \cdot \text{K} \times 0.409 \text{ m}^2 \times 0.357 \times 38.6 \text{ K} = 2449 \text{ W}. \)
**PROBLEM 7.90**

**KNOWN:** Dimensions and properties of chip, board and pin fin assembly. Convection conditions for chip and board surface. Maximum allowable chip temperature.

**FIND:** Effect of design and operating conditions on maximum chip power dissipation.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Uniform chip temperature, (2) One-dimensional conduction in pins, (3) Insulated pin tips, (4) Negligible radiation, (5) Uniform convection coefficient over pin and base surfaces.

**PROPERTIES:** Table A.1, copper (T ≈ 340 K): $k_p = 397 \text{ W/m} \cdot \text{K}$. Table A.4, air: properties evaluated using IHT Properties Tool Pad.

**ANALYSIS:** The chip heat rate may be expressed as

$$q_c = \frac{A_c \left(T_c - T_{\infty}\right)}{R_{t,c}^\eta + \left(L_b/k_b\right) + \left(1/h_b\right)} + q_t$$

where $A_c = W^2$ and $q_c$ is the total heat rate for the pin array. This heat rate must account for the variation of the air temperature across the array. Hence, the appropriate driving potential is

$$\Delta T_{lm} = \left[\left(T_c - T_i\right) - \left(T_c - T_o\right)\right] / \ln\left[\left(T_c - T_i\right) / \left(T_c - T_o\right)\right]$$

However, the total surface area must account for the finite pin length and the exposed base (prime) surface. Hence, from Eqs. 3.101 and 3.102, with $\Delta T_{lm}$ replacing $\theta_b$,

$$q_t = \frac{\bar{h}A_t \eta_0 \Delta T_{lm}}{\eta_0}$$

where $A_t = N^2 A_f + A_b$, $A_b = A_c - N^2 A_{p,c}$, $A_{p,c} = \pi D_p^2 / 4$ and

$$\eta_0 = 1 - \frac{N^2 A_f}{A_t} \left(1 - \eta_f\right)$$

For an adiabatic tip, Eq. 3.95 yields

$$\eta_f = \frac{\tanh m L_p}{m L_p}$$

where $m = \left(4 \bar{h} / k_p D_p\right)^{1/2}$. The air outlet temperature is given by the expression

$$\frac{T_c - T_o}{T_c - T_i} = \exp\left(-\frac{\bar{h}A_t \eta_0}{m c_p}\right)$$

Continued...
PROBLEM 7.90 (Cont.)

where \( \dot{m} = \rho V W L_p \) and \( \overline{h} \) is obtained from the Zhukauskas correlation,

\[
\overline{\text{Nu}}_D = C_2 C \text{Re}^{m}_{D,\text{max}} \text{Pr}^{0.36} \left( \text{Pr}/\text{Pr}_s \right)^{1/4}
\]

The foregoing model, including the convection correlation, was entered from the keyboard into the workspace of IHT and used with the Properties Tool Pad to perform the following parametric calculations.

Remainning within the limit \( ND_p \leq 9 \text{ mm} \), there is clearly considerable benefit associated with increasing \( N \) from 4 to 6 for \( D_p = 1.5 \text{ mm} \) or with increasing \( D_p \) from 1.5 to 2.25 mm for \( N = 4 \). However, the best configuration corresponds to \( N = 6 \) and \( D_p = 1.5 \text{ mm} \) (a larger number of smaller diameter pins), for which both \( A_t \) and \( \overline{h} \) are approximately 50\% and 20\% larger than values associated with \( N = 4 \) and \( D_p = 2.25 \text{ mm} \). The peak heat rate is \( q_c = 64.5 \text{ W} \) for \( V = 10 \text{ m/s} \), \( N = 6 \), and \( D_p = 1.5 \text{ mm} \).

COMMENTS: (1) The heat rate through the board is only \( q_b = 0.295 \text{ W} \) and hence a negligible portion of the total heat rate. (2) Values of \( C = 0.27 \) and \( m = 0.63 \) were used for the entire range of conditions. However, \( \text{Re}_{D,\text{max}} \) was less than 1000 in the mid to low range of \( V \), for which the correlation was therefore used outside its prescribed limits and the results are somewhat approximate. (3) Using the IHT solver, the model was implemented in three stages, beginning with (i) the correlation and the Properties Tool Pad and sequentially adding (ii) expressions for \( q_t \) and \( (T_c - T_o)/(T_c - T_i) \) without \( \eta_o \), and (iii) inclusion of \( \eta_o \) in the model. Results computed from one calculation were loaded as initial guesses for the next calculation.
PROBLEM 7.91

KNOWN: Tube geometry and flow conditions for steam condenser. Surface temperature and pressure of saturated steam.

FIND: (a) Coolant outlet temperature, (b) Heat and condensation rates, (c) Effects of reducing longitudinal pitch and change in velocity.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Negligible radiation, (3) Negligible effect of temperature change on air properties, (parts a and b), (4) Applicability of convection correlation outside designated range.

PROPERTIES: Table A.4, air (T_i = 300 K): \( \rho = 1.16 \text{ kg/m}^3, c_p = 1007 \text{ J/kg·K}, \nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}, k = 0.0263 \text{ W/m·K}, Pr = 0.707. \) (T_s = 390 K): \( Pr = 0.692. \) Table A.6, saturated water at 2.455 bars: \( h_{fg} = 2.183 \times 10^{6} \text{ J/kg}. \)

ANALYSIS: (a) From Section 7.6 of the textbook,

\[
T_o = T_s - (T_s - T_1) \exp \left( - \frac{\pi D \bar{N} h}{\rho V N_T S_T c_p} \right)
\]

With

\[
V_{\text{max}} = \frac{S_T}{S_T - D} V = \frac{30}{10} 4 \text{ m/s} = 12 \text{ m/s}
\]

\[
Re_{D,\text{max}} = \frac{V_{\text{max}} D}{\nu} = \frac{12 \text{ m/s} \times 0.02 \text{ m}}{15.89 \times 10^{-6} \text{ m}^2/\text{s}} = 15,104
\]

Using the Zhukauskas correlation outside its designated range \( \left( \frac{S_T}{S_L} = 0.5 \right) \), Table 7.7 yields \( C = 0.27 \) and \( m = 0.63. \) Hence, with \( C_2 = 1, \)

\[
\bar{N} = C Re_{D,\text{max}}^m Pr^{0.36} \left( \frac{Pr}{Pr_s} \right)^{1/4} = 0.27 \left( 15,104 \right)^{0.63} \left( 0.707 \right)^{0.36} \left( \frac{0.707}{0.692} \right)^{1/4} = 103
\]

\[
\bar{h} = \frac{\bar{N} D}{k} = 103 \left( 0.0263 \text{ W/m·K} / 0.02 \text{ m} \right) = 135 \text{ W/m}^2·\text{K}
\]

\[
T_o = 390 \text{K} - (90 \text{K}) \exp \left[ - \frac{\pi (0.02 \text{ m}) 400 \left( 135 \text{ W/m}^2·\text{K} \right)}{1.16 \text{ kg/m}^3 \times (4 \text{ m/s}) \times 20 \times (0.03 \text{ m}) \times 1007 \text{ J/kg·K}} \right] = 363 \text{K}
\]

(b) With \( q = q' L, \)

Continued...
PROBLEM 7.91 (Cont.)

\[ q = N \left( \ln \pi DL \Delta T_{lm} \right) \]

where

\[ \Delta T_{lm} = \frac{(T_s - T_i) - (T_s - T_o)}{\ln \left( \frac{T_s - T_i}{T_s - T_o} \right)} = \frac{(90 - 27) K}{\ln \left( \frac{90}{27} \right)} = 52.3 K \]

Hence \[ q = 400 \left( 135 W/m^2 \cdot K \right) \pi (0.02 m) 2 m (52.3 K) = 355 kW \]

The condensation rate is

\[ \dot{m}_{\text{cond}} = \frac{q}{h_{\text{fg}}} = \frac{3.55 \times 10^5 W}{2.183 \times 10^6 J/kg} = 0.163 kg/s \]

(c) For \( S_L = 0.03 m, N_L = 40 \) and \( N = 800 \), using IHT with the foregoing model and the Properties Tool Pad to evaluate air properties at \( (T_i + T_o)/2 \), we obtain

\[ T_o = 383.6 K, \quad \Delta T_{lm} = 31.6 C, \quad q = 414 kW, \quad \dot{m}_{\text{cond}} = 0.190 kg/s \]

As expected, \( q \) and \( \dot{m}_{\text{cond}} \) increase with increasing \( N_L \). However, due to a corresponding increase in \( T_o \), and hence a reduction in \( \Delta T_{lm} \), the increase is not commensurate with the two-fold increase in surface area for the tube bank.

The effect of velocity is shown below.

The heat rate, and hence condensation rate, is strongly affected by velocity, because in addition to increasing \( \bar{h} \), an increase in \( V \) decreases \( T_o \), and hence increases \( \Delta T_{lm} \).

COMMENTS: (1) The calculations of part (a) should be repeated with air properties evaluated at \( (T_i + T_o)/2 \). (2) the condensation rate could be increased significantly by using a water-cooled (larger \( \bar{h} \)), rather than an air-cooled, condenser.
PROBLEM 7.92

FIND: Maximum allowable operating power.

SCHEMATIC:

\[
\begin{align*}
T_e &= 15^\circ C \\
V_e &= 20 \text{ m/s} \\
T_s &= 85^\circ C \\
D &= 2 \text{ mm} \\
H &= 10 \text{ mm} \\
D_f &= 10 \text{ mm (r = 5 mm)}
\end{align*}
\]

ASSUMPTIONS: (1) Steady-state conditions, (2) Isothermal surface, (3) Bell-shaped nozzle, (4) All of the transistor power is dissipated to the jet.

PROPERTIES: Table A-4, Air \((T_f = 323 \text{ K}, 1 \text{ atm})\): \(v = 18.2 \times 10^{-6} \text{ m}^2/\text{s}\), \(k = 0.028 \text{ W/m\cdot K}\), \(Pr = 0.704\).

ANALYSIS: The maximum power or heat transfer rate by convection is

\[
P_{\text{max}} = q_{\text{max}} = \bar{h} \left( \frac{\pi D_f^2}{4} \right) (T_s - T_e)_{\text{max}}.
\]

For a single round nozzle,

\[
\frac{Nu}{Pr^{0.42}} = G \left( \frac{r}{D}, \frac{H}{D} \right) \frac{f}{Re}
\]

where \(D/r = 0.4\) and

\[
G = \frac{D}{r} \frac{1 - 1.1(D/r)}{1 + 0.1(H/D - 6)(D/r)} = 0.4 \frac{1 - 0.44}{1 + 0.1(-1)0.4} = 0.233.
\]

With

\[
Re = \frac{V_e D}{v} = \frac{(20 \text{ m/s})0.002 \text{ m}}{18.2 \times 10^{-6} \text{ m}^2/\text{s}} = 2198
\]

\[
F_1 = 2Re^{1/2} \left(1 + 0.005Re^{0.55}\right)^{1/2} = 2 \left(2198\right)^{1/2} \left[1 + 0.005 \left(2198\right)^{0.55}\right]^{1/2} = 108.7
\]

Hence

\[
\bar{h} = \frac{k}{Df} \frac{GFr^{0.42}}{Pr^{0.42}} = \frac{0.028 \text{ W/m\cdot K}}{0.002 \text{ m}} \left(0.233\right)\left(108.7\right)(0.704)^{0.42} = 306 \text{ W/m}^2 \cdot \text{K}
\]

Hence

\[
P_{\text{max}} = \left(306 \text{ W/m}^2 \cdot \text{K}\right) \left(\frac{\pi}{4}\right) \left(0.01 \text{ m}\right)^2 \left(70^\circ \text{C}\right) = 1.68 \text{ W}.
\]

COMMENTS: (1) All conditions required for use of the correlation are satisfied.

(2) Power dissipation may be enhanced by allowing for heat loss through the side and base of the transistor.
**PROBLEM 7.93**

**KNOWN:** Dimensions of heated plate and slot jet array. Jet exit temperature and velocity. Initial plate temperature.

**FIND:** Initial plate cooling rate.

**SCHEMATIC:**

![Schematic](image)

**ASSUMPTIONS:** (a) Negligible variation in $h$ along plate, (b) Negligible heat loss from back surface of plate, (c) Negligible radiation from front surface of plate.

**PROPERTIES:** *Table A-1*, AISI 304 Stainless steel (1200 K): $k = 28.0$ W/m·K, $c_p = 640$ J/kg·K, $\rho = 7900$ kg/m$^3$; *Table A-4*, Air ($T_f = 800$ K): $v = 84.9 \times 10^{-6}$ m$^2$/s, $k = 0.0573$ W/m·K, $Pr = 0.709$.

**ANALYSIS:** Performing an energy balance on a control surface about the plate,

$$-q_{conv} = -hA_s(T_i - T_e) = \dot{E}_{st} = \rho (A_s c_p) (dT/dt)_i,$$

For an array of slot nozzles,

$$\frac{Nu}{Pr^{0.42}} = \frac{2}{3} A_{r,o}^{3/4} \left( \frac{2Re}{A_r / A_{r,o} + A_{r,o} / A_r} \right)^{2/3}$$

where $A_r = W/S = 0.1$

$$A_{r,o} = \left( 60 + 4 \left( \frac{H}{2W} - 2 \right) \right)^{-1/2} = \left( 60 + 4(64) \right)^{-1/2} = 0.0563$$

$$Re = \frac{V_e (2W)}{v} = \frac{30 \text{ m/s}(0.02 \text{ m})}{84.9 \times 10^{-6} \text{ m}^2/\text{s}} = 7067$$

$$\bar{h} = \frac{0.0573 \text{ W/m} \cdot \text{K}}{0.02 \text{ m}} \frac{2}{3} \left( 0.0563 \right)^{3/4} \left[ \frac{2 \times 7067}{1.776 + 0.563} \right]^{2/3} = 73.2 \text{ W/m}^2 \cdot \text{K.}$$

Hence,

$$\left( \frac{dT}{dt} \right)_i = -\frac{73.2 \text{ W/m}^2 \cdot \text{K}(800 \text{ K})}{\left( 7900 \text{ kg/m}^3 \right) \left( 640 \text{ J/kg} \cdot \text{K} \right) \left( 0.008 \text{ m} \right)} = 1.45 \text{ K/s.}$$

**COMMENTS:** (1) $Bi = \frac{\bar{h}t}{k} = (73.2 \text{ W/m}^2 \cdot \text{K}) (0.008 \text{ m})/28 \text{ W/m} \cdot \text{K} = 0.02$ and use of the lumped capacitance method is justified.

(2) Radiation may be significant.

(3) Conditions required for use of the correlation are satisfied.
PROBLEM 7.94

KNOWN: Air at 10 m/s and 15°C is available for cooling hot plastic plate. An array of slotted nozzles with prescribed width, pitch and nozzle-to-plate separation.

FIND: (a) Improvement in cooling rate achieved using the slotted nozzle arrangement in place of turbulent air in parallel flow over the plate, (b) Change in heat rates if air velocities were doubled, (c) Air mass rate requirement for the slotted nozzle arrangement.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) For parallel flow over plate, flow is turbulent, (3) Negligible radiation effects.

PROPERTIES: Table A-4, Air ($T_f = (140 + 15)°C/2 = 350 K$, 1 atm): $\rho = 0.995 \text{ kg/m}^3$, $\nu = 20.92 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 30.3 \times 10^{-3} \text{ W/m} \cdot \text{K}$, $Pr = 0.700$.

ANALYSIS: (a) For turbulent flow over the plate of length $L$ with

\[
Re_L = \frac{u_\infty L}{\nu} = \frac{10 \text{ m/s} \times 0.5 \text{ m}}{20.92 \times 10^{-6} \text{ m}^2/\text{s}} = 2.390 \times 10^5
\]

using the turbulent flow correlation, find

\[
\bar{Nu}_L = \frac{\overline{h}L}{k} = 0.037Re_4^{4/5}Pr^{1/3} = 0.037 \left(2.390 \times 10^5\right)^{4/5} (0.700)^{1/3} = 659.6
\]

\[
\bar{h} = \frac{\overline{Nu}_L k}{L} = 659.6 \times 0.030 \text{ W/m} \cdot \text{K}/0.5 \text{ m} = 39.6 \text{ W/m}^2 \cdot \text{K}
\]

For an array of slot nozzles,

\[
\overline{Nu} = \frac{\overline{h}D}{k} = \frac{2}{3} A_r^{3/4} \left[ \frac{2Re}{A_r/A_{r,0} + A_{r,0}/A_r} \right]^{2/3} Pr^{0.42}
\]

where \[
Re = \frac{V_e D h}{\nu} = \frac{10 \text{ m/s} \left(2 \times 0.004 \text{ m} \right)}{20.92 \times 10^{-6} \text{ m}^2/\text{s}} = 3824
\]

\[
A_{r,0} = \left\{60 + 4 \left[H/(2W) - 2\right]^2\right\}^{-1/2} = \left\{60 + 4 \left[40/2 \times 4 - 2\right]^2\right\}^{-1/2} = 0.1021
\]

\[
A_r = W/S = 4 \text{ mm}/56 \text{ mm} = 0.0714
\]

\[
\overline{Nu} = \frac{2}{3} (0.1021)^{3/4} \left[ \frac{2 \times 3824}{0.0714/0.1021 + 0.1021/0.0714} \right]^{2/3} (0.700)^{0.42} = 24.3
\]

\[
\bar{h} = \frac{\overline{Nu} k}{D h} = 24.3 \times 0.030 \text{ W/m} \cdot \text{K}/2 \times 0.004 \text{ m} = 91.1 \text{ W/m}^2 \cdot \text{K}
\]

Continued …..
PROBLEM 7.94 (Cont.)

The improvement in heat rate with the slot nozzles (sn) over the flat plate (fp) is

\[ \frac{q^*_{sn}}{q^*_{fp}} = \frac{h_{sn}}{h_{fp}} = \frac{91.1 \text{ W/m}^2 \cdot \text{K}}{39.6 \text{ W/m}^2 \cdot \text{K}} = 2.3. \]

(b) If the air velocities were doubled for each arrangement in part (a), the heat transfer coefficients are affected as

\[ h_{sn} \sim \text{Re}^{2/3}, \quad h_{fp} \sim \text{Re}^{4/5}. \]

Hence

\[ \frac{h_{sn}}{h_{fp}} = 2.3 \left( \frac{2^{2/3}}{2^{4/5}} \right) = 2.1. \]

That is, comparative advantage of the slot nozzle over the flat plate decreases with increasing velocity.

(c) The mass rate of air flow through the array of slot nozzles is

\[ \dot{m} = \rho N A_{c,e} = 0.995 \text{ kg/m}^3 \times 9 \times (0.5 \text{ m} \times 0.004 \text{ m}) \times 10 \text{ m/s} = 0.179 \text{ kg/s} \]

where the number of slots is determined as

\[ N = \frac{L}{S} = 0.5 \text{ m} / 0.056 \text{ m} = 8.9 = 9. \]

COMMENTS: Note, for the slot nozzle, the hydraulic diameter is \( D_h = 2W \) and the relative nozzle area \( A_{c,e}/A_{cell} \) is \( A_r = W/S \).
PROBLEM 7.95

KNOWN: Air jet velocity and temperature of 10 m/s and 15°C, respectively, for cooling hot plastic plate.

FIND: Design of optimal round nozzle array. Compare cooling rate with results for a slot nozzle array and flow over a flat plate. Discuss features associated with these three methods relevant to selecting one for this application.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible radiation effects.

PROPERTIES: Table A-4, Air \(T_f = (140 + 15)\degree C/2 = 350\) K, 1 atm): \(\rho = 0.995\) kg/m\(^3\), \(\nu = 20.92 \times 10^{-6}\) m\(^2\)/s, \(k = 30.0 \times 10^{-3}\) W/m·K, \(Pr = 0.700\).

ANALYSIS: To design an \textit{optimal array} of round nozzles, we require that \(D_{h, op} \approx 0.2H\) and \(S_{op} \approx 1.4H\). Choose \(H = 40\) mm, the nozzle-to-plate separation, hence

\[
D_{h, op} = D = 0.2 \times 40\ mm = 8\ mm \quad \text{and} \quad S_{op} = 1.4 \times 40\ mm = 56\ mm.
\]

For an array of round nozzles,

\[
\overline{h}_{op} = \frac{Nu}{k/D_{h, op}} \cdot G \cdot (A_r, H/D) \cdot F_2 \cdot (Re) \cdot Pr^{0.42}
\]

where for an \textit{in-line} array, see Fig. 7.17,

\[
A_r = \frac{\pi D^2}{4S^2} = \frac{\pi (8\ mm)^2}{4(56\ mm)^2} = 0.0160
\]

\[
K = \left[ 1 + \left( \frac{H/D}{0.6/A_r^{1/2}} \right)^{6-0.05} \right]^{-1/2} \approx 0.9577
\]

\[
G = \frac{2A_r^{1/2}}{1 + 0.2(H/D - 6)A_r^{1/2}} = \frac{2 \times 0.0160^{1/2}}{1 + 0.2(40/8 - 6)0.0160^{1/2}} = \frac{1 - 2.2 	imes 0.0160}{1 + 0.2(40/8 - 6)0.0160^{1/2}} = 0.2504
\]

\[
F_2 = 0.5Re^{2/3} = 0.5 \left( \frac{10\ m/s \times 0.008\ m}{20.92 \times 10^{-6}\ m^2/s} \right)^{2/3} = 122.2.
\]

The average heat transfer coefficient for the \textit{optimal in-line} (op, il) array of round nozzles is,

\[
\overline{h}_{op, il} = \overline{Nu} \cdot k/D_{h, op} = \frac{0.030\ W/m \cdot K}{0.008\ m} \times 0.9577 \times 0.2504 \times 122.2 (0.700)^{0.42}
\]

\[
\overline{h}_{op, il} = 94.6\ W/m^2 \cdot K.
\]

Continued ….
PROBLEM 7.95 (Cont.)

If an optimal staggered \((op,s)\) array were used, see Fig. 7.17, with

\[
A_r = \frac{\pi D^2}{2(3)^{1/2} S^2} = \frac{\pi \times (8 \text{ mm})^2}{2(3)^{1/2} (56 \text{ mm})^2} = 0.0185
\]

find \(K = 0.9447, \ G = 0.2632, \ F_2 = 122.2\) and \(\overline{h}_{op,s} = 100.0 \text{ W/m}^2 \cdot \text{K.}\)

Using the previous results for parallel flow \((pf)\) and the slot nozzle \((sn)\) array, the heat rates, which are proportional to the average convection coefficients, can be compared.

<table>
<thead>
<tr>
<th>Arrangement</th>

<td>0.046</td>
<td></td>
</tr>
</tbody>
</table>

For these flow conditions, we conclude that there is only slightly improved performance associated with using the round nozzles. As expected, the staggered array is better than the in-line arrangement, since the former has a higher area ratio \((A_r)\). The air flow requirements for the round nozzle arrays are

\[
\dot{m} = \rho N A_{c,e} V_e = \rho \left( A_s / A_{cell} \right) A_{c,e} V_e = \rho A_r A_s V_e
\]

where \(N = A_s/A_{cell}\) is the number of nozzles and \(A_s\) is the area of the plate to be cooled. Substituting numerical values, find

\[
\dot{m}_{op,il} = 0.995 \text{ kg/m}^3 \times 0.0160 \left( 0.5 \times 0.5 \text{ m}^2 \right) \times 10 \text{ m/s} = 0.040 \text{ kg/s}
\]

\[
\dot{m}_{op,s} = 0.995 \text{ kg/m}^3 \times 0.0185 \left( 0.5 \times 0.5 \text{ m}^2 \right) \times 10 \text{ m/s} = 0.046 \text{ kg/s.}
\]

For this application, selection of a nozzle arrangement should be based upon air flow requirements (round nozzles have considerable advantage) and costs associated with fabrication of the arrays (slot nozzle may be easier to form from sheet metal).
**PROBLEM 7.96**

**KNOWN:** Exit diameter of plasma generator and radius of jet impingement surface. Temperature and velocity of plasma jet. Temperature of impingement surface. Droplet deposition rate.

**FIND:** Rate of heat transfer to substrate due to convection and release of latent heat.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible radiation, (3) Negligible sensible energy change due to cooling of droplets to $T_s$.

**ANALYSIS:** The total heat rate to the substrate is due to convection from the jet and release of the latent heat of fusion due to solidification, $q = q_{conv} + q_{lat}$. With $Re = \frac{V_e D}{\nu} = (400 \text{ m/s}) \frac{0.01 \text{ m}}{5.6 \times 10^{-3} \text{ m}^2/\text{s}} = 714$, $D/r = 0.4$, and $H/D = 10$, $F_1 = 2Re^{1/2}(1 + 0.005 Re^{0.55})^{1/2} = 58.2$ and $G = (D/r)(1 - 1.1D/r)/(1 + 0.1(H/D - 6)/D/r) = 0.193$, the correlation for a single round nozzle (Chapter 7.7) yields

$$Nu = GF_1 Pr^{0.42} = 0.193(58.2)(0.60^{0.42}) = 9.07$$

$$\overline{h} = \overline{Nu} \left(\frac{k}{D}\right) = 9.07 \left(0.671 \text{ W/m} \cdot \text{K}/0.01 \text{ m}\right) = 6.09 \text{ W/m}^2 \cdot \text{K}$$

Hence,

$$q = \overline{h} A_s (T_e - T_s) = 609 \text{ W/m}^2 \cdot \text{K} \times \pi (0.025 \text{ m})^2 (10,000 - 300) \text{ K} = 11,600 \text{ W}$$

The release of latent heat is

$$q_{lat} = A_s \dot{m}_p h_{sf} = \pi (0.025 \text{ m})^2 \left(0.02 \text{ kg/s} \cdot \text{m}^2\right) 3.577 \times 10^6 \text{ J/kg} = 140 \text{ W}$$

**COMMENTS:** (1) The large plasma temperature renders heat transfer due to droplet deposition negligible compared to convection from the plasma. (2) Note that $Re = 714$ is outside the range of applicability of the correlation, which has therefore been used as an approximation to actual conditions.
**PROBLEM 7.97**

**KNOWN:** A round nozzle with a diameter of 1 mm located a distance of 2 mm from the surface mount area with a diameter of 2.5 mm; air jet has a velocity of 70 m/s and a temperature of 400°C.

**FIND:** (a) Estimate the average convection coefficient over the area of the surface mount, (b) Estimate the time required for the surface mount region on the PCB, modeled as a semi-infinite medium initially at 25°C, to reach 183°C; (c) Calculate and plot the surface temperature of the surface mount region for air jet temperatures of 400, 500 and 600°C as a function time for 0 ≤ t ≤ 40 s.

Comment on the outcome of your study, the appropriateness of the assumptions, and the feasibility of using the jet for a soldering application.

**SCHEMATIC:**

![Diagram of nozzle and surface mount](image)

**ASSUMPTIONS:** (1) Air jet is a single round nozzle, (2) Uniform temperature over the PCB surface, and (3) Surface mount region can be modeled as a one-dimensional semi-infinite medium.

**PROPERTIES:** *Table A-4*, Air (T_f = 486 K, 1 atm): ν = 3.693 × 10^{-6} m^2/s, k = 0.03971 W/m·K, Pr = 0.685; Solder (given): ρ = 8333 kg/m^3, c_p = 188 J/kg·K, and k = 51 W/m·K; eutectic temperature, T_{sol} = 183°C; PCB (given): glass transition temperature, T_{gl} = 250°C.

**ANALYSIS:** For a single round nozzle, from the correlation of Eqs. 7.79, 7.80 and 7.81b, estimate the convective coefficient,

\[
\frac{\bar{Nu}}{Pr^{0.42}} = G \left( \frac{r}{D} \right) F_1(Re) \quad \bar{Nu} = \frac{hD}{k} \tag{1,2}
\]

where

\[
F_1 = 2 \text{Re}^{1/2} \left( 1 + 0.005 \text{Re}^{0.55} \right)^{1/2} \tag{3}
\]

\[
G = 2 A_r^{1/2} \frac{1 - 2.2 A_r^{1/2}}{1 + 0.2(H/D - 6)A_r^{1/2}} \tag{4}
\]

\[
A_r = D^2 / 4r_o^2 \tag{5}
\]

The Reynolds number is based on the jet diameter and velocity at the nozzle,

\[
\text{Re}_D = V_e D / \nu \tag{6}
\]

and r_o is the radius of the region over which the average coefficient is being evaluated. The thermophysical properties are evaluated at the film temperature, T_f = (T_e + T_s)/2. The results of the calculation are tabulated below.

Continued ......
Consider the surface mount region as a semi-infinite medium, with solder properties, initially at a uniform temperature of 25°C, that experiences sudden exposure to the convection process with the air jet at a temperature $T_{\infty} = 400°C$ and the convection coefficient as found in part (a). The surface temperature, $T(0,t)$, is determined from Case 3, Fig. 5.7 and Eq. 5.60,

$$\frac{T(0,t) - T_i}{T_{\infty} - T_i} = -\exp\left(\frac{h\alpha t}{k^2}\right) \times \text{erfc}\left(\frac{h(\alpha t)^{1/2}}{k}\right)$$

(7)

where $\alpha = k/\rho c_p$. With $T_i = 25°C$ and $T_{\infty} = T_e$, by trial-and-error, or by using the appropriate $IHT$ model, find

$$T(0, t_o) = 183°C \quad t_o = 31.9 \text{ s}$$

(c) Using the foregoing relations in $IHT$, the surface temperature $T(0,t)$ is calculated and plotted for jet air temperatures of 400, 500 and 600°C for $0 \leq t \leq 40$ s.

The effect of increasing the jet air temperature is to reduce the time for the surface temperature to reach the solder temperature of 183°C. With the 600°C air jet, it takes about 10 s to reach the solder temperature, and the glass transition temperature is achieved in 27 s. The analysis represents a first-order model giving approximate results only. While the estimates for the average convection coefficients are reasonable, modeling the surface mount region as a semi-infinite medium is an over simplification. The region is of limited extent on the PCB, which is thin and also a poor approximation to an infinite medium. However, the model has provided insight into the conditions under which an air jet could be used for a soldering operation.

COMMENTS: (1) Note that for our application, the round nozzle correlation of part (a) meets the ranges of validity.

(2) The jet convection coefficient is not strongly dependent upon the air temperature. Values for 400, 500, and 600°C, respectively, are 903, 889, and 876 W/m²·K.
PROBLEM 7.98

KNOWN: Diameter and properties of aluminum spheres used in packed bed. Porosity of bed and velocity and temperature of inlet air.

FIND: Time for sphere to acquire 90% of maximum possible thermal energy.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible heat transfer to or from a sphere by radiation or conduction due to contact with other spheres, (2) Validity of lumped capacitance method, (3) Constant properties.

PROPERTIES: Prescribed, Aluminum: \( \rho = 2700 \text{ kg/m}^3, \ c = 950 \text{ J/kg} \cdot \text{K}, \ k = 240 \text{ W/m} \cdot \text{K} \). Table A-4, Air (573K): \( \rho_a = 0.609 \text{ kg/m}^3, \ c_{p,a} = 1045 \text{ J/kg} \cdot \text{K}, \ nu = 48.8 \times 10^{-6} \text{ m}^2/\text{s}, \ k_a = 0.0453 \text{ W/m} \cdot \text{K}, \ Pr = 0.684 \).

ANALYSIS: From Eqs. 5.7 and 5.8a, achievement of 90% of the maximum possible thermal energy storage corresponds to

\[
\frac{Q}{\rho \ c \ \forall \ \theta_1} = 0.9 = 1 - \exp\left(\frac{-t}{\tau_t}\right) = 1 - \exp\left(\frac{-\overline{h} A_s t}{\rho \ c \ \forall \ c}\right)
\]

where the convection coefficient is given by

\[
\epsilon_j = \frac{\overline{h}}{\rho_a V c_{p,a}} = \frac{\overline{h}}{\rho_a V c_{p,a}} = \frac{\epsilon}{\rho_a V c_{p,a}} = Pr^{2/3} \approx 0.575
\]

With \( Re_D = \frac{VD}{v} = 1 \text{ m/s} \times 0.075 \text{ m/s} = 1537 \),

\[
\overline{h} = \frac{0.609 \text{ kg/m}^3 \times 1 \text{ m/s} \times 1045 \text{ J/kg} \cdot \text{K}}{0.45 (0.684)^{2/3} (1537)^{0.575}} = 30.2 \text{ W/m}^2 \cdot \text{K}
\]

Hence, with \( A_s / \forall = 6 / D \),

\[
t = \frac{\rho c D}{6 \overline{h}} \ln(0.1) = \frac{2700 \text{ kg/m}^3 \times 950 \text{ J/kg} \cdot \text{K} \times 0.075 \text{ m}^3 \times 2.30}{6 \times 30.2 \text{ W/m}^2 \cdot \text{K}} = 2445 \text{s}
\]

COMMENTS: (1) With \( Bi = \frac{\overline{h}(D/6)}{k} = 0.002 \), the spheres are spatially isothermal and the lumped capacitance approximation is excellent. (2) Before the packed bed becomes fully charged, the temperature of the air decreases as it passes through the bed. Hence, the time required for a sphere to reach a prescribed state of thermal energy storage increases with increasing distance from the bed inlet.
**PROBLEM 7.99**

**KNOWN:** Overall dimensions of a packed bed of rocks. Rock diameter and thermophysical properties. Initial temperature of rock and bed porosity. Flow rate and upstream temperature of atmospheric air passing through the pile.

**FIND:** Rate of heat transfer to pile.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Rocks are spherical and at a uniform temperature, (2) Steady-state conditions.

**PROPERTIES:** Table A-4, Atmospheric air (\(T_\infty = 363\)K): \(\nu = 22.35 \times 10^{-6}\) m\(^2\)/s, \(k = 0.031\) W/m\(\cdot\)K, \(Pr = 0.70\), \(\rho = 0.963\) kg/m\(^3\), \(c_p = 1010\) J/kg\(\cdot\)K.

**ANALYSIS:** The heat transfer rate may be expressed as \(q = \overline{h}A_{p,t}\Delta T_{\ell m}\) where the total surface area of the rocks is

\[
A_{p,t} = V_r \frac{\pi D_r^2}{\pi D_r^2 / 6} = (1 - \varepsilon) \left( \frac{\pi D_b^2}{4} L_b \right) \frac{6}{D_r} = (1 - 0.42) \left( \pi \frac{1\ m^2}{4 \times 2\ m} \right) 6/0.03\ m = 182.2\ m^2.
\]

The upstream velocity and Reynolds number are

\[
V = \frac{\dot{m}_a}{\rho \pi D_b^2 / 4} = \frac{4 \times 1\ \text{kg/s}}{\left( 0.963\ \text{kg/m}^3 \right) \pi \times 1\ m^2} = 1.32\ \text{m/s} \quad \text{Re}_D = \frac{V D_r}{\nu} = \frac{1.32\ \text{m/s} \times 0.03\ m}{22.35 \times 10^{-6}\ \text{m}^2/\text{s}} = 1772.
\]

From Section 7.8, it follows that

\[
\overline{h} = \frac{2.06}{\varepsilon} \rho \nu c_p \text{Re}_D^{-0.575} Pr^{-2/3}
\]

\[
\overline{h} = \frac{2.06}{0.42} \frac{0.963\ \text{kg/m}^3 \times 1.32\ \text{m/s} \times 1010\ J/\text{kg \cdot K}}{(1772)^{-0.575} (0.70)^{-2/3}} = 108\ \text{W/m}^2\cdot\text{K}.
\]

The appropriate form of the mean temperature difference, \(\Delta T_{\ell m}\), may be obtained by performing an energy balance on a differential control volume about the rock. That is,

\[
\dot{m}_a\ c_p\ T_a - \dot{m}_a\ c_p\ (T_a + dT_a) - dq_r = 0
\]

where \(dq_r = \overline{h}A'_{p,t}dx(T_a - T_s)\) and \(A'_{p,t}\) is the rock surface area per unit length of bed. Hence

\[
\dot{m}_a\ c_p\ dT_a = -\overline{h}A'_{p,t}dx(T_a - T_s) \quad \frac{dT_a}{dx} = -\frac{\overline{h}A'_{p,t}}{\dot{m}_a\ c_p}(T_a - T_s).
\]

Continued …..
PROBLEM 7.99 (cont.)

Integrating between inlet and outlet, it follows that

\[ \ell n \left( \frac{T_a - T_s}{T_{a,i} - T_s} \right)_{i}^{o} = -\frac{\bar{h}A_{p,t}}{\dot{m}_a c_p} L_b = -\frac{\bar{h}A_{p,t}}{\dot{m}_a c_p} \quad \ell n \left( \frac{T_{a,o} - T_s}{T_{a,i} - T_s} \right) = -\frac{\bar{h}A_{p,t}}{\dot{m}_a c_p}. \]

With

\[ q = \dot{m}_a c_p \left( T_{a,i} - T_{a,o} \right) = \dot{m}_a c_p \left[ \left( T_{a,i} - T_s \right) - \left( T_{a,o} - T_s \right) \right] \]

it follows that

\[ q = \frac{\bar{h}A_{p,t}}{\ell n \left[ \left( T_{a,i} - T_s \right) / \left( T_{a,o} - T_s \right) \right]} \left( T_{a,i} - T_s \right) - \left( T_{a,o} - T_s \right) = \bar{h}A_{p,t} \Delta T_{\ell m} \]

where

\[ \Delta T_{\ell m} = \frac{\left( T_{a,i} - T_s \right) - \left( T_{a,o} - T_s \right)}{\ell n \left[ \left( T_{a,i} - T_s \right) / \left( T_{a,o} - T_s \right) \right]} \]

The air outlet temperature may be obtained from the requirement

\[ \frac{T_{a,o} - T_s}{T_{a,i} - T_s} = \exp \left( -\frac{\bar{h}A_{p,t}}{\dot{m}_a c_p} \right) = \exp \left( -\frac{-108 \text{ W/m}^2 \cdot \text{K} \times 182.2 \text{ m}^2}{1 \text{ kg/s} \times 1010 \text{ J/kg} \cdot \text{K}} \right) = 3.46 \times 10^{-9} \]

\[ T_{a,o} = 25^\circ \text{C} + 65^\circ \text{C} \left(3.46 \times 10^{-9} \right) = 25^\circ \text{C} + 2.25 \times 10^{-7} \, ^\circ \text{C} \]

\[ T_{a,o} \approx T_s = 25^\circ \text{C}. \]

Hence

\[ \Delta T_{\ell m} = \frac{65^\circ \text{C} - 2.25 \times 10^{-7} \, ^\circ \text{C}}{\ell n \left( 65^\circ \text{C} / 2.25 \times 10^{-7} \, ^\circ \text{C} \right)} = 3.34^\circ \text{C} \]

and

\[ q = 108 \text{ W/m}^2 \cdot \text{K} \left( 182.2 \text{ m}^2 \right) \left(3.34^\circ \text{C} \right) = 65.7 \text{ kW}. \]

**COMMENTS:**

(1) The above result may be checked from the requirement that \( q = \dot{m}_a c_p \left( T_{a,i} - T_{a,o} \right) = 1 \text{ kg/s} \times 1010 \text{ J/kg} \cdot \text{K} \times 65^\circ \text{C} = 65.7 \text{ kW}. \)

(2) The heat rate would be *grossly* overpredicted by using a rate equation of the form \( q = \bar{h}A_{p,t} \left( T_{a,i} - T_s \right). \)

(3) The foregoing results are reasonable during the early stages of the heating process; however \( q \) would decrease with increasing time as the temperature of the rock increases. The axial temperature distribution of the rock in the pile would be as shown for different times.
**PROBLEM 7.100**

**KNOWN:** Dimensions of packed bed of graphite-coated uranium oxide fuel elements. Volumetric generation rate in uranium oxide and upstream velocity and temperature of helium passing through the bed.

**FIND:** (a) Mean temperature of helium leaving bed, (b) Maximum temperature of uranium oxide.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties, (3) Negligible kinetic and potential energy changes, (4) Negligible longitudinal conduction in bed, (5) Bed is insulated from surroundings, (6) One-dimensional conduction in pellets.

**PROPERTIES:** Helium (given): \( \rho = 0.089 \text{ kg/m}^3, c_p = 5193 \text{ J/kg} \cdot \text{K}, k = 0.236 \text{ W/m} \cdot \text{K}, \mu = 3 \times 10^{-5} \text{ kg/s} \cdot \text{m}, \text{Pr} = 0.66; \) Graphite (given): \( k = 2 \text{ W/m} \cdot \text{K}; \) Uranium oxide (given): \( k = 2 \text{ W/m} \cdot \text{K}. \)

**ANALYSIS:** (a) From an energy balance for the entire packed bed

\[
q = \dot{m}c_p (T_{m,o} - T_{m,i})
\]

where the heat rate is due to volumetric generation in the pellets.

\[
q = \dot{q} \cdot V_p = \dot{q} \left( \pi D^2 / 4 \right) L (1 - \varepsilon) \left[ D_p / (D_p + 2\varepsilon) \right]^3
\]

\[
q = 4 \times 10^7 \text{ W/m}^3 \left( \pi / 4 \right) (0.1 \text{ m})^2 (0.3 \text{ m}) (0.6) (0.010/0.012)^3
\]

\[
q = 4 \times 10^7 \text{ W/m}^3 \left( 8.181 \times 10^{-4} \text{ m}^3 \right) = 3.272 \times 10^4 \text{ W.}
\]

With \( \dot{m} = \rho VA = 0.089 \text{ kg/m}^3 \times 30 \text{ m/s} \left( \pi / 4 \right) (0.1 \text{ m})^2 = 0.021 \text{ kg/s} \)

the outlet temperature is

\[
T_{m,o} = T_{m,i} + \frac{\dot{q}}{\dot{m}c_p} = 400 \text{ K} + \frac{3.272 \times 10^4 \text{ W}}{0.021 \text{ kg/s} \times 5193 \text{ J/kg} \cdot \text{K}} = 700 \text{ K.}
\]

(b) The maximum temperature occurs at the center of the pellet in the exit plane. Beginning with the heat equation for pellet, find

\[
\frac{d}{dr} \left( r^2 \frac{dT}{dr} \right) = -\frac{\dot{q}}{k} r^2
\]

\[
r^2 \frac{dT}{dr} = -\frac{\dot{q}}{3k} r^3 + C_1
\]

\[
T(r) = -\frac{\dot{q}}{6k} r^2 - \frac{C_1}{r} + C_2.
\]

Continued .....
PROBLEM 7.100 (Cont.)

Applying boundary conditions:

\[ \text{at } r = 0 \quad \left. \frac{dT}{dr} \right|_{r=0} = 0 \quad \rightarrow \quad C_1 = 0 \]

\[ \text{at } r = r_i \quad T(r_i) = T_{s,i} \quad \rightarrow \quad C_2 = T_{s,i} + \frac{\dot{q}}{6k} r_i^2 \]

\[ T(r) = T_{s,i} + \frac{\dot{q}}{6k} \left( r_i^2 - r^2 \right) \]

\[ T(0) = T_{s,i} + \frac{\dot{q} D_p^2}{24k} \]

For one-dimensional conduction in a spherical shell,

\[ T_{s,i} = T_{s,o} + \frac{q_p}{4\pi k} \left[ \frac{1}{r_i} - \frac{1}{r_o} \right] \]

where \[ T_{s,o} = T_0 + \frac{q_p}{\hbar \pi \left( D_p + 2\delta \right)^2} \]

\[ q_p = \dot{q} \left( \pi D_p^3 / 6 \right) = 4 \times 10^7 \text{ W/m}^3 \left( \pi / 6 \right) (0.010 \text{ m})^3 = 20.9 \text{ W}. \]

The convection coefficient may be obtained from

\[ \bar{h} = 2.06 \text{Re}_D^{0.575} \]

with \[ \text{Re}_D = VD/\nu = 30 \text{ m/s} (0.012 \text{ m}) \times 0.089 \text{ kg/m}^3 / 3 \times 10^{-5} \text{ kg/s} \cdot \text{m} = 1068. \]

Hence \[ \bar{h} = \frac{\rho V c_p}{\varepsilon} \left( \text{Re}_D^{0.575} / \text{Pr}^{2/3} \right) \times 2.06 \]

\[ \bar{h} = \frac{0.089 \text{ kg/m}^3 \times 30 \text{ m/s} \times 5193 \text{ J/kg} \cdot \text{K}}{0.4} \times 2.06(1.068)^{-0.575} / (0.66)^{2/3} = 1709 \text{ W/m}^2 \cdot \text{K}. \]

Evaluating the temperatures,

\[ T_{s,o} = 700 \text{ K} + \frac{20.9 \text{ W}}{\left( 1709 \text{ W/m}^2 \cdot \text{K} \right) \pi (0.012 \text{ m})^2} = 727 \text{ K} \]

\[ T_{s,i} = 727 \text{ K} + \frac{20.9 \text{ W}}{4\pi \times 2 \text{ W/m} \cdot \text{K}} \left( \frac{1}{0.005 \text{ m}} - \frac{1}{0.006 \text{ m}} \right) = 755 \text{ K} \]

\[ T(0) = 755 \text{ K} + \frac{4 \times 10^7 \text{ W/m}^3 (0.01)^2}{24 \times 2 \text{ W/m} \cdot \text{K}} = 838 \text{ K}. \]

**COMMENTS:** The prescribed conditions provide for operation well below the melting point of uranium oxide. Hence \( \dot{q} \) could be substantially increased to achieve a higher helium outlet temperature.
PROBLEM 7.101

KNOWN: Diameter and properties of phase-change material. Dimensions of cylindrical vessel and porosity of packed bed. Inlet temperature and velocity of air.

FIND: (a) Outlet temperature of air and rate of melting, (b) Effect of inlet velocity and capsule diameter on outlet temperature, (c) Location at which complete melting of PCM is first to occur and subsequent variation of outlet temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible thickness (and thermal resistance) of capsule shell, (2) All capsules are at T_{mp}, (3) Constant properties, (4) Negligible heat transfer from surroundings to vessel.

PROPERTIES: Prescribed, PCM: T_{mp} = 4°C, \rho = 1200 \text{kg/m}^3, h_{sf} = 165 \text{kJ/kg}. Table A-4, Air (Assume (T_i + T_o)/2 = 17°C = 290K): \rho_a = 1.208 \text{kg/m}^3, c_p = 1007 \text{J/kg K}, \nu = 15.00 \times 10^{-6} \text{m}^2/s, Pr = 0.71.

ANALYSIS: (a) For a packed bed (Section 7.8), the outlet temperature is given by

$$T_o = T_{mp} - \left( T_{mp} - T_i \right) \exp \left[ - \frac{\bar{h} A_{p,t}}{\rho_a \nu A_{c,b} c_p} \right]$$

where $A_{c,b} = \pi D_v^2 / 4 = \pi \left( 0.40 \text{m}^2 / 4 \right) = 0.126 \text{m}^2$ and $A_{p,t} = (1 - \epsilon) (\nu_c / \nu_v) \left( \pi D_c^2 \right) = (1 - \epsilon)$

$(1.5 \pi L_v D_v^2 / D_c) = 0.5 \left( 1.5 \pi \times 0.4^3 / 0.05 \right) = 3.02 \text{m}^2$. With $Re_D = V D_c / \nu = 1 \text{m/s} \times 0.05 \text{m} / 15.00 \times 10^{-6} \text{m}^2 / \text{s} = 3333$, the convection correlation for a packed bed yields

$$\bar{h} = \frac{2.06 \rho_a \nu c_p}{\epsilon Pr^{2/3} Re_D^{0.575}} = \frac{6.06 \times 1.208 \text{kg/m}^3 \times 1 \text{m} / \text{s} \times 1007 \text{J/kg K}}{0.5 (0.71)^{2/3} (3333)^{0.575}} = 59.4 \text{W/m}^2 \cdot \text{K}$$

Hence, $T_o = 4°C \left( 21°C \right) \exp \left( - \frac{59.4 \text{W/m}^2 \cdot \text{K} \times 3.02 \text{m}^2}{1.208 \text{kg/m}^3 \times 1 \text{m} / \text{s} \times 0.126 \text{m}^2 \times 1007 \text{J/kg K}} \right) = 10.5°C <$

The rate at which PCM in the vessel changes from the solid to liquid state, $\dot{M} \left( \text{kg/s} \right)$, may be obtained from an energy balance that equates the total rate of heat transfer to the capsules to the rate of increase in latent energy of the PCM. That is

$$q = \frac{d}{dt} \left( M h_{sf} \right) = h_{sf} \dot{M}$$

Continued …..
PROBLEM 7.101 (Cont.)

where \( M \) is the total mass of PCM and

\[
q = -\bar{h}A_{p,t} \left( \frac{\left( T_{mp} - T_i \right) - \left( T_{mp} - T_o \right)}{\ln \left( \frac{T_{mp} - T_i}{T_{mp} - T_o} \right)} \right) = -59.4 \text{ W/m}^2 \cdot \text{K} \times 3.02 \text{ m}^2 \times \frac{-14.5^\circ\text{C}}{-21} = 2220 \text{ W}
\]

Hence,

\[
\dot{M} = q / h_{sf} = 2220 \text{ W} / 165,000 \text{ J/kg} = 0.0134 \text{ kg/s}
\]

(b) The effect of the inlet velocity and capsule diameter are shown below.

Despite the reduction in \( \bar{h} \) with decreasing \( V \), the reduction in the mass flow rate of air through the vessel and the corresponding increase in the residence time of air in the vessel allow it to more closely achieve thermal equilibrium with the capsules before it leaves the vessel. Hence, \( T_o \) decreases with decreasing \( V \), approaching \( T_{mp} \) in the limit \( V \to 0 \). Of course, the production of chilled air in kg/s decreases accordingly. With decreasing capsule diameter, there is an increase in the number of capsules in the vessel and in the total surface area \( A_{p,t} \) for heat transfer from the air. Hence, the heat rate increases with decreasing \( D_c \) and the outlet temperature of the air decreases.

(c) Because the temperature of the air decreases as it moves through the vessel, heat rates to the capsules are largest and smallest at the entrance and exit, respectively, of the vessel. Hence, complete melting will first occur in capsules at the entrance. After complete melting begins to occur in the capsules, progressing downstream with increasing time, heat transfer from the air will increase the temperatures of the capsules, thereby decreasing the heat rate. With decreasing heat rate, the outlet temperature will increase, approaching the inlet temperature after melting has occurred in all capsules and they achieve thermal equilibrium with the inlet air.

COMMENTS:  (1) The estimate of \( T_o \) used to evaluate the properties of air was good, and iteration of the solution is not necessary.  (2) The total mass of phase change material in the vessel is \( M = N_c \rho \sigma \sigma_c = \left[ (1 - \epsilon) \sigma_v / \sigma_c \right] \rho \sigma_c = (1 - \epsilon) \rho L_v \left( \pi D_c^2 / 4 \right) = (\pi / 4) 0.5 \times 1200 \text{ kg/m}^3 (0.4 \text{ m})^3 = 30.2 \text{ kg}. \)  At the maximum possible melting rate of \( \dot{M} = 0.0134 \text{ kg/s} \), it would therefore take 2250s = 37.5 min to melt all of the PCM in the vessel. Why would it, in fact, take longer to melt all of the PCM?
PROBLEM 7.102

KNOWN: Diameter and properties of phase-change material. Dimensions of cylindrical vessel and porosity of packed bed. Inlet temperature and velocity of air.

FIND: (a) Outlet temperature of air and rate of freezing, (b) Effect of inlet velocity and capsule diameter on outlet temperature, (c) Location at which complete melting of PCM is first to occur and subsequent variation of outlet temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible thickness (and thermal resistance) of capsule shell, (2) All capsules are at \( T_{mp} \). (3) Constant properties, (4) Negligible heat transfer from vessel to surroundings.

PROPERTIES: Prescribed, PCM: \( T_{mp} = 50^\circ C \), \( \rho = 900 \text{ kg/m}^3 \), \( h_{sf} = 200 \text{ kJ/kg} \). Table A-4, Air (Assume \( (T_i + T_o)/2 = 30^\circ C = 303K \)): \( \rho_a = 1.151 \text{ kg/m}^3 \), \( c_p = 1007 \text{ J/kg} K \), \( \nu = 16.2 \times 10^{-6} \text{ m}^2 / s \), \( Pr = 0.707 \).

ANALYSIS: (a) For a packed bed (Section 7.8), the outlet temperature is given by

\[
T_o = T_{mp} - \left( T_{mp} - T_i \right) \exp \left( \frac{-h A_{p,t}}{\rho_a V A_{c,b} c_p} \right)
\]

where \( A_{c,b} = \pi D_v^2 / 4 = 0.126 \text{ m}^2 \) and \( A_{p,t} = (1 - \varepsilon) \left( \nu / \nu_c \right) \pi D_c^2 = 3.02 \text{ m}^2 \). With \( Re_D = V D_c / \nu = 3086 \), the convection correlation for a packed bed yields

\[
\varepsilon \frac{\bar{h}}{\bar{h}} = \varepsilon St Pr^{2/3} = \varepsilon \frac{\bar{h}}{\rho_a V c_p} Pr^{2/3} = 2.06 Re_D^{-0.575}
\]

\[
\bar{h} = \frac{2.06 \rho_a V c_p}{\varepsilon Pr^{2/3} Re_D^{0.575}} = \frac{2.06 \times 1.151 \text{ kg/m}^3 \times 1 \text{ m/s} \times 1007 \text{ J/kg} \cdot \text{K}}{0.5 \times (0.7)^{2/3} (3086)^{0.575}} = 59.1 \text{ W/m}^2 \cdot \text{K}
\]

Hence,

\[
T_o = 50^\circ C - (30^\circ C) \exp \left( -\frac{59.1 \text{ W/m}^2 \cdot \text{K} \times 3.02 \text{ m}^2}{1.151 \text{ kg/m}^3 \times 1 \text{ m/s} \times 0.126 \text{ m}^2 \times 1007 \text{ J/kg} \cdot \text{K}} \right) = 41.2^\circ C \quad <
\]

The rate at which PCM in the vessel solidifies, \( \dot{M} \text{ (kg/s)} \), may be obtained from an energy balance that equates the total rate of heat transfer from the capsules to the rate at which the latent energy of the PCM decreases. That is,

\[
\dot{q} = \frac{d}{dt} \left( M h_{s,f} \right) = h_{sf} \dot{M}
\]

where \( M \) is the total mass of PCM and

Continued…..
PROBLEM 7.102 (Cont.)

\[
q = \bar{h} A_{p,t} \left( T_{mp} - T_i \right) - \left( T_{mp} - T_o \right) = 59.1 \text{ W/m}^2 \cdot \text{K} \times 3.02 \text{ m}^2 = 178.7 \text{ W}
\]

Hence,

\[
\frac{\dot{Q}}{h_s f} = \frac{3085 \text{ W}}{200,000 \text{ J/kg}} = 0.0154 \text{ kg/s}
\]

(b) The effect of V and D_c are shown below

Despite the reduction in \( \bar{h} \) with decreasing V, the reduction in the mass flow rate of air in the vessel and the corresponding increase in the residence time of air in the vessel allow it to more closely reach thermal equilibrium with the capsules before it leaves the vessel. Hence, \( T_o \) increases with decreasing V, approaching \( T_{mp} \) in the limit \( V \to 0 \). Of course, the production of warm air in kg/s decreases accordingly. With decreasing capsule diameter, there is an increase in the number of capsules in the vessel and in the total surface area \( A_{p,t} \) for heat transfer to the air. Hence, the heat rate and the air outlet temperature increase with decreasing \( D_c \).

(c) Because the air temperature increases as it moves through the vessel, heat rates from the capsules are largest and smallest at the entrance and exit, respectively, of the vessel. Hence, complete freezing will first occur in capsules at the entrance. After complete freezing begins to occur in the capsules, progressing downstream with increasing time, heat transfer to the air will decrease the temperatures of the capsules, thereby decreasing the heat rate. With decreasing heat rate, the outlet temperature will decrease, approaching the inlet temperature after freezing has occurred in all capsules and they achieve thermal equilibrium with the inlet air.

COMMENTS: (1) The estimate of \( T_o \) used to evaluate the properties of air was good, and iteration of the solution is not necessary. (2) The total mass of phase change material in the vessel is

\[
M = N_c \rho \varphi_c = \left( 1 - \varepsilon \right) \frac{\varphi}{\varphi_c} \rho \varphi_c = \left( 1 - \varepsilon \right) \rho L_v \left( \pi D_c^2 / 4 \right) = 22.6 \text{ kg.}
\]

At the maximum possible melting rate of \( \dot{M} = 0.0154 \text{ kg/s} \), it would therefore take \( 1470 \text{ s} = 24.5 \text{ min} \) to freeze all of the PCM in the vessel. Why would it, in fact, take longer to freeze all of the PCM?
PROBLEM 7.103

KNOWN: Flow of air over a flat, smooth wet plate.

FIND: (a) Average mass transfer coefficient, \( \overline{h}_m \). (b) Water vapor mass loss rate, \( n_A \) (kg/s).

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Heat-mass transfer analogy applies, (3) \( Re_{X,c} = 5 \times 10^5 \).

PROPERTIES: Table A-4, Air (300K): \( \nu = 15.89 \times 10^{-6} \) m\(^2\)/s, \( Pr = 0.707 \); Table A-8, Water vapor-air (300K, 1 atm): \( D_{AB} = 0.26 \times 10^{-4} \) m\(^2\)/s, \( Sc = \nu/D_{AB} = 0.611 \); Table A-6, Water vapor (300K): \( \rho_{A,\text{sat}} = 1/\nu_g = 0.0256 \) kg/m\(^3\).

ANALYSIS: (a) The Reynolds number for the plate, \( x = L \), is

\[
Re_L = \frac{u_\infty L}{\nu} = \frac{35 \text{ m/s} \times 0.5 \text{ m}}{15.89 \times 10^{-6} \text{ m}^2/\text{s}} = 1.10 \times 10^6.
\]

Hence flow is mixed and the appropriate flat plate convection correlation is given by Eq. 7.42,

\[
\overline{Sh}_L = \frac{\overline{h}_m L}{D_{AB}} = \left( 0.037 \left( \frac{4}{5} Re_L^{4/5} - 871 \right) Sc^{1/3} \right) \left( 0.037 \left( 1.10 \times 10^6 \right)^{0.8} - 871 \right) 0.611^{0.33}
\]

giving

\[
\overline{Sh}_L = 1399 \quad \overline{h}_m = \frac{1399 \times 0.26 \times 10^{-4} \text{ m}^2/\text{s}}{0.5 \text{ m}} = 0.0728 \text{ m/s}.
\]

(b) The evaporative mass loss rate is

\[
n_A = \overline{h}_m A_s \left( \rho_{A,\text{sat}} - \rho_{A,\infty} \right)
\]

where \( A_s = L \cdot w \), \( \rho_{A,\infty} = 0 \) (dry air) and \( \rho_{A,\text{sat}} = \rho_{A,\text{sat}} \). Hence,

\[
n_A = 0.0728 \text{ m/s} \times (0.5 \times 3) \text{ m}^2 \times (0.0256 - 0) \text{ kg/m}^3 = 0.0028 \text{ kg/s}.
\]
PROBLEM 7.104

KNOWN: Air flow conditions over a wetted flat plate of known length and temperature.

FIND: (a) Heat loss and evaporation rate, per unit plate width, \( q' \) and \( n'_A \), respectively, (b) Compute and plot \( q' \) and \( n'_A \) for a range of water temperatures \( T_s \leq 350 \) K with air velocities of 10, 20 and 35 m/s, and (c) Water temperature \( T_s \) at which the heat loss will be zero for the air velocities and temperatures of part (b).

SCHEMATIC:

ASSUMPTIONS: (1) Heat and mass transfer analogy is applicable, (2) Constant properties, (3) \( Re_{x,c} = 5 \times 10^5 \).

PROPERTIES: \( Table A.4 \), Air (\( T = 300 \) K, 1 atm): \( \nu = 15.89 \times 10^{-6} \) m/s; \( Table A.6 \), Water (300 K): \( v_g = 39.13 \) m/kg, \( h_{fg} = 2438 \) kJ/kg; \( Table A.8 \), Water-air (298 K, 1 atm): \( D_{AB} = 0.26 \times 10^{-4} \) m/s, \( Sc = 0.61 \).

ANALYSIS: (a) The heat loss from the plate is due only to the transfer of latent heat. Per unit width of the plate,

\[
q' = n'_A h_{fg}
\]

\[
n'_A = \overline{h}_m L \left[ \rho_{A,sat} (T_s) - \rho_{A,\infty} \right] = \overline{h}_m L \rho_{A,sat} (T_s)
\]

With

\[
Re_L = \frac{u_\infty L}{\nu} = \frac{35 \text{ m/s} \times 0.5 \text{ m}}{15.89 \times 10^{-6} \text{ m}^2/\text{s}} = 1.10 \times 10^6
\]

mixed boundary layer condition exists and the appropriate correlation is Eq. 7.42,

\[
\overline{Sh}_L = \left( 0.037 \, Re_L^{4/5} - 871 \right) Sc^{1/3} = \left[ 0.037 \left( 1.10 \times 10^6 \right)^{4/5} - 871 \right] (0.61)^{1/3}
\]

(3)

\[
\overline{Sh}_L = 1398
\]

\[
\overline{h}_m = \frac{D_{AB}}{L \, \overline{Sh}_L} = \frac{0.26 \times 10^{-4} \text{ m}^2/\text{s}}{5 \text{ m}} = 0.0727 \text{ m/s}
\]

With \( \rho_{A,sat} (T_s) = v_g^{-1} = 0.0256 \) kg/m\(^3\),

\[
n'_A = 0.0727 \text{ m/s} (0.5 \text{ m}) \left( 0.0256 \text{ kg/m}^3 \right) = 9.29 \times 10^{-4} \text{ kg/s} \cdot \text{m}
\]

Hence, the evaporative heat loss per unit plate width is

\[
q' = n'_A h_{fg} = 9.29 \times 10^{-4} \text{ kg/s} \cdot \text{m} \left( 2.438 \times 10^6 \text{ J/kg} \right) = 2265 \text{ W/m}
\]

Continued...
PROBLEM 7.104 (Cont.)

Heat would have to be applied to the plate in the amount of 2265 W/m to maintain its temperature at 300 K with the evaporative heat loss.

(b) When $T_s$ and $T_\infty$ are different, convection heat transfer will also occur, and the heat loss from the water surface is

$$q'_\text{loss} = q'_\text{conv} + q'_\text{evap} = \bar{h}L(T_s - T_\infty) + n'_A h_{fg}$$

(4)

Invoking the heat-mass analogy, Eq. 6.92 with $n = 1/3$,

$$\frac{\bar{h}}{h_m} = \rho c \left(\alpha/D_{AB}\right)^{2/3}$$

(5)

where $\bar{h}_m$ and $n'_A$ are evaluated using Eqs. (3) and (2), respectively. Using the foregoing relations in the *IHT Workspace*, but evaluating $\bar{h}$ (rather than $\bar{h}_m$) with the *Correlations Tool, External Flow*, for the *Average* coefficient for *Laminar or Mixed Flow*, $q'_\text{loss}$ was evaluated as a function of $u_\infty$ with $T_\infty = 300$ K.

(c) To determine the water temperature $T_s$ at which the heat loss is zero, the foregoing IHT model was run with $q'_\text{loss} = 0$ with the result that, for all velocities,

$$T_s = 281 \text{ K}$$

**COMMENTS:** Why is the result for part (c) independent of the air velocity?
PROBLEM 7.105

KNOWN: Flow over a heated flat plate coated with a volatile substance.

FIND: Electric power required to maintain surface at $T_s = 134^\circ$C.

SCHEMATIC: 

ASSUMPTIONS: (1) Steady-state conditions, (2) Heat-mass transfer analogy is applicable, (3) Transition occurs at $Re_{xc} = 5 \times 10^5$, (4) Perfect gas behavior of vapor A, (5) Upstream air is dry, $\rho_{A,\infty} = 0$.

PROPERTIES: Table A-4, Air ($T_f = (134 + 20)^\circ$C/2 = 350 K, 1 atm): $v = 20.92 \times 10^{-6}$ m$^2$/s, $k = 0.030$ W/m$\cdot$K, $Pr = 0.700$; Substance A (given): $M_A = 150$ kg/kmol, $p_{A,\text{sat}} (134^\circ$C) = 0.12 atm, $D_{AB} = 7.75 \times 10^{-7}$ m$^2$/s, $h_{fg} = 5.44 \times 10^6$ J/kg.

ANALYSIS: From an overall energy balance on the plate, the power required to maintain $T_s$ is

$$q_{elec} = q_{conv} + q_{evap} + h_{L,A_s}(T_s - T_\infty) + h_{m,L,A_s}(\rho_{A,s} - \rho_{A,\infty})h_{fg}.$$  

(1)

To estimate $h_{L}$, first determine $Re_L$,

$$Re_L = u_{\infty}L/v = 8 \text{ m/s} \times 4 \text{ m} / 20.92 \times 10^{-6} \text{ m}^2/\text{s} = 1.530 \times 10^6.$$

Hence the flow is mixed and the appropriate correlation:

$$\frac{\overline{Nu}_L}{k} = \left(0.037 \frac{Re_L^{4/5}}{Pr} - 871\right)Pr^{1/3}$$

$$h_{L} = 0.037 \left(1.530 \times 10^6\right)^{4/5} - 871 \left(0.700\right)^{1/3} = 16.0 \text{ W/m}^2 \cdot \text{K}.$$

To estimate $h_{m,L}$, invoke the heat-mass analogy, with $Sc = vB/D_{AB}$,

$$h_{m,L} = \frac{D_{AB}}{k} \left(\frac{Sc}{Pr}\right)^{1/3} = 16.0 \frac{W}{m^2 \cdot K} \left(\frac{7.75 \times 10^{-7} \text{ m}^2/\text{s}}{0.030 \text{ W/m} \cdot \text{K}}\right) \left(\frac{20.92 \times 10^{-6} \text{ m}^2/\text{s}}{7.75 \times 10^{-7} \text{ m}^2/\text{s}}\right)^{1/3} = 0.00140 \text{ m/s}.$$

The density of species A at the surface, $\rho_{A,s}(T_s)$, follows from the perfect gas law,

$$\rho_{A,s} = \frac{p_{A,s}/T_s}{M_A} = \frac{0.12 \text{ atm}/(134 + 273) \text{ K}}{150 \text{ kg/kmol}} = 0.539 \frac{\text{kg}}{\text{m}^3}.$$

Using values calculated for $h_{L}$, $h_{m,L}$ and $\rho_{A,s}$ in Eq. (1), find

$$q_{elec} = (4 \text{ m} \times 0.25 \text{ m}) \left[16.0 \frac{W}{m^2 \cdot K} (134 - 20)^{\circ}C \times 0.00140 \frac{\text{m}}{\text{s}} \left(0.539 - 0\right) \frac{\text{kg}}{\text{m}^3} \times 5.44 \times 10^6 \frac{\text{J}}{\text{kg}} \right]$$

$$q_{elec} = 1.0 \text{ m}^2 [1.824 + 4.105] \text{ W/m}^2 = 5.93 \text{ kW}.$$

COMMENTS: For these conditions, nearly 70% of the heat loss is by evaporation.
PROBLEM 7.106

KNOWN: Flow of dry air over a water-saturated plate for prescribed flow conditions and mixed temperature.

FIND: (a) Mass rate of evaporation per unit plate width, \( n'_A \ (\text{kg/s}\cdot\text{m}) \), and (b) Calculate and plot \( n'_A \) as a function of velocity for the range \( 1 \leq u_\infty \leq 25 \text{ m/s} \) for air and water temperatures of \( T_s = T_\infty = 300, \ 325, \ \text{and} \ 350 \text{ K} \).

SCHEMATIC:

ASSUMPTIONS: (1) Water surface is smooth, (2) Heat and mass transfer analogy is applicable, (3) \( \text{Re}_{x,c} = 5 \times 10^5 \).

PROPERTIES: Table A.6, Water vapor (\( T_s = 350 \text{ K}, \ 1 \text{ atm} \)): \( \rho_{A,s} = 1/\sqrt{g} = 1/3.846 \ m^3/\text{kg} = 0.2600 \ \text{kg/m}^3 \); Table A.4, Air (\( T_f = T_\infty = 350 \text{ K}, \ 1 \text{ atm} \)): \( \nu = 20.92 \times 10^{-6} \ \text{m}^2/\text{s}, \ \alpha = 29.9 \times 10^{-6} \ \text{m}^2/\text{s} \); Table A.8, Air-water (\( T_f = T_\infty = 350 \text{ K}, \ 1 \text{ atm} \)): \( \overline{D_{AB}} = 0.26 \times 10^{-4} \ \text{m}^2/\text{s} (350 \text{ K}/293 \text{ K})^{3/2} = 0.339 \times 10^{-4} \ \text{m}^2/\text{s} \).

ANALYSIS: (a) Determine the nature of the air flow by calculating \( \text{Re}_L \). With \( L = 1 \text{ m} \),

\[
\text{Re}_L = \frac{u_\infty L}{\nu} = \frac{25 \text{ m/s} \times 1 \text{ m}}{20.92 \times 10^{-6} \ \text{m}^2/\text{s}} = 1.195 \times 10^6.
\]

Since \( \text{Re}_L > 5 \times 10^5 \), it follows that the flow is mixed, and with Eq. 7.42 using \( \text{Sc} = \nu/D_{AB} \).

\[
\overline{Sh}_L = \frac{\overline{h}_m L}{D_{AB}} = \left(0.037 \text{Re}_L^{4/5} - 871\right) \text{Sc}^{1/3}.
\]

\[
\overline{Sh}_L = \left(0.037 \left[1.195 \times 10^6\right]^{4/5} - 871\right) \left(\frac{20.92 \times 10^{-6} \ \text{m}^2/\text{s}}{0.339 \times 10^{-4} \ \text{m}^2/\text{s}}\right)^{1/3} = 1550
\]

The average mass transfer coefficient for the entire plate is

\[
\overline{h}_m = \overline{Sh}_L \frac{D_{AB}}{L} = 1550 \frac{0.339 \times 10^{-4} \ \text{m}^2/\text{s}}{1 \text{ m}} = 0.0526 \text{ m/s}.
\]

The mass rate of water evaporation per unit plate width is

\[
n'_A = \overline{h}_m L \left(\rho_{A,s} - \rho_{A,\infty}\right) = 0.0526 \text{ m/s} \times 1 \text{ m} \left(0.260 - 0\right) \text{kg/m}^3 = 0.0137 \text{ kg/s} \cdot \text{m}
\]

(b) Using Eq. (1) and (3) in the IHT Workspace with the Correlations Tool, External Flow, Flat Plate, Average coefficient for Laminar or Mixed Flow, replacing heat transfer with mass transfer parameters, the evaporation rate as a function of a velocity for selected air-water velocities was calculated and is plotted below.

Continued...
COMMENTS: (1) Note carefully the use of the heat-mass transfer analogy, recognizing that air is species B.

(2) How do you explain the abrupt slope changes in the evaporation rate as a function of velocity in the above plot?
**PROBLEM 7.107**

**KNOWN:** Temperature of water bath used to dissipate heat from 100 integrated circuits. Air flow conditions.

**FIND:** Heat dissipation per circuit.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Heat and mass transfer analogy is applicable, (2) Vapor may be approximated as a perfect gas, (3) Turbulent boundary layer over entire surface, (4) All heat loss is across air-water interface.

**PROPERTIES:** Table A-4, Air (325 K, 1 atm): \( \nu = 18.4 \times 10^{-6} \text{ m}^2/\text{s}, k = 0.0282 \text{ W/m} \cdot \text{K}, \text{Pr} = 0.704; \) Table A-8, Air-vapor (325 K, 1 atm): \( D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}(325/298)^{3/2} = 0.296 \times 10^{-4} \text{ m}^2/\text{s}, \text{Sc} = \nu/D_{AB} = 0.622; \) Table A-6, Saturated water vapor \( (T_b = 350 \text{ K}) \): \( \rho_g = 0.260 \text{ kg/m}^3, h_{fg} = 2.32 \times 10^6 \text{ J/kg}; (T_\infty = 300 \text{ K}): \rho_g = 0.026 \text{ kg/m}^3. \)

**ANALYSIS:** The heat rate is

\[
q_l = \frac{q}{N} = \frac{L^2}{N} \left[ q^* + N_A h_{fg}(T_b) \right].
\]

Evaluate the heat and mass transfer convection coefficients with

\[
\text{Re}_L = \frac{u_\infty L}{\nu} = \frac{10 \text{ m/s} \times 0.1 \text{ m}}{18.4 \times 10^{-6} \text{ m}^2/\text{s}} = 54,348
\]

\[
\overline{h} = (k/L)(0.037\text{Re}_L^{4/5}\text{Pr}^{1/3}) = (0.0282 \text{ W/m} \cdot \text{K}/0.1 \text{ m})0.037(54,348)^{4/5}(0.704)^{1/3} = 57 \text{ W/m}^2 \cdot \text{K}
\]

\[
\overline{h}_m = (D_{AB}/L)(0.037\text{Re}_L^{4/5}\text{Sc}^{1/3}) = (0.296 \times 10^{-4} \text{ m}^2/\text{s}/0.1 \text{ m})0.037(54,348)^{4/5}(0.622)^{1/3} = 0.0574 \text{ m/s}
\]

The convection heat transfer rate is

\[
q^* = \overline{h}(T_b - T_\infty) = 57 \text{ W/m}^2 \cdot \text{K} (350 - 300) \text{ K} = 2850 \text{ W/m}^2
\]

and the evaporative cooling rate is

\[
N_A h_{fg} = \overline{h}_m \left[ \rho_{A,\text{sat}}(T_b) - \phi_\infty \rho_{A,\text{sat}}(T_\infty) \right] h_{fg}(T_b)
\]

\[
N_A h_{fg} = 0.0574 \text{ m/s} \left[ 0.260 - 0.5 \times 0.026 \right] \text{kg/m}^3 \times 2.32 \times 10^6 \text{ J/kg} = 32,890 \text{ W/m}^2
\]

Hence

\[
q_l = \frac{(0.1 \text{ m})^2}{100} (2850 + 32,890) \text{ W/m}^2 = 3.57 \text{ W.}
\]

**COMMENTS:** Heat loss due to evaporative cooling is approximately an order of magnitude larger than that due to the convection of sensible energy.
PROBLEM 7.108

KNOWN: Dry air flows at 300 K over water-filled trays, each 222 mm long, with velocity of 15 m/s while radiant heaters maintain the surface temperature at 330 K.

FIND: (a) Evaporative flux (kg/s·m²) at a distance 1 m from leading edge, (b) Radiant flux at this distance required to maintain water temperature at 330 K, (c) Evaporation rate from the tray at location L = 1 m, (d) Irradiation which should be applied to each of the first four trays such that their rates are identical to that found in part (c).

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Heat-mass transfer analogy applicable, (3) Water vapor behaves as perfect gas, (4) All incident radiant power absorbed by water, (5) Critical Reynolds number is 5 × 10⁵.

PROPERTIES: Table A.4, Air (T_f = 315 K, 1 atm): \( \nu = 17.40 \times 10^{-6} \) m²/s, \( k = 0.0274 \) W/m·K, \( Pr = 0.705 \); Table A.8, Water vapor-air (T_f = 315 K): \( D_{AB} = 0.26 \times 10^{-4} \) m²/s \((315/298)^{3/2} = 0.28 \times 10^{-4} \) m²/s, \( Sc = \nu/D_{AB} = 0.616 \); Table A.6, Saturated water vapor (T_s = 330 K): \( \rho_{A,sat} = 1/v_g = 0.1134 \) kg/m³, \( h_{fg} = 2366 \) kJ/kg.

ANALYSIS: (a) The evaporative flux of water vapor (A) at location x is

\[
\dot{n}'_{A,x} = h_{m,x} \left( \rho_{A,s} - \rho_{A,\infty} \right) = h_{m,x} \left[ \rho_{A,sat} (T_s) - \phi_\infty \rho_{A,sat} (T_\infty) \right] \tag{1}
\]

Evaluate \( Re_x \) to determine the nature of the flow and then select the proper correlation.

\[
Re_x = \frac{u_{\infty,x}}{\nu} = 15 \text{ m/s} \times 1 \text{ m} / 17.40 \times 10^{-6} \text{ m}^2 / \text{s} = 8.621 \times 10^5 .
\]

Hence, the flow is turbulent, and invoking the heat-mass analogy with Eq. 7.45,

\[
Sh_x = \frac{h_{m,x}}{D_{AB}} = 0.0296 \text{Re}_x^{4/5} Sc^{1/3}
\]

\[
h_m = \frac{0.28 \times 10^{-4} \text{ m}^2 / \text{s}}{1 \text{ m}} \times 0.0296 \left( 8.621 \times 10^5 \right)^{4/5} (0.616)^{1/3} = 3.952 \times 10^{-2} \text{ m/s}.
\]

Hence, the evaporative flux at \( x = 1 \) m is

\[
\dot{n}'_{A,x} = 3.952 \times 10^{-2} \text{ m/s} \left( 0.1134 \text{ kg/m}^3 - 0 \right) = 4.48 \times 10^{-3} \text{ kg/s} \cdot \text{m}^2 \tag{2}
\]

(b) From an energy balance on the differential element at \( x = 1 \) m,

\[
q_rad = q_{conv} + q_{evap} = h_x (T_s - T_\infty) + \dot{n}'_{A,x} h_{fg} \tag{3}
\]

Continued...
To estimate $h_x$, invoke the heat-mass analogy using the correlation, Eq. 7.45,

$$\frac{Nu_x}{Sh_x} = (Pr/Sc)^{1/3} \quad \text{or} \quad h_x = h_{m,x} k/D_{AB} (Pr/Sc)^{1/3} \quad (4)$$

$$h_x = 3.95 \times 10^{-2} \, \text{kg/s} \cdot \text{m}^2 \left(0.0274 \, \text{W/m} \cdot \text{K} / 0.28 \times 10^{-4} \, \text{m}^2/\text{s} \right) \left(0.705/0.616 \right)^{1/3} = 40.45 \, \text{W/m}^2 \cdot \text{K}$$

Hence, the required radiant flux is

$$q^*_{rad} = 40.45 \, \text{W/m}^2 \cdot \text{K} (330 - 300) \, \text{K} + 4.48 \times 10^{-3} \, \text{kg/s} \cdot \text{m}^2 \times 2366 \times 10^3 \, \text{J/kg}$$

$$q^*_{rad} = 1,214 \, \text{W/m}^2 + 10,600 \, \text{W/m}^2 = 11,813 \, \text{W/m}^2$$

(c) The flow is turbulent over tray 5 having its mid-length at $x = 1$ m, so that it is reasonable to assume

$$\bar{h}_5 = h_x (1 \, \text{m}) \quad (5)$$

so that the evaporation rate can be determined from the evaporative flux as,

$$n'_A = n''_{A,x} \Delta L = 4.48 \times 10^{-3} \, \text{kg/s} \cdot \text{m}^2 \times 0.222 \, \text{m} = 9.95 \times 10^{-4} \, \text{kg/s} \cdot \text{m}$$

(d) For tray 5, following the form of Eq. (3), the energy balance is

$$q^*_{rad,5} \Delta L = \bar{h}_5 \Delta L (T_s,5 - T_{\infty}) + n'_{A,5} h_{fg} \quad (6)$$

and the evaporation rate for the tray is

$$n'_{A,5} = \bar{h}_{m,5} \Delta L (\rho_{A,s} - 0) \quad (7)$$

While $\bar{h}_5$ and $\bar{h}_{m,5}$ represent tray averages, Eq. (4) is still applicable. Using the *IHT Correlation Tool*, *External Flow, Average coefficient for Laminar, or Mixed Flow*, $\bar{h}_5$ is evaluated as

$$\bar{h}_5 = \left[ \bar{h}_x (1.10 \, \text{m}) L_5 - \bar{h}_x (0.880 \, \text{m}) L_4 \right] / \Delta L \quad (8)$$

where $\Delta L = L_5 - L_4 = 0.22$ m. The same relations can be applied to trays 2, 3 and 4. For tray 1, $\bar{h}_1 = \bar{h} (0.22 \, \text{m}) L_1$, where $L_1 = \Delta L$. With Eqs. (3, 6, 7 and 8) in the IHT Workspace, along with the *Correlations and Properties Tools*, the following results were obtained with the requirement that the evaporation rate for each tray is equal at $n'_{A,5} = 10.01 \times 10^{-4} \, \text{kg/s} \cdot \text{m}$.

<table>

**COMMENTS:**

(1) Note carefully at which temperatures the thermophysical properties are evaluated.

(2) Recognize that in part (d), if we require equal evaporation rates for each tray, $n'_{A,5}$, the water temperature, $T_s$, and radiant flux, $q^*_{rad}$, for each tray must be different since the convection coefficients $\bar{h}_x$ and $\bar{h}_{m,x}$ are different for each of the trays. How do you explain the changes in $T_s$? Which tray has the highest $\bar{h}$? The lowest $\bar{h}$?

(3) For tray 5, using Eq. (5) we found $\bar{h}_5 = 40.45$ W/m$^2$·K; using the more accurate formulation, Eq. (8), the result is 40.49 W/m$^2$·K. If the flow were laminar or mixed over the tray, Eq. (5) would be inappropriate.
PROBLEM 7.109

KNOWN: Irradiation on sequential water-filled trays of prescribed length and width. Temperature and velocity of airflow over the trays.

FIND: Rate of water loss from first, third and fourth trays and temperature of water in each tray.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform irradiation of each container, (3) Complete absorption of irradiation by water, (4) Negligible heat transfer between containers and from bottom of containers, (5) Validity of heat-mass transfer analogy, (6) Applicability of convection correlations for an isothermal surface, (7) Re = 5 × 10^5.

PROPERTIES: Table A.4, air (1 atm, assume T = 315 K): \( \nu = 17.4 \times 10^{-6} \text{ m}^2/\text{s}, k = 0.0274 \text{ W/m} \cdot \text{K}, \text{Pr} = 0.705. \) Table A.8, vapor/air (1 atm, 315 K): \( D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s} \) \( \frac{(315/298)^{3/2}}{2.8} = 0.28 \times 10^{-4} \text{ m}^2/\text{s}, \text{Sc} = \frac{\nu}{D_{AB}} = 0.616. \)

ANALYSIS: The temperature of each tray is determined by a balance between the absorbed radiation and the convection and evaporative losses. Hence,

\[
G = q_{\text{conv}}^* + q_{\text{evap}}^* = \overline{h}(T_s - T_\infty) + \overline{h}_m \rho_{A, \text{sat}} h_{fg}
\]

where, assuming an exponent of \( n = 1/3 \), the heat-mass transfer analogy yields

\[
\overline{h}_m = \left( \frac{D_{AB}}{k} \right) (\text{Sc} / \text{Pr})^{1/3} \overline{h} = \left( 0.26 \times 10^{-4} \text{ m}^2/\text{s} / 0.0274 \text{ W/m} \cdot \text{K} \right) (0.616/0.705)^{1/3} \overline{h} = \left( 9.07 \times 10^{-4} \text{ m}^3/\text{K} / \text{W} \cdot \text{s} \right) \overline{h}
\]

Hence,

\[
G = \overline{h}\left[(T_s - T_\infty) + 9.07 \times 10^{-4} \rho_{A, \text{sat}} h_{fg}\right]
\]

With \( \text{Re}_N = u_>/\Delta x / \nu = 15 \text{ m/s}(N \times 0.25 \text{ m})/17.4 \times 10^{-6} \text{ m}^2/\text{s} = (2.155 \times 10^5)N \), the flow is laminar for \( N = 1.2 \) with transition to turbulence occurring for \( N = 3 \).

For tray 1,

\[
\overline{h} = \left( k / \Delta x \right) 0.664 \text{Re}_1^{1/2} \text{Pr}^{1/3} = \left( 0.0274 \text{ W/m} \cdot \text{K}/0.25 \text{ m} \right) 0.664 \left( 2.155 \times 10^5 \right)^{1/2} \left( 0.705 \right)^{1/3} = 30.1 \text{ W/m}^2 \cdot \text{K}
\]

For tray 4, with \( x = 0.875 \text{ m} \) (\( N = 7/2 \)),

\[
\overline{h}_4 = \left( k / x \right) 0.0296 \text{Re}_4^{4/5} \text{Pr}^{1/3} = \left( 0.0274 \text{ W/m} \cdot \text{K}/0.875 \text{ m} \right) 0.0296 \left( 7.543 \times 10^5 \right)^{4/5} \left( 0.705 \right)^{1/3} = 41.5 \text{ W/m}^2 \cdot \text{K}
\]

Continued...
PROBLEM 7.109 (Cont.)

For tray 3, \( \bar{h}_3 = \left( \bar{h}_{1-3} L_3 - \bar{h}_{1-2} L_2 \right) / \Delta x \), where

\[
\bar{h}_{1-3} L_3 = k \left( 0.037 \text{Re}^{4/5} - 871 \right) \text{Pr}^{1/3}
\]

\[
= 0.0274 \text{W/m} \cdot \text{K} \left( 0.037 \times 44,510 - 871 \right) \left( 0.705 \right)^{1/3} = 18.9 \text{W/m} \cdot \text{K}
\]

\[
\bar{h}_{1-2} L_2 = k \left( 0.664 \text{Re}^{1/2} \text{Pr}^{1/3} \right)
\]

\[
= 0.0274 \text{W/m} \cdot \text{K} \left( 0.664 \times 656.5 \right) \left( 0.705 \right)^{1/3} = 10.6 \text{W/m} \cdot \text{K}
\]

\[
\bar{h}_3 = (18.9 - 10.6) \text{W/m} \cdot \text{K} / 0.25 \text{m} = 33.1 \text{W/m}^2 \cdot \text{K}
\]

For tray 1, the energy balance yields

\[
10^4 \text{W/m}^2 = 30.1 \text{W/m}^2 \cdot \text{K} \left[ (T_s - T_{\infty}) + 9.07 \times 10^{-4} \rho_{A,\text{sat}} h_{fg} \right]
\]

Since \( \rho_{A,\text{sat}} \) depends strongly on \( T_s \), the solution to this equation must be obtained by trial-and-error, with \( \rho_{A,\text{sat}} \) (and \( h_{fg} \)) determined from Table A.6. The solution yields

\[
T_{s,1} \approx 334.7 \text{K}
\]

Similarly, for trays 3 and 4

\[
T_{s,3} \approx 332.8 \text{K} \quad T_{s,4} \approx 327.1 \text{K}
\]

The evaporation rate for tray \( N \) is

\[
\dot{m}_{\text{evap}} = \bar{h} \rho_{A,\text{sat}} (W \Delta x) = 2.27 \times 10^{-4} \bar{h} \rho_{A,\text{sat}}
\]

from which it follows that

\[
\dot{m}_{\text{evap},1} \approx 9.5 \times 10^{-4} \text{kg/s}, \quad \dot{m}_{\text{evap},3} \approx 9.5 \times 10^{-4} \text{kg/s}, \quad \dot{m}_{\text{evap},4} \approx 9.3 \times 10^{-4} \text{kg/s}
\]

COMMENTS:  (1) The largest convection coefficient is associated with the tray for which the entire flow is turbulent.  (2) The temperature of the water varies inversely with the average convection coefficient for its tray.
PROBLEM 7.110

KNOWN: Apparatus as described in Problem 7.40 providing a nearly uniform airstream over a flat test plate to experimentally determine the heat and mass transfer coefficients. Temperature history of the pre-heated plate for airstream velocities of 3 and 9 m/s were fitted to a fourth-order polynomial for determining the heat transfer coefficient. Water mass loss observations from a water-saturated paper over the plate and its surface temperature for determining the heat transfer coefficient.

FIND: (a) From the temperature-time history, determine the heat transfer coefficients and evaluate the constants C and m for a correlation of the form \( \overline{Nu_L} = C \cdot Re^m \cdot Pr^{1/3} \); compare results with a standard-plate correlation and comment on the goodness of the comparison; explain any differences; (b) From the water mass loss observations, determine the mass transfer coefficients for the two flow conditions; evaluate the constants C and m for a correlation of the form \( \overline{Sh_L} = C \cdot Re^m \cdot Sc^{1/3} \); and (c) Using the heat-mass analogy, compare the experimental results with each other and against standard correlations; comment on the goodness of the comparison; explain any differences.

SCHEMATIC:

(a) Heat transfer experiment

(b) Mass transfer experiment

ASSUMPTIONS: (1) Airstream over the test plate approximates parallel flow over a flat plate, (2) Plate is spacewise isothermal, (3) Negligible radiation exchange between plate and surroundings, (4) Constant properties, and (5) Negligible heat loss from the bottom surface or edges of the test plate.

PROPERTIES: Heat transfer coefficient, Table A.4, Air (\( T_f = (T_s - T_\infty) / 2 \) = 310 K, 1 atm): \( k_a = 0.0269 \text{ W/m-K, } v = 1.669 \times 10^{-5} \text{ m}^2/\text{s, Pr} = 0.706 \). Test plate (Given): \( \rho = 2770 \text{ kg/m}^3, c_p = 875 \text{ J/kg-K, k = 177 W/m-K. Mass transfer coefficient, Table A.6, Water vapor (} T_s = 15.3^\circ C = 288.3 \text{ K): } \rho_{A,sat} = 1/v_s = 79.81 \text{ m}^3/\text{kg = 0.01253 kg/m}^3; Table A.6, Water vapor (} T_s = 16.0^\circ C = 289 \text{ K): } \rho_{A,sat} = 0.01322 \text{ kg/m}^3; Table A.6, Water vapor (} T_{inf} = 27^\circ C = 300 \text{ K): } \rho_{A,sat} = 0.02556 \text{ kg/m}^3; Table A.8, Water vapor-air [\( T_f = (T_s + T_\infty) / 2 = 295 \text{ K}]: D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s (295/298)}^{1.5} = 0.256 \times 10^{-4} \text{ m}^2/\text{s.}

ANALYSIS: (a) Using the lumped-capacitance method, the energy balance on the plate is

\[
-h_L A_s \left[ T_s(t) - T_\infty \right] = \rho V c_p \frac{dT}{dt}
\]

Continued...
and the average convection coefficient can be determined from the temperature history, $T_s(t)$,

$$
\overline{h}_L = \frac{\rho V_c p}{A_S} \left( \frac{dT_s}{dt} \right) / (T_s(t) - T_\infty)
$$

(2)

where the temperature-time derivative is

$$
\frac{dT_s}{dt} = b + c2 t^2 + 4 e t^3
$$

(3)

The temperature time history plotted below shows the experimental behavior of the observed data.

Consider now the integrated form of the energy balance, Eq. (5.6), expressed as

$$
\ln \left( \frac{T_s(t) - T_\infty}{T_i - T_\infty} \right) = -\left( \frac{\overline{h}_L A_S}{\rho V_c} \right) t
$$

(4)

If we were to plot the LHS vs $t$, the slope of the curve would be proportional to $\overline{h}_L$. Using IHT, plots were generated of $\overline{h}_L$ vs. $T_s$, Eq. (1), and $\ln \left[ (T_s(t) - T_\infty)/(T_i - T_\infty) \right]$ vs. $t$, Eq. (4). From the latter plot, recognize that the regions where the slope is constant corresponds to early times ($\leq 100$ s when $u_\infty = 3$ m/s and $\leq 50$ s when $u_\infty = 5$ m/s).
Selecting two elapsed times at which to evaluate $L_h$, the following results were obtained:

<table>
<thead>
<tr>
<th>$u_\infty$ (m/s)</th>
<th>t (s)</th>
<th>$T_s$ (°C)</th>
<th>$L_h$ (W/m$^2$K)</th>
<th>$\overline{Nu_L}$</th>
<th>$Re_L$</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>100</td>
<td>44.77</td>
<td>30.81</td>
<td>152.4</td>
<td>$2.39 \times 10^4$</td>
</tr>
<tr>
<td>9</td>
<td>50</td>
<td>45.80</td>
<td>56.7</td>
<td>280.4</td>
<td>$7.17 \times 10^4$</td>
</tr>
</tbody>
</table>

where the dimensionless parameters are evaluated as:

$$\overline{Nu_L} = \frac{\overline{h}_L L}{k_a} \quad \text{Re}_L = \frac{u_\infty L}{\nu}$$

where $k_a, \nu$ are thermophysical properties of the airstream.

(b) Using the above pairs of $\overline{Nu_L}$ and $Re_L$, $C$ and $m$ in the correlation can be evaluated,

$$\overline{Nu_L} = C Re_L^m Pr^{1/3}$$

$$152.4 = C (2.39 \times 10^4)^m (0.706)^{1/3} \quad 280.4 = C (7.17 \times 10^4)^m (0.706)^{1/3}$$

Solving, find $C = 0.633 \quad m = 0.555$

The plot below compares the experimental correlation ($C = 0.633, m = 0.555$) with those for laminar flow ($C = 0.664, m = 0.5$) and fully turbulent flow ($C = 0.037, m = 0.8$). The experimental correlation yields $\overline{Nu_L}$ values which are 25% higher than for the correlation. The most likely explanation for this unexpected trend is that the airstream reaching the plate is not parallel, but with a slight impingement effect and/or the flow is very highly turbulent at the leading edge.

(b) From the convection mass transfer rate equation,

$$n_A = \overline{h}_{m,L} A_S \left( \rho_{A,sat} - \rho_{A,\infty} \right)$$

where the evaporation rate can be determined from the paper mass and time interval observations,

$$n_A = \left[ m(t + \Delta t) - m(t) \right] / \Delta t$$

and the species densities, $\rho_{A,sat}$ and $\rho_{A,\infty}$, correspond to $\rho_{A,sat}(T_S)$ and $\phi_\infty \rho_{A,sat}(T_\infty)$, respectively.

Using the ASHRAE psychrometric chart (1 atm) with $T_{wb} = 13^\circ C$ and $T_{db} = 27^\circ C$, find the relative humidity as $\phi_\infty = 0.17$. The correlation dimensionless parameters are evaluated as

$$\overline{Sh}_L = \frac{\overline{h}_{m,L} L}{D_{AB}} \quad \overline{Re}_L = \frac{u_\infty L}{\nu} \quad Sc = \frac{\nu}{D_{AB}}$$

Continued...
PROBLEM 7.110 (Cont.)

where all the properties are evaluated at $T_f = \left( T_S + T_\infty \right) / 2$. The results of the analyses are summarized in the following table.

<table>
<thead>
<tr>
<th>$u_m$ (m/s)</th>
<th>$n_A$ (kg/s)</th>
<th>$\overline{h}_{m,L}$ (m/s)</th>
<th>$\overline{Sh}_L$</th>
<th>$Re_L$</th>
<th>$Sc$</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>$2.463 \times 10^{-6}$</td>
<td>0.0168</td>
<td>87.58</td>
<td>$2.594 \times 10^4$</td>
<td>0.603</td>
</tr>
<tr>
<td>9</td>
<td>$4.583 \times 10^{-6}$</td>
<td>0.0288</td>
<td>150</td>
<td>$7.767 \times 10^4$</td>
<td>0.603</td>
</tr>
</tbody>
</table>

Using the two sets of tabulated values for $\overline{Sh}_L$, $Re_L$ and $Sc$ and the standard correlation of the form,

$$\overline{Sh}_L = C Re_L^m Sc^{1/3}$$  \hspace{1cm} (15)

$$87.58 = C \left( 2.594 \times 10^4 \right)^m \left( 0.603 \right)^{1/3}$$

$$150 = C \left( 7.767 \times 10^4 \right)^m \left( 0.603 \right)^{1/3}$$

solve simultaneously to find

$C = 0.711$

$m = 0.490$  \hspace{1cm} (16,17)

From the heat-mass analogy, we expect the constants $C$ and $m$ in Eq. (7) for heat transfer and in Eq. (13) for mass transfer to be the same. From the two experiments, we found

\begin{tabular}{|l|c|c|}
| Heat transfer & $C$ & $m$  \\
| Mass transfer & 0.633 & 0.555  \\
| & 0.711 & 0.490  |
\end{tabular}

In the plot below, the parameters $\overline{Sh}_L/Sc^{1/3}$ or $\overline{Nu}_L/Pr^{1/3}$ are plotted against $Re_L$ using Eq. (15) or (7). Note that the curves are nearly parallel on the log-log axes since their “$m$” constants are of similar value. The mass transfer results are, however, nearly 50% higher than those for heat transfer. We have no way to explain this systematic difference without more information on the apparatus, observation procedures and repeated observations. However, overall the results support the general form of the heat-mass analogy.
**PROBLEM 7.111**

**KNOWN:** Dry air at prescribed temperature and velocity flowing over a wetted plate of length 500 mm and width 150 mm. Imbedded electrical heater maintains the surface at $T_s = 20^\circ C$.

**FIND:** (a) Water evaporation rate (kg/h) and electrical power $P_e$ (W) required to maintain steady-state conditions, and (b) The temperature of the plate after all the water has evaporated, for the same airstream conditions and heater power of part (a).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties and (3) Heat-mass transfer analogy is applicable.

**PROPERTIES:** Table A.4, Air ($T_f = (T_s + T_\infty)/2 = 300 \text{ K, } 1 \text{ atm}$): $\rho = 1.16 \text{ kg/m}^3$, $c_p = 1007 \text{ J/kg} \cdot \text{K}$, $k = 0.0263 \text{ W/m} \cdot \text{K}$, $\nu = 15.94 \times 10^{-6} \text{ m}^2/\text{s}$, $\alpha = 2.257 \times 10^{-5} \text{ m}^2/\text{s}$, Table A.6, Water ($T_s = 20^\circ C = 293 \text{ K}$): $\rho_{A,s} = 1/\nu_g = 1/59.04 = 0.0169 \text{ kg/m}^3$, $h_{fg} = 2454 \text{ kJ/K}$; Table A.8, Water-air ($T_f = 300 \text{ K}$): $D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}$.

**ANALYSIS:** (a) Perform an energy balance on the plate,

$$E_{in} - E_{out} = 0 \quad \text{P}_e - q_{conv} - q_{evap} = 0 \quad (1)$$

where the convection and evaporation rate equations are,

$$q_{conv} = \left( \begin{array}{c} \frac{h_L}{\rho} A_s \left( T_s - T_\infty \right) \\ \frac{h_m}{\rho} A_s \left( \rho_{A,s} - \rho_{A,\infty} \right) - h_{fg} \end{array} \right)$$

The Reynolds number for the plate length $L$ is

$$Re_L = \frac{u_\infty L}{\nu} = \frac{20 \text{ m/s} \times 0.50 \text{ m}}{15.94 \times 10^{-6} \text{ m}^2/\text{s}} = 6.274 \times 10^5$$

so that the flow is mixed and Eq. 7.41 is appropriate to estimate $h_L$,

$$\frac{h_L}{\nu} = \left( \frac{0.037 \text{ Re}_D^{4/5} - 871}{Pr^{1/3}} \right) h_{fg}$$

$$= \frac{0.0263 \text{ W/m} \cdot \text{K}}{0.0169 \text{ m}} \left( 0.037 \left( 6.274 \times 10^5 \right)^{4/5} - 871 \right) (0.707)^{1/3} = 34.5 \text{ W/m}^2 \cdot \text{K}$$

Evoking the heat-mass analogy, Eq. 6.92, with $n = 1/3$

$$\frac{h_L}{h_m} = \rho c_p \left( \frac{D}{D_{AB}} \right)^{-2/3} = 1.16 \text{ kg/m}^3 \times 1007 \text{ J/kg} \cdot \text{K} \left( \frac{2.257 \times 10^{-5} \text{ m}^2/\text{s}}{0.26 \times 10^{-4} \text{ m}^2/\text{s}} \right)^{-2/3} = 1284 \text{ J/m}^3 \cdot \text{K}$$

Continued...
PROBLEM 7.111 (Cont.)

\[ \bar{h}_m = 34.5 \text{ W/m}^2 \cdot \text{K}/12841\text{J/m}^3 \cdot \text{K} = 0.0269 \text{ m/s} \]

Substituting numerical values, the energy balance, Eq. (1), with \( A_s = 0.5 \text{ m} \times 0.15 \text{ m} = 0.075 \text{ m}^2 \),

\[ P_e - 34.5 \text{ W/m}^2 \cdot \text{K} \times 0.075 \text{ m}^2 (20 - 35) \text{K} \]
\[ - 0.0269 \text{ m/s} \times 0.075 \text{ m}^2 (0.0169 - 0) \text{kg/m}^3 \times 2454 \times 10^3 \text{ J/kg} \cdot \text{K} = 0 \]

\[ P_e = -38.8 \text{ W} + 83.7 = 44.9 \text{ W} \]

The evaporation rate is

\[ n_A = \bar{h}_m A_s (\rho_{A,s} - \rho_{A,\infty}) = 0.0269 \text{ m/s} \times 0.075 \text{ m}^2 \times 0.0169 \text{ kg/m}^3 = 0.123 \text{ kg/h} \]

(b) When the plate is dry, the energy balance is

\[ P_e = \bar{h}_L A_s (T_s - T_\infty) \]

and with \( P_e \) and \( \bar{h}_L \) as determined in part (a),

\[ T_s = T_\infty + P_e / \bar{h}_L A_s = 35^\circ \text{C} + 44.9 \text{ W}/34.5 \text{ W/m}^2 \cdot \text{K} \times 0.075 \text{ m}^2 = 52.3^\circ \text{C} \]

COMMENTS: Using IHT Correlations Tool, External Flow, Flat Plate, the calculation of part (b) was performed using the proper film temperature, \( T_f = 318 \text{ K} \), to find \( \bar{h}_L = 32.7 \text{ W/m}^2 \cdot \text{K} \) and \( T_s = 53.3^\circ \text{C} \).
PROBLEM 7.112

KNOWN: Convection mass transfer with turbulent flow over a flat plate (van roof).

FIND: (a) Location on van that will dry last, (b) Evaporation rate at trailing edge, kg/s⋅m².

SCHEMATIC:

ASSUMPTIONS: (1) Turbulent flow over entire plate (van top), (2) Heat-mass transfer analogy is applicable, (3) Perfect gas behavior for water vapor (A).

PROPERTIES: Table A-4, Air (300 K, 1 atm): \( \nu = 15.89 \times 10^{-6} \) m²/s, \( k = 0.0263 \) W/m⋅K, \( Pr = 0.707 \); Table A-8, Air-water vapor (25°C): \( D_{AB} = 0.26 \times 10^{-4} \) m²/s; Table A-6, Saturated water vapor (300K): \( \rho_{A,sat} = \frac{\nu_g^{-1}}{g} = 0.0256 \) kg/m³.

ANALYSIS: (a) The mass transfer coefficient, \( h_{m}(x) \), will be largest at \( x = 0 \) and smallest at \( x = L \) for turbulent flow conditions. Hence, the trailing edge will dry last.

(b) The evaporation rate on a per unit area basis, at the trailing edge where \( x = L \), is given by the rate equation,

\[
n^*_A = h_{m,L} \left( \rho_{A,s} - \rho_{A,\infty} \right) = h_{m,L} \rho_{A,sat} (1 - \phi_{\infty})
\]

For turbulent flow the appropriate correlation for estimating \( h_{m,L} \) is of the form

\[
Sh_x = h_{m,x} x / D_{AB} = 0.0296 \Re_{x}^{4/5} \Sc^{1/3}
\]

Substituting numerical values,

\[
\Re_L = \frac{\nu L}{u_B} = \frac{90 \times 10^3 \text{ m/h}}{3600 \text{ s/h}} \times 6 \times 15.89 \times 10^{-6} \text{ m}^2 / \text{s} = 9.44 \times 10^6
\]

\[
\Sc = \frac{\sqrt{D_{AB}}}{V_B} = \frac{15.89 \times 10^{-6} \text{ m}^2 / \text{s}}{0.26 \times 10^{-4} \text{ m}^2 / \text{s}} = 0.611
\]

\[
h_{m,L} = \left( 0.26 \times 10^{-4} \text{ m}^2 / \text{s} \right) \times 0.0296 \left( 9.44 \times 10^6 \right)^{4/5} (0.611)^{1/3} = 0.0414 \text{ m/s}
\]

Hence, the evaporation flux (rate per unit area) is

\[
n^*_A = 0.0414 \text{ m/s} \times 0.0256 \text{ kg/m}^3 \left( 1 - 0.8 \right) = 2.12 \times 10^{-4} \text{ kg/s} \cdot \text{m}^2.
\]

COMMENTS: Recognize how the heat-mass analogy is utilized and the appropriate correlation selected from Table 7.9.
PROBLEM 7.113

KNOWN: Length and thickness of a layer of benzene. Velocity and temperature of air in parallel flow over the layer.

FIND: Time required for complete evaporation.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Smooth liquid surface and negligible free-stream turbulence, (3) Heat and mass transfer analogy is applicable, (4) Negligible benzene vapor concentration in free-stream air, (5) Isothermal conditions at 25°C.

PROPERTIES: Table A-4, Air (25°C, 1 atm): $\nu = 15.7 \times 10^{-6}$ m$^2$/s; Table A-8, Benzene-air, (25°C, 1 atm): $D_{AB} = 0.88 \times 10^{-5}$ m$^2$/s, Sc = 1.78.

ANALYSIS: Applying conservation of mass to a control volume about the liquid,

$$\frac{dM}{dt} = \frac{d(\rho_f V)}{dt} = -n_A.$$

For a unit width, $V = L \delta$. Hence

$$\rho_f L \frac{d\delta}{dt} = -n'_A = -\bar{h}_m L \left( \rho_{A,\text{sat}} - \rho_{A,\infty} \right)$$

and integrating

$$\int_{\delta_i}^{0} d\delta = \bar{h}_m \rho_{A,\text{sat}} \int_{0}^{t} dt$$

$$t = \frac{\delta_i \rho_f}{\bar{h}_m \rho_{A,\text{sat}}}.$$

With $Re_L = \frac{u_\infty L}{\nu} = \frac{1 \text{ m/s} \times 2 \text{ m}}{15.7 \times 10^{-6} \text{ m}^2/\text{s}} = 1.27 \times 10^5$, the flow is laminar throughout and from Eq. 7.32,

$$\bar{h}_m = \frac{D_{AB}}{L} 0.664 \left( \frac{1.26 \times 10^{-3} \text{ m/s}}{2 \text{ m}} \right) \left( \frac{0.88 \times 10^{-5} \text{ m}^2/\text{s}}{2 \text{ m}} \right) \left( \frac{1.27 \times 10^5}{1.78} \right)^{1/3},$$

and

$$t = 0.001 \text{ m} \left( \frac{900 \text{ kg/m}^3}{1.26 \times 10^{-3} \text{ m/s} \times 0.417 \text{ kg/m}^3} \right) = 1713 \text{ s} \approx 28.6 \text{ min}.$$
PROBLEM 7.114

KNOWN: Parallel air flow over a series of water-filled trays.

FIND: Power required to maintain each of the first three trays at 300K.

SCHEMATIC:

ASSUMPTIONS: (a) Steady-state conditions, (2) Heat-mass transfer analogy applicable, (3) Perfect gas behavior for water vapor, (4) \( \text{Re}_{x,c} = 5 \times 10^5 \).

PROPERTIES: Table A-4, Air (300 K, 1 atm): \( \nu = \nu_B = 15.89 \times 10^{-6} \text{ m}^2/\text{s} \); Table A-8, Water vapor-air (300K): \( D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}, \text{Sc} = \nu_B/D_{AB} = 0.611 \); Table A-6, Saturated water vapor (300K): \( \rho_{A,\text{sat}} = \nu_g^{-1} = 0.02556 \text{ kg/m}^3, h_{fg} = 2438 \text{ kJ/kg} \).

ANALYSIS: Since \( T_s = T_\infty \), there is no convective heat transfer, hence,

\[
q_{\text{tray}} = \dot{m}_{\text{tray}} h_{fg} = \overline{h}_m \cdot A_s \cdot \rho_{A,\text{sat}} \left(1 - \phi_\infty\right) h_{fg}
\]

where

\[
\phi_\infty \equiv \rho_{A,\infty} / \rho_{A,\text{sat}} \quad \text{and} \quad \rho_{A,s} = \rho_{A,\text{sat}} (T_s).
\]

Calculate the Reynolds number at \( x_3 \),

\[
\text{Re}_{x3} = u_\infty x_3 / \nu_B = 12 \text{ m/s} \times 1.5 \text{ m}/15.89 \times 10^{-6} \text{ m}^2/\text{s} = 1.133 \times 10^6
\]

finding that transition occurs at \( x = 0.662 \text{ m} \), a location on tray 2. The average mass transfer coefficients \( \overline{h}_m \) and heat rates for each tray are as follows:

**Tray 1:** The flow is laminar and the appropriate correlation for \( \overline{h}_{m,1} \) and heat are

\[
\overline{Sh}_{x1} = \overline{h}_{m,1} x_1 / D_{AB} = 0.664 \text{ Re}^{1/2} \text{ Sc}^{1/3}
\]

\[
\overline{h}_{m,1} = \left(0.26 \times 10^{-4} \text{ m}^2/\text{s}/0.5 \text{ m}\right) \times 0.664 \left(\frac{12 \text{ m/s} \times 0.5 \text{ m}}{15.89 \times 10^{-6} \text{ m}^2/\text{s}}\right)^{1/2} (0.611)^{1/3} = 1.800 \times 10^{-2} \text{ m/s}
\]

\[
q_1' = 1.800 \times 10^{-2} \text{ m/s} \times 0.5 \text{ m} \times 0.02556 \text{ kg/m}^3 \times (1 - 0.40) \times 2438 \times 10^3 \text{ J/kg} = 337 \text{ W/m}.
\]

**Tray 2:** Since transition occurs over the span of tray 2, the rate equation has the form

\[
q_2' = \left[ x_2 \overline{h}_{m,0-2} - x_1 \overline{h}_{m,0-1} \right] \rho_{A,\text{sat}} \left(1 - \phi_\infty\right) h_{fg}.
\]

Continued ….
PROBLEM 7.114 (Cont.)

Note that $\bar{h}_{m,0-1} = \bar{h}_{m,1}$ from above and that $\bar{h}_{m,0-2}$ is evaluated using the correlation

\[
\bar{S}h_x = \left( 0.037 \, \text{Re}_x^{4/5} - 871 \right) \text{Sc}^{1/3}
\]

\[
\bar{h}_{m,0-2} = 2.193 \times 10^{-2} \, \text{m/s} \quad q_2' = 483 \, \text{W/m}.
\]

Tray 3: The rate equation is of the same form as Eq. (2). Alternatively, an approximation can be used,

\[
q_3' = h_m(\bar{x}) \left( x_3 - x_2 \right) \rho_{A,\text{sat}} \left( 1 - \phi_\infty \right) h_{fg}
\]

where $h_m(\bar{x})$ is the local value at the midspan, $\bar{x} = \left( x_2 + x_3 \right) / 2$. Using

\[
\bar{S}h_x = 0.0296 \, \text{Re}_x^{4/5} \, \text{Sc}^{1/3}
\]

and substituting numerical values, find

\[
h_{m}(\bar{x}) = 3.148 \times 10^{-2} \, \text{m/s} \quad q_3' = 589 \, \text{W/m}.
\]
PROBLEM 7.115

KNOWN: Air and surface conditions for a drying process in which photographic plates are aligned in the direction of the air flow.

FIND: (a) Variation of local mass transfer convection coefficient, (b) Drying rate for fastest drying plate, (c) Heat addition needed to maintain the plate temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Heat and mass transfer analogy is applicable, (2) Critical Reynolds number is \( \text{Re}_{x,c} = 5 \times 10^5 \), (3) Radiation effects are negligible.

PROPERTIES: Table A-4, Air (50°C = 323K): \( \nu = 18.2 \times 10^{-6} \text{ m}^2/\text{s} \); Table A-6, Water vapor (50°C = 323K): \( \rho_{A,\text{sat}} = 0.082 \text{ kg/m}^3 \), \( h_{fg} = 2383 \text{ kJ/kg} \); Table A-8, Water vapor-air (25°C = 298K) \( D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s} \); since \( D_{AB} \propto T^{3/2} \), \( D_{AB}(50°C = 323K) = 0.26 \times 10^{-4} \)

\( (323/298)^{3/2} = 0.29 \times 10^{-4} \text{ m}^2/\text{s} \), \( Sc = \nu/D_{AB} = 0.62 \).

ANALYSIS: (a) With \( \text{Re}_{x,c} = u_{x,c}/\nu = 5 \times 10^5 \), the point of transition is

\[
 x_c = \frac{5 \times 10^5 \left( 18.2 \times 10^{-6} \text{ m}^2/\text{s} \right)}{9.1 \text{ m/s}} = 1 \text{ m}
\]

and the variation of the local mass transfer coefficient is as shown below

(b) The largest evaporation will be associated with either the first plate or the fifth plate. For the first plate,

\[
 n_{A,1} = \bar{h}_{m,x} A_{s,1} \left( \rho_{A,s} - \rho_{A,\infty} \right)
\]

where \( \rho_{A,\infty} = 0 \) since the upstream air is dry. Since the boundary layer is laminar over the entire plate, with

\[
 \text{Re}_{x,1} = \left( 9.1 \text{ m/s} \right) \left( 0.25 \text{ m} \right) / \left( 18.2 \times 10^{-6} \text{ m}^2/\text{s} \right) = 1.25 \times 10^5
\]

Continued …..
PROBLEM 7.115 (Cont.)

Eq. 7.32 may be used to obtain

\[
\bar{h}_{m,1} = \left( \frac{D_{AB}}{x_1} \right) \frac{0.664 \text{ Re}^{1/2}}{x_1} \text{ Sc}^{1/3} = \left( \frac{0.29 \times 10^{-4}}{0.25 \text{ m}} \right) \left( 1.25 \times 10^5 \right)^{1/2} \left( 0.62 \right)^{1/3}
\]
\[
\bar{h}_{m,1} = 0.0232 \text{ m/s}.
\]

Hence

\[
n_{A,1} = 0.0232 \text{ m/s} (0.25 \text{ m} \times 1 \text{ m}) \left( 0.082 \text{ kg/m}^3 \right) = 4.72 \times 10^{-4} \text{ kg/s} \cdot \text{m}.
\]

For the fifth plate,

\[
n_{A,5} = n_{A,0-5} - n_{A,0-4} = \left[ (\bar{h}_m A_s)_{0-5} - (\bar{h}_m A_s)_{0-4} \right] (\rho_{A,s} - \rho_{A,\infty}).
\]

With \( \text{Re}_{x,5} = 6.25 \times 10^5 \), Eq. 7.42 gives

\[
\bar{h}_{m,0-5} = \left( \frac{D_{AB}}{x_5} \right) \left[ 0.037 \text{ Re}^{4/5}_{x,5} - 871 \right] \text{ Sc}^{1/3}
\]
\[
\bar{h}_{m,0-5} = \left( \frac{0.29 \times 10^{-4}}{1.25 \text{ m}} \right) \left[ 0.037 \left( 6.25 \times 10^5 \right)^{4/5} - 871 \right] (0.62)^{1/3}
\]
\[
\bar{h}_{m,0-5} = 0.0145 \text{ m/s}.
\]

With \( \text{Re}_{x,4} = 5 \times 10^5 \), Eq. 7.32 gives

\[
\bar{h}_{m,0-4} = \left( \frac{D_{AB}}{x_4} \right) \left[ 0.664 \text{ Re}^{1/4}_{x,4} \text{ Sc}^{1/3} \right]
\]
\[
\bar{h}_{m,0-4} = \left( \frac{0.29 \times 10^{-4}}{1 \text{ m}} \right) \left[ 0.664 \left( 5 \times 10^5 \right)^{1/2} (0.62)^{1/3} \right]
\]
\[
\bar{h}_{m,0-4} = 0.0116 \text{ m/s}.
\]

Hence,

\[
n_{A,5} = [0.0145 \text{ m/s} \times 1.25 \text{ m} \times 1 \text{ m} - 0.0116 \text{ m/s} \times 1 \text{ m} \times 1 \text{ m}] \left( 0.082 \text{ kg/m}^3 \right)
\]
\[
n_{A,5} = 5.35 \times 10^{-4} \text{ kg/s} \cdot \text{m}.
\]

Hence the evaporation rate is largest for Plate 5.

(c) Heat would have to be supplied to each plate at a rate which is equal to the evaporative cooling rate in order to maintain the prescribed temperature. Hence

\[
q_5 = n_{A,5} h_{fg} = 5.35 \times 10^{-4} \text{ kg/s} \cdot \text{m} \times 2.383 \times 10^6 \text{ J/kg} = 1.275 \text{ kW/m}.
\]

COMMENTS: The large value of \( q_5 \) is a consequence of the significant evaporative cooling effect.
PROBLEM 7.116

KNOWN: Dimensions and temperature of a cooling pond. Conditions of air flow.

FIND: Daily make-up water requirement.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Turbulent boundary layer over the entire surface, (3) Heat and mass transfer analogy is applicable.

PROPERTIES: Table A-4, Air (T = 300K, 1 atm): \( v = 15.89 \times 10^{-6} \text{ m}^2/\text{s}, k = 0.0263 \text{ W/m-K}, \) \( Pr = 0.707; \) Table A-6, Water vapor (300K): \( \rho_{A, \text{sat}} = \frac{1}{v_g} = 0.0256 \text{ kg/m}^3; \) Table A-8, Water vapor-air (300K): \( D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}, Sc = \frac{v}{D_{AB}} = 0.61. \)

ANALYSIS: The make-up water requirement must equal the daily water loss due to evaporation,

\[
\Delta M = \dot{m}_{\text{evap}} \Delta t = \dot{m}_{\text{m}} (W \cdot L) \left[ \rho_{A, \text{sat}} (T_s) - \phi_{\infty} \rho_{A, \text{sat}} (T_{\infty}) \right] \Delta t.
\]

From Eq. 7.45, \( \bar{Sh}_L = 0.037 \frac{Re_{L}^{4/5}}{Sc^{1/3}} \), with

\[
Re_{L} = \frac{u_{\infty} L}{v} = \frac{2 \text{ m/s} \times 1000 \text{ m}}{15.89 \times 10^{-6} \text{ m}^2/\text{s}} = 1.26 \times 10^8
\]

\[
\bar{Sh}_L = 0.037 \left( \frac{1.26 \times 10^8}{0.61} \right)^{4/5} = 9.48 \times 10^4
\]

\[
\bar{h}_{m,L} = \frac{D_{AB} \bar{Sh}_L}{L} = \frac{0.26 \times 10^{-4} \text{ m}^2/\text{s} \times 9.48 \times 10^4}{1000 \text{ m}} = 2.47 \times 10^{-3} \text{ m/s}
\]

Hence, the make-up water requirement is

\[
\Delta M = 2.47 \times 10^{-3} \text{ m/s} \times (500 \text{ m} \times 1000 \text{ m}) \times 0.0256 \text{ kg/m}^3 \times 24 \text{ h} \times 3600 \text{ s/h}
\]

\[
\Delta M = 2.73 \times 10^6 \text{ kg/day.}
\]
PROBLEM 7.117

KNOWN: Dimensions and initial temperature of plate covered by liquid film. Properties of liquid. Velocity and temperature of air flow over the plates.

FIND: Initial rate of heat transfer from plate and rate of change of plate temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible effect of conveyor velocity on boundary layer development, (2) Plates are isothermal and at same temperature as liquid film, (3) Negligible heat transfer from sides of plate, (4) Smooth air-liquid interface, (5) Applicability of heat/mass transfer analogy, (6) Negligible solvent vapor in free stream, (7) \( \text{Re}_{x,c} = 5 \times 10^5 \), (8) Constant properties.

PROPERTIES: Table A-1, AISI 1010 steel (313K): \( c = 441 \text{ J/kg} \cdot \text{K}, \rho = 7832 \text{ kg/m}^3 \). Table A-4, Air (\( p = 1 \text{ atm}, T_f = 303K \)): \( v = 16.2 \times 10^{-6} \text{ m}^2 / \text{s}, k = 0.0265 \text{ W/m} \cdot \text{K}, \text{Pr} = 0.707 \). Prescribed: Solvent: \( \rho_{A,sat} = 0.75 \text{ kg/m}^3, D_{AB} = 10^{-5} \text{ m}^2 / \text{s}, h_fg = 9 \times 10^5 \text{ J/kg} \).

SOLUTION: The initial rate of heat transfer from the plate is due to both convection and evaporation.

\[
q = q_{\text{conv}} + q_{\text{evap}} = \bar{h} A_s (T_i - T_\infty) + n_A h_fg = \bar{h} A_s (T_i - T_\infty) + \bar{h}_m A_s \rho_{A,sat} h_fg
\]

With \( \text{Re}_L = u_\infty L / v = 1 \text{ m/s} \times 1 \text{ m} / 16.2 \times 10^{-6} \text{ m}^2 / \text{s} = 6.17 \times 10^4 \), flow is laminar over the entire surface. Hence,

\[
\bar{N}u_L = 0.664 \text{Re}_L^{1/2} \text{Pr}^{1/3} = 0.664 \left(6.17 \times 10^4\right)^{1/2} (0.707)^{1/3} = 147
\]

\[
\bar{h} = (k / L) \bar{N}u_L = (0.0265 \text{ W/m} \cdot \text{K} / 1 \text{ m}) 147 = 3.9 \text{ W/m} \cdot \text{K}
\]

Also, with \( \text{Sc} = v / D_{AB} = 16.2 \times 10^{-6} \text{ m}^2 / \text{s} / 10^{-5} \text{ m}^2 / \text{s} = 1.62,\)

\[
\bar{Sh}_L = 0.664 \text{Re}_L^{1/2} \text{Sc}^{1/3} = 0.664 \left(6.17 \times 10^4\right)^{1/2} (1.62)^{1/3} = 194
\]

\[
\bar{h}_m = (D_{AB} / L) \bar{Sh}_L = \left(10^{-5} \text{ m}^2 / \text{s} / 1 \text{ m}\right) 194 = 0.00194 \text{ m/s}
\]

Hence, with \( A_s = 2 \text{ L}^2 = 2 \text{ m}^2,\)

\[
q = 2 \text{ m}^2 \left[3.9 \text{ W/m}^2 \cdot \text{K} (20^\circ\text{C}) + 0.00194 \text{ m/s} \times 0.75 \text{ kg/m}^3 \times 9 \times 10^5 \text{ J/kg} \right] = 156 \text{ W} + 2619 \text{ W} = 2775 \text{ W}
\]

Performing an energy balance at an instant of time for a control surface about the plate, \( -\dot{E}_{\text{out}} = \dot{E}_{\text{st}},\) we obtain (Eq. 5.2),

\[
\frac{dT_i}{dt} = -\frac{q}{\rho \delta L^2 c} = -\frac{2775 \text{ W}}{7832 \text{ kg/m}^3 \times 0.006 \text{ m} \times (1 \text{ m})^2 \times 441 \text{ J/kg} \cdot \text{K}} = -0.13^\circ \text{C/s}
\]

COMMENTS: (1) Heat transfer by evaporation exceeds that due to convection by more than an order of magnitude, (2) The total heat rate is small enough to render the lumped capacitance approximation excellent.
PROBLEM 7.118

FIND: Drying rate per unit surface area.

SCHEMATIC:

ASSUMPTIONS: (1) Applicability of heat and mass transfer analogy. (2) Paper motion has a negligible effect on convection (u << V_e), (3) Air is dry.

PROPERTIES: Table A-4, Air (300K, 1 atm): \( v = 15.89 \times 10^{-6} \text{ m}^2 / \text{s} \); Table A-6, Saturated water (300K): \( \rho_{A,\text{sat}} = v^{-1}_g = 0.0256 \text{ kg} / \text{m}^3 \); Table A-8, water vapor-air (300K): \( D_{AB} = 0.26 \times 10^{-4} \text{ m}^2 / \text{s} \), \( Sc = 0.61 \).

ANALYSIS: The average mass evaporation flux is
\[
\dot{n}_A^* = \bar{h}_m (\rho_{A,S} - \rho_{A,e}) = \bar{h}_m \rho_{A,S}
\]

For an array of round nozzles,
\[
\overrightarrow{Sh} = 0.5 K G R e^{2/3} S c^{0.42}
\]

where \( Re = V_e D / v = 20 \text{ m/s} \times 0.02 \text{m}/15.89 \times 10^{-6} \text{ m}^2 / \text{s} = 25,170 \) and, with \( H/D = 10 \) and \( A_t = \pi D^2 / 4 S^2 = 0.0314 \),
\[
K = \left[ 1 + \left( \frac{H/D}{0.6 / A_t^{1/2}} \right)^6 \right]^{-0.05} = \left[ 1 + \left( \frac{10}{3.39} \right)^6 \right]^{-0.05} = 0.723
\]
\[
G = 2 A_t^{1/2} \frac{1 - 2.2 A_t^{1/2}}{1 + 0.2(H/D - 6) A_t^{1/2}} = 0.354 \frac{1 - 0.390}{1 + 0.2(4)0.177} = 0.189
\]

Hence,
\[
\bar{h}_m = \frac{D_{AB} \overrightarrow{Sh}}{D} = \frac{0.26 \times 10^{-4} \text{ m}^2 / \text{s}}{0.02 \text{m}} \left[ 0.5 \times 0.723 \times 0.189 \left( 25,170 \right)^{2/3} \left( 0.61 \right)^{0.42} \right] = 0.062 \text{ m/s}
\]
The average evaporative flux is then
\[
\dot{n}_A^* = 0.062 \text{ m/s} \left( 0.0256 \text{ kg} / \text{m}^3 \right) = 0.0016 \text{ kg} / \text{s} \cdot \text{m}^2
\]

COMMENTS: Note that, for maximum evaporation, the ratio \( D/H = 0.1 \) is less than the optimum of \( D/H \)_{op} = 0.2, as is \( S/H = 0.5 \) less than \( S/H \)_{op} = 1.4. If \( H \) is reduced by a factor of 2 and \( S \) is increased by 40%, a near optimal condition could be achieved.
PROBLEM 7.119

FIND: (a) Evaporative flux at a distance 1 m from roll edge; corresponding irradiation, \( G \) (W/m\(^2\)), required to maintain surface at \( T_s = 300 \) K, and (b) Compute and plot variations of \( h_{m,x}(x) \), \( N_A'' \), and \( G(x) \) for the range \( 0 \leq x \leq 1 \) m when the velocity and temperature are increased to 10 m/s and 340 K, respectively.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Heat-mass transfer analogy, (3) Paper slurry (water-fiber mixture) has water properties, (4) Water vapor behaves as perfect gas, (5) All irradiation absorbed by slurry, (6) Negligible emission from the slurry, (7) \( Re_{x,c} = 5 \times 10^5 \).

PROPERTIES: Table A.4, Air \((T_f = 315 \) K, 1 atm): \( \nu = 17.40 \times 10^{-6} \) m\(^2\)/s, \( k = 0.0274 \) W/m\( \cdot \)K, \( Pr = 0.705 \); Table A.8, Water vapor-air \((T_f = 315 \) K): \( D_{AB} = 0.26 \times 10^{-4} \) m\(^2\)/s \((315/298)^{3/2} = 0.28 \times 10^{-4} \) m\(^2\)/s, \( Sc = \nu_B/D_{AB} = 0.616 \); Table A.6, Saturated water vapor \((T_s = 330 \) K): \( \rho_{A,sat} = 1/v_g = 0.1134 \) kg/m\(^3\), \( h_{fg} = 2366 \) kJ/kg.

ANALYSIS: (a) Recognize that the drying process can be modeled as flow over a flat plate with heat and mass transfer. For a unit area at \( x = 1 \) m,

\[
n''_{A,x} = h_{m,x} \left( \rho_{A,s} - \rho_{A,\infty} \right) = h_{m,x} \left[ \rho_{A,sat}(T_s) - \phi_{\infty} \rho_{A,sat}(T_\infty) \right] \quad (1)
\]

Evaluate \( Re_x \) to determine the nature of flow, select a correlation to estimate \( h_{m,x} \),

\[
Re_x = \frac{u_\infty x}{\nu_B} = \frac{(5 \text{ m/s} \times 1 \text{ m})}{17.40 \times 10^{-6} \text{ m}^2/\text{s}} = 2.874 \times 10^5.
\]

Since \( Re_x < 5 \times 10^5 \), the flow is laminar. Invoking the heat-mass analogy,

\[
Sh_x = \frac{h_{m,x} x}{D_{AB}} = 0.332 \sqrt{Re_x} Sc^{1/3} \quad (2)
\]

\[
h_{m,x} = \left(0.28 \times 10^{-4} \text{ m}^2/\text{s}/\text{m} \right) \times 0.332 \left(2.874 \times 10^5\right)^{1/2} (0.616)^{1/3} = 4.24 \times 10^{-3} \text{ m/s}.
\]

Hence, the evaporative flux at \( x = 1 \) m is

\[
n''_{A,x} = 4.24 \times 10^{-3} \text{ m/s} \left(0.1134 \text{ kg/m}^3 \right) = 4.81 \times 10^{-4} \text{ kg/s} \cdot \text{m}^2 <
\]

From an energy balance on the differential element at \( x = 1 \) m (see above),

\[
G = q''_{conv} + q''_{evap} = h_x \left( T_s - T_\infty \right) + n''_{A,x} h_{fg} \quad (3)
\]

Continued...
PROBLEM 7.119 (Cont.)

To estimate \( h_x \), invoke the heat-mass transfer analogy using the correlation of Eq. (2),

\[
h_x = h_{m,x} \frac{k}{D_{AB}} \left( \frac{Pr}{Sc} \right)^{1/3} = 4.24 \times 10^{-3} \text{ m/s} \left( \frac{0.0274 \text{ W/m} \cdot \text{K}}{0.28 \times 10^{-4} \text{ m}^2/\text{s}} \right) \left( 0.705 \right)^{1/3} = 4.34 \text{ W/m}^2 \cdot \text{K} \quad (4)
\]

Hence, from Eq. (3), the radiant power required to maintain the slurry at \( T_s = 330 \text{ K} \) is

\[
G = 4.34 \text{ W/m}^2 \cdot \text{K} (330 - 300) \text{ K} + 4.81 \times 10^{-4} \text{ kg/s} \cdot \text{m}^2 \times 2366 \times 10^3 \text{ J/kg}
\]

\[
G = (130 + 1138) \text{ W/m}^2 = 1268 \text{ W/m}^2.
\]

(b) Equations (1), (3) and (4) were entered into the IHT Workspace. The Correlations Tool, External Flow, Local coefficients for Laminar or Turbulent Flow was used to estimate the heat transfer convection coefficient. The results for \( h_{m,x}(x) \), \( n_{A,x}''(x) \) and \( G(x) \) were evaluated, and are plotted below for \( T_s = 340 \text{ K} \) and \( u_\infty = 10 \text{ m/s} \).

![Graph of local coefficient](image1)

![Graph of evaporative flux](image2)

![Graph of irradiation](image3)

**COMMENTS:** (1) The abrupt change in the parameter plots occurs at the transition, \( x_c = 0.9 \text{ m} \).
PROBLEM 7.120

KNOWN: Geometry and air flow conditions for a water storage channel.

FIND: (a) Evaporation rate, (b) Expression for rate of change of water layer depth and time required for complete evaporation.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Smooth water surface and negligible free stream turbulence, (3) Heat and mass transfer analogy is applicable, (4) \(Re_{xc} = 5 \times 10^5\), (5) Perfect gas behavior for water vapor.

PROPERTIES: Table A-4 Air (25°C = 298K): \(\nu = 15.71 \times 10^{-6} \text{ m}^2/\text{s}\); Table A-6, Water (25°C = 298K): \(\rho_{A,\text{sat}} = v_g^{-1} = 0.0226 \text{ kg/m}^3\), \(\rho_f = v_f^{-1} = 997 \text{ kg/m}^3\); Table A-8, Water vapor-air (25°C = 298K): \(D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}\), Sc = \(\nu/D_{AB} = 0.60\).

ANALYSIS: (a) The evaporation rate is 
\[ n_A = \bar{n}_m A_s \left( \rho_{A,\text{sat}} - \rho_{A,\infty} \right) = \bar{n}_m (w \times L) \rho_{A,\text{sat}} (1-\phi_\infty) \].
With 
\[ \text{Re}_L = u_\infty L/\nu = 5 \text{ m/s} \times 25 \text{ m}/15.71\times10^{-6} \text{ m}^2/\text{s} = 7.96 \times 10^6 \]

Eq. 7.42 yields 
\[ \bar{Sh}_L = \left[ 0.037 \left(7.96\times10^6\right)^{4/5} - 871 \right] (0.6)^{1/3} = 9616 \]

\[ \bar{n}_m = 9616 D_{AB} / L = 9616 \times 0.26 \times 10^{-4} \text{ m}^2/\text{s}/(25 \text{ m}) = 0.010 \text{ m/s}. \]

With \( w = 2z = 2 \text{m}, \)
\[ n_A = 0.01 \text{ m/s} \left( 2 \text{m} \times 25 \text{m} \right) 0.0226 \text{ kg/m}^3 \left( 0.5 \right) = 0.00565 \text{ kg/s} = 20.3 \text{ kg/h}. \]

(b) Performing a mass balance on a control volume about the water,
\[ -n_A = \dot{m}_{A,\text{st}} = \frac{d}{dt} \left( \rho_f V \right) - \bar{n}_m \left( 2zL \right) \rho_{A,\text{sat}} (1-\phi_\infty) = \frac{d}{dt} \left( \rho_f z^2 L \right) \]

\[ \frac{dz}{dt} = -\bar{n}_m \frac{\rho_{A,\text{sat}}}{\rho_f} (1-\phi_\infty). \]

Integrating,
\[ \int_z^0 dz = -\bar{n}_m \frac{\rho_{A,\text{sat}}}{\rho_f} (1-\phi_\infty) \int_0^t dt \]

\[ t = \frac{z \rho_f}{\bar{n}_m \rho_{A,\text{sat}}} \left( \frac{1}{1-\phi_\infty} \right) = \frac{1}{0.01 \text{ m/s} \times 0.0226 \text{ kg/m}^3 \left( 1-0.5 \right)} = 8.82 \times 10^6 \text{ s} = 2451 \text{ h} = 102 \text{ d}. \]

COMMENTS: Although the evaporation rate decreases with increasing time due to decreasing \(A_s\), \(dz/dt\) remains constant and the water depth decreases linearly.
PROBLEM 7.121

KNOWN: Mass change for a given time period of a solid naphthalene cylinder subjected to cross flow of air for prescribed conditions.

FIND: (a) Mass transfer coefficient, \( \bar{h}_m \), based upon experimental observations and (b) \( \bar{h}_m \) based upon appropriate correlation.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible naphthalene vapor in free stream, (3) Heat-mass transfer analogy applies.

PROPERTIES: Table A-4, Air (299K, 1 atm): \( \nu = 15.80 \times 10^{-6} \text{ m}^2/\text{s} \); Table A-6, Naphthalene vapor-air (298K, 1 atm): \( D_{AB} = 0.62 \times 10^{-5} \text{ m}^2/\text{s} \); Naphthalene (given): \( M = 128.16 \text{ kg/kmol} \), \( p_{sat} = p \times 10^E \) where \( E = 8.67 - (3766/T) \) with \( p \) [bar] and \( T \) [K].

ANALYSIS: (a) The rate equation for the sublimation of naphthalene vapor from the solid naphthalene can be written in terms of the mass transfer coefficient,

\[
\bar{h}_m = \frac{n_A}{A_s \left( \rho_{A,s} - \rho_{A,\infty} \right)}
\]

where \( A_s = \pi D \ell \). From the mass loss and time observations

\[
n_A = \frac{\Delta m}{\Delta t} = \frac{0.35 \times 10^{-3} \text{ kg}}{39 \times 60 \text{ s}} = 1.50 \times 10^{-7} \text{ kg/s}.
\]

The saturation density of the vapor at the solid surface, \( \rho_{A,s} \), can be determined from the perfect gas relation,

\[
\rho_{A,s} = \frac{p_{sat} (T_s)}{(\mathcal{R} M_A) T_s}.
\]

The saturation pressure, \( p_{sat} \), is given by

\[
p_{sat} = p \times 10^E
\]

where \( E = 8.67 - (3766/T) = 8.67 - (3766/299K) = -3.925 \)

\[
p = 750.6 \text{ mm Hg} \times \frac{1 \text{ N/m}^2}{2.953 \times 10^{-4} \text{ in Hg}} \times \frac{1 \text{ in}}{25.4 \text{ mm}} \times \frac{1 \text{ bar}}{1 \times 10^5 \text{ N/m}^2} = 1.001 \text{ bar}
\]

or \( p_{sat} = 1.001 \text{ bar} \times 10^{-3.925} = 1.190 \times 10^{-4} \text{ bar} \).

Continued .....
PROBLEM 7.121 (Cont.)

Substituting into Eq. (2),

\[ \rho_{A,s} = 1.190 \times 10^{-4} \text{ bar/} \frac{8.314 \times 10^{-2} \text{ m}^3 \cdot \text{bar/kmol} \cdot \text{K}}{128.16 \text{ kg/kmol}} \times 299 \text{ K} = 6.135 \times 10^{-4} \text{ kg/m}^3. \]

Using the parameters required for Eq. (1), the mass transfer coefficient is

\[ \bar{h}_m = \frac{1.50 \times 10^{-7} \text{ kg/s}}{\pi \left( 18.4 \times 10^{-3} \text{ m} \right) \left( 88.9 \times 10^{-3} \text{ m} \right)} \left[ 6.135 \times 10^{-4} - 0 \right] \text{ kg/m}^3 \]

\[ \bar{h}_m = 4.76 \times 10^{-2} \text{ m/s}. \]

(b) Invoking the heat-mass transfer analogy and assuming a Prandtl number ratio of unity, Eq. 7.56 can be used to estimate \( \bar{h}_m \).

\[ \frac{\text{Sh}_D}{D_{AB}} = \bar{h}_m D = \frac{C m^m}{D} \text{ Re} \text{ Sc}^n. \]

With

\[ \text{Re}_D = \frac{V D}{v} = 12 \text{ m/s} \left( 18.4 \times 10^{-3} \text{ m} \right) / 15.80 \times 10^{-6} \text{ m}^2 / \text{s} = 13,975 \]

it follows from Table 7.4 that \( C = 0.26 \) and \( m = 0.6 \). With

\[ \text{Sc} = v / D_{AB} = 15.80 \times 10^{-6} \text{ m}^2 / \text{s} / 0.62 \times 10^{-5} \text{ m}^2 / \text{s} = 2.55 \]

\( n = 0.37 \) and

\[ \text{Sh}_D = 0.26 (13.975)^{0.6} (2.55)^{0.37} = 112.9 \]

and

\[ \bar{h}_m = \text{Sh}_D \frac{D_{AB}}{D} = 112.9 \times \frac{0.62 \times 10^{-5} \text{ m}^2 / \text{s}}{18.4 \times 10^{-3} \text{ m}} = 3.8 \times 10^{-2} \text{ m/s}. \]

COMMENTS: The result from the correlation is 20% less than the experimental result. This may be considered reasonable in view of the uncertainties associated with the observations and the approximate nature of the correlation.
**PROBLEM 7.122**

**KNOWN:** Flow of dry air over a cylindrical medium saturated with water.

**FIND:** (a) Mass rate of water vapor evaporated per unit length \( n'_A \), when water-air is at 300 K, (b) Briefly explain change in mass rate if temperatures are at 325 K.

**SCHEMATIC:**

![Diagram](image)

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Heat-mass transfer analogy.

**PROPERTIES:** Table A.4, Air (300 K, 1 atm): \( \nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s} \), \( \text{Pr} = 0.707 \); Air (325 K, 1 atm): \( \nu = 18.41 \times 10^{-6} \text{ m}^2/\text{s} \), \( \text{Pr} = 0.703 \); Table A.8, Water vapor-air (300 K): \( D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s} \); Table A.6, Water vapor (300 K, 1 atm): \( \rho_{A,\text{sat}} = (\nu g)^{-1} = (39.13 \text{ m}^3/\text{kg})^{-1} = 0.0256 \text{ kg/m}^3 \); Water vapor (325 K, 1 atm): \( \rho_{A,\text{sat}} = (\nu g)^{-1} = (11.06 \text{ m}^3/\text{kg})^{-1} = 0.0904 \text{ kg/m}^3 \).

**ANALYSIS:** (a) For cross-flow over a cylinder, Eq. 7.55,

\[
\bar{Sh}_D = C \Re^m \Sc^{1/3}
\]

where \( m \), \( n \) are taken from Table 7.2. Calculate the Reynolds number, \( \Re_D = V D/\nu = 15 \text{ m/s} \times 0.04 \text{ m}/15.89 \times 10^{-6} \text{ m}^2/\text{s} = 37,760 \). With \( C = 0.193 \), \( m = 0.618 \), and \( \Sc \equiv \nu / D_{AB} \),

\[
\frac{\bar{Sh}_D}{D_{AB}} = 0.193 (37,760)^{0.618} \left[\frac{15.89 \times 10^{-6} \text{ m}^2/\text{s}}{0.26 \times 10^{-4} \text{ m}^2/\text{s}}\right]^{1/3} = 110.4
\]

\[
\bar{h}_m = \bar{Sh}_D D_B / D = 110.4 \times 0.26 \times 10^{-4} \text{ m}^2/\text{s}/0.04 \text{ m} = 0.0717 \text{ m/s}
\]

The evaporation rate, with \( A_S = \pi D \cdot \ell \), is

\[
n_A = \bar{h}_m A_S \left( \rho_{A,S} - \rho_{A,\infty} \right) \quad n'_A = n_A / \ell = \bar{h}_m \pi D \left( \rho_{A,S} - \rho_{A,\infty} \right)
\]

\[
= 0.0717 \text{ m/s} \left( \pi \times 0.04 \text{ m} \right) (0.0256 - 0) \text{kg/m}^3 = 2.31 \times 10^{-4} \text{ kg/s} \cdot \text{m}
\]

(b) The foregoing equations were entered into the IHT Workspace, and using the Properties Tools for air and water vapor thermophysical properties, the evaporation rate \( n'_A \) was calculated as a function of air-water temperatures (\( T_s = T_{\text{inf}} \)).

Continued...
As expected, the evaporation rate increased with increasing temperature markedly. For a 50 K increase, the evaporation rate increased by a factor of approximately 12.

COMMENTS: (1) What parameters cause this high sensitivity of $n'_A$ to $T_s$? From the IHT analysis, we observed only modest changes in $D_{AB} \left( 0.26 \text{ to } 0.33 \times 10^{-4} \text{ m}^2/\text{s} \right)$ and $\overline{U}_m \left( 0.07273 \text{ to } 0.0779 \text{ m/s} \right)$ over the range 300 to 350 K. The density of water vapor, $\rho_{A,S}$, however, is highly temperature dependent as can be seen by examining the steam tables, Table A.6. Find $\rho_{A,S} \left( 300 \text{ K} \right) = 0.02556 \text{ kg/m}^3$ while $\rho_{A,S} \left( 350 \text{ K} \right) = 0.260 \text{ kg/m}^3$, which accounts for more than a factor of 10 change.

(2) A copy of the IHT Workspace used to perform the analysis is shown below.

```plaintext
// The Mass Transfer Rate Equation:
n'A = \frac{h_m \pi D (\rho_{A,s} - 0)}{\Delta \rho} \quad // Eq (3)
n'A_{\text{plot}} = 1e4 \times n'A \quad // Scale change for plotting

// Mass Transfer Coefficient Correlation:
ShDbar = C \times ReD^m \times Sc^{(1/3)} \quad // Eq (1,2)
ShDbar = h_m / D_{AB}
C = 0.193 \quad // Table 7.2, 4000 <= ReD <= 40000
m = 0.618
ReD = u_{inf} D / \nu
Sc = \nu / D_{AB}

T_{inf} = T_s \quad // Airstream temperature, K
```
PROBLEM 7.123

KNOWN: Dry air at prescribed temperature and velocity flowing over a long, wetted cylinder of diameter 20 mm. Imbedded electrical heater maintains the surface at $T_s = 20^\circ C$.

FIND: (a) Water evaporation rate per unit length (kg/h⋅m) and electrical power per unit length $P'_e$ (W/m) required to maintain steady-state conditions, and (b) The temperature of the cylinder after all the water has evaporated for the same airstream conditions and heater power of part (a).

SCHEMATIC:

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties and (3) Heat-mass transfer analogy is applicable.

**PROPERTIES:** Table A.4, Air ($T_f = (T_s + T_\infty)/2 = 300$ K, 1 atm): $\rho = 1.16$ kg/m$^3$, $c_p = 1007$ J/kg⋅K, $k = 0.0263$ W/m⋅K, $\nu = 15.94 \times 10^{-6}$ m$^2$/s, $\alpha = 2.257 \times 10^{-5}$ m$^2$/s, Table A.6, Water ($T_s = 20^\circ C = 293$ K): $\rho_{A,s} = 1/\nu_g = 1/59.04 = 0.0169$ kg/m$^3$, $h_{fg} = 2454$ kJ/K; Table A.8, Water-air ($T_f = 300$ K): $D_{AB} = 0.26 \times 10^{-4}$ m$^2$/s.

**ANALYSIS:** (a) Perform an energy balance on the cylinder,

$$\dot{E}_{in} - \dot{E}_{out} = 0 \quad P'_e - q'_\text{conv} - q'_\text{evap} = 0$$

where the convection and evaporation rate equations are,

$$q'_\text{conv} = \bar{h}_D \pi D (T_s - T_\infty)$$

$$q'_\text{evap} = n_A h_{fg} = \bar{h}_m \pi D (\rho_{A,s} - \rho_{A,\infty}) h_{fg}$$

The convection coefficient can be estimated from the Churchill-Bernstein correlation, Eq. 7.57,

$$\overline{Nu}_D = 0.3 + \frac{0.62 \frac{Re}{Pr}^{1/3}}{1 + \left(0.4/Pr\right)^{2/3}} \left[1 + \left(\frac{Re_D}{282,000}\right)^{3/8}\right]^{4/5}$$

$$Re_D = \frac{VD}{\nu} = \frac{15 \text{ m/s} \times 0.020 \text{ m}}{15.94 \times 10^{-6} \text{ m}^2/\text{s}} = 18,821$$

$$\overline{Nu}_D = 0.3 + \frac{0.62 \left(18,821\right)^{1/2} \left(0.707\right)^{1/3}}{1 + \left(0.4/0.707\right)^{2/3}} \left[1 + \left(\frac{18,821}{282,000}\right)^{3/8}\right]^{4/5} = 76.5$$

$$\bar{h}_D = \frac{k}{\overline{Nu}_D} \frac{0.0263 \text{ W/m} \cdot \text{K}}{0.020 \text{ m}} \times 76.5 = 101 \text{ W/m}^2 \cdot \text{K}$$

Continued...
PROBLEM 7.123 (Cont.)

Evoking the heat-mass analogy, Eq. 6.92, with \( n = 1/3 \)

\[
\overline{h}_{D} = \frac{\rho c_{p}}{D_{AB}} \left( \frac{\alpha}{D_{AB}} \right)^{-2/3} = 1.16 \text{kg/m}^3 \times 1007 \text{J/kg} \cdot \text{K} \left( \frac{2.257 \times 10^{-5} \text{m}^2/\text{s}}{0.26 \times 10^{-4} \text{m}^2/\text{s}} \right)^{-2/3} = 1284 \text{J/m}^3 \cdot \text{K}
\]

\[
\overline{h}_{m} = 101 \text{W/m}^2 \cdot \text{K}/1284 \text{J/m}^3 \cdot \text{K} = 0.0787 \text{m/s}
\]

Substituting numerical values, the energy balance, Eq. (1),

\[
P_{c} - 101 \text{W/m}^2 \cdot \text{K} \times \pi \times 0.020 \text{m} \times (20 - 35) \text{K} - 0.0787 \text{m/s} \times \pi \times 0.020 \text{m} \times (0.0169 - 0) \text{kg/m}^3 \times 2454 \times 10^3 \text{J/kg} \cdot \text{K} = 0
\]

\[
P_{c} = -95.1 \text{W/m} + 205.1 \text{W/m} = 110 \text{W/m} <
\]

The evaporation rate is

\[
n_{A} = \overline{h}_{m} \pi D \left( \rho_{A,s} - \rho_{A,\infty} \right) = 0.0787 \text{m/s} \pi \times 0.0020 \text{m} \times (0.0169 - 0) \text{kg/m}^3 = 0.301 \text{kg/h} \cdot \text{m} <
\]

(b) When the cylinder is dry, the energy balance is

\[
P_{c}' = \overline{h}_{D} \pi D \left( T_{s} - T_{\infty} \right)
\]

\[
T_{s} = T_{\infty} + P_{c}' / \overline{h}_{D} \pi D = 35^\circ \text{C} + 110 \text{W/m}/(101 \text{W/m}^2 \cdot \text{K} \pi \times 0.020 \text{m}) = 52.3^\circ \text{C}
\]

COMMENTS: Using IHT Correlations Tool, External Flow, Cylinder, the calculation of part (b) was performed using the proper film temperature, \( T_{f} = 316.8 \text{K} \), to find \( \overline{h}_{D} = 99.4 \text{W/m}^2 \cdot \text{K} \) and \( T_{s} = 52.6^\circ \text{C} \).
PROBLEM 7.124

KNOWN: Dry air at prescribed temperature and velocity flows over a rod covered with a thin porous coating saturated with water. The ends of the rod are attached to heat sinks maintained at a constant temperature.

FIND: Temperature at the midspan of the rod and evaporation rate from the surface using a steady-state, finite-difference analysis. Validate your code, without the evaporation process, by comparing the temperature distribution with the analytical solution of a fin.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in rod, (3) Constant properties, and (4) Heat-mass transfer analogy is applicable.

PROPERTIES: Table A.4, Air (T_f, see Eq. (2); 1 atm): \( \rho, c_p, k, \alpha, \text{Pr} \); Table A.6, Water (T_m = T_{sat,m}, 1 atm): \( \rho_{A,sat} = \rho_{v} / \rho_{g} \), \( h_{fg} \); Table A.8, Water Vapor-Air (T_f, 1 atm): D_{AB} = D_{AB}(298 \text{ K}) \times (T_f/298)^{1.5}.

ANALYSIS: As suggested, the 10-node network shown above represents the half-length of the system. Performing an energy balance on the control volume about the m-th node, the finite-difference equation for the system is derived.

\[
\begin{align*}
\dot{E}_{in} - \dot{E}_{out} &= 0 \\
q_a - q_{evap} + q_b + q_c &= 0 \\
kA_c \left( \frac{T_{m+1} - T_m}{\Delta x} \right) &= n_{A,m} h_{fg,m} + \bar{h} \rho \Delta x (T_{\infty} - T_m) + kA_c \left( \frac{T_{m-1} - T_m}{\Delta x} \right) = 0
\end{align*}
\]

where the cross-sectional area and perimeter are \( A_c = \pi D^2 / 4 \) and \( P = \pi D \), respectively. The average heat transfer coefficient \( \bar{h} \) can be evaluated using the Churchill-Bernstein correlation, Eq. 7.57, evaluating thermophysical properties at an average film temperature for the system.

\[
\bar{T}_f = \left[ \frac{(T_1 + T_b) / 2 + T_\infty}{2} \right]/2
\]

The evaporation rate from Eq. (1) can be expressed as

\[
n_{A,m} = \bar{h}_{D,m} \rho \Delta x \left( \rho_{A,s,m} - 0 \right)
\]

where \( \bar{h}_{D,m} \) can be determined from the heat-mass analogy, Eq. 6.92, with \( n = 1/3 \),

\[
\frac{\bar{h}}{\bar{h}_m} = \rho c_p \left( \frac{\alpha}{D_{AB}} \right)^{2/3}
\]

Continued...
where all properties are evaluated at $T_f$. The density of water vapor, $\rho_{A,s,m}$, as well as the heat of vaporization, $h_{fg,m}$, must be evaluated at the nodal temperature $T_m$.

Using the IHT Correlation Tool, External Flow, Cylinder, an estimate of $\overline{h_D} = 101 \text{ W/m}^2\text{K}$ was obtained with $\overline{T_f} = 298.5 \text{ K}$ (based upon assumed value of $T_1 = 27^\circ \text{C}$). From the analogy, Eq. (4), find that $\overline{h_{D,m}} = 0.0772 \text{ m/s}$. Using the IHT Workspace, the finite-difference equations, Eq. (1), were entered and the temperature distribution (K, Case 1) determined as tabulated below. Using this same code with $\overline{h_{D,m}} = 1.0 \times 10^{-10} \text{ m/s}$, the temperature distribution (K, Case 2) was obtained. The results compared identically with the analytical solution for a fin with an adiabatic tip using the IHT Model, Extended Surface, Rectangular Pin Fin.

```
PROBLEM 7.125

KNOWN: The dimensions of a cylinder which approximates the human body.

FIND: (a) Heat loss by forced convection to ambient air, (b) Total heat loss when a water film covers the surface.

SCHEMATIC:

ASSUMPTIONS: (1) Direct contact between skin and air (no clothing), (2) Negligible radiation effects, (3) Heat and mass transfer analogy is applicable, (4) Water vapor is an ideal gas.

PROPERTIES: Table A-6, Water (30°C = 303 K): \( \rho_{A,\text{sat}} = \frac{v_{g}}{g^1} = 0.0336 \text{ kg/m}^3 \), \( h_{fg} = 2431 \text{ kJ/kg} \)

Water (20°C = 293K): \( \rho_{A,\text{sat}} = 0.017 \text{ kg/m}^3 \); Table A-4, Air: \( T_\infty = 20^\circ\text{C} = 293\text{K} \): \( \nu = 15.27 \times 10^{-6} \text{ m}^2/\text{s}, \, k = 25.7 \times 10^{-3} \text{ W/mK} \), \( Pr = 0.71 \); Table A-8, Water vapor-air (300K): \( D_{AB} = 26 \times 10^{-6} \text{ m}^2/\text{s}, \, Sc = \nu/D_{AB} = 0.59 \).

ANALYSIS: (a) The heat rate is

\[
q = \bar{h} (\pi D L) (T_s - T_\infty).
\]

With

\[
\text{Re}_D = \frac{VD}{\nu} = \frac{(10 \text{ m/s}) (0.3 \text{ m})}{15.27 \times 10^{-6} \text{ m}^2/\text{s}} = 1.96 \times 10^5
\]

obtain \( \bar{h} \) from Eq. 7.56, where \( n = 0.37 \) and, from Table 7.4, \( C = 0.26 \) and \( m = 0.6 \),

\[
\text{Nu}_D = 0.6 \left( 1.96 \times 10^5 \right)^{0.6} (0.71)^{0.37} (0.71/0.71)^{0.25} = 343.
\]

Hence

\[
\bar{h} = \frac{k}{D} = \frac{343 \times 25.7 \times 10^{-3}}{0.3 \text{ m}} \text{ W/m} \cdot \text{K} = 29.4 \text{ W/m}^2 \cdot \text{K}
\]

and

\[
q = 29.4 \text{ W/m}^2 \cdot \text{K} \left( \pi \times 0.3 \text{ m} \times 1.75 \text{ m} \right) \left( 30 - 20 \right) \circ \text{C} = 485 \text{ W}.
\]

(b) The total heat loss with the water film includes latent, as well as sensible, contributions and may be expressed as

\[
q = \bar{h} (\pi D L) (T_s - T_\infty) + \bar{n}_A h_{fg}
\]

where

\[
\bar{n}_A = \frac{\bar{n}_m}{D} (\pi D L) \left[ \rho_{A,\text{sat}} (T_s) - \rho_{A,\infty} \right]
\]

\[
\rho_{A,\text{sat}} (T_s) = 0.0336 \text{ kg/m}^3 \hspace{1cm} \rho_{A,\infty} = \phi \rho_{A,\text{sat}} (T_\infty) = 0.6 (0.017) = 0.010 \text{ kg/m}^3.
\]

Continued ….
The convection mass transfer coefficient may be obtained from Eq. 6.92 or by expressing the mass transfer analog of Eq. 7.56. Neglecting the Pr ratio, the analogous form is

\[
\overline{\text{Sh}}_D = 0.26 \, \text{Re}_D^{0.6} \, \text{Sc}^{0.37}
\]

\[
\overline{\text{Sh}}_D = 0.26 \left( 1.96 \times 10^5 \right)^{0.6} \left( 0.59 \right)^{0.37} = 320.
\]

Hence

\[
\overline{h}_m = 320 \frac{D_{AB}}{D} = \frac{320 \times 0.26 \times 10^{-4}}{0.3} \text{ m}^2/\text{s} = 0.028 \text{ m/s}.
\]

The evaporation rate is then

\[
\dot{n}_A = 0.028 \text{ m/s} \left( \pi \times 0.3 \times 1.75 \text{ m} \right) [0.0336 - 0.010] \text{ kg/m}^3
\]

\[
\dot{n}_A = 1.09 \times 10^{-3} \text{ kg/s}.
\]

Hence,

\[
q = 485 \text{ W} + 1.09 \times 10^{-3} \text{ kg/s} \times 2.431 \times 10^6 \text{ J/kg}
\]

\[
q = 485 \text{ W} + 2650 \text{ W} = 3135 \text{ W}.
\]

**COMMENTS:** The evaporative (latent) heat loss dominates over the sensible heat loss. Its effect is often felt when stepping out of a swimming pool or other body of water.
PROBLEM 7.126

KNOWN: Horizontal tube exposed to transverse stream of dry air.

FIND: Equation to determine heat transfer enhancement due to wetting. Evaluate enhancement for prescribed conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Heat-mass transfer analogy applicable, (3) Water vapor behaves as perfect gas.

PROPERTIES: *Table A-4*, Air (310K, 1 atm): \( \rho = 1.1281 \, \text{kg/m}^3, \ c_p = 1007.4 \, \text{J/kg}, \ \nu = 16.90 \times 10^{-6} \, \text{m}^2/\text{s}, \ \text{Pr} = 0.706; *Table A-8*, Air-water vapor mixture (310K): \( \text{D}_{AB} = 0.26 \times 10^{-4} \, \text{m}^2/\text{s}, \ \text{Sc} = \nu B/\text{D}_{AB} = 0.650; *Table A-6*, Saturated water vapor (320K): \( \rho_{A,sat} = 1/\nu_g = 0.07153 \, \text{kg/m}^3, h_{fg} = 2390 \, \text{kJ/kg}.

ANALYSIS: The enhancement due to wetting can be expressed as the ratio of the wet-to-dry cylinder heat fluxes.

\[
\frac{q_{w}^{*}}{q_{d}^{*}} = \frac{q_{conv}^{*} + q_{evap}^{*}}{q_{conv}^{*}} = 1 + \frac{q_{evap}^{*}}{q_{conv}^{*}}
\]

where

\[
q_{conv}^{*} = h(T_s - T_\infty) \quad q_{evap}^{*} = m_A^{*} h_{fg} = \frac{q_{A,sat} h_{fg}}{\rho A,\infty} \left( \rho_{A,sat} - \rho_{A,\infty} \right) h_{fg} = \frac{q_{A,sat} h_{fg}}{\rho A,\infty}.
\]

Invoking the heat-mass transfer analogy, using Eq. 6.92, find

\[
\frac{h}{h_m} = \left( \rho \ c_p \right)_B \text{Le}^{1-n} = \left( \rho \ c_p \right)_B (\text{Sc/Pr})^{2/3}
\]

assuming \( n = 1/3 \) with \( \rho_{A,\infty} = 0 \), find

\[
\frac{q_{w}^{*}}{q_{d}^{*}} = 1 + \left[ \left( \rho \ c_p \right)_B (\text{Sc/Pr})^{2/3} \right]^{-1} \frac{\rho_{A,sat} h_{fg}}{\rho_{A,\infty}} \left( T_s - T_\infty \right).
\]

Substituting numerical values, the enhancement is

\[
\frac{q_{w}^{*}}{q_{d}^{*}} = 1 + \left[ \left( 1.1281 \times 1007.4 \right) \left( \frac{0.650}{0.706} \right) \right]^{2/3} \left[ \frac{0.07153 \times 2390 \times 10^3}{(320 - 300)\,\text{K}} \right]^{-1} = 9.0.
\]

COMMENTS: For the prescribed conditions, the effect of wetting is to enhance the heat transfer by nearly an order of magnitude. Will the enhancement increase or decrease with increasing \( T_s \)?
PROBLEM 7.127

KNOWN: Moisture-soaked paper is cylindrical form maintained at given temperature by imbedded heaters. Dry air at prescribed velocity and temperature in cross flow over cylinder.

FIND: (a) Required electrical power and the evaporation rate per unit length, \( q'_{\text{evap}} \) and \( n_A' \), respectively, and (b) Calculate and plot \( q' \) and \( n_A' \) as a function of dry air velocity \( 5 \leq V \leq 20 \text{ m/s} \) and paper temperatures of 65, 70 and 75°C.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Heat-mass transfer analogy applicable, (3) Negligible radiation effects.

PROPERTIES: Table A.4, Air \(( T_\infty = 20 \degree C = 293 \text{ K}, 1 \text{ atm})\): \( \rho = 1.1941 \text{ kg/m}^3 \), \( c_p = 1007 \text{ J/kg K} \), \( k = 25.7 \times 10^{-3} \text{ W/m K} \), \( \nu = 15.26 \times 10^{-6} \text{ m/s} \), \( \text{Pr} = 0.709 \); \( T_s = 70 \degree C = 343 \text{ K} \): \( \text{Pr}_s = 0.701 \); Table A.6, Sat. water vapor \(( T_s = 70 \degree C = 343 \text{ K})\): \( \rho_{A,s} = 1/\nu_s = 0.196 \text{ kg/m}^3 \), \( h_{fg} = 2334 \times 10^3 \text{ J/kg} \); Table A.8, Air-water vapor mixture \(( T_f = (T_\infty + T_s)/2 = 318 \text{ K}, 1 \text{ atm})\): \( D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}(318/298)^{3/2} = 0.29 \times 10^{-4} \text{ m}^2/\text{s} \).

ANALYSIS: (a) From an energy balance on the cylinder on a per unit length basis,

\[
q'_{\text{elec}} = q'_{\text{conv}} + q'_{\text{evap}} = \pi D \left[ \bar{h}(T_s - T_\infty) + \bar{h}_m \left( \rho_{A,s} - \rho_{A,\infty} \right) h_{fg} \right]
\]

where \( \rho_{A,\infty} = 0 \), the freestream air is dry, and \( \rho_{A,s} = \rho_{A,sat}(T_s) \). To estimate \( \bar{h} \), find

\[
\text{Re}_D = \frac{VD}{\nu} = \frac{10 \text{ m/s} \times 0.15 \text{ m}}{15.26 \times 10^{-6} \text{ m}^2/\text{s}} = 98,296
\]

and using the Zhukauskus correlation, from Table 7.4: \( C = 0.26 \), \( m = 0.6 \), and \( n = 0.37 \),

\[
\text{Nu}_D = \frac{\bar{h}D}{k} = 0.26 \text{Re}^{0.6} \text{Pr}^{0.37} (\text{Pr}/\text{Pr}_s)^{0.25}
\]

\[
\bar{h} = \frac{0.0257 \text{ W/m K}}{0.15 \text{ m}} \times 26.92,966^{0.6} (0.709)^{0.37} (0.709/0.701)^{0.25} = 38.9 \text{ W/m}^2 \cdot \text{K}
\]

Using the heat-mass analogy with \( n = 1/3 \), find

\[
\frac{\bar{h}}{\bar{h}_m} = \left( \frac{\rho c_p}{B} \right) \left( \frac{Sc}{Pr} \right)^{2/3} = \left( \frac{\rho c_p}{B} \right) \left( \frac{V}{D_{AB}/Pr} \right)^{2/3}
\]

\[
\bar{h}_m = 38.9 \text{ W/m}^2 \cdot \text{K} \left[ \frac{1.1941 \text{ kg/m}^3 \times 1007 \text{ J/kg K}}{0.709} \right]^{2/3}
\]

\[
\bar{h}_m = 0.03946 \text{ m/s}
\]

Hence, the electric power requirement is

\[
q'_{\text{elec}} = \pi \times 0.15 \text{ m} \left[ 38.9 \text{ W/m}^2 \cdot \text{K} \times (70 - 20) + 0.03946 \text{ m/s} \times 0.196 - 0 \right] \text{ J/kg}
\]

Continued...
(b) The foregoing equations were entered into the IHT Workspace, and using the Properties Tools, for air and water vapor required thermophysical properties, the required electrical power, $q'_{\text{elec}}$, and evaporation rate, $n'_{A}$, were calculated as a function of dry air velocity for selected water temperatures.

**COMMENTS:**

(1) Note at which temperatures the thermophysical properties are evaluated.

(2) From Equation (5), note that the evaporation heat rate far exceeds that due to convection.

(3) From the plots, note that both $q'_{\text{elec}}$ and $n'_{A}$ are nearly proportional to air velocity, and increase with increasing water temperature.
PROBLEM 7.128

KNOWN: Dry-and wet-bulb temperatures associated with a moist airflow through a large diameter duct of prescribed surface temperature.

FIND: Temperature and relative humidity of airflow.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Conduction along the thermometers is negligible, (3) Duct wall forms a large enclosure about the thermometers.

PROPERTIES: Table A-4, Air (318K, 1 atm): \( \nu = 17.7 \times 10^{-6} \) m\(^2\)/s, \( k = 0.0276 \) W/m\(\cdot\)K, \( Pr = 0.70 \); Table A-4, Air (298K, 1 atm): \( \nu = 15.7 \times 10^{-6} \) m\(^2\)/s, \( k = 0.0261 \) W/m\(\cdot\)K, \( Pr = 0.71 \); Table A-6, Saturated water vapor (298K): \( v_g = 44.3 \) m\(^3\)/kg, \( h_{fg} = 2442 \) kJ/kg; Saturated water vapor (318.5K): \( v_g = 15.5 \) m\(^3\)/kg; Table A-8, Water vapor-air (298K): \( D_{AB} = 0.26 \times 10^{-4} \) m\(^2\)/s, \( Sc = 0.60 \).

ANALYSIS: Dry-bulb Thermometer: Since \( T_{db} > T_s \), there is net radiation transfer from the surface of the dry-bulb thermometer to the duct wall. Hence to maintain steady-state conditions, the thermometer temperature must be less than that of the air \( (T_{db} < T_{\infty}) \) to allow for convection heat transfer from the air. Hence, from application of a surface energy balance to the thermometer, \( q_{conv} = q_{rad} \), or, from Eqs. 6.4 and 1.7,

\[
\overline{h}A_{db}(T_{\infty} - T_{db}) = \epsilon_g A_{db} \sigma (T_{db}^4 - T_s^4).
\]

The air temperature is then

\[
T_{\infty} = T_{db} + (\epsilon_g \sigma / \overline{h})(T_{db}^4 - T_s^4)
\]

(1)

where \( \overline{h} \) may be obtained from Eq. 7.56.

Wet-bulb Temperature: The relative humidity may be obtained by performing an energy balance on the wet-bulb thermometer. In this case convection heat transfer to the wick is balanced by evaporative and radiative heat losses from the wick,

\[
q_{conv} = q_{evap} + q_{rad}, \quad q_{evap} = n^* A_{wb} \rho_{fg} = \overline{h}_m [\rho_{A,sat}(T_{wb}) - \phi_{\infty} \rho_{A,sat}(T_{\infty})] A_{wb} \rho_{fg}.
\]

\[
\overline{h}_{wb}(T_{\infty} - T_{wb}) = \overline{h}_m [\rho_{A,sat}(T_{wb}) - \phi_{\infty} \rho_{A,sat}(T_{\infty})] A_{wb} \rho_{fg} + \epsilon_w A_{wb} \sigma (T_{wb}^4 - T_s^4)
\]

\[
\phi_{\infty} = \left\{ \frac{\rho_{A,sat}(T_{wb}) + [\epsilon_w \sigma (T_{wb}^4 - T_s^4) - h(T_{\infty} - T_{wb})]}{\rho_{A,sat}(T_{\infty})} \right\}/\rho_{A,sat}(T_{\infty})
\]

(2)

where \( \overline{h}_m \) may be determined from the mass transfer analog of Eq. 7.56.
**PROBLEM 7.128 (Cont.)**

*Convection Calculations*: For the prescribed conditions, the Reynolds number associated with the dry-bulb thermometer is

\[
Re_{D(db)} = \frac{VD_{bd}}{\nu} = 5 \text{ m/s} \times 0.003 \text{ m}/17.7 \times 10^{-6} \text{ m}^2/\text{s} = 847.
\]

Approximating the Prandtl number ratio as unity, from Eq. 7.56 and Table 7.4,

\[
\overline{Nu}_{D(db)} = CRe_{D(db)}^{m} Pr^{n} = 0.51(847)^{0.5}(0.70)^{0.37} = 13.01
\]

\[
\overline{h} = 13.01 \frac{k}{D_{db}} = 13.01 \frac{0.0276 \text{ W/m} \cdot \text{K}}{0.003 \text{ m}} = 120 \text{ W/m}^2 \cdot \text{K}.
\]

From Eq. (1) the air temperature is

\[
T_{\infty} = 45^\circ \text{C} + \frac{0.95 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4}{120 \text{ W/m}^2 \cdot \text{K}} (318^4 - 308^4) \text{K}^4 = 45^\circ \text{C} + 0.55^\circ \text{C} = 45.6^\circ \text{C}.
\]

The relative humidity may now be obtained from Eq. (2). The Reynolds number associated with the wet-bulb thermometer is

\[
Re_{D(wb)} = \frac{VD_{wb}}{\nu} = 5 \text{ m/s} \times 0.004 \text{ m}/15.7 \times 10^{-6} \text{ m}^2/\text{s} = 1274.
\]

From Eq. 7.56 and Table 7.4, it follows that

\[
\overline{Nu}_{D(wb)} = 0.26 (1274)^{0.6} (0.71)^{0.37} = 16.71
\]

\[
\overline{h} = 16.71 \frac{k}{D_{wb}} = 16.71 \frac{0.0261 \text{ W/m} \cdot \text{K}}{0.004 \text{ m}} = 109 \text{ W/m}^2 \cdot \text{K}.
\]

Using the mass transfer analog of Eq. 7.56, it also follows that

\[
\overline{Sh}_{D(wb)} = 0.26 Re_{D(wb)}^{0.6} Sc^{0.37} = 0.26 (1274)^{0.6} (0.6)^{0.37} = 15.7
\]

\[
\overline{h}_{m} = 15.7 \frac{DAB}{D_{wb}} = 15.7 \times 0.26 \times 10^{-4} \text{ m}^2/\text{s} = 0.102 \text{ m/s}.
\]

Also,

\[
\rho_{A,sat}(T_{wb}) = v_{g} (298 \text{ K})^{-1} = \left(44.3 \text{ m}^3/\text{kg} \right)^{-1} = 0.0226 \text{ kg/m}^3
\]

\[
\rho_{A,sat}(T_{\infty}) = v_{g} (318.5 \text{ K})^{-1} = \left(15.5 \text{ m}^3/\text{kg} \right)^{-1} = 0.0645 \text{ kg/m}^3.
\]

Hence the relative humidity is, from Eq. (2)

\[
\phi_{\infty} = \left[0.0226 \text{ kg/m}^3 + \frac{0.95 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K} \left(298^4 - 308^4 \right) \text{K}^4 - 109 \text{ W/m}^2 \cdot \text{K} \left(45.55 - 25 \right) \text{K}}{(2.442 \times 10^5 \text{ J/kg})(0.102 \text{ m/s})} \right]/0.0645 \text{ kg/m}^3
\]

\[
\phi_{\infty} = 0.21
\]

**COMMENTS**: (1) The effect of radiation exchange between the duct wall and the thermometers is small. For this reason \(T_{\infty} = T_{db}\). (2) The evaporative heat loss is significant due to the small value of \(\phi_{\infty}\), causing \(T_{wb}\) to be significantly less than \(T_{\infty}\). <
PROBLEM 7.129

KNOWN: Velocity, diameter and temperature of a spherical droplet. Conditions of surroundings.

FIND: (a) Expressions for droplet evaporation and cooling rates, (b) Evaporation and cooling rates for prescribed conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible temperature gradients in the drop, (2) Heat and mass transfer analogy is applicable, (3) Perfect gas behavior for vapor.

PROPERTIES: Table A-4, Air (T∞ = 298K, 1 atm): \( \nu = 15.71 \times 10^{-6} \text{ m}^2/\text{s} \), \( k = 0.0261 \text{ W/m} \cdot \text{K} \), \( Pr = 0.71 \); Table A-6, Water (T = 40°C): \( \rho_{A,sat} = 0.050 \text{ kg/m}^3 \), \( h_{fg} = 2407 \text{ kJ/kg} \), \( \rho_{\ell} = 992 \text{ kg/m}^3 \), \( c_{p,\ell} \) = 4179 J/kg-K; (T∞ = 25°C): \( \rho_{A,sat} = 0.023 \text{ kg/m}^3 \); Table A-8, Water vapor-air (298K): \( D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s} \).

ANALYSIS: (a) The evaporation rate is given by

\[
\dot{m}_{evap} = h_m A_s \left( \rho_{A,s} - \rho_{A,\infty} \right) = h_m \pi D^2 \left[ \rho_{A,sat}(T) - \phi_\infty \rho_{A,sat}(T_\infty) \right].
\]

The cooling rate is obtained from an energy balance performed for a control surface about the droplet,

\[
\dot{E}_{st} = -q_{out} = -(q_{conv} + q_{rad} + q_{evap})
\]

or

\[
\frac{d}{dt} \left( \frac{\rho_\ell \pi D^3}{6 c_{p,\ell} T} \right) = -A_s \left[ h(T_s - T_\infty) + \varepsilon \sigma \left( T_s^4 - T_{sur}^4 \right) + \dot{m}_{evap} h_{fg} \right].
\]

With \( A_s = \pi D^2 \), it follows that

\[
\frac{dT}{dt} = -\frac{6}{\rho_\ell c_{p,\ell} D} \left[ h(T_s - T_\infty) + \varepsilon \sigma \left( T_s^4 - T_{sur}^4 \right) + \dot{m}_{evap} h_{fg} \right].
\]

(b) To obtain \( h_m \), the mass transfer analog of the Ranz-Marshall correlation gives

\[
Sh_D = 2 + 0.6 \Re_D^{1/2} \Sc^{1/3}
\]

where

\[
\Re_D = \frac{VD}{\nu} = \frac{7 \text{ m/s} \times 0.003 \text{ m}}{15.71 \times 10^{-6} \text{ m}^2/\text{s}} = 1337, \quad \Sc = \frac{\nu}{D_{AB}} = \frac{15.71 \times 10^{-6}}{26 \times 10^{-6}} = 0.60.
\]

Continued …..
Hence
\[
\bar{Sh}D = 2 + 0.6(1337)^{1/2}(0.6)^{1/3} = 20.5
\]
\[
\bar{h}_m = \frac{ShD}{D} = 20.5 \times \frac{0.26 \times 10^{-4}}{0.003} \text{ m}^2/\text{s} = 0.18 \text{ m/s}
\]
\[
m_{\text{evap}} = 0.18 \text{ m/s} \pi (0.003 \text{ m})^2 [0.05 - 0.6 \times 0.023] \text{ kg/m}^3 = 1.82 \times 10^{-7} \text{ kg/s}.
\]
The evaporative heat flux is then
\[
q_{\text{evap}} = \frac{q_{\text{evap}}}{A_s} = \frac{m_{\text{evap}} h_{fg}}{\pi D^2} = \frac{1.82 \times 10^{-7} \text{ kg/s} \left(2.407 \times 10^6 \text{ J/kg}\right)}{\pi (0.003 \text{ m})^2}
\]
\[
q_{\text{evap}} = 15,494 \text{ W/m}^2.
\]
Using the heat transfer correlation, the Nusselt number is
\[
\bar{Nu}D = 2 + 0.6ReD^{1/2}Pr^{1/3} = 2 + 0.6(1337)^{1/2}(0.71)^{1/3} = 21.58.
\]
Hence
\[
\bar{h} = \frac{k}{\bar{Nu}D} \frac{0.0261 \text{ W/m}\cdot\text{K}}{0.003 \text{ m}} = 188 \text{ W/m}^2\cdot\text{K}
\]
and the sensible heat flux is
\[
q_{\text{conv}} = \bar{h}(T - T_\infty) = 188 \text{ W/m}^2\cdot\text{K}(40 - 25) \text{°C}
\]
\[
q_{\text{conv}} = 2815 \text{ W/m}^2.
\]
The net radiative flux is
\[
q_{\text{rad}} = \varepsilon \sigma \left(T^4 - T_\text{sur}^4\right) - 0.95 \times 5.67 \times 10^{-8} \text{ W/m}^2\cdot\text{K}^4 \left[313^4 - 288^4\right] \text{ K}^4
\]
\[
q_{\text{rad}} = 146 \text{ W/m}^2\cdot\text{K}.
\]
Hence
\[
\frac{dT}{dt} = -\frac{6}{992 \text{ kg/m}^3 \times 4179 \text{ J/kg} \cdot \text{K}(0.003 \text{ m})} (2815 + 146 + 15,494) \text{ W/m}^2
\]
\[
\frac{dT}{dt} = -8.9 \text{ K/s}.
\]
COMMENTS: (1) Evaporative cooling provides the dominant heat loss from the drop. (2) To test the validity of assuming negligible temperature gradients in the drop, calculate
\[
Bi = \frac{h_{\text{eff}} (r_0 / 3)}{k_\ell}, \quad \text{where} \quad h_{\text{eff}} = \frac{q_{\text{tot}}}{T - T_\infty} = \frac{18,455}{25} = 738 \text{ W/m}^2\cdot\text{K}.
\]
From Table A-6, \( k_\ell = 0.631 \text{ W/m}\cdot\text{K} \), hence
\[
Bi = \frac{738 \text{ W/m}^2\cdot\text{K}(0.0005 \text{ m})}{0.631 \text{ W/m}\cdot\text{K}} = 0.58.
\]
Hence, although suspect, the assumption is not totally unreasonable.
PROBLEM 7.130

KNOWN: Cranberries with an average diameter of 15 mm rolling over a fine screen. Thickness of the water film is 0.2 mm.

FIND: Time required to dry the berries exposed to heated air with a velocity of 2 m/s and temperature of 30°C.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Air stream is dry, (3) Water film on the berries is also at 30°C, (4) Convection process is uniform over the exposed surface, and (5) Heat-mass analogy is applicable.

PROPERTIES: *Table A-6*, Water (T<sub>f</sub> = 30°C = 303 K): ρ<sub>A,f</sub> = 995.8 kg/m<sup>3</sup>, ρ<sub>A,g</sub> = 0.02985 kg/m<sup>3</sup>; *Table A-8*, Water-air (T<sub>f</sub> = 303 K, 1 atm): D<sub>AB</sub> = 0.26 × 10<sup>-4</sup> m<sup>2</sup>/s (303/298)<sup>1.5</sup> = 2.67 × 10<sup>-5</sup> m<sup>2</sup>/s; *Table A-4*, Air (T<sub>f</sub> = 303 K, 1 atm): μ = μ<sub>s</sub> = 1.86 × 10<sup>-5</sup> N⋅s/m<sup>2</sup>, ν = 1.619 × 10<sup>-5</sup> m<sup>2</sup>/s, α = 2.294 × 10<sup>-5</sup> m<sup>2</sup>/s, k = 0.02652 W/m⋅K, Pr = 0.861.

ANALYSIS: The evaporation rate of water from the berry surface is given by the rate equation,

\[
\dot{m}_h A_s = \rho_{A,s} - \rho_{A,\infty}
\]

where A<sub>s</sub> = πD<sup>2</sup> and \( \dot{m}_h \) is determined using the heat-mass analogy, Eq. 6.67,

\[
\frac{\bar{h}}{\dot{m}_h} = \frac{k}{D_{AB}} \frac{\text{Le}^{-n}}{D_{AB}}
\]

where Le = α/D<sub>AB</sub> and typically n = 1/3. The heat transfer coefficient \( \bar{h} \) is estimated with the Whitaker correlation, Eq. 7.59,

\[
\frac{\text{Nu}_D}{k} = 2 + \left[ 0.4 \sqrt{\text{Re}_D} + 0.06 \left( \frac{\text{Re}_D}{\text{Pr}} \right)^{2/3} \right] \text{Pr}^{0.4} \left( \frac{\mu}{\mu_s} \right)^{1/4}
\]

Substituting numerical values, find

\[
\text{Re}_D = \frac{VD}{\nu} = \frac{2 \text{ m/s} \times 0.015 \text{ m}}{1.86 \times 10^{-5} \text{ m}^2/\text{s}} = 1853
\]

\[
\text{Nu}_D = 2 + \left[ 0.4 (1853)^{1/2} + 0.06 (1853)^{2/3} \right] \times (0.707)^{0.4} \times 1 = 24.9
\]

\[
\bar{h} = 24.9 \times 0.02652 \text{ W/m⋅K/0.015 m} = 43.4 \text{ W/m}^2\cdot\text{K}
\]

and using the heat-mass analogy,

\[
\frac{\bar{h}_m}{\text{Pr}} = 43.4 \text{ W/m}^2\cdot\text{K} \times \left( \frac{2.67 \times 10^{-5} \text{ m}^2/\text{s}/\text{0.02652 W/m} \cdot \text{K}}{0.861} \right)^{1/3}
\]

\[\bar{h}_m = 0.0420 \text{ m/s}\]

Continued .....
where

\[ \text{Le} = \alpha / D_{AB} = \frac{2.294 \times 10^{-5} \text{ m}^2 / \text{s}}{2.667 \times 10^{-5} \text{ m}^2 / \text{s}} = 0.861 \]

Using Eq. (1), the evaporation rate is

\[ n = 0.0420 \text{ m/s} \times \left( \frac{\pi (0.015 \text{ m})^2}{4} \right) (0.02985 - 0) \text{ kg/m}^3 = 8.87 \times 10^{-7} \text{ kg/s} \]

The time, \( t_o \), required to evaporate the water film of thickness \( \delta = 0.2 \text{ mm} \) is

\[ nt_o = M_{film} = \rho_{\text{A},\ell} (\pi D) \delta \]

\[ t_o = 995.8 \text{ kg/m}^3 (\pi \times 0.015 \text{ m}) \times 0.0002 \text{ m} / 8.87 \times 10^{-7} \text{ kg/s} \]

\[ t_o = 159 \text{ s} \]
PROBLEM 7.131

KNOWN: Spherical droplet at prescribed temperature and velocity falling in still, hotter dry air.

FIND: Instantaneous rate of evaporation.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Heat-mass transfer analogy applicable.

PROPERTIES: Table A-4, Air ($T_\infty = 100^\circ C = 373K$, 1 atm): $\rho = 0.9380 \text{ kg/m}^3$, $c_p = 1011 \text{ J/kg.K}$, $k = 0.0317 \text{ W/m.K}$, $v = 23.45 \times 10^{-6} \text{ m}^2/\text{s}$, $Pr = 0.695$; Table A-6, Sat. water ($T_s = 60^\circ C = 333K$): $\rho_\ell = 1/\nu_\ell = 983 \text{ kg/m}^3$, $\rho_{A,s} = 1/\nu_f = 0.129 \text{ kg/m}^3$; Table A-8, Air-water vapor mixture ($T_\infty = 373K$, 1 atm): $D_{AB} = 0.267 \times 10^{-4} \text{ m}^2/\text{s}$ ($373/298)^{3/2} = 0.36 \times 10^{-4} \text{ m}^2/\text{s}$.

ANALYSIS: The instantaneous evaporation rate is

$$\dot{n}_A = \dot{h}_m A_s \left( \rho_{A,s} - \rho_{A,\infty} \right)$$

where $A_s = \pi D^2$, $\rho_{A,\infty} = 0$ and $\rho_{A,s} = \rho_{A,sat} (T_s)$. To estimate $\dot{h}_m$ use the Whitaker correlation, written in terms of mass transfer parameters and with $\mu/\mu_s = 1$,

$$\frac{\dot{h}_m D}{D_{AB}} = 2 + \left( 0.4\frac{Re_D^{1/2}}{D} + 0.06\frac{Re_D^{2/3}}{D} \right) Sc^{0.4}$$

$$\dot{h}_m = \frac{0.36 \times 10^{-4} \text{ m}^2/\text{s}}{0.0005 \text{ m}} \left[ 2 + \left( 0.4 \left( 45.8 \right)^{1/2} + 0.06 \left( 45.8 \right)^{2/3} \right) \times 0.651^{0.4} \right] = 0.355 \text{ m/s}$$

where $Re_D = \frac{VD}{\nu} = \frac{2.15 \text{ m/s} \times 0.0005 \text{ m}}{23.45 \times 10^{-6} \text{ m}^2/\text{s}} = 45.8$

$Sc = \frac{\nu}{D_{AB}} = \frac{23.45 \times 10^{-6} \text{ m}^2/\text{s}}{0.36 \times 10^{-4} \text{ m}^2/\text{s}} = 0.651$

Hence, the evaporation rate is

$$\dot{n}_A = 0.355 \text{ m/s} \times \pi \left( 0.0005 \text{ m} \right)^2 (0.129 - 0) \text{ kg/m}^3 = 3.60 \times 10^{-8} \text{ kg/s.}$$

COMMENTS: If this evaporation rate were to remain constant with time, the droplet of mass $M$ would be completely evaporated in

$$\Delta t = \frac{M}{\dot{n}_A} = \frac{\rho_\ell \left( 4\pi D^3 / 3 \right)}{\dot{n}_A} = \frac{983 \text{ kg/m}^3 \left( 4\pi \left( 0.0005 \text{ m} \right)^3 / 3 \right)}{3.60 \times 10^{-8} \text{ kg/s}} = 14.3 \text{ s.}$$

To determine whether the droplet temperature will increase or decrease with time, it is necessary to compare convective heat and evaporation rates. Hence it is not clear whether the time to completely evaporate will be less or greater than 14.3 s.
PROBLEM 7.132

KNOWN: Diameter, velocity and surface vapor concentration of alcohol droplet falling in quiescent air. Latent heat of vaporization and diffusion coefficient. Air temperature.

FIND: Droplet surface temperature

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Applicability of heat and mass transfer analogy, (3) Negligible radiation, (4) Negligible vapor concentration in air (\( \rho_{A,\infty} = 0 \)).

PROPERTIES: Table A.4, air (\( T_{\infty} = 300 \) K): \( \nu = 15.89 \times 10^{-6} \) m\(^2\)/s, \( k = 0.0263 \) W/m\( \cdot \)K, \( Pr = 0.707 \).

ANALYSIS: Application of a surface energy balance yields

\[
q_{\text{evap}} = q_{\text{conv}}
\]

\[
\overline{h_m} (\rho_{A,s} - \rho_{A,\infty}) h_{fg} = \overline{h} (T_{\infty} - T_s)
\]

\[
T_s = T_{\infty} - \frac{\overline{h_m}}{\overline{h}} \rho_{A,s} h_{fg}
\]

With \( Re_D = VD/\nu = 1.8 \) m/s\( \times \)\( 5 \times 10^{-4} \) m/\( 15.89 \times 10^{-6} \) m\(^2\)/s = 56.6 and \( Sc = V/D_{AB} = 1.59 \), the Ranz-Marshall correlation yields

\[
\overline{Nu_D} = 2 + 0.6 \overline{Re}_{D}^{1/2} Pr^{1/3} = 2 + 0.6 (56.6)^{1/2} (0.707)^{1/3} = 6.02
\]

\[
\overline{Sh_D} = 2 + 0.6 \overline{Re}_{D}^{1/2} Sc^{1/3} = 2 + 0.6 (56.6)^{1/2} (1.59^{1/3}) = 7.27
\]

With \( \overline{h_m}/\overline{h} = \overline{Sh_D} (D_{AB}/D)/\overline{Nu_D} (k/D) \),

\[
\frac{\overline{h_m}}{\overline{h}} = \frac{\overline{Sh_D} (D_{AB})}{\overline{Nu_D} (k)} = \frac{7.27 \times 10^{-5} \text{ m}^2/\text{s}}{6.02 \times 0.0263 \text{ W/m} \cdot \text{K}} = 4.59 \times 10^{-4} \text{ m}^3 \cdot \text{K}/\text{J}
\]

Hence,

\[
T_s = 300 \text{ K} - 4.59 \times 10^{-4} \text{ m}^3 \cdot \text{K}/\text{J} \left(0.0573 \text{ kg/m}^3\right) \left(8.42 \times 10^5 \text{ J/kg}\right) = 277.9 \text{ K}
\]

COMMENTS: The large vapor density, \( \rho_{A,s} \), renders the evaporative cooling effect significant.
PROBLEM 7.133

KNOWN: Diameter, velocity and temperature of water droplets in air of known temperature.

FIND: Evaporation rate for a single drop.

SCHEMATIC:

ASSUMPTIONS: (a) Steady-state conditions, (b) Dry air, (c) Drop oscillations and distortions are negligible.

PROPERTIES: Table A-4, Air (35°C = 308K): \( v = 16.7 \times 10^{-6} \text{ m}^2/\text{s} \); Table A-8, Water vapor-air (35°C = 308K): \( D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s} \); Table A-6, Saturated water vapor (25°C = 298K): \( v_g = 44.3 \text{ m}^3/\text{kg} \).

ANALYSIS: The mass evaporation rate is

\[
 n_A = \bar{h}_m \left( \pi D^2 \right) \left( \rho_{A,s} - \rho_{A,\infty} \right)
\]

where \( \rho_{A,s} = v_g^{-1} = 0.023 \text{ kg/m}^3 \) and \( \rho_{A,\infty} = 0 \). From Eq. 7.58,

\[
 \bar{Sh}_D = 2 + \left( 0.4 \frac{Re_D^{1/2} + 0.06 Re_D^{2/3}}{Sc} \right) Sc^{0.4}
\]

where

\[
 Re_D = \frac{VD}{v} = \frac{(5 \text{ m/s}) \left( 3 \times 10^{-3} \text{ m} \right)}{16.7 \times 10^{-6} \text{ m}^2/\text{s}} = 898 \quad Sc = \frac{v}{D_{AB}} = 0.64
\]

\[
 \bar{Sh}_D = 2 + \left[ 0.4 (898)^{1/2} + 0.06 (898)^{2/3} \right] (0.64)^{0.4} = 16.7
\]

\[
 \bar{h}_m = \bar{Sh}_D \frac{D_{AB}}{D} = 16.7 \frac{0.26 \times 10^{-4} \text{ m}^2/\text{s}}{3 \times 10^{-3} \text{ m}} = 0.145 \text{ m/s}
\]

Hence,

\[
 n_A = 0.145 \text{ m/s} \pi \left( 3 \times 10^{-3} \text{ m} \right)^2 \times 0.023 \text{ kg/m}^3 = 9.43 \times 10^{-8} \text{ kg/s}
\]

COMMENTS: For the small difference between \( T_s \) and \( T_\infty \), it is reasonable to neglect the viscosity ratio in Eq. 7.58. Use of Eq. 7.59 gives \( \bar{h}_m = 0.152 \text{ m/s} \), which is in good agreement with the result from Eq. 7.58.
PROBLEM 7.134

KNOWN: Humidity and temperature of air entering heater; temperature of air leaving heater. Diameter, temperature and relative velocity of injected droplets.

FIND: Droplet evaporation rate.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible change in droplet diameter due to evaporation, (2) Negligible cooling of droplet due to evaporation, (3) Applicability of heat/mass transfer analogy, (4) Ideal gas behavior for vapor.

PROPERTIES: Table A.4, air \( (T_\infty = T_o = 320 \text{ K}) \): \( \nu = 17.90 \times 10^{-6} \text{ m}^2/\text{s}, k = 0.0278 \text{ W/m} \cdot \text{K}, \text{Pr} = 0.705. \) Table A.6, saturated water \( (T_i = 290 \text{ K}) \): \( p_{\text{sat}} = 0.01917 \text{ bars} \); \( (T_o = 320 \text{ K}) \): \( p_{\text{sat}} = 0.1053 \text{ bars} \), \( v_s = 13.98 \text{ m}^3/\text{kg} \). Table A.8, \( \text{H}_2\text{O}/\text{air} \) \( (T = 320 \text{ K}) \): \( D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s} \left( \frac{320}{298} \right)^{3/2} = 0.289 \times 10^{-4} \text{ m}^2/\text{s} \).

ANALYSIS: Due to an increase in temperature, the air leaves the heater with a smaller relative humidity. With \( \phi_i = 0.7 \) and \( p_{\text{sat},i} = 0.01917 \text{ bars} \), the vapor pressure at the heater inlet is \( p_i = \phi_i p_{\text{sat},i} = 0.7(0.01917 \text{ bars}) = 0.0134 \text{ bars} \). Since the vapor pressure doesn’t change with passage through the heater,

\[ \frac{p_i}{p_{\text{sat},o}} = \frac{0.0134 \text{ bars}}{0.1053 \text{ bars}} = 0.127 \]

The vapor density associated with air flow around the droplets is therefore

\[ \rho_{A,\infty} = \phi_o \rho_{A,\text{sat}}(T_o) = \phi_o v_g(T_o)^{-1} = 0.127 \times 0.0715 \text{ kg/m}^3 = 0.0091 \text{ kg/m}^3 \]

The droplet evaporation rate is

\[ \dot{m}_{\text{evap}} = \bar{h}_m A_s \left[ \rho_{A,\text{sat}}(T_s) - \rho_{A,\infty} \right] \]

where \( \bar{h}_m \) may be obtained from the mass transfer analog to the Whitaker correlation. With \( \text{Re}_D = \frac{VD}{\nu} = 15 \text{ m/s} \times 0.001 \text{ m}/17.9 \times 10^{-6} \text{ m}^3/\text{s} = 838, \text{Sc} = \frac{v}{D_{AB}} = 17.9 \times 10^{-6} \text{ m}^3/\text{s}/28.9 \times 10^{-6} \text{ m}^2/\text{s} = 0.62, \) and \( \mu/\mu_s = 1, \)

\[ \text{Sh}_D = 2 + \left( 0.4 \text{Re}_D^{1/2} + 0.06 \text{Re}_D^{2/3} \right) \text{Sc}^{0.4} = 2 + \left[ 0.4 \left( \frac{838}{320} \right)^{1/2} + 0.06 \left( \frac{838}{320} \right)^{2/3} \right] (0.62)^{0.4} = 16.0 \]

\[ \bar{h}_m = \text{Sh}_D \left( \frac{D_{AB}}{D} \right) = 16 \left( 0.289 \times 10^{-4} \text{ m}^2/\text{s}/0.001 \text{ m} \right) = 0.462 \text{ m/s} \]

\[ \dot{m}_{\text{evap}} = (0.462 \text{ m/s}) \pi \left( \frac{0.001 \text{ m}}{2} \right)^2 \left( 0.0715 - 0.0091 \right) \text{ kg/m}^3 = 9.06 \times 10^{-8} \text{ kg/s} \]

COMMENTS: The energy required for evaporation must be supplied by convection heat transfer from the heated air to the droplet. Hence, in actuality, the droplet temperature \( T_s \) must be less than that of the freestream air, \( T_\infty \), which in turn will decrease from the value \( T_o \) at the heater outlet.
PROBLEM 7.135

KNOWN: Diameter and temperature of sphere wetted with kerosene. Air flow conditions.

FIND: (a) Minimum kerosene flow rate, (b) Air temperature required to maintain wetted surface at 300K.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Sphere mount has a negligible influence on the flow field and hence on \( \overline{h} \), (3) Negligible kerosene vapor concentration in free stream.

PROPERTIES: Table A-4, Air (300K): \( \nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s} \), \( k = 0.0263 \text{ W/mK} \), \( \rho = 1.161 \text{ kg/m}^3 \), \( \text{Pr} = 0.707 \); Kerosene (given): \( \rho_{A,sat} = 0.015 \text{ kg/m}^3 \), \( h_{fg} = 300 \text{ kJ/kg} \); Kerosene vapor-air (given): \( D_{AB} = 10^{-5} \text{ m}^2/\text{s} \).

ANALYSIS: (a) The kerosene flowrate is \( n_A = \overline{h} \cdot m_A (\rho_{A,sat} - \rho_{A,\infty}) \). Using the mass transfer analog of Eq. 7.58 and neglecting the viscosity ratio,

\[
\overline{Sh_D} = 2 + \left( 0.4 \frac{Re_D^{1/2}}{D} + 0.06 \frac{Re_D^{2/3}}{D} \right) Sc^{0.4}
\]

with \( \frac{Re_D}{D} = \frac{VD}{\nu} = \frac{15 \text{ m/s} \times 0.001 \text{ m}}{15.89 \times 10^{-6} \text{ m}^2/\text{s}} = 944 \), \( Sc = \frac{v}{D_{AB}} = \frac{15.89 \times 10^{-6}}{10^{-6}} = 1.59 \)

\[
\overline{Sh_D} = 2 + \left( 0.4 \times 944^{1/2} + 0.06 \times 944^{2/3} \right) (1.59)^{0.4} = 23.7
\]

\[
\overline{h}_m = \overline{Sh_D} D_{AB}/D = 23.7 \times 10^{-5} \text{ m}^2/\text{s}/0.001 \text{ m} = 0.237 \text{ m/s}
\]

\[
n_A = 0.237 \text{ m/s} \pi \left( 10^{-3} \text{ m} \right)^2 0.015 \text{ kg/m}^3 = 1.12 \times 10^{-8} \text{ kg/s}.
\]

(b) An energy balance on the sphere yields \( n_A \cdot h_{fg} = \overline{h}A (T_\infty - T_S) \). Using the Whitaker correlation and neglecting the viscosity ratio,

\[
\overline{Nu_D} = 2 + \left( 0.4 \times 944^{1/2} + 0.06 \times 944^{2/3} \right) (0.707)^{0.4} = 17.72
\]

\[
\overline{h} = \overline{NuD}k/D = 17.72 \times 0.0263 \text{ W/m} \cdot \text{K}/0.001 \text{ m} = 466 \text{ W/m}^2 \cdot \text{K}
\]

\[
T_\infty = T_S + \frac{n_A \cdot h_{fg}}{\overline{h} \pi D^2} = 300 \text{K} + \frac{1.12 \times 10^{-8} \text{ kg/s} \times 3 \times 10^5 \text{ J/kg}}{466 \text{ W/m}^2 \cdot \text{K} \times \pi \left(0.001 \text{ m} \right)^2}
\]

\[
T_\infty = 300 \text{K} + 2.3 \text{K} = 302.3 \text{K}
\]

or \( T_\infty - T_S = 2.3 \text{K} \).

COMMENTS: The small temperature excess (2.3K) is due to comparatively small values of \( \rho_{A,sat} \) and \( h_{fg} \) for kerosene.
PROBLEM 7.136

KNOWN: Geometry and surface temperature of a tube bank with or without wetted surfaces. Temperature, velocity and flowrate associated with air in cross flow.

FIND: (a) Ratio of air cooling with water film to that without film, (b) Air outlet temperature and specific humidity for prescribed conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Heat and mass transfer analogy is applicable, (3) Air is dry, (4) Heat and mass transfer driving potentials are \( T_{a,i} - T_s \) and \( \rho_{A,sat}(T_s) \). (5) Vapor has negligible effect on flowrate.

PROPERTIES: Table A-4, Air (assume \( T_a = 305 \)K): \( \rho = 1.1448 \text{ kg/m}^3 \), \( c_p = 1007 \text{ J/kg} \cdot \text{K} \), \( \nu = 16.39 \times 10^{-6} \text{ m}^2/\text{s} \), \( k = 0.0267 \text{ W/m} \cdot \text{K} \), \( Pr = 0.706 \). \( \alpha = 23.2 \times 10^{-6} \text{ m}^2/\text{s} \); Table A-6, Water vapor (\( T_s = 10^\circ \text{C} \)): \( v_g = 111.8 \text{ m}^3/\text{kg} \), \( \rho_{A,sat} = 8.94 \times 10^{-3} \text{ kg/m}^3 \), \( h_{fg} = 2.478 \times 10^6 \text{ J/kg} \); Table A-8, Water vapor-air (\( T_f \approx 298 \)K): \( D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s} \), \( Sc = (\nu/D_{AB}) = 0.642 \).

ANALYSIS: (a) The rate of heat loss from the air may be expressed as

\[
q = \dot{m}_a c_{p,a} \left( T_{a,i} - T_{a,o} \right)
\]

in which case, the amount of air cooling is

\[
\left( T_{a,i} - T_{a,o} \right) = \frac{q}{\dot{m}_a c_{p,a}}.
\]

Without the water film, \( q_{wo} \approx \bar{h}A \left( T_{a,i} - T_s \right) \) \hfill (2)

With the film, \( q_w \approx \bar{h}A \left( T_{a,i} - T_s \right) + \dot{m}_{evap} h_{fg} \)

\[
\left( T_{a,i} - T_{a,o} \right) = \frac{q}{\dot{m}_a c_{p,a}}.
\]

or substituting from Eq. 6.92, with \( Le = \frac{\alpha}{D_{AB}} \) and a value of \( n = 0.33 \),

\[
\left( T_{a,i} - T_{a,o} \right) = 1 + \frac{D_{AB} / \alpha}{\rho \ c_p} \frac{\rho_{A,sat} h_{fg}}{(T_{a,i} - T_s)}<
\]

Continued …..
PROBLEM 7.136 (Cont.)

For the prescribed conditions,

\[
\frac{(T_{a,i} - T_{a,o})_{\text{w}}}{(T_{a,i} - T_{a,o})_{\text{wo}}} = 1 + \frac{\left( \frac{0.26 \times 10^{-4} \text{m}^2}{\text{s}} \right)^{0.67}}{1.145 \text{ kg/m}^3 \times 1007 \text{ J/kg} \cdot \text{K}} \times 8.94 \times 10^{-3} \text{kg/m}^3 \times 2.478 \times 10^6 \text{J/kg} = 1.83.
\]

(b) \( T_{a,o} \) may be obtained from Eq. (1), where \( q \) is approximated by Eq. (2) or Eq. (3). With \( S_D = 26.83 \text{ mm} > (S_T + D)/2 = 16, \) \( V_{\text{max}} \) is at the transverse plane. Hence

\[
V_{\text{max}} = \frac{S_T}{S_T - D} \frac{V}{16} = \frac{24 \text{ m/s}}{4.5 \text{ m/s}} = 5.33 \text{ m/s}, \quad \text{Re}_{D,\text{max}} = \frac{4.5 \text{ m/s} \times 0.008 \text{ m}}{16.39 \times 10^{-6} \text{ m}^2/\text{s}} = 2196.
\]

From Tables 7.7 and 7.8, \( C = 0.35, m = 0.60, C_2 = 0.98 \) and the Zhukauskas relation gives

\[
\frac{\text{Nu}_D}{\frac{C}{2}} = 0.35(0.98)(2196)^{0.6} \left(0.706\right)^{0.36} = 30.6
\]

where \( \left( \frac{\text{Pr}}{\text{Pr}_s} \right)^{1/4} \) is 1.00. Hence

\[
\bar{h} = \frac{\text{Nu}_D}{k/D} = 30.6(0.0267 \text{ W/m} \cdot \text{K})/0.008 \text{ m} = 102 \text{ W/m}^2 \cdot \text{K}.
\]

Also

\[
\bar{h}_m = \bar{h} \left( \frac{\Delta T}{\alpha} \right)^{0.67} = 102 \text{ W/m}^2 \cdot \text{K} \left( \frac{0.26/0.232}{0.67} \right)^{0.67} = 0.0956 \text{ m/s}.
\]

Hence

\[
q_{\text{conv}} = \bar{h} A \left( T_{a,i} - T_s \right) = 102 \text{ W/m}^2 \cdot \text{K} \times \pi (0.008 \text{ m}) 0.5 \text{ m} \times 60(35-10) ^\circ \text{C} = 1923 \text{ W}
\]

\[
q_{\text{evap}} = n_A h_{fg} = \bar{h}_m A \rho_{A,\text{sat}} h_{fg}
\]

\[
q_{\text{evap}} = 0.0956 \text{ m/s} \times \pi (0.008 \text{ m}) 0.5 \text{ m} \times 60 \left(8.94 \times 10^{-3} \text{kg/m}^3\right) 2.478 \times 10^6 \text{ J/kg}
\]

\[
q_{\text{evap}} \approx 1597 \text{ W}.
\]

With water film,

\[
T_{a,o} = T_{a,i} - \frac{q_{\text{conv}} + q_{\text{evap}}}{m_a c_{p,a}} = 35 \circ \text{C} - \frac{(1923 + 1597) \text{ W}}{0.5 \text{ kg/s} \times 1007 \text{ J/kg} \cdot \text{K}} = 28.0 \circ \text{C}.
\]

The specific humidity of the outlet air is

\[
\omega_o = \frac{n_A}{m_a} = \frac{\bar{h}_m 60 \pi D L \rho_{A,\text{sat}}}{m_a}
\]

\[
\omega_o = \frac{0.0956 \text{ m/s} (60 \pi) (0.008 \text{ m}) 0.5 \text{ m} \left(8.94 \times 10^{-3} \text{kg/m}^3\right)}{0.5 \text{ kg/s}} = 0.00129.
\]

COMMENTS: (1) Enhancement of air cooling by evaporation is significant \( T_{a,o} = T_{a,i} - q_{\text{conv}} / m_a c_{p,a} = 31.1 ^\circ \text{C} \) without the film. (2) Small value of \( \omega_o \) justifies neglecting effect of evaporation on \( m_a \). (3) \( q_{\text{conv}} \) has been overestimated by using \( (T_{a,i} - T_s) \) as the driving potential for convection heat transfer. A more accurate determination involves \( \Delta T_{\text{fm}} \) rather than \( (T_{a,i} - T_s) \). (4) Apparently the air properties were evaluated at an appropriate \( T_{a,i} \).
**PROBLEM 7.137**

**KNOWN:** Dimensions of slot jet array. Jet exit velocity and temperature. Temperature of paper.

**FIND:** Drying rate per unit surface area.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Applicability of heat and mass transfer analogy, (2) Paper motion has negligible effect on convection ($U \ll V_e$).

**PROPERTIES:** Table A-4, Air (300 K, 1 atm): $\nu = 15.89 \times 10^{-6}$ m$^2$/s; Table A-6, Saturated water (300 K): $\rho_{A,\text{sat}} = V_g^{-1} = 0.0256$ kg/m$^3$; Table A-8, Water vapor-air (300 K): $D_{AB} = 0.26 \times 10^{-4}$ m$^2$/s, $Sc = 0.61$.

**ANALYSIS:** The mass evaporation flux is

$$n_A^* = \overline{h}_m \left( \rho_{A,s} - \rho_{A,e} \right) = \overline{h}_m \rho_{A,\text{sat}}$$

For an array of slot nozzles,

$$\frac{Sh}{Sc^{0.42}} = \frac{2}{3} \left( \frac{2Re}{A_r / A_{r,o} + A_{r,o} / A_r} \right)^{2/3}$$

where

$$A_r = W / S = 0.1$$

$$A_{r,o} = \left\{ 60 + 4 \left[ (H/2) W \right] - 2 \right\}^{1/2} = \left\{ 60 + 4 \left( 64 \right) \right\}^{-1/2} = 0.0563$$

$$Re = \frac{V_e (2W)}{\nu} = \frac{20 \text{ m/s}(0.02 \text{ m})}{15.89 \times 10^{-6} \text{ m}^2/\text{s}} = 25,173.$$  

Hence

$$\frac{Sh}{Sc^{0.42}} = 0.667 \left( 0.0563 \right)^{3/4} \left( \frac{50.346}{1.776 + 0.563} \right)^{2/3} = 59.6$$

$$\overline{h}_m = \frac{D_{AB}}{2W} 59.6 Sc^{0.42} = \frac{0.26 \times 10^{-4} \text{ m}^2/\text{s}}{0.02 \text{ m}} 59.6 \left( 0.61 \right)^{0.42} = 0.063 \text{ m/s}.$$  

The evaporative flux is then

$$n_A^* = 0.063 \text{ m/s} \left( 0.0256 \text{ kg/m}^3 \right) = 0.0016 \text{ kg/s} \cdot \text{m}^2.$$  

**COMMENTS:** The mass fraction of water vapor to air leaving the sides of the dryer is

$$n_A^* (S \times L) / \rho_{\text{air}} V_e (W \times L) = 7 \times 10^{-4}.$$  

Hence, the assumption of dry air throughout the dryer is reasonable.
PROBLEM 8.1

KNOWN: Flowrate and temperature of water in fully developed flow through a tube of prescribed diameter.

FIND: Maximum velocity and pressure gradient.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Isothermal flow.

PROPERTIES: Table A-6, Water (300K): \( \rho = 998 \text{ kg/m}^3 \), \( \mu = 855 \times 10^{-6} \text{ N s/m}^2 \).

ANALYSIS: From Eq. 8.6,

\[
\text{Re}_D = \frac{4 \dot{m}}{\pi D \mu} = \frac{4 \times 0.01 \text{ kg/s}}{\pi (0.025 \text{ m}) 855 \times 10^{-6} \text{ kg s/m}} = 596.
\]

Hence the flow is laminar and the velocity profile is given by Eq. 8.15,

\[
\frac{u(r)}{u_m} = 2 \left[ 1 - \left( \frac{r}{r_D} \right)^2 \right].
\]

The maximum velocity is therefore at \( r = 0 \), the centerline, where

\[ u(0) = 2 u_m. \]

From Eq. 8.5

\[
u_m = \frac{\dot{m}}{\rho \pi D^2 / 4} = \frac{4 \times 0.01 \text{ kg/s}}{998 \text{ kg/m}^3 \times \pi (0.025 \text{ m})^2} = 0.020 \text{ m/s},
\]

hence

\[ u(0) = 0.041 \text{ m/s}. \]

Combining Eqs. 8.16 and 8.19, the pressure gradient is

\[
\frac{dp}{dx} = -\frac{64}{\text{Re}_D} \frac{\rho u_m^2}{2D}
\]

\[
\frac{dp}{dx} = -\frac{64}{596} \times \frac{998 \text{ kg/m}^3 (0.020 \text{ m/s})^2}{2 \times 0.025 \text{ m}} = -0.86 \text{ kg/m}^2 \cdot \text{s}^2
\]

\[ \frac{dp}{dx} = -0.86 \text{ N/m}^2 \cdot \text{m} = -0.86 \times 10^{-5} \text{ bar/m}. \]
PROBLEM 8.2

KNOWN: Temperature and mean velocity of water flow through a cast iron pipe of prescribed length and diameter.

FIND: Pressure drop.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Fully developed flow, (3) Constant properties.

PROPERTIES: Table A-6, Water (300K): \( \rho = 997 \text{ kg/m}^3, \mu = 855 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 \).

ANALYSIS: From Eq. 8.22, the pressure drop is

\[
\Delta p = f \frac{\rho u_m^2 L}{2D}
\]

With

\[
Re_D = \frac{\rho u_m D}{\mu} = \frac{997 \text{ kg/m}^3 \times 0.2 \text{ m/s} \times 0.15 \text{ m}}{855 \times 10^{-6} \text{ N} \cdot \text{s/m}^2} = 3.50 \times 10^4
\]

the flow is turbulent and with \( e = 2.6 \times 10^{-4} \text{ m} \) for cast iron (see Fig. 8.3), it follows that \( e/D = 1.73 \times 10^{-3} \) and

\[
f \approx 0.027.
\]

Hence,

\[
\Delta p = 0.027 \frac{997 \text{ kg/m}^3(0.2 \text{ m/s})^2}{2 \times 0.15 \text{ m}}(600 \text{ m})
\]

\[
\Delta p = 2154 \text{ kg/s}^2 \cdot \text{m} = 2154 \text{ N/m}^2
\]

\[
\Delta p = 0.0215 \text{ bar.}
\]

COMMENTS: For the prescribed geometry, \( L/D = (600/0.15) = 4000 \gg (x_{fd,h}/D)_{\text{turb}} = 10 \), and the assumption of fully developed flow throughout the pipe is justified.
PROBLEM 8.3

KNOWN: Temperature and velocity of water flow in a pipe of prescribed dimensions.

FIND: Pressure drop and pump power requirement for (a) a smooth pipe, (b) a cast iron pipe with a clean surface, and (c) smooth pipe for a range of mean velocities 0.05 to 1.5 m/s.

SCHEMATIC:

ASSUMPTIONS: (1) Steady, fully developed flow.

PROPERTIES: Table A.6, Water (300 K): \( \rho = 997 \text{ kg/m}^3, \mu = 855 \times 10^{-6} \text{ N} \cdot \text{s/m}^2, \nu = \mu/\rho = 8.576 \times 10^{-7} \text{ m}^2/\text{s} \).

ANALYSIS: From Eq. 8.22a and 8.22b, the pressure drop and pump power requirement are

\[
\Delta p = f \frac{\rho u_m^2 L}{2D}, \quad P = \Delta p \dot{V} = \Delta p \left( \frac{\pi D^2}{4} \right) u_m \tag{1,2}
\]

The friction factor, \( f \), may be determined from Figure 8.3 for different relative roughness, \( e/D \), surfaces or from Eq. 8.21 for the smooth condition, \( 3000 \leq \text{Re}_D \leq 5 \times 10^6 \),

\[
f = \left( 0.790 \ln \left( \text{Re}_D \right) - 1.64 \right)^{-2} \tag{3}
\]

where the Reynolds number is

\[
\text{Re}_D = \frac{u_m D}{\nu} = \frac{1 \text{ m/s} \times 0.25 \text{ m}}{8.576 \times 10^{-7} \text{ m}^2/\text{s}} = 2.915 \times 10^5 \tag{4}
\]

(a) Smooth surface: from Eqs. (3), (1) and (2),

\[
f = \left( 0.790 \ln \left( 2.915 \times 10^5 \right) - 1.64 \right)^{-2} = 0.01451
\]

\[
\Delta p = 0.01451 \left( 997 \text{ kg/} \text{m}^3 \times 1 \text{ m}^2/\text{s}^2 /2 \times 0.25 \text{ m} \right) 1000 \text{ m} = 2.89 \times 10^4 \text{ kg/s}^2 \cdot \text{m} = 0.289 \text{ bar} \leq < \]

\[
P = 2.89 \times 10^4 \text{ N/m}^2 \left( \pi \times 0.25^2 \text{ m}^2/4 \right) 1 \text{ m/s} = 1418 \text{ N} \cdot \text{m/s} = 1.42 \text{ kW} \leq <
\]

(b) Cast iron clean surface: with \( e = 260 \mu \text{m} \), the relative roughness is \( e/D = 260 \times 10^{-6} \text{ m}/0.25 \text{ m} = 1.04 \times 10^{-3} \). From Figure 8.3 with \( \text{Re}_D = 2.92 \times 10^5 \), find \( f = 0.021 \). Hence,

\[
\Delta p = 0.419 \text{ bar} \quad P = 2.06 \text{ kW} \leq <
\]

(c) Smooth surface: Using IHT with the expressions of part (a), the pressure drop and pump power requirement as a function of mean velocity, \( u_m \), for the range 0.05 \( \leq u_m \leq 1.5 \text{ m/s} \) are computed and plotted below.

Continued...
The pressure drop is a strong function of the mean velocity. So is the pump power since it is proportional to both $\Delta p$ and the mean velocity.

**COMMENTS:**
1. Note that $L/D = 4000 >> (x_{fg,h}/D) \approx 10$ for turbulent flow and the assumption of fully developed conditions is justified.
2. Surface fouling results in increased surface roughness and increases operating costs through increasing pump power requirements.
3. The *IHT Workspace* used to generate the graphical results follows.
**PROBLEM 8.4**

**KNOWN:** Temperature and mass flow rate of various liquids moving through a tube of prescribed diameter.

**FIND:** Mean velocity and hydrodynamic and thermal entry lengths.

**SCHEMATIC:**

![Diagram of a tube with various liquids and notations](image)

**ASSUMPTIONS:** Constant properties.

**PROPERTIES:** \((T = 300\text{K})\)

<table>
<thead>
<tr>
<th>Liquid</th>
<th>Table</th>
<th>(\rho(\text{kg/m}^3))</th>
<th>(\mu(\text{N} \cdot \text{s/m}^2))</th>
<th>(\nu(\text{m}^2/\text{s}))</th>
<th>(Pr)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Engine oil</td>
<td>A-5</td>
<td>884</td>
<td>0.486</td>
<td>(550 \times 10^{-6})</td>
<td>6400</td>
</tr>
<tr>
<td>Mercury</td>
<td>A-5</td>

<td>0.152 \times 10^{-2}</td>
<td>0.113 \times 10^{-6}</td>
<td>0.0248</td>
</tr>
<tr>
<td>Water</td>
<td>A-6</td>
<td>1000</td>
<td>0.855 \times 10^{-3}</td>
<td>0.855 \times 10^{-6}</td>
<td>5.83</td>
</tr>
</tbody>
</table>

**ANALYSIS:** The mean velocity is given by

\[
u_m = \frac{\dot{m}}{\rho A_c} = \frac{0.03 \text{ kg/s}}{\rho \pi (0.025 \text{m})^2 / 4} = \frac{61.1 \text{ kg/s} \cdot \text{m}^2}{\rho}.
\]

The hydrodynamic and thermal entry lengths depend on \(Re_D\),

\[
Re_D = \frac{4 \dot{m}}{\pi D \mu} = \frac{4 \times 0.03 \text{ kg/s}}{\pi (0.025 \text{m})} = \frac{1.53 \text{ kg/s} \cdot \text{m}}{\mu}.
\]

Hence, even for water \((\mu = 0.855 \times 10^{-3} \text{ N} \cdot \text{s/m}^2)\), \(Re_D < 2300\) and the flow is laminar. From Eqs. 8.3 and 8.23 it follows that

\[
x_{fd,h} = 0.05 D Re_D = \frac{1.91 \times 10^{-3}}{\mu} \text{kg/s}.
\]

\[
x_{fd,t} = 0.05 D Re_D Pr = \frac{(1.91 \times 10^{-3}) \text{kg/s}}{\mu} \text{Pr}.
\]

Hence:

<table>
<thead>
<tr>
<th>Liquid</th>
<th>(u_m(\text{m/s}))</th>
<th>(x_{fd,h}(\text{m}))</th>
<th>(x_{fd,t}(\text{m}))</th>
</tr>

</tbody>
</table>

**COMMENTS:** Note the effect of viscosity on the hydrodynamic entry length and the effect of \(Pr\) on the thermal entry length.
PROBLEM 8.5

KNOWN: Number, diameter and length of tubes and flow rate for an engine oil cooler.

FIND: Pressure drop and pump power (a) for flow rate of 24 kg/s and (b) as a function of flow rate for the range $10 \leq \dot{m} \leq 30$ kg/s.

SCHEMATIC:

ASSUMPTIONS: (1) Fully developed flow throughout the tubes.

PROPERTIES: Table A.5, Engine oil (300 K): $\rho = 884$ kg/m$^3$, $\mu = 0.486$ kg/s$\cdot$m.

ANALYSIS: (a) Considering flow through a single tube, find

$$Re_D = \frac{4\dot{m}}{\pi D \mu} = \frac{4(24\text{ kg/s})}{25\pi (0.010\text{ m}) 0.486\text{ kg/s} \cdot \text{m}} = 251.5$$

Hence, the flow is laminar and from Equation 8.19,

$$f = \frac{64}{Re_D} = \frac{64}{251.5} = 0.2545.$$  

With

$$u_m = \frac{\dot{m}}{\rho \left( \pi D^2 / 4 \right)} = \frac{(25/25)\text{ kg/s}}{(884\text{ kg/m}^3) \pi (0.010\text{ m})^2} = 13.8\text{ m/s}$$

Equation 8.22a yields

$$\Delta p = f \frac{2u_m^2 L}{2D} = 0.2545 \frac{(884\text{ kg/m}^3)(13.8\text{ m/s})^2}{2(0.010\text{ m})} = 5.38 \times 10^6 \text{ N/m}^2 = 53.8\text{ bar}$$

The pump power requirement from Equation 8.23b,

$$P = \Delta p \cdot \dot{V} = \Delta p \cdot \frac{\dot{m}}{\rho} = 5.38 \times 10^6 \text{ N/m}^2 \cdot \frac{24\text{ kg/s}}{884\text{ kg/m}^3} = 1.459 \times 10^5 \text{ N/m/s} = 146\text{ W}.$$  

(b) Using IHT with the expressions of part (a), the pressure drop and pump power requirement as a function of flow rate, $\dot{m}$, for the range $10 \leq \dot{m} \leq 30$ kg/s are computed and plotted below.
**PROBLEM 8.5 (Cont.)**

In the plot above, note that the pressure drop is linear with the flow rate since, from Eqs. (2), the friction factor is inversely dependent upon mean velocity. The pump power, however, is quadratic with the flow rate.

**COMMENTS:**  
(1) If there is a hydrodynamic entry region, the average friction factor for the entire tube length would exceed the fully developed value, thereby increasing $\Delta p$ and $P$.

(2) The *IHT Workspace* used to generate the graphical results follows.

```
PROBLEM 8.6

KNOWN: The x-momentum equation for fully developed laminar flow in a parallel-plate channel

$$\frac{dP}{dx} = \text{constant} = \mu \frac{d^2 u}{dy^2}$$

FIND: Following the same approach as for the circular tube in Section 8.1: (a) Show that the velocity profile, \( u(y) \), is parabolic of the form

$$u(y) = \frac{3}{2} u_m \left[ 1 - \frac{y^2}{(a/2)^2} \right]$$

where \( u_m \) is the mean velocity expressed as

$$u_m = \frac{a^2}{12 \mu} \left( \frac{dp}{dx} \right)$$

and \(-dp/dx = \Delta p/L\) where \( \Delta p \) is the pressure drop across the channel of length \( L \); (b) Write the expression defining the friction factor, \( f \), using the hydraulic diameter as the characteristic length, \( D_h \); What is the hydraulic diameter for the parallel-plate channel? (c) The friction factor is estimated from the expression \( f = C/Re_{D_h} \) where \( C \) depends upon the flow cross-section as shown in Table 8.1; What is the coefficient \( C \) for the parallel-plate channel (\( b/a \rightarrow \infty \)) ? (d) Calculate the mean air velocity and the Reynolds number for air at atmospheric pressure and 300 K in a parallel-plate channel with separation of 5 mm and length of 100 mm subjected to a pressure drop of \( \Delta P = 3.75 \text{N/m}^2 \); Is the assumption of fully developed flow reasonable for this application? If not, what effect does this have on the estimate for \( u_m \)?

SCHEMATIC:

ASSUMPTIONS: (1) Fully developed laminar flow, (2) Parallel-plate channel, \( a \ll b \).

PROPERTIES: Table A-4, Air (300 K, 1 atm): \( \mu = 184.6 \times 10^{-7} \text{N} \cdot \text{s/m}^2 \), \( \nu = 15.89 \times 10^{-6} \text{m}^2/\text{s} \).

ANALYSIS: (a) The x-momentum equation for fully developed laminar flow is

$$\mu \left( \frac{d^2 u}{dy^2} \right) = \frac{dp}{dx} = \text{constant}$$

(1)

Since the longitudinal pressure gradient is constant, separate variables and integrate twice,

$$\frac{d}{dy} \left( \frac{du}{dy} \right) = \frac{1}{\mu} \left( \frac{dp}{dx} \right) \quad \frac{du}{dy} = \frac{1}{\mu} \left( \frac{dp}{dx} \right) y + C_1$$

$$u = \frac{1}{2 \mu} \left( \frac{dp}{dx} \right) y^2 + C_1 y + C_2$$

Continued …..
PROBLEM 8.6 (Cont.)

The integration constants are determined from the boundary conditions,

\[
\frac{du}{dy}\bigg|_{y=0} = 0 \quad u\left(\frac{a}{2}\right) = 0
\]

to find

\[
C_1 = 0 \quad C_2 = -\frac{1}{2\mu}\left(\frac{dp}{dx}\right)\left(\frac{a}{2}\right)^2
\]

giving

\[
u(y) = -\left(\frac{a}{2}\right)^2\left(\frac{dp}{dx}\right)\left[1 - \frac{y^2}{\left(\frac{a}{2}\right)^2}\right]
\]  \hspace{1cm} (2)

The mean velocity is

\[
u_m = \frac{2}{a}\int_0^{a/2} u(y)dy = -\frac{2}{a}\left(\frac{a}{2}\right)^2\left(\frac{dp}{dx}\right)\left[y - \frac{y^3}{3}\right]\bigg|_0^{a/2}
\]

\[
u_m = \frac{a^2}{12\mu}\left(-\frac{dp}{dx}\right)
\]  \hspace{1cm} (3)

Substituting Eq. (3) for \(\frac{dp}{dx}\) into Eq. (2) find the velocity distribution in terms of the mean velocity

\[
u(y) = \frac{3}{2}\nu_m\left[1 - \frac{y^2}{\left(\frac{a}{2}\right)^2}\right]
\]  \hspace{1cm} (4)

(b) The friction factor follows from its definition, Eq. 8.16,

\[
f = \frac{-\left(\frac{dp}{dx}\right)D_h}{\rho \cdot u_m^2 / 2}
\]  \hspace{1cm} (5)

where the hydraulic diameter for the channel using Eq. 8.67 is

\[
D_h = \frac{4 \cdot A_c}{P} = \frac{4(a \times b)}{2(a + b)} = 2a
\]  \hspace{1cm} (6)

since \(a \ll b\).

(c) Substituting for the pressure gradient, Eq. (3), and rearranging, find using Eq. (6),

\[
f = \frac{\frac{u_m}{a^2 / 12\mu}}{\frac{\rho u_m^2}{2}} = \frac{96}{u_m D_h / \nu} = \frac{96}{\text{Re}_{D_h}}
\]  \hspace{1cm} (7)

where the Reynolds number is

\[
\text{Re}_{D_h} = \frac{u_m D_h}{\nu}
\]  \hspace{1cm} (8)

Continued .....
PROBLEM 8.6 (Cont.)

This result is in agreement with Table 8.1 for the cross-section with $b/a \to \infty$ where

$$C = 96.$$

(d) For the conditions shown in the schematic, with air properties evaluated at 300 K, using Eqs. (3) and (8), find

$$u_m = \frac{(0.005 \text{ m})^2}{12 \times 184.6 \times 10^{-7} \text{ N} \cdot \text{s/m}^2} \left( \frac{3.75 \text{ N/m}^2}{0.100 \text{ m}} \right) = 1.06 \text{ m/s}$$

$$\text{Re}_D = \frac{1.06 \text{ m/s} \times 2 \times 0.005 \text{ m}}{15.89 \times 10^{-6} \text{ m}^2/\text{s}} = 667$$

The flow is laminar as $\text{Re}_D < 2300$, and from Eq. 8.3, the entry length is

$$\left( \frac{x_{fd,h}}{D_h} \right)_{\ell_{am}} = 0.05 \text{ Re}_D$$

$$x_{fd,h} = 2 \times 0.005 \text{ m} \times 0.05 \times 667 = 0.334 \text{ m} = 334 \text{ mm}$$

We conclude that the flow is not fully developed, and the friction factor in the entry region will be higher than for fully developed conditions. Hence, for the same pressure drop, the mean velocity will be less than our estimate.
PROBLEM 8.7

KNOWN: Mean velocity and temperature of oil, water and mercury flowing through a tube of prescribed diameter.

FIND: Corresponding hydrodynamic and thermal entry lengths.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties.

PROPERTIES: \(T_m = 300\text{K}\)

<table>
<thead>
<tr>
<th>Liquid</th>
<th>Table</th>
<th>(\rho(\text{kg/m}^3))</th>
<th>(\mu(\text{N}\cdot\text{s/m}^2))</th>
<th>(Pr)</th>

</tr>
<tr>
<td>Water A-6</td>
<td>997</td>
<td>0.855 \times 10^{-3}</td>
<td>5.83</td>
<td></td>
</tr>
</tbody>
</table>

ANALYSIS: With

\[
Re_D = \frac{\rho \cdot u_m D}{\mu} = \frac{\rho}{\mu} \times 5 \times 10^{-3} \text{m/s} \times 0.025\text{m} = 1.25 \times 10^{-4} \text{m}^2/\text{s} \cdot \frac{\rho}{\mu}
\]

It follows that

\[
\begin{align*}
\text{Oil} & \quad 0.227 \\
\text{Mercury} & \quad 1113 \\
\text{Water} & \quad 146
\end{align*}
\]

Hence for each fluid, the flow is laminar and from Eqs. 8.3 and 8.23,

\[
x_{fd,h} = 0.05 \, Re_d \quad x_{fd,t} = 0.5 \, D \, Re_D \, Pr.
\]

Hence:

COMMENTS: Note the effect of viscosity on the hydrodynamic entry length and the effect of Prandtl number on the thermal entry length.
PROBLEM 8.8

KNOWN: Velocity and temperature profiles for laminar flow in a tube of radius $r_o = 10$ mm.

FIND: Mean (or bulk) temperature, $T_m$, at this axial position.

SCHEMATIC:

ASSUMPTIONS: (1) Laminar incompressible flow, (2) Constant properties.

ANALYSIS: The prescribed velocity and temperature profiles, (m/s and K, respectively) are

\[
\begin{align*}
&u(r) = 0.1 \left[1 - (r/r_o)^2\right] \quad \text{and} \quad T(r) = 344.8 + 75.0 \left(r/r_o\right)^2 - 18.8 \left(r/r_o\right)^4 \quad (1,2) \\
\end{align*}
\]

For incompressible flow with constant $c_v$ in a circular tube, from Eq. 8.27, the mean temperature and $u_m$, the mean velocity, from Eq. 8.8 are, respectively,

\[
T_m = \frac{2}{u_m r_0^2} \int_0^{r_0} u(r) \cdot T(r) \cdot r \cdot dr
\]

\[
u_m = \frac{2}{r_o^2} \int_0^{r_o} u(r) \cdot r \cdot dr
\]

Substituting the velocity profile, Eq. (1), into Eq. (4) and integrating, find

\[
u_m = \frac{2}{r_o^2} \int_0^{r_o} 0.1 \left[1 - (r/r_o)^2\right] (r/r_o) dr = 2 \left\{0.1 \left[\frac{1}{2} (r/r_o)^2 - \frac{1}{4} (r/r_o)^4\right]\right\}_0^{1} = 0.05 \text{ m/s}
\]

Substituting the profiles and $u_m$ into Eq. (3), find

\[
T_m = \frac{2}{(0.05 \text{ m/s}) r_o^2} \int_0^{1} \left\{0.1 \left[1 - (r/r_o)^2\right]\right\} \left\{344.8 + 75.0 \left(r/r_o\right)^2 - 18.8 \left(r/r_o\right)^4\right\} (r/r_o) dr
\]

\[
T_m = 4 \int_0^{1} \left\{344.8 (r/r_o) + 75.0 (r/r_o)^3 - 18.8 (r/r_o)^5\right\} - \left\{344.8 (r/r_o)^3 + 75.0 (r/r_o)^5 - 18.8 (r/r_o)^7\right\} dr \\
T_m = 4 \{[172.40 + 18.75 - 3.13] - [86.20 + 12.50 - 2.35]\} = 367 \text{ K}
\]

The velocity and temperature profiles appear as shown below. Do the values of $u_m$ and $T_m$ found above compare with their respective profiles as you thought? Is the fluid being heated or cooled?
**PROBLEM 8.9**

**KNOWN:** Velocity and temperature profiles for laminar flow in a parallel plate channel.

**FIND:** Mean velocity, $u_m$, and mean (or bulk) temperature, $T_m$, at this axial position. Plot the velocity and temperature distributions. Comment on whether values of $u_m$ and $T_m$ appear reasonable.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Laminar incompressible flow, (2) Constant properties.

**ANALYSIS:** The prescribed velocity and temperature profiles (m/s and °C, respectively) are

$$u(y) = 0.75 \left[ 1 - \left(\frac{y}{y_o}\right)^2 \right] \quad T(y) = 5.0 + 95.66 \left(\frac{y}{y_o}\right)^2 - 47.83 \left(\frac{y}{y_o}\right)^4$$

The mean velocity, $u_m$, follows from its definition, Eq. 8.7,

$$\dot{m} = \rho A_c u_m = \rho \int_{A_c} u(y) \cdot dA_c$$

where the flow cross-sectional area is $dA_c = 1 \cdot dy$, and $A_c = 2y_o$.

$$u_m = \frac{1}{2y_o} \int_{-1}^{+1} y_o \left[ 0.75 \left[ 1 - \left(\frac{y}{y_o}\right)^2 \right] \right] d \left(\frac{y}{y_o}\right)$$

$$u_m = \frac{1}{2y_o} \left[ 0.75 \left[ \left(\frac{y}{y_o}\right) - \frac{1}{3} \left(\frac{y}{y_o}\right)^3 \right] \right]_{-1}^{+1}$$

$$u_m = \frac{1}{2} \cdot 0.75 \left[ \left(1 - \frac{1}{3}\right) - \left(-1 + \frac{1}{3}\right) \right] = \frac{1}{2} \cdot 0.75 \cdot 4/3 = 2/3 \cdot 0.75 = 0.50 \text{ m/s}$$

The mean temperature, $T_m$, follows from its definition, Eq. 8.25,

$$\dot{E}_t = \dot{m} c_v T_m$$

$$\dot{m} = \rho A_c u_m$$

$$\rho A_c u_m c_v T_m = \rho c_v \int_{A_c} u(y) \cdot T(y) dA_c$$

Hence, substituting velocity and temperature profiles,

$$T_m = \frac{1}{u_m A_c} \int_{-y_o}^{+y_o} u(y) \cdot T(y) dy$$

$$T_m = \frac{1}{(0.5 \text{ m/s}) 2y_o} \int_{-1}^{+1} \left[ 0.75 \left[ 1 - \left(\frac{y}{y_o}\right)^2 \right] \right] \left[ 5.0 + 95.66 \left(\frac{y}{y_o}\right)^2 - 47.83 \left(\frac{y}{y_o}\right)^4 \right] d \left(\frac{y}{y_o}\right)$$

$$T_m = \frac{0.75}{0.5 \times 2} \left[ \left\{ 5 \left(\frac{y}{y_o}\right) + 31.89 \left(\frac{y}{y_o}\right)^3 - 9.57 \left(\frac{y}{y_o}\right)^5 \right\} - \left\{ 1.67 \left(\frac{y}{y_o}\right)^3 + 19.13 \left(\frac{y}{y_o}\right)^5 - 6.83 \left(\frac{y}{y_o}\right)^7 \right\} \right]_{-1}^{+1}$$

$$T_m = \frac{0.75}{0.5 \times 2} \left[ \left[ 27.32 - 13.97 \right] - \left[ -27.32 - (-13.97) \right] \right] = 20.0 \degree C$$

Continued...
The velocity and temperature profiles along with the $u_m$ and $T_m$ values are plotted below.

For the velocity profile, the mean velocity is $2/3$ that of the centerline velocity, $u_m = 2u(0)/3$. Note that the areas above and below the $u_m$ line appear to be equal. Considering the temperature profile, we’d expect the mean temperature to be closer to the centerline temperature since the velocity profile weights the integral toward the centerline.

**COMMENTS:** The integrations required to obtain $u_m$ and $T_m$, Eqs. (3) and (4), could also be performed using the intrinsic function $\text{INTEGRAL}(y,x)$ in the IHT Workspace.
PROBLEM 8.10

KNOWN: Flow rate, inlet temperature and pressure, and outlet pressure of water flowing through a pipe with a prescribed surface heat rate.

FIND: (a) Outlet temperature, (b) Outlet temperature assuming negligible flow work changes.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible kinetic and potential energy changes, (2) Constant properties, (3) Incompressible liquid.

PROPERTIES: Table A-6, Water (T = 300K): \( \rho = 997 \text{ kg/m}^3 \), \( c_p = c_v = 4179 \text{ J/kg K} \).

ANALYSIS: (a) Accounting for the flow work effect, Eq. 8.35 may be integrated from inlet to outlet to obtain

\[
q_{\text{conv}} = \dot{m} \left[ c_v \left( T_{m,o} - T_{m,i} \right) + (p_v)_o - (p_v)_i \right]
\]

Hence,

\[
T_{m,o} = T_{m,i} + \frac{q_{\text{conv}}}{\dot{m} c_v} + \frac{1}{\rho c_v} (p_i - p_o)
\]

\[
T_{m,o} = 25^\circ \text{C} + \frac{10^5 \text{ W}}{2 \text{ kg/s} \times 4179 \text{ J/kg K}} + \frac{(100 - 2) \text{ bar}(10^5 \text{ N/m}^2)/\text{bar}}{997 \text{ kg/m}^3 \times 4179 \text{ J/kg K}}
\]

\[
T_{m,o} = 25^\circ \text{C} + 12^\circ \text{C} + 2.4^\circ \text{C}
\]

\[
T_{m,o} = 39.4^\circ \text{C}.
\]

(b) Neglecting the flow work effect, it follows from Eq. 8.37 that,

\[
T_{m,o} = T_{m,i} + \frac{q_{\text{conv}}}{\dot{m} c_p} = 25^\circ \text{C} + 12^\circ \text{C}
\]

\[
T_{m,o} = 37^\circ \text{C}.
\]

COMMENTS: Even for the large pressure drop of this problem, flow work effects make a small contribution to heating the water. The effects may justifiably be neglected in most practical problems.
PROBLEM 8.11

KNOWN: Internal flow with prescribed wall heat flux as a function of distance.

FIND: (a) Beginning with a properly defined differential control volume, the temperature distribution, $T_m(x)$, (b) Outlet temperature, $T_{m,o}$, (c) Sketch $T_m(x)$, and $T_s(x)$ for fully developed and developing flow conditions, and (d) Value of uniform wall flux $q_s''$ (instead of $q_s' = ax$) providing same outlet temperature as found in part (a); sketch $T_m(x)$ and $T_s(x)$ for this heating condition.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Incompressible flow.

PROPERTIES: Table A.6, Water (300 K): $c_p = 4.179 \text{ kJ/kg}\cdot\text{K}$.

ANALYSIS: (a) Applying energy conservation to the control volume above,

$$dq_{\text{conv}} = m p dT_m$$

where $T_m(x)$ is the mean temperature at any cross-section and $dq_{\text{conv}} = q' \cdot dx$. Hence,

$$ax = m p \frac{dT_m}{dx}.$$ 

(b) To find the outlet temperature, let $x = L$, then

$$T_m(L) = T_{m,o} = T_{m,i} + aL^2/2m c_p.$$ 

Solving for $T_{m,o}$ and substituting numerical values, find

$$T_{m,o} = 27^\circ C + \frac{20 \text{ W/m}^2 (30 \text{ m}^2)}{2 \left(450 \text{ kg/h}/(3600 \text{ s/h})\right) \times 4179 \text{ J/kg} \cdot \text{K}} = 27^\circ C + 17.2^\circ C = 44.2^\circ C.$$ 

(c) For linear wall heating, $q_s' = ax$, the fluid temperature distribution along the length of the tube is quadratic as prescribed by Eq. (4). From the convection rate equation,

$$q_s' = h(x) \cdot \pi D \left(T_s(x) - T_m(x)\right)$$

For fully developed flow conditions, $h(x) = h$ is a constant; hence, $T_s(x) - T_m(x)$ increases linearly with $x$. For developing conditions, $h(x)$ will decrease with increasing distance along the tube eventually achieving the fully developed value.
(d) For uniform wall heat flux heating, the overall energy balance on the tube yields

\[ q = q^* \pi D L = \dot{m} c_p (T_{m,o} - T_{m,i}) \]

Requiring that \( T_{m,o} = 44.2^\circ C \) from part (a), find

\[ q^* = \frac{(450/3600) \text{kg/s} \times 4179 \text{J/kg} \cdot \text{K} \times (44.2 - 27) \text{K}}{\pi D \times 30 \text{m}} = 95.3/D \text{ W/m}^2 \]

where \( D \) is the diameter (m) of the tube which, when specified, would permit determining the required heat flux, \( q^* \). For uniform heating, Section 3.3.2, we know that \( T_m(x) \) will be linear with distance. \( T_s(x) \) will also be linear for fully developed conditions and appear as shown below when the flow is developing.

**COMMENTS:**
(1) Note that \( c_p \) should be evaluated at \( T_m = (27 + 44) \circ C/2 = 309 \) K.
(2) Why did we show \( T_s(0) = T_m(0) \) for both types of history when the flow was developing?
(3) Why must \( T_m(x) \) be linear with distance in the case of uniform wall flux heating?
PROBLEM 8.12

KNOWN: Internal flow with constant surface heat flux, $q_s''$.

FIND: (a) Qualitative temperature distributions, $T(x)$, under developing and fully-developed flow, (b) Exit mean temperature for both situations.

SCHEMATIC:

ASSUMPTIONS: (a) Steady-state conditions, (b) Constant properties, (c) Incompressible flow.

ANALYSIS: Based upon the analysis leading to Eq. 8.40, note for the case of constant surface heat flux conditions,

$$\frac{dT_m}{dx} = \text{constant}.$$  

Hence, regardless of whether the hydrodynamic or thermal boundary layer is fully developed, it follows that

$$T_m(x) \quad \text{is linear and}$$

$$T_{m,2} \quad \text{will be the same for all flow conditions.}$$

The surface heat flux can also be written, using Eq. 8.28, as

$$q_s'' = h \left[ T_s(x) - T_m(x) \right].$$

Under fully-developed flow and thermal conditions, $h = h_{fd}$ is a constant. When flow is developing $h > h_{fd}$. Hence, the temperature distributions appear as below.

```
```

```
```

```
```
**PROBLEM 8.13**

**KNOWN:** Geometry and coolant flow conditions associated with a nuclear fuel rod. Axial variation of heat generation within the rod.

**FIND:** (a) Axial variation of local heat flux and total heat transfer rate, (b) Axial variation of mean coolant temperature, (c) Axial variation of rod surface temperature and location of maximum temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant fluid properties, (3) Uniform surface convection coefficient, (4) Negligible axial conduction in rod and fluid, (5) Negligible kinetic energy, potential energy and flow work changes, (6) Outer surface is adiabatic.

**ANALYSIS:**

(a) Performing an energy balance for a control volume about the rod,

\[ \dot{E}_{in} - \dot{E}_{out} + \dot{E}_g = 0 \quad -dq + \dot{E}_g = 0 \]

or

\[ -q'' (\pi \ D \ dx) + \dot{q}_0 \ sin(\pi x/L) \left( \pi \ D^2 / 4 \right) dx = 0 \quad q'' = \dot{q}_0 \left( D/4 \right) \sin(\pi x/L). \]  

The total heat transfer rate is then

\[ q = \int_0^L q'' \pi \ D \ dx = \left( \pi \ D^2 / 4 \right) \dot{q}_0 \int_0^L \sin(\pi x/L) \ dx \]

\[ q = \frac{\pi D^2}{4} \dot{q}_0 \left( -\frac{L}{\pi} \cos \frac{\pi x}{L} \right) \bigg|_0^L = \frac{D^2 \dot{q}_0 L}{4} \left( 1 + 1 \right) \]

\[ q = \frac{D^2 L}{2} \dot{q}_0. \quad (1) \]

(b) Performing an energy balance for a control volume about the coolant,

\[ \dot{m} c_p T_m + dq = \dot{m} c_p \left( T_m + dT_m \right) = 0. \]

Hence

\[ \dot{m} c_p \ dT_m = dq = \left( \pi \ D \ dx \right) q'' \]

\[ \frac{dT_m}{dx} = \frac{\pi D}{\dot{m} c_p} \frac{\dot{q}_0 D}{4} \sin \left( \frac{\pi x}{L} \right). \]

Continued ......
PROBLEM 8.13 (Cont.)

Integrating,

\[ T_m(x) - T_{m,i} = \frac{\pi D^2}{4} \frac{\dot{q}_o}{m c_p} \int_0^x \sin \left( \frac{\pi x}{L} \right) \, dx \]

\[ T_m(x) = T_{m,i} + \frac{L D^2}{4} \frac{\dot{q}_o}{m c_p} \left[ 1 - \cos \left( \frac{\pi x}{L} \right) \right] \]

(2) \( < \)

(c) From Newton’s law of cooling,

\[ \dot{q}^* = h (T_s - T_m) \]

Hence

\[ T_s = \frac{\dot{q}^*}{h} + T_m \]

\[ T_s = \frac{\dot{q}_o D}{4h} \sin \left( \frac{\pi x}{L} \right) + T_{m,i} + \frac{L D^2}{4} \frac{\dot{q}_o}{m c_p} \left[ 1 - \cos \left( \frac{\pi x}{L} \right) \right]. \]

To determine the location of the maximum surface temperature, evaluate

\[ \frac{dT_s}{dx} = 0 = \frac{\dot{q}_o D \pi}{4 h L} \cos \left( \frac{\pi x}{L} \right) + \frac{L D^2}{4} \frac{\dot{q}_o}{m c_p} \frac{\pi}{L} \sin \left( \frac{\pi x}{L} \right) \]

or

\[ \frac{1}{hL} \cos \left( \frac{\pi x}{L} \right) + \frac{D}{m c_p} \sin \left( \frac{\pi x}{L} \right) = 0. \]

Hence

\[ \tan \left( \frac{\pi x}{L} \right) = -\frac{m c_p}{D h L} \]

\[ x = \frac{L}{\pi} \tan^{-1} \left( -\frac{m c_p}{D h L} \right) = x_{\text{max}}. \]

**COMMENTS:** Note from Eq. (2) that

\[ T_{m,o} = T_m(L) = T_{m,i} + \frac{L D^2 \dot{q}_o}{2 \dot{m} c_p} \]

which is equivalent to the result obtained by combining Eq. (1) and Eq. 8.37.
**PROBLEM 8.14**

**KNOWN:** Axial variation of surface heat flux for flow through a tube.

**FIND:** Axial variation of fluid and surface temperatures.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Convection coefficient is independent of $x$, (2) Negligible axial conduction and kinetic and potential energy changes, (3) Fluid is an ideal gas or a liquid for which $d(pv) < < d(c_v T_m)$.

**ANALYSIS:** Since Equation 8.38 is applicable,

$$\frac{dT_m}{dx} = \frac{q_s^p}{\dot{m} c_p} = \left(\frac{\pi D}{\dot{m} c_p}\right)q_{s,m}^p \sin \left(\frac{\pi x}{L}\right)$$

Separating variables and integrating from $x = 0$

$$\int_{T_{m,i}}^{T_{m,o}} dT_m = \frac{\pi D q_{s,m}^p}{\dot{m} c_p} \int_0^x \sin \left(\frac{\pi x}{L}\right) dx$$

$$T_m(x) - T_{m,i} = -\frac{L D q_{s,m}^p}{\dot{m} c_p} \cos \left(\frac{\pi x}{L}\right) \bigg|_0^x$$

$$T_m(x) = T_{m,i} + \frac{L D q_{s,m}^p}{\dot{m} c_p} (1 - \cos \frac{\pi x}{L}).$$

From Newton’s law of cooling, Eq. 8.28,

$$T_s(x) = \left(\frac{q_s^p}{h}\right) + T_m(x)$$

$$T_s(x) = \frac{q_{s,m}^p}{h} \sin \left(\frac{\pi x}{L}\right) + T_{m,i} + \frac{L D q_{s,m}^p}{\dot{m} c_p} (1 - \cos \frac{\pi x}{L}).$$

**COMMENTS:** For the prescribed surface condition, the flow is not fully developed. Hence, the assumption of constant $h$ should be viewed as a first approximation.
PROBLEM 8.15

KNOWN: Surface heat flux for air flow through a rectangular channel.

FIND: (a) Differential equation describing variation in air mean temperature, (b) Air outlet temperature for prescribed conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible change in kinetic and potential energy of air, (2) No heat loss through bottom of channel, (3) Uniform heat flux at top of channel.

PROPERTIES: Table A-4, Air (T = 50°C, 1 atm): \(c_p = 1008 \text{ J/kg}\cdot\text{K}\).

ANALYSIS: (a) For the differential control volume about the air,

\[
\dot{E}_{\text{in}} = \dot{E}_{\text{out}}
\]

\[
\dot{m} c_p T_m + q_o^* (w \cdot dx) = \dot{m} c_p (T_m + dT_m)
\]

\[
\frac{dT_m}{dx} = \frac{q_o^* \cdot w}{\dot{m} c_p}
\]

Separating and integrating between the limits of \(x = 0\) and \(x\), find

\[
T_m(x) = T_{m,i} + \frac{q_o^* (w \cdot x)}{\dot{m} c_p}
\]

\[
T_{m,o} = T_{m,i} + \frac{q_o^* (w \cdot L)}{\dot{m} c_p}.
\]

(b) Substituting numerical values, the air outlet temperature is

\[
T_{m,o} = 40^\circ \text{C} + \frac{\left(700 \text{ W/m}^2\right) \times \left(1 \times 3\right) \text{m}^2}{0.1 \text{ kg/s} \times 1008 \text{ J/kg} \cdot \text{K}}
\]

\[
T_{m,o} = 60.8^\circ \text{C}.
\]

COMMENTS: Due to increasing heat loss with increasing \(T_m\), the net flux \(q_o^*\) will actually decrease slightly with increasing \(x\).
**PROBLEM 8.16**

**KNOWN:** Air inlet conditions and heat transfer coefficient for a circular tube of prescribed geometry. Surface heat flux.

**FIND:** (a) Tube heat transfer rate, \( q \), air outlet temperature, \( T_{m,o} \), and surface inlet and outlet temperatures, \( T_{s,i} \) and \( T_{s,o} \), for a uniform surface heat flux, \( q_s^u \). Air mean and surface temperature distributions. (b) Values of \( q \), \( T_{m,o} \), \( T_{s,i} \) and \( T_{s,o} \) for a linearly varying surface heat flux \( q_s^v = 500x \) (m). Air mean and surface temperature distributions. (c) For each type of heating process (a & b), compute and plot the mean fluid and surface temperatures, \( T_m(x) \) and \( T_s(x) \), respectively, as a function of distance; What is effect of four-fold increase in convection coefficient, and (d) For each type of heating process, heat fluxes required to achieve an outlet temperature of \( T_{m,o} = 125^\circ C \); Plot temperatures.

**SCHEMATIC:**

![Diagram of a circular tube with labeled temperatures and conditions.]

**ASSUMPTIONS:** (1) Fully developed conditions in the tube, (2) Applicability of Eq. 8.36, (3) Heat transfer coefficient is the same for both heating conditions.

**PROPERTIES:** Table A.4, Air (for an assumed value of \( T_{m,o} = 100^\circ C \), \( \bar{T}_m = (T_{m,i} + T_{m,o})/2 = 60^\circ C = 333 K \)): \( c_p = 1.008 \text{ kJ/kg} \cdot \text{K} \).

**ANALYSIS:** (a) With constant heat flux, from Eq. 8.39,

\[
q = q_s^u (\pi DL) = 1000 \text{ W/m}^2 (\pi \times 0.05 \text{ m} \times 3 \text{ m}) = 471 \text{ W}.
\]

From the overall energy balance, Eq. 8.37,

\[
T_{m,o} = T_{m,i} + \frac{q}{mc_p} = 20^\circ C + \frac{471 \text{ W}}{0.005 \text{ kg/s} \times 1008 \text{ J/kg} \cdot \text{K}} = 113.5^\circ C
\]  \( (2) \)

From the convection rate equation, it follows that

\[
T_{s,i} = T_{m,i} + \frac{q_s^u}{h} = 20^\circ C + \frac{1000 \text{ W/m}^2}{25 \text{ W/m}^2 \cdot \text{K}} = 60^\circ C
\]  \( (3) \)

\[
T_{s,o} = T_{m,o} + q_s^v/h = 113.5^\circ C + 40^\circ C = 153.5^\circ C
\]  \(<\)

From Eq. 8.40, \((dT_m/dx)\) is a constant, as is \((dT_s/dx)\) for constant \( h \) from Eq. 8.31. In the more realistic case for which \( h \) decreases with \( x \) in the entry region, \((dT_m/dx)\) is still constant but \((dT_s/dx)\) decreases with increasing \( x \). See the plot below.

(b) From Eq. 8.38,

\[
\frac{dT_m}{dx} = \frac{500x(\pi D)}{mc_p} = \frac{500x \text{ W/m}^2 (\pi \times 0.05 \text{ m})}{0.005 \text{ kg/s} \times 1008 \text{ J/kg} \cdot \text{K}} = 15.6x \text{ K/m}.
\]  \( (4) \)

Continued...
PROBLEM 8.16 (Cont.)

Integrating from $x = 0$ to $L$ it follows that

$$T_{m,o} = T_{m,i} + 15.6 \int_0^3 x \, dx = 20^\circ C + 15.6 \frac{x^2}{2} \bigg|_0^3 = 20^\circ C + 70.2^\circ C = 90.2^\circ C. \quad (5)$$

The heat rate is

$$q = \int q_s \, dA_s = 500 (\pi \times 0.05 \, m) \int_0^3 x \, dx = 78.5 \frac{x^2}{2} \bigg|_0^3 = 353 \, W$$

From Eq. 8.28 it then follows that

$$T_s = T_m + q_s / h = T_{m,i} + 15.6 \frac{x^2}{2} + \frac{500}{25} x = 20^\circ C + 7.8x^2 + 20x \quad (6)$$

Hence, at the inlet ($x = 0$) and outlet ($x = L$),

$$T_{s,i} = T_{m,i} = 20^\circ C \quad \text{and} \quad T_{s,o} = 150.2^\circ C \quad (7)$$

Note that $(dT_s/dx)$ and $(dT_m/dx)$ both increase linearly with $x$, but $(dT_s/dx) > (dT_m/dx)$.

(c) The foregoing relations can be used to determine $T_m(x)$ and $T_s(x)$ for the two heating conditions:

Uniform surface flux, $q''_s$: Eqs. (1-3),

$$T_m (x) = T_{m,i} + q''_s \pi D / mc_p \quad T_s (x) = T_m (x) + q''_s / h \quad (7.8)$$

Linear surface heat flux, $q''_s = a_o x$, $a_o = 500 \, W/m^3$: Eqs. (4-6),

$$T_m (x) = T_{m,i} + \left( a_o \pi D / 2mc_p \right) x^2 \quad T_s (x) = T_m (x) + a_o x / h \quad (9, 10)$$

Using Eqs. (7-10) in IHT, the mean fluid and surface temperatures as a function of distance are evaluated and plotted below. The calculations were repeated with the coefficient increased four-fold, $h = 4 \times 25 = 100 \, W/m^2\cdot K$. As expected, the fluid temperature remained unchanged, but the surface temperatures decreased since the thermal resistance between the surface and fluid decreased.

(d) The foregoing set of equations, Eqs. (7-10), in the IHT model can be used to determine the required heat fluxes for the two heating conditions to achieve $T_{m,o} = 125^\circ C$. The results with $h = 25 \, W/m^2\cdot K$ are:

**Uniform flux:** $q''_s = 1123 \, W/m^2$  
**Linear flux:** $q''_s = 748.7x \, W/m^2$  

Continued...
The temperature distributions resulting from these heat fluxes are plotted below. The heat rate for both heating processes is 529 W.

**COMMENTS:** Note that the assumed value for $T_{m,0}$ (100°C) in determining the specific heat of the air was reasonable.
**PROBLEM 8.17**

**KNOWN:** Water at prescribed temperature and flow rate enters a 0.25 m diameter, black thin-walled tube of 8-m length, which passes through a large furnace whose walls and air are at a temperature of \( T_{\text{fur}} = T_{\infty} = 700 \text{ K} \). The convection coefficients for the internal water flow and external furnace air are 300 W/m\(^2\)-K and 50 W/m\(^2\)-K, respectively.

**FIND:** (a) An expression for the linearized radiation coefficient for the radiation exchange process between the outer surface of the pipe and the furnace walls; represent the tube by an average temperature and explain how to calculate this value, and (b) determine the outlet temperature of the water, \( T_o \).

**SCHEMATIC:**

![Diagram of water flow through a furnace](image)

**ASSUMPTIONS:** (1) Steady-state conditions; (2) Tube is small object with large, isothermal surroundings; (3) Furnace air and walls are at the same temperature; and (3) Tube is thin-walled with black surface.

**PROPERTIES:** Table A-6, Water \((T_m = (T_{m,i} + T_{m,o})/2 = 331 \text{ K})\): \( c_p = 4192 \text{ J/kg} \cdot \text{K} \).

**ANALYSIS:**

(a) The linearized radiation coefficient follows from Eq. 1.9 with \( \varepsilon = 1 \),

\[
h_{\text{rad}} = \sigma \left( T_{\text{t}} + T_{\text{fur}} \right)^2 \left( T_{\text{t}}^2 + T_{\text{fur}}^2 \right)
\]

where \( T_{\text{t}} \) represents the average tube wall surface temperature, which can be evaluated from an energy balance on the tube as represented by the thermal circuit above.

\[
T_m = \left( T_{m,i} + T_{m,o} \right)/2
\]

\[
R_{\text{tot}} = R_{\text{cv,i}} + \frac{1}{1/R_{\text{cv,o}} + 1/R_{\text{rad}}}
\]

\[
T_m - T_{\text{t}} = \frac{T_{\text{t}} - T_{\text{fur}}}{1/R_{\text{cv,o}} + 1/R_{\text{rad}}}
\]

The thermal resistances, with \( A_s = PL = \pi DL \), are

\[
R_{\text{cv,i}} = 1/h_i A_s \quad R_{\text{cv,o}} = 1/h_o A_s \quad R_{\text{rad}} = 1/h_{\text{rad}}
\]

(b) The outlet temperature can be calculated using the energy balance relation, Eq. 8.46b, with \( T_{\text{fur}} = T_{\infty} \),

\[
\frac{T_{\infty} - T_{m,o}}{T_{\infty} - T_{m,i}} = \exp \left( -\frac{1}{m c_p R_{\text{tot}}} \right)
\]

where \( c_p \) is evaluated at \( T_m \). Using IHT, the following results were obtained.

\[
R_{\text{cv,i}} = 6.631 \times 10^{-5} \text{ K/W} \quad R_{\text{cv,o}} = 3.978 \times 10^{-4} \text{ K/W} \quad R_{\text{rad}} = 4.724 \times 10^{-4} \text{ K/W}
\]

\[
T_m = 331 \text{ K} \quad T_{\text{t}} = 418 \text{ K}
\]

\[
T_{m,o} = 362 \text{ K}
\]

**COMMENTS:** Since \( T_{\infty} = T_{\text{fur}} \), it was possible to use Eq. 8.46b with \( R_{\text{tot}} \). How would you write the energy balance relation if \( T_{\infty} \neq T_{\text{fur}} \)?
PROBLEM 8.18

KNOWN: Laminar, slug flow in a circular tube with uniform surface heat flux.

FIND: Temperature distribution and Nusselt number.

SCHEMATIC:

ASSUMPTIONS: (1) Steady, incompressible flow, (2) Constant properties, (3) Fully developed, laminar flow, (4) Uniform surface heat flux.

ANALYSIS: With \( v = 0 \) for fully developed flow and \( \partial T / \partial x = dT_m / dx = \text{const} \), from Eqs. 8.33 and 8.40, the energy equation, Eq. 8.48, reduces to

\[
u_o \frac{dT_m}{dx} = \frac{\alpha}{r} \frac{\partial}{\partial r} \left( r \frac{\partial T}{\partial r} \right)
\]

Integrating twice, it follows that

\[
T(r) = \frac{u_o}{\alpha} \frac{dT_m}{dx} \frac{r}{4} + C_1 \ell n(r) + C_2.
\]

Since \( T(0) \) must remain finite, \( C_1 = 0 \). Hence, with \( T(r_0) = T_s \)

\[
C_2 = T_s - \frac{u_o}{\alpha} \frac{dT_m}{dx} \frac{r_0^2}{4} \quad T(r) = T_s - \frac{u_o}{4\alpha} \frac{dT_m}{dx} \left( \frac{r^2}{r_0^2} - 1 \right).
\]

From Eq. 8.27, with \( u_m = u_o \),

\[
T_m = \frac{2}{r_o^2} \int_0^{r_o} T_r \, dr = \frac{2}{r_o^2} \int_0^{r_o} \left[ T_s r - \frac{u_o}{2\alpha} \frac{dT_m}{dx} \left( \frac{r^4}{4} - r_0^4 \right) \right] \, dr
\]

\[
T_m = \frac{2}{r_o^2} \left[ T_s \frac{r^2}{2} - \frac{u_o}{4\alpha} \frac{dT_m}{dx} \left( \frac{r_0^4}{2} - r_0^4 \right) \right] = T_s - \frac{u_o r_o^2}{8\alpha} \frac{dT_m}{dx}.
\]

From Eq. 8.28 and Fourier’s law,

\[
h = \frac{q_s'}{T_s - T_m} = \frac{k}{T_s - T_m} \left. \frac{\partial T}{\partial r} \right|_{r_0}
\]

hence,

\[
h = \frac{k \left( \frac{u_o r_o}{2\alpha} \right) \frac{d T_m}{dx}}{\frac{u_o r_o^2}{8\alpha} \frac{d T_m}{dx}} = \frac{4k}{r_o} = \frac{8k}{D} \quad \text{Nu}_D = \frac{hD}{k} = 8.
\]
PROBLEM 8.19

KNOWN: Heat transfer between fluid flow over a tube and flow through the tube.

FIND: Axial variation of mean temperature for inner flow.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible change in kinetic and potential energy, (2) Negligible axial conduction, (3) Constant $c_p$, (4) Uniform $T_\infty$.

ANALYSIS: From Eq. 8.36,

$$dq = \dot{m} \, c_p \, d \, T_m$$

with

$$dq = U_d A \, (T_\infty - T_m) = U P (T_\infty - T_m) \, dx.$$  

The overall heat transfer coefficient may be defined in terms of the inner or outer surface area, with $U_i P_i = U_o P_o$.

For the inner surface, from Eq. 3.31,

$$U_i = \left[ \frac{1}{h_i} + \frac{r_i}{k} \ln \frac{r_o}{r_i} + \frac{r_i}{r_o} \frac{1}{h_o} \right]^{-1}.$$  

Hence,

$$\frac{d \, T_m}{T_\infty - T_m} = \frac{UP}{\dot{m} \, c_p} \, dx$$

or, with $\Delta T \equiv T_\infty - T_m$,

$$\int_{\Delta T_i}^{\Delta T_o} \frac{d(A \, \Delta T)}{\Delta T} = - \frac{P}{\dot{m} \, c_p} \int_0^L U \, dx.$$  

Hence,

$$\ln \frac{\Delta T_o}{\Delta T_i} = - \frac{PL}{\dot{m} \, c_p} \left( \frac{1}{L} \int_0^L U \, dx \right)$$

$$\frac{T_\infty - T_{m,o}}{T_\infty - T_{m,i}} = \exp \left( - \frac{PL}{\dot{m} \, c_p} \bar{U} \right).$$

COMMENTS: The development and results parallel those for a constant surface temperature, with $\bar{U}$ and $T_\infty$ replacing $\bar{h}$ and $T_s$. 
PROBLEM 8.20

KNOWN: Thin-walled tube experiences sinusoidal heat flux distribution on the wall.

FIND: (a) Total rate of heat transfer from the tube to the fluid, \( q \), (b) Fluid outlet temperature, \( T_{m,o} \), (c) Axial distribution of the wall temperature \( T_s(x) \) and (d) Magnitude and position of the highest wall temperature, and (e) For prescribed conditions, calculate and plot the mean fluid and surface temperatures, \( T_{m}(x) \) and \( T_s(x) \), respectively, as a function of distance along the tube; identify features of the distributions; explore the effect of \( \pm 25\% \) changes in the convection coefficient on the distributions.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible kinetic and potential energy changes, (3) Turbulent, fully developed flow.

ANALYSIS: (a) The total rate heat transfer from the tube to the fluid is

\[
q = \int_0^L q_s^o \, P \, dx = q_o^o \pi D \int_0^D \sin \left( \frac{\pi x}{L} \right) \, dx = q_o^o \pi D \left( \frac{L}{\pi} \right) \left[ -\cos \left( \frac{\pi x}{L} \right) \right]_0^L = 2DLq_o^o \tag{1}
\]

(b) The fluid outlet temperature follows from the overall energy balance with knowledge of the total heat rate,

\[
q = \dot{m} c_p \left( T_{m,o} - T_{m,i} \right) = 2DLq_o^o \quad T_{m,o} = T_{m,i} + \left( 2DLq_o^o / \dot{m} c_p \right) \tag{2}
\]

(c) The axial distribution of the wall temperature can be determined from the rate equation

\[
q_s^o = h \left[ T_s(x) - T_m(x) \right] \quad T_s(x) = T_{m,x}(x) + q_s^o / h \tag{3}
\]

where, by combining expressions of parts (a) and (b), \( T_{m,x}(x) \) is

\[
\int_0^x q_s^o \, P \, dx = \dot{m} c_p \left( T_{m,x} - T_{m,i} \right) \quad T_{m,x} = T_{m,i} + \frac{q_o^o \pi D}{\dot{m} c_p} \int_0^x \sin \left( \frac{\pi x}{L} \right) \, dx = T_{m,i} + \frac{DLq_o^o}{\dot{m} c_p} \left[ 1 - \cos \left( \frac{\pi x}{L} \right) \right] \tag{4}
\]

Hence, substituting Eq. (4) into (3), find

\[
T_s(x) = T_{m,i} + \frac{DLq_o^o}{\dot{m} c_p} \left[ 1 - \cos \left( \frac{\pi x}{L} \right) \right] + \frac{q_o^o}{h} \sin \left( \frac{\pi x}{L} \right) \tag{5}
\]

(d) To determine the location of the maximum wall temperature \( x' \) where \( T_s(x') = T_{s,max} \), set

\[
\frac{dT_s(x)}{dx} = 0 = \frac{d}{dx} \left\{ \frac{DLq_o^o}{\dot{m} c_p} \left[ 1 - \cos \left( \frac{\pi x}{L} \right) \right] + \frac{q_o^o}{h} \sin \left( \frac{\pi x}{L} \right) \right\}
\]

\[
\frac{DLq_o^o \pi}{\dot{m} c_p} \cdot \sin \left( \frac{\pi x'}{L} \right) + \frac{q_o^o \pi}{h} \cdot \cos \left( \frac{\pi x'}{L} \right) = 0 \quad \tan \left( \frac{\pi x'}{L} \right) = -\frac{q_o^o / h}{DLq_o^o / \dot{m} c_p} = -\frac{\dot{m} c_p}{DLh}
\]

Continued...
PROBLEM 8.20 (Cont.)

\[ x' = \frac{L}{\pi} \tan^{-1} \left( \frac{-mc_p}{DLh} \right) \]  \hspace{1cm} (6) \<

At this location, the wall temperature is

\[ T_{s,\text{max}} = T_s(x') = T_{m,i} + \frac{DLq''}{mc_p} \left[ 1 - \cos \left( \frac{\pi x'/L}{\pi} \right) \right] + \frac{q''}{h} \sin \left( \frac{\pi x'/L}{\pi} \right) \]  \hspace{1cm} (7) \<

(e) Consider the prescribed conditions for which to compute and plot \( T_m(x) \) and \( T_s(x) \),

\[
\begin{align*}
D &= 40 \text{ mm} & \dot{m} &= 0.025 \text{ kg/s} & h &= 1000 \text{ W/m}^2 \\
L &= 4 \text{ m} & c_p &= 4180 \text{ J/kg-K} & q'' &= 10,000 \text{ W/m}^2 \\
T_{m,i} &= 25^\circ C
\end{align*}
\]

Using Eqs. (4) and (5) in IHT, the results are plotted below.

The effect of a lower convection coefficient is to increase the wall temperature. The position of the maximum temperature, \( T_{s,\text{max}} \), moves away from the tube exit with decreasing convection coefficient.

**COMMENTS:**
(1) Because the flow is fully developed and turbulent, assuming \( h \) is constant along the entire length of the tube is reasonable.

(2) To determine whether the \( T_s(x) \) distribution has a maximum (rather than a minimum), you should evaluate \( d^2T_s(x)/dx^2 \) to show the value is indeed negative.
**PROBLEM 8.21**

**KNOWN:** Water is heated in a tube having a wall flux that is dependent upon the wall temperature.

**FIND:** (a) Beginning with a properly defined differential control volume in the tube, derive expressions that can be used to obtain the temperatures for the water and the wall surface as a function of distance from the inlet, \( T_m(x) \) and \( T_s(x) \), respectively; (b) Using a numerical integration scheme, calculate and plot the temperature distributions, \( T_m(x) \) and \( T_s(x) \), on the same graph. Identify and comment on the main features of the distributions; and (c) Calculate the total heat transfer rate to the water.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Fully developed flow and thermal conditions, (3) No losses to the outer surface of the tube, and (3) Constant properties.

**PROPERTIES:** *Table A-6, Water* 

\[
\text{Water mean temperature, } T_m(x) = T_m, i + T_m, o/2 = 300 \text{ K, } c_p = 4179 \text{ J/kg·K}
\]

**ANALYSIS:** (a) The properly defined control volume of perimeter \( P = \pi D \) shown in the above schematic follows from Fig. 8.6. The energy balance on the CV includes advection, convection at the inner tube surface, and the heat flux dissipated in the tube wall. (See Eq. 8.38).

\[
\dot{m} c_p \frac{dT_m}{dx} = q_s^* (x) P = h P \left[ T_s (x) - T_m (x) \right]
\]

where \( q_s^* (x) \) is dependent upon \( T_s(x) \) according to the relation

\[
q_s^* (x) = q_s^* , o \left[ 1 + \alpha \left( T_s (x) - T_{ref} \right) \right]
\]

(b) Eqs. (1 and 2) with Eq. (3) can be solved by numerical integration using the Der function in IHT as shown in Comment 1. The temperature distributions for the water and wall surface are plotted below.

---

Continued …..
PROBLEM 8.21 (Cont.)

(c) The total heat transfer to the water can be evaluated from an overall energy balance on the water,
\[
q = \dot{m} c_p \left( T_{m,o} - T_{m,i} \right)
\]  \hspace{1cm} (4)
\[
q = 0.1 \text{ kg/s} \times 4179 \text{ J/kg K} \times (34.4 - 20) \text{ K} = 6018 \text{ W}
\]

Alternatively, the heat rate can be evaluated by integration of the heat flux from the tube surface over the length of the tube,
\[
q = \int_0^L q_s^e(x) \, dx
\]  \hspace{1cm} (5)

where \(q_s^e(x)\) is given by Eq. (3), and \(T_s(x)\) and \(T_m(x)\) are determined from the differential form of the energy equation, Eqs. (1) and (2). The result as shown in the IHT code below is 6005 W.

COMMENTS:
1. Note that \(T_m(x)\) increases with distance greater than linearly, as expected since \(q_s^e(x)\) does. Also as expected, the difference, \(T_s(x) - T_m(x)\), likewise increases with distance greater than linearly.
2. In the foregoing analysis, \(c_p\) is evaluated at the mean fluid temperature \(T_m = (T_{m,i} + T_{m,o})/2\).
3. The IHT code representing the foregoing equations to calculate and plot the temperature distribution and to calculate the total heat rate to the water is shown below.

**PROBLEM 8.22**

**KNOWN:** Flow rate of engine oil through a long tube.

**FIND:** (a) Heat transfer coefficient, \( h \), (b) Outlet temperature of oil, \( T_{m,o} \).

**SCHEMATIC:**

![Schematic of engine oil flow through a long tube]

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties, (3) Combined entry conditions exist.

**PROPERTIES:** Table A-5, Engine Oil \((T_s = 100^\circ C = 373K)\): \( \mu_s = 1.73 \times 10^{-2} \text{ N} \cdot \text{s/m}^2 \); Table A-5, Engine Oil \((T_m = 77^\circ C = 350K)\): \( c_p = 2118 \text{ J/kg} \cdot \text{K}, \mu = 3.56 \times 10^{-2} \text{ N} \cdot \text{s/m}^2, k = 0.138 \text{ W/mK}, Pr = 546.\)

**ANALYSIS:** (a) The overall energy balance and rate equations have the form

\[
q = \dot{m} c_p (T_{m,o} - T_{m,i}) \quad q = \overline{h} A_s \Delta T_{lm}
\]

Using Eq. 8.42b, with \( P = \pi D \), and Eq. 8.6

\[
\frac{\Delta T_o}{\Delta T_i} = \frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp \left( - \frac{PL}{\dot{m} c_p} \overline{h} \right).
\]

\[
Re_D = \frac{4 \dot{m}}{\pi D \mu} = \frac{4 \times 0.02 \text{ kg/s}}{\pi \times 3 \times 10^{-3} \text{ m} \times 3.56 \times 10^{-2} \text{ N} \cdot \text{s/m}^2} = 238.
\]

For laminar and combined entry conditions, use Eq. 8.57

\[
\overline{Nu}_D = 1.86 \left( \frac{Re_D Pr}{L/D} \right)^{1/3} \left( \frac{\mu}{\mu_s} \right)^{0.14} = \left( \frac{238 \times 546}{30 \times 3 \times 10^{-3}} \right)^{1/3} \left( \frac{3.56}{1.73} \right)^{0.14} = 4.83
\]

\[
\overline{h} = \overline{Nu}_D k/D = 4.83 \times 0.138 \text{ W/m} \cdot \text{K} \times 3 \times 10^{-3} \text{ m} = 222 \text{ W/m}^2 \cdot \text{K}.
\]

(b) Using Eq. (3) with the foregoing value of \( \overline{h} \),

\[
\left( \frac{100 - T_{m,o}}{100 - 60} \right)^\circ C = \exp \left( - \frac{\pi \times 3 \times 10^{-3} \text{ m} \times 30 \text{ m}}{0.02 \text{ kg/s} \times 2118 \text{ J/kg} \cdot \text{K}} \times 222 \text{ W/m}^2 \cdot \text{K} \right) \quad T_{m,o} = 90.9^\circ C.
\]

**COMMENTS:** (1) Note that requirements for the correlation, Eq. 8.57, are satisfied.

(2) The assumption of \( T_m = 77^\circ C \) for selecting property values was satisfactory.

(3) For thermal entry effect only, Eq. 8.56, \( \overline{h} = 201 \text{ W/m}^2 \cdot \text{K} \) and \( T_{m,o} = 89.5^\circ C \).
PROBLEM 8.23

KNOWN: Inlet temperature and flowrate of oil flowing through a tube of prescribed surface temperature and geometry.

FIND: (a) Oil outlet temperature and total heat transfer rate, and (b) Effect of flowrate.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible temperature drop across tube wall, (2) Negligible kinetic energy, potential energy and flow work effects.

PROPERTIES: Table A.5, Engine oil (assume $T_{m,o} = 140\,^\circ\text{C}$, hence $T_m = 80\,^\circ\text{C} = 353\,\text{K}$): $\rho = 852\,\text{kg/m}^3$, $\nu = 37.5 \times 10^{-6}\,\text{m}^2/\text{s}$, $k = 138 \times 10^{-3}\,\text{W/m}\cdot\text{K}$, $Pr = 490$, $\mu = \rho \cdot \nu = 0.032\,\text{kg/m}\cdot\text{s}$, $c_p = 2131\,\text{J/kg}\cdot\text{K}$.

ANALYSIS: (a) For constant surface temperature the oil outlet temperature may be obtained from Eq. 8.42b. Hence

\[
T_{m,o} = T_s - \left(T_s - T_{m,i}\right) \exp \left(\frac{-\pi DL\bar{h}}{mc_p}\right)
\]

To determine $\bar{h}$, first calculate $Re_D$ from Eq. 8.6,

\[
Re_D = \frac{4m}{\pi D \mu} = \frac{4(0.5\,\text{kg/s})}{\pi(0.05\,\text{m})(0.032\,\text{kg/m}\cdot\text{s})} = 398
\]

Hence the flow is laminar. Moreover, from Eq. 8.23 the thermal entry length is

\[
x_{fd,t} = 0.05D Re_D Pr = 0.05(0.05\,\text{m})(398)(490) = 486\,\text{m}.
\]

Since $L = 25\,\text{m}$ the flow is far from being thermally fully developed. However, from Eq. 8.3, $x_{fd,t} = 0.05D Re_D Pr = 0.05(0.05\,\text{m})(398) = 1\,\text{m}$ and it is reasonable to assume fully developed hydrodynamic conditions throughout the tube. Hence $\bar{h}$ may be determined from Eq. 8.56

\[
\overline{Nu_D} = 3.66 + \frac{0.0668(D/L)Re_D Pr}{1 + 0.04[D/(L)Re_D Pr]^{2/3}}.
\]

With $(D/L)Re_D Pr = (0.05/25)398 \times 490 = 390$, it follows that

\[
\overline{Nu_D} = 3.66 + \frac{26}{1 + 2.14} = 11.95.
\]

Hence, $\bar{h} = \frac{\overline{Nu_D} \cdot k}{D} = 11.95 \frac{0.138\,\text{W/m}\cdot\text{K}}{0.05\,\text{m}} = 33\,\text{W/m}^2\cdot\text{K}$ and it follows that Continued...
PROBLEM 8.23 (Cont.)

\[
T_{m,o} = 150^\circ C - \left(150^\circ C - 20^\circ C\right) \exp \left[-\frac{\pi \left(0.05 m\right)\left(25 m\right)}{0.5 \text{kg}/\text{s} \times 2131 \text{J}/\text{kg} \cdot \text{K}} \times 33 \text{W}/\text{m}^2 \cdot \text{K}\right]
\]

\[T_{m,o} = 35^\circ C.\]

From the overall energy balance, Eq. 8.37, it follows that

\[
q = m c_p \left(T_{m,o} - T_{m,i}\right) = 0.5 \text{kg}/\text{s} \times 2131 \text{J}/\text{kg} \cdot \text{K} \times (35 - 20)^\circ C
\]

\[q = 15,980 \text{ W}.\]

The value of \(T_{m,o}\) has been grossly overestimated in evaluating the properties. The properties should be re-evaluated at \(T = (20 + 35)/2 = 27^\circ C\) and the calculations repeated. Iteration should continue until satisfactory convergence is achieved between the calculated and assumed values of \(T_{m,o}\). Following such a procedure, one would obtain \(T_{m,o} = 36.4^\circ C\), \(Re_D = 27.8\), \(\overline{h} = 32.8 \text{ W}/\text{m}^2 \cdot \text{K}\), and \(q = 15,660 \text{ W}\). The small effect of reevaluating the properties is attributed to the compensating effects on \(Re_D\) (a large decrease) and \(Pr\) (a large increase).

(b) The effect of flowrate on \(T_{m,o}\) and \(q\) was determined by using the appropriate IHT Correlations and Properties Toolpads.

![Graph of Outlet Temperature vs Mass Flowrate](image1)

![Graph of Heat Rate vs Mass Flowrate](image2)

The heat rate increases with increasing \(m\) due to the corresponding increase in \(Re_D\) and hence \(\overline{h}\). However, the increase is not proportional to \(m\), causing \(\left(T_{m,o} - T_{m,i}\right) = q/m c_p\), and hence \(T_{m,o}\) to decrease with increasing \(m\). The maximum heat rate corresponds to the maximum flowrate (\(m = 0.20 \text{ kg/s}\)).

COMMENTS: Note that significant error would be introduced by assuming fully developed thermal conditions and \(Nu_D = 3.66\). The flow remains well within the laminar region over the entire range of \(m\).
PROBLEM 8.24

KNOWN: Inlet temperature and flowrate of oil moving through a tube of prescribed diameter and surface temperature.

FIND: (a) Oil outlet temperature $T_{m,o}$ for two tube lengths, 5 m and 100 m, and log mean and arithmetic mean temperature differences, (b) Effect of $L$ on $T_{m,o}$ and $\overline{N_uD}$.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible kinetic energy, potential energy and flow work changes, (3) Constant properties.

PROPERTIES: Table A.4, Oil (330 K): $c_p = 2035$ J/kg·K, $\mu = 0.0836$ N·s/m², $k = 0.141$ W/m·K, Pr = 1205.

ANALYSIS: (a) Using Eqs. 8.42b and 8.6

$$T_{m,o} = T_s - (T_s - T_{m,i}) \exp \left(\frac{-\pi DL\overline{h}}{mc_p}\right)$$

$$Re_D = \frac{4m}{\pi D \mu} = 4 \times 0.5 \text{kg/s} \times \frac{\pi \times 0.025 \text{m} \times 0.0836 \text{N/s/m}^2}{2035 \text{J/kg·K}} = 304.6$$

Since entry length effects will be significant, use Eq. 8.56

$$\overline{h} = \frac{k}{D} \left[3.66 + \frac{0.0688(D/L)Re_D Pr}{1 + 0.04[D/L]Re_D Pr^{2/3}}\right] = 0.141 \text{W/m·K} \left[3.66 + \frac{2.45 \times 10^4 D/L}{0.025 m \times 1 + 205(D/L)^{2/3}}\right]$$

For $L = 5$ m, $\overline{h} = 5.64(3.66 + 17.51) = 119 \text{W/m}^2\cdot\text{K}$, hence

$$T_{m,o} = 100^\circ \text{C} - (75^\circ \text{C}) \exp \left(-\frac{\pi \times 0.025 \text{m} \times 5 \text{m} \times 119 \text{W/m}^2\cdot\text{K}}{0.5 \text{kg/s} \times 2035 \text{J/kg·K}}\right) = 28.4^\circ \text{C} <$$

For $L = 100$ m, $\overline{h} = 5.64(3.66 + 3.38) = 40 \text{W/m}^2\cdot\text{K}$, $T_{m,o} = 44.9^\circ \text{C}$. <

Also, for $L = 5$ m,

$$\Delta T_m = \frac{\Delta T_o - \Delta T_i}{\ln(\Delta T_o / \Delta T_i)} = \frac{71.6 - 75}{\ln(71.6/75)} = 73.3^\circ \text{C} \quad \Delta T_{am} = (\Delta T_o + \Delta T_i)/2 = 73.3^\circ \text{C} <$$

For $L = 100$ m,

$$\Delta T_m = 64.5^\circ \text{C}, \quad \Delta T_{am} = 65.1^\circ \text{C} <$$

(b) The effect of tube length on the outlet temperature and Nusselt number was determined by using the Correlations and Properties Toolpads of IHT.

Continued...
The outlet temperature approaches the surface temperature with increasing L, but even for L = 100 m, \( T_{m,o} \) is well below \( T_s \). Although \( \overline{\text{Nu}} \) decays with increasing L, it is still well above the fully developed value of \( \text{Nu}_{D,fd} = 3.66 \).

**COMMENTS:**  
(1) The average, mean temperature, \( \overline{T_m} = 330 \) K, was significantly overestimated in part (a). The accuracy may be improved by evaluating the properties at a lower temperature. (2) Use of \( \Delta T_{am} \) instead of \( \Delta T_{\ell/m} \) is reasonable for small to moderate values of \( (T_{m,i} - T_{m,o}) \). For large values of \( (T_{m,i} - T_{m,o}) \), \( \Delta T_{\ell/m} \) should be used.
PROBLEM 8.25

KNOWN: Oil at 80°C enters a single-tube preheater of 9-mm diameter and 5-m length; tube surface maintained at 165°C by swirling combustion gases.

FIND: Determine the flow rate and heat transfer rate when the outlet temperature is 95°C.

SCHEMATIC:

ASSUMPTIONS: (1) Combined entry length, laminar flow, (2) Tube wall is isothermal, (3) Negligible kinetic and potential energy, and flow work, (4) Constant properties.

PROPERTIES: Table A-5, Engine oil, new \((T_m = (T_{m,i} + T_{m,o})/2 = 361 \text{ K})\): \(\rho = 847.5 \text{ kg/m}^3\), \(c_p = 2163 \text{ J/kg} \cdot \text{K}\), \(\nu = 2.931 \times 10^{-5} \text{ m}^2/\text{s}\), \(k = 0.1879 \text{ W/m} \cdot \text{K}\), \(Pr = 3902\); \((T_s = 430 \text{ K})\): \(\mu_s = 0.047 \text{ N} \cdot \text{s/m}^2\).

ANALYSIS: The overall energy balance, Eq. 8.37, and rate equation, Eq. 8.42b, are

\[
q = \dot{m} c_p (T_{m,o} - T_{m,i})
\]

\[
\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp\left(-\frac{P L \bar{h}}{\dot{m} c_p}\right)
\]

Not knowing the flow rate \(\dot{m}\), the Reynolds number cannot be calculated. Assume that the flow is laminar, and the combined entry length condition occurs. The average convection coefficient can be estimated using the Sieder-Tate correlation, Eq. 8.57,

\[
\frac{\overline{Nu_D}}{k} = 1.86 \left(\frac{Re_D Pr}{L/D}\right)^{1/3} \left(\frac{\mu}{\mu_s}\right)^{0.14}
\]

where all properties are evaluated at \(T_m = (T_{m,i} + T_{m,o})/2\), except for \(\mu_s\) at the wall temperature \(T_s\).

The Reynolds number follows from Eq. 8.6,

\[
Re_D = 4\dot{m} / \pi D \mu
\]

A tedious trial-and-error solution is avoided by using IHT to solve the system of equations with the following result:

\[
\begin{align*}
Re_D & = 251 \\
\overline{Nu_D} & = 9.54 \\
\bar{h}_D (\text{W/m}^2 \cdot \text{K}) & = 146 \\
q (\text{W}) & = 1432 \\
\dot{m} (\text{kg/h}) & = 159
\end{align*}
\]

Note that the flow is laminar, and evaluating \(x_{fd}\) using Eq. 8.3, find \(x_{fd,h} = 44 \text{ m}\) so the combined entry length condition is appropriate.
PROBLEM 8.26

KNOWN: Ethylene glycol flowing through a coiled, thin walled tube submerged in a well-stirred water bath maintained at a constant temperature.

FIND: Heat rate and required tube length for prescribed conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Tube wall thermal resistance negligible, (3) Convection coefficient on water side infinite; cooling process approximates constant wall surface temperature distribution, (4) KE, PE and flow work changes negligible, (5) Constant properties, (6) Negligible heat transfer enhancement associated with the coiling.

PROPERTIES: Table A-5, Ethylene glycol (T_m = (85 + 35°C/2 = 60°C = 333 K): \( c_p = 2562 \text{ J/kg} \cdot \text{K} \), \( \mu = 0.522 \times 10^{-2} \text{ N} \cdot \text{s/m}^2 \), \( k = 0.260 \text{ W/m-K} \), \( Pr = 51.3 \).

ANALYSIS: From an overall energy balance on the tube,

\[
q_{\text{conv}} = m c_p (T_{m,o} - T_{m,i}) = 0.01 \text{ kg/s} \times 2562 \text{ J/kg} \times (35 - 85)^\circ \text{C} = -1281 \text{ W}. \quad (1)
\]

For the constant surface temperature condition, from the rate equation,

\[
A_s = q_{\text{conv}} / h \Delta T_{l,m}
\]

\[
\Delta T_{l,m} = (\Delta T_o - \Delta T_i) / \ln \left( \frac{\Delta T_o}{\Delta T_i} \right) = \left[ (35 - 25)^\circ \text{C} - (85 - 25)^\circ \text{C} \right] / \ln \left( \frac{35 - 25}{85 - 25} \right) = 27.9^\circ \text{C}. \quad (3)
\]

Find the Reynolds number to determine flow conditions,

\[
Re = \frac{4m}{\pi D \mu} = \frac{4 \times 0.01 \text{ kg/s}}{\pi \times 0.003 \text{ m} \times 0.522 \times 10^{-2} \text{ N} \cdot \text{s/m}^2} = 813. \quad (4)
\]

Hence, the flow is laminar and, assuming the flow is fully developed, the appropriate correlation is

\[
\overline{Nu}D = \frac{\overline{n}D}{k} = 3.66, \quad \overline{n} = Nu \frac{k}{D} = 3.66 \times 0.260 \times \frac{17 W}{m \cdot K} / 0.003 m = 317 \text{ W/m}^2 \cdot \text{K}. \quad (5)
\]

From Eq. (2), the required area, \( A_s \), and tube length, \( L \), are

\[
A_s = 1281 \text{ W} / 317 \text{ W/m}^2 \cdot \text{K} \times 27.9^\circ \text{C} = 0.1448 \text{ m}^2
\]

\[
L = A_s / \pi D = 0.1448 \text{ m}^2 / \pi (0.003 \text{ m}) = 15.4 \text{ m}. \quad (6)
\]

COMMENTS: Note that for fully developed laminar flow conditions, the requirement is satisfied:

\[
Gz = (L/D) / Re Pr = (15.3 / 0.003) / (813 \times 51.3) = 0.122 > 0.05. \quad \text{Note also the sign of the heat rate } q_{\text{conv}} \text{ when using Eqs. (1) and (2).
PROBLEM 8.27

KNOWN: Inlet and outlet temperatures and velocity of fluid flow in tube. Tube diameter and length.

FIND: Surface heat flux and temperatures at x = 0.5 and 10 m.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Negligible heat loss to surroundings, (4) Negligible potential and kinetic energy changes and axial conduction.

PROPERTIES: Pharmaceutical (given): $\rho = 1000 \text{ kg/m}^3$, $c_p = 4000 \text{ J/kg·K}$, $\mu = 2 \times 10^{-3} \text{ kg/s·m}$, $k = 0.48 \text{ W/m·K}$, $Pr = 10$.

ANALYSIS: With

$$m = \rho VA = 1000 \text{ kg/m}^3 (0.2 \text{ m/s}) \pi (0.0127 \text{ m})^2 / 4 = 0.0253 \text{ kg/s}$$

Eq. 8.37 yields

$$q = m c_p (T_{m,o} - T_{m,i}) = 0.0253 \text{ kg/s} (4000 \text{ J/kg·K}) 50 \text{ K} = 5060 \text{ W}.$$  

The required heat flux is then

$$q_s^* = q/A_s = 5060 \text{ W/π (0.0127 m)10 m} = 12,682 \text{ W/m}^2.$$  

With

$$Re_D = \rho V D/\mu = 1000 \text{ kg/m}^3 (0.2 \text{ m/s}) 0.0127 \text{ m}/2 \times 10^{-3} \text{ kg/s·m} = 1270$$

the flow is laminar and Eq. 8.23 yields

$$x_{fd,1} = 0.05Re_D PrD = 0.05(1270)10(0.0127 \text{ m}) = 8.06 \text{ m}.$$  

Hence, with fully developed hydrodynamic and thermal conditions at x = 10 m, Eq. 8.53 yields

$$h (10 \text{ m}) = Nu_{D,fd} (k/D) = 4.36 (0.48 \text{ W/m·K}/0.0127 \text{ m}) = 164.8 \text{ W/m}^2·\text{K}.$$  

Hence, from Newton’s law of cooling,

$$T_{s,o} = T_{m,o} + (q_s^*/h) = 75^{°}C + \left(12,682 \text{ W/m}^2/164.8 \text{ W/m}^2·\text{K}\right) = 152^{°}C.$$  

At x = 0.5 m, $(x/D)/(ReDPr) = 0.0031$ and Figure 8.9 yields $Nu_D \approx 8$ for a thermal entry region with uniform surface heat flux. Hence, $h(0.5 \text{ m}) = 302.4 \text{ W/m}^2·\text{K}$ and, since $T_m$ increases linearly with x, $T_m(x = 0.5 \text{ m}) = T_{m,i} + (T_{m,o} - T_{m,i}) (x/L) = 27.5^{°}C$. It follows that

$$T_s (x = 0.5 \text{ m}) = 27.5^{°}C + \left(12,682 \text{ W/m}^2/302.4 \text{ W/m}^2·\text{K}\right) = 69.4^{°}C.$$
PROBLEM 8.28

KNOWN: Inlet temperature, flow rate and properties of hot fluid. Initial temperature, volume and properties of pharmaceutical. Heat transfer coefficient at outer surface and dimensions of coil.

FIND: (a) Expressions for $T_c(t)$ and $T_{h,o}(t)$, (b) Plots of $T_c(t)$ and $T_{h,o}(t)$ for prescribed conditions. Effect of flow rate on time for pharmaceutical to reach a prescribed temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Constant properties, (2) Negligible heat loss from vessel to surroundings, (3) Pharmaceutical is isothermal, (4) Negligible work due to stirring, (5) Negligible thermal energy generation (or absorption) due to chemical reactions associated with the batch process, (6) Negligible kinetic energy, potential energy and flow work changes for the hot fluid, (7) Negligible tube wall conduction resistance.

ANALYSIS: (a) Performing an energy balance for a control surface about the stirred liquid, it follows that

$$\frac{d U_c}{dt} = \frac{d}{dt} \left( \rho_c \nu_c T_c \right) = \rho_c \nu_c \frac{dT_c}{dt} = q(t)$$

where,

$$q(t) = \dot{m}_h c_{p,h} \left( T_{h,i} - T_{h,o} \right)$$

or,

$$q(t) = U A_s \Delta T_{\ell m}$$

where

$$\Delta T_{\ell m} = \frac{\left( T_{h,i} - T_c \right) - \left( T_{h,o} - T_c \right)}{\ln \left( \frac{T_{h,i} - T_c}{T_{h,o} - T_c} \right)} = \frac{T_{h,i} - T_{h,o}}{\ln \left( \frac{T_{h,i} - T_c}{T_{h,o} - T_c} \right)}$$

Substituting (3b) into (3a) and equating to (2),

$$\dot{m}_h c_{p,h} \left( T_{h,i} - T_{h,o} \right) = U A_s \frac{T_{h,i} - T_{h,o}}{\ln \left( \frac{T_{h,i} - T_c}{T_{h,o} - T_c} \right)}$$

Hence,

$$\ln \left( \frac{T_{h,i} - T_c}{T_{h,o} - T_c} \right) = \frac{U A_s}{\dot{m}_h c_{p,h}}$$

or,

$$T_{h,o}(t) = T_c + \left( T_{h,i} - T_c \right) \exp \left( -\frac{U A_s}{\dot{m}_h c_{p,h}} \right)$$

Substituting Eqs. (2) and (4) into Eq. (1),

Continued …..
PROBLEM 8.28 (Cont.)

\[
\rho_c \forall c \, c_v, c \frac{dT_c}{dt} = \dot{m}_h c_p, h \left[ T_{h, i} - T_c - (T_{h, i} - T_c) \exp \left( -\frac{U A_s}{\dot{m}_h c_p, h} \right) \right]
\]

\[
\frac{dT_c}{dt} = \frac{\dot{m}_h c_p, h (T_{h, i} - T_c)}{\rho_c \forall c \, c_v, c} \left[ 1 - \exp \left( -\frac{U A_s}{\dot{m}_h c_p, h} \right) \right]
\]

\[-\int_{T_{c, i}}^{T_c(t)} \frac{dT_c}{T_c - T_{h, i}} = \frac{\dot{m}_h c_p, h}{\rho_c \forall c \, c_v, c} \left[ 1 - \exp \left( -\frac{U A_s}{\dot{m}_h c_p, h} \right) \right] \int_0^t dt \]

\[-\ln \left( \frac{T_c - T_{h, i}}{T_{c, i} - T_{h, i}} \right) = \frac{\dot{m}_h c_p, h}{\rho c \forall c \, c_v, c} \left[ 1 - \exp \left( -\frac{U A_s}{\dot{m}_h c_p, h} \right) \right] t \]

\[T_c(t) = T_{h, i} - (T_{h, i} - T_{c, i}) \exp \left\{ -\frac{\dot{m}_h c_p, h \left[ 1 - \exp \left( -\frac{U A}{\dot{m}_h c_p, h} \right) \right] t}{\rho c \forall c \, c_v, c} \right\} \quad (5) \]

Eq. (5) may be used to determine \( T_c(t) \) and the result used with (4) to determine \( T_{h, o}(t) \).
