(b) To evaluate the temperature histories, the overall heat transfer coefficient, \( U = \left( \frac{1}{h_o} + \frac{1}{h_i} \right)^{-1} \), must first be determined. With \( \text{Re}_D = 4 \dot{m} / \pi \mu D = 4 \times 2.4 \text{ kg/s/m} \) \( 2 \times 0.002 \text{ N} \cdot \text{s/m} \cdot 0.05 \text{m} \) \( 30,600 \), the flow is turbulent and

\[
h_i = \frac{k}{D} \frac{\text{Nu}_D}{\text{Re}_D} = \frac{0.260 \text{ W/m} \cdot \text{K}}{0.05 \text{m}} \left[ \frac{0.023 (30,600)^{4/5} (20)^{0.3}}{30,600} \right] = 1140 \text{ W/m}^2 \cdot \text{K}
\]

Hence, \( U = \left[ \left( \frac{1000}{30,600} \right)^{-1} + (1140)^{-1} \right]^{-1} \text{ W/m}^2 \cdot \text{K} = 532 \text{ W/m}^2 \cdot \text{K} \). As shown below, the temperature of the pharmaceuticals increases with time due to heat transfer from the hot fluid, approaching the inlet temperature of the hot fluid (and its maximum possible temperature of 200°C) at \( t = 3600 \text{s} \).
PROBLEM 8.28 (Cont.)

With increasing $T_c$, the rate of heat transfer from the hot fluid decreases (from $4.49 \times 10^5$ W at $t = 0$ to 6760 W at 3600s), in which case $T_{h,o}$ increases (from 125.2°C at $t = 0$ to 198.9°C at 3600s). The time required for the pharmaceuticals to reach a temperature of $T_c = 160\,^\circ C$ is

$$t_c = 1266 \text{s}$$

With increasing $m_h$, the overall heat transfer coefficient increases due to increasing $h_i$ and the hot fluid maintains a higher temperature as it flows through the tube. Both effects enhance heat transfer to the pharmaceutical, thereby reducing the time to reach 160°C from 2178s for $m_h = 1\,\text{kg/s}$ to 906s at 5 kg/s.

For $1 \leq \dot{m}_h \leq 5\,\text{kg/s}$, $12,700 \leq \text{Re}_D \leq 63,700$ and $565 \leq h_i \leq 2050\,\text{W/m}^2\cdot\text{K}$.

**COMMENTS:** Although design changes involving the length and diameter of the coil can be used to alter the heating rate, process control parameters are limited to $T_{h,i}$ and $\dot{m}_h$. 

![Graph showing time vs mass flow rate](chart.png)
PROBLEM 8.29

KNOWN: Tubing with glycerin welded to transformer lateral surface to remove dissipated power. Maximum allowable temperature rise of coolant is 6°C.

FIND: (a) Required coolant rate \( \dot{m} \), tube length \( L \) and lateral spacing \( S \) between turns, and (b) Effect of flowrate on outlet temperature and maximum power.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) All heat dissipated by transformer transferred to glycerin, (3) Fully developed flow (part a), (4) Negligible kinetic and potential energy changes, (5) Negligible tube wall thermal resistance.

PROPERTIES: Table A.5. Glycerin \( (T_m = 300 \, \text{K}) \): \( \rho = 1259.9 \, \text{kg/m}^3, \ c_p = 2427 \, \text{J/kg} \cdot \text{K}, \ \mu = 79.9 \times 10^{-2} \, \text{N} \cdot \text{s} / \text{m}^2, \ k = 286 \times 10^{-3} \, \text{W/m} \cdot \text{K}, \ \text{Pr} = 6780. \)

ANALYSIS: (a) From an overall energy balance assuming the maximum temperature rise of the glycerin coolant is 6°C, find the flow rate as

\[
\dot{m} = \frac{q}{c_p (T_{m,o} - T_{m,i})} = \frac{1000 \, \text{W}}{2427 \, \text{J/kg} \cdot \text{K}} (6 \, \text{K}) = 6.87 \times 10^{-2} \, \text{kg/s} \]

From Eq. 8.43, the length of tubing can be determined,

\[
\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp \left( -\frac{PLh}{\dot{m}c_p} \right)
\]

where \( P = \pi D \). For the tube flow, find

\[
\text{Re}_D = \frac{4\dot{m}}{\pi D \mu} = \frac{4 \times 6.87 \times 10^{-2} \, \text{kg/s}}{\pi \times 0.020 \, \text{m} \times 79.9 \times 10^{-2} \, \text{N} \cdot \text{s} / \text{m}^2} = 5.47
\]

which implies laminar flow, and if fully developed,

\[
\text{Nu}_D = \frac{\text{h}D}{k} = 3.66 \quad \text{and} \quad \text{h} = \frac{3.66 \times 286 \times 10^{-3} \, \text{W/m} \cdot \text{K}}{0.020 \, \text{m}} = 52.3 \, \text{W/m}^2 \cdot \text{K}
\]

\[
\frac{(47 - 30) \, \text{C}}{(47 - 24) \, \text{C}} = \exp \left[ -\left( \pi (0.020 \, \text{m}) \times 52.3 \, \text{W/m}^2 \cdot \text{K} \times L \right) / \left( 6.87 \times 10^{-2} \, \text{kg/s} \times 2427 \, \text{J/kg} \cdot \text{K} \right) \right]
\]

\[
L = 15.3 \, \text{m}.
\]

The number of turns of the tubing, \( N \), is \( N = L / (\pi D) = (15.3 \, \text{m}) / (\pi (0.3 \, \text{m}) = 16.2 \) and hence the spacing \( S \) will be

\[
S = H/N = 500 \, \text{mm} / 16.2 = 30.8 \, \text{mm}.
\]

Continued...
(b) Parametric calculations were performed using the IHT Correlations Toolpad based on Eq. 8.56 (a thermal entry length condition), and the following results were obtained.

With $T_s$ maintained at $47^\circ C$, the maximum allowable transformer power (heat rate) and glycerin outlet temperature increase and decrease, respectively, with increasing $\dot{m}$. The increase in $q$ is due to an increase in $\overline{Nu_D}$ (and hence $\overline{h}$) with increasing $Re_D$. The value of $\overline{Nu_D}$ increased from 5.3 to 9.4 with increasing $\dot{m}$ from 0.05 to 0.25 kg/s.

**COMMENTS:** Since $Gz_h^{-1} = (L/D)/Re_D Pr = (15.3 \text{ m}/0.02 \text{ m})/(5.47 \times 6780) = 0.0206 < 0.05$, entrance length effects are significant, and Eq. 8.56 should be used to determine $\overline{Nu_D}$. 
PROBLEM 8.30

KNOWN: Diameter and length of copper tubing. Temperature of collector plate to which tubing is soldered. Water inlet temperature and flow rate.

FIND: (a) Water outlet temperature and heat rate, (b) Variation of outlet temperature and heat rate with flow rate. Variation of water temperature along tube for the smallest and largest flowrates.

SCHEMATIC:

ASSUMPTIONS: (1) Straight tube with smooth surface, (2) Negligible kinetic/potential energy and flow work changes, (3) Negligible thermal resistance between plate and tube inner surface, (4) Re_{D,c} = 2300.

PROPERTIES: Table A.6, water (assume \( \overline{T_m} = \frac{(T_{m,i} + T_s)}{2} = 47.5^\circ C = 320.5\, K \)): \( \rho = 986\, kg/m^3 \), \( c_p = 4180\, J/kg\cdot K \), \( \mu = 577 \times 10^{-6}\, N\cdot s/m^2 \), \( k = 0.640\, W/m\cdot K \), \( Pr = 3.77 \).

ANALYSIS: (a) For \( \dot{m} = 0.01\, kg/s \), Re_{D} = 4 \( \frac{mD\pi}{\mu} \times \frac{4(0.01\, kg/s)/\pi(0.01\, m)}{577 \times 10^{-6}\, N\cdot s/m^2} = 2200 \), in which case the flow may be assumed to be laminar. With \( x_{fd,t}/D = 0.05\, Re_{D}Pr = 0.05(2200)(3.77) = 415 \) and \( L/D = 800 \), the flow is fully developed over approximately 50% of the tube length. With \( \left[\frac{Re_{D}Pr}{(L/D)}\right]^{1/3} \left(\frac{\mu}{\mu_s}\right)^{0.14} = 2.30 \), Eq. 8.57 may therefore be used to compute the average convection coefficient

\[
\overline{h} = \left(\frac{k}{D}\right)\overline{Nu_D} = 4.27(0.640\, W/m\cdot K)/0.01m = 273\, W/m^2 \cdot K
\]

From Eq. 8.42b,

\[
\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp\left(-\frac{\pi DL}{\overline{mc_p}h}\right) = \exp\left(-\frac{\pi \times 0.01m \times 8m \times 273\, W/m^2 \cdot K}{0.01kg/s \times 4180\, J/kg \cdot K}\right)
\]

\[
T_{m,o} = T_s - 0.194\left(T_s - T_{m,i}\right) = 70^\circ C - 8.7^\circ C = 61.3^\circ C
\]

Hence, \( q = \overline{mc_p} \left(T_{m,o} - T_{m,i}\right) = 0.01kg/s \times (4186\, J/kg \cdot K)(36.3\, K) = 1519\, W \)

(b) The IHT Correlations, Rate Equations and Properties Tool Pads were used to determine the parametric variations. The effect of \( \dot{m} \) was considered in two steps, the first corresponding to \( \dot{m} < 0.011\, kg/s \) (Re_{D} < 2300) and the second for \( \dot{m} > 0.011\, kg/s \) (Re_{D} > 2300). In the first case, Eq. 8.57 was used to determine \( \overline{h} \), while in the second Eq. 8.60 was used. The effects of \( \dot{m} \) are as follows.
The outlet temperature decreases with increasing \( \dot{m} \), although the effect is more pronounced for laminar flow. If \( q \) were independent of \( \dot{m} \), \( (T_{m,o} - T_{m,i}) \) would decrease inversely with increasing \( \dot{m} \). In turbulent flow, however, the convection coefficient, and hence the heat rate, increases approximately as \( \dot{m}^{0.8} \), thereby attenuating the foregoing effect. In laminar flow, \( q \sim \dot{m}^{0.5} \) and this attenuation is not as pronounced.

The temperature distributions were computed from Eq. 8.43, with \( \bar{h} \) assumed to be independent of \( x \). For laminar flow (\( \bar{m} = 0.005 \text{ kg/s} \)), \( \bar{h} \) was based on the entire tube length (L = 8 m) and computed from Eq. 8.57, while for turbulent flow (\( \bar{m} = 0.05 \text{ kg/s} \)) it was assumed to correspond to the value for fully developed flow and computed from Eq. 8.60. The corresponding temperature distributions are as follows.

Continued...
The more pronounced increase for turbulent flow is due to the much larger value of $\bar{h}$ ($4300 \text{ W/m}^2\cdot\text{K}$ for $\dot{m} = 0.05 \text{ kg/s}$ relative to $217 \text{ W/m}^2\cdot\text{K}$ for $\dot{m} = 0.05 \text{ kg/s}$).
**PROBLEM 8.31**

**KNOWN:** Diameter and surface temperature of ten tubes in an ice bath. Inlet temperature and flowrate per tube. Volume (∪) of container and initial volume fraction, \( f_v,i \), of ice.

**FIND:** (a) Tube length required to achieve a prescribed air outlet temperature \( T_{m,o} \) and time to completely melt the ice, (b) Effect of mass flowrate on \( T_{m,o} \) and suitable design and operating conditions.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Negligible kinetic/potential energy and flow work changes, (3) Constant properties, (4) Fully developed flow throughout each tube, (5) Negligible tube wall thermal resistance.

**PROPERTIES:** Table A.4, air (assume \( T_m = 292 \) K): \( c_p = 1007 \) J/kg⋅K, \( \mu = 180.6 \times 10^{-7} \) N⋅s/m², \( k = 0.0257 \) W/m⋅K, \( Pr = 0.709 \); Ice: \( \rho = 920 \) kg/m³, \( h_{sf} = 3.34 \times 10^5 \) J/kg.

**ANALYSIS:** (a) With \( Re_D = 4 \frac{m}{\pi D \mu} = 4(0.01 \text{ kg/s})/\pi (0.05 \text{ m})180.6 \times 10^{-7} \text{ N} \cdot \text{s/m}^2 = 14,100 \) for \( m/G_06 = 0.01 \text{ kg/s} \), the flow is turbulent, and from Eq. 8.60,

\[
\overline{Nu_D} = Nu_D = 0.023 Re_D^{0.8} Pr^{0.3} = 0.023(14,100)^{0.8}(0.709)^{0.3} = 43.3
\]

\[
\bar{h} = \overline{Nu_D} \left( \frac{k}{D} \right) = 43.3 \left( \frac{0.0257 \text{ W/m} \cdot \text{K}}{0.05 \text{ m}} \right) = 22.2 \text{ W/m}^2 \cdot \text{K}
\]

With \( T_{m,o} = 14^\circ \text{C} \), the tube length may be obtained from Eq. 8.42b,

\[
\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \frac{-14}{-24} = \exp \left( -\frac{\pi D L \bar{h}}{m c_p} \right) = \exp \left[ -\frac{\pi (0.05 m) \left( \frac{22.2 \text{ W/m}^2 \cdot \text{K}}{0.01 \text{ kg/s} (1007 \text{ J/kg} \cdot \text{K})} \right)L}{0.01 \text{ kg/s} (1007 \text{ J/kg} \cdot \text{K})} \right]
\]

\[ L = 1.56 \text{ m} \]

The time required to completely melt the ice may be obtained from an energy balance of the form,

\[ (-q)t = f_{v,i} \bigcup (\rho h_{sf}) \]

where \( q = N m c_p \left( T_{m,i} - T_{m,o} \right) = 10(0.01 \text{ kg/s})1007 \text{ J/kg} \cdot \text{K (10 K)} = 1007 \text{ W} \). Hence,

\[ t = \frac{0.8 \left( 10 \text{ m}^3 \right) \left( 920 \text{ kg/m}^3 \right) \left( 3.34 \times 10^5 \text{ J/kg} \right)}{1007 \text{ W}} = 2.44 \times 10^6 \text{ s} = 28.3 \text{ days} \]

(b) Using the appropriate IHT Correlations and Properties Tool Pads, the following results were obtained.

Continued...
Although heat extraction from the air passing through each tube increases with increasing flowrate, the increase is not in proportion to the change in \( \dot{m} \) and the temperature difference \( (T_{m,i} - T_{m,o}) \) decreases. If 0.05 kg/s of air is routed through a single tube, the outlet temperature of \( T_{m,o} = 16.2^\circ C \) slightly exceeds the desired value of 16\(^\circ\)C. The prescribed value could be achieved by slightly increasing the tube length. However, in the interest of reducing pressure drop requirements, it would be better to operate at a lower flowrate per tube. If, for example, air is routed through four of the tubes at 0.01 kg/s per tube and the discharge is mixed with 0.01 kg/s of the available air at 24\(^\circ\)C, the desired result would be achieved.

**COMMENTS:** Since the flow is turbulent and \( L/D = 31 \), the assumption of fully developed flow throughout a tube is marginal and the foregoing analysis overestimates the discharge temperature.
**PROBLEM 8.32**

**KNOWN:** Thermal conductivity and inner and outer diameters of plastic pipe. Volumetric flow rate and inlet and outlet temperatures of air flow through pipe. Convection coefficient and temperature of water.

**FIND:** Pipe length and fan power requirement.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Negligible heat transfer from air in vertical legs of pipe, (3) Negligible flow work and potential and kinetic energy changes for air flow through pipe, (4) Smooth interior surface, (5) Constant properties.

**PROPERTIES:** *Table A-4*, Air \( T_{m,i} = 29°C \): \( \rho_i = 1.155 \text{ kg/m}^3 \). Air \( \bar{T}_m = 25°C \): \( c_p = 1007 \text{ J/kg K} \). Water \( k_a = 0.0261 \text{ W/m-K} \), \( Pr = 0.707 \).

**ANALYSIS:** From Eq. (8.46a) \( \frac{T_{\infty} - T_{m,o}}{T_{\infty} - T_{m,i}} = \exp \left( -\frac{\overline{UA_s}}{\dot{m} c_p} \right) \)

where, from Eq. (3.32), \( (\overline{UA_s})^{-1} = R_{tot} = \frac{1}{\overline{h}_i \pi D_i L} + \frac{\ln (D_o / D_i)}{2 \pi L k_o} + \frac{1}{h_o \pi D_o L} \)

With \( \dot{m} = \rho_i \dot{V}_i = 0.0289 \text{ kg/s} \) and \( Re_D = 4 \dot{m} / \pi D_i \mu = 13,350 \), flow in the pipe is turbulent. Assuming fully developed flow throughout the pipe, and from Eq. (8.60),

\[
\overline{h}_i = \frac{k_a}{D_i} 0.023 \text{Re}_D^{4/5} Pr^{0.3} = \frac{0.0261 \text{ W/m-K} \times 0.023}{0.15} (13,350)^{4/5} (0.707)^{0.3} = 7.20 \text{ W/m-K} \\
(\overline{UA_s})^{-1} = \frac{1}{L} \left( \frac{1}{7.21 \text{ W/m-K} \times \pi \times 0.15} + \frac{\ln (0.17/0.15)}{2 \pi \times 0.15 \text{ W/m-K}} + \frac{1}{1500 \text{ W/m-K} \times \pi \times 0.17 \text{m}} \right) \\
\overline{UA_s} = \frac{L}{(0.294 + 0.133 + 0.001)} = 2.335 \text{ L W/K} \\
\frac{T_{\infty} - T_{m,o}}{T_{\infty} - T_{m,i}} = \frac{17 - 21}{17 - 29} = 0.333 = \exp \left( -\frac{2.335 \text{ L}}{0.0289 \text{ kg/s} \times 1007 \text{ J/kg K}} \right) = \exp (-0.0802) \\
L = -\ln (0.333) / 0.0802 < 13.7 \text{ m} \\
\]

From Eqs. (8.22a) and (8.22b) and with \( u_{m,i} = \dot{V}_i / \left( \pi D_i^2 / 4 \right) = 1.415 \text{ m/s} \), the fan power is

\[
P = (\Delta p) \dot{V} = \rho u_{m,i}^2 2D_i L \dot{V}_i = 0.0294 \frac{1.155 \text{ kg/m}^3}{(1.415 \text{ m/s})^2} 13.7 \text{ m} \times 0.025 \text{ m}^3 / \text{s} = 0.078 \text{ W} \]

where \( f = 0.316 \text{Re}_D^{-1/4} = 0.0294 \) from Eq. (8.20a).

**COMMENTS:** (1) With \( L/D_i = 91 \), the assumption of fully developed flow throughout the pipe is justified. (2) The fan power requirement is small, and the process is economical. (3) The resistance to heat transfer associated with convection at the outer surface is negligible.
PROBLEM 8.33

KNOWN: Flow rate, inlet temperature and desired outlet temperature of water passing through a tube of prescribed diameter and surface temperature.

FIND: (a) Required tube length, L, for prescribed conditions, (b) Required length using tube diameters over the range 30 ≤ D ≤ 50 mm with flow rates m = 1, 2 and 3 kg/s; represent this design information graphically, and (c) Pressure gradient as a function of tube diameter for the three flow rates assuming the tube wall is smooth.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible potential energy, kinetic energy and flow work changes, (3) Constant properties.

PROPERTIES: Table A.6, Water (Tm = 323 K): c_p = 4181 J/kg·K, µ = 547 × 10^{-6} N·s/m², k = 0.643 W/m·K, Pr = 3.56.

ANALYSIS: (a) From Eq. 8.6, the Reynolds number is

\[
\Re_D = \frac{4 \dot{m}}{\pi D \mu} = \frac{4 \times 2 \text{ kg/s}}{\pi (0.04 \text{ m}) 547 \times 10^{-6} \text{ N·s/m}^2} = 1.16 \times 10^5.
\]

Hence the flow is turbulent, and assuming fully developed conditions throughout the tube, it follows from the Dittus-Boelter correlation, Eq. 8.60,

\[
\frac{h}{k} = \frac{0.023 \Re_D^{4/5} \Pr^{0.4}}{0.04 m} = \frac{0.643 \text{ W/m·K}}{0.04 m} 0.023 (1.16 \times 10^5)^{4/5} (3.56)^{0.4} = 6919 \text{ W/m}^2·\text{K}
\]

From Eq. 8.42a, we then obtain

\[
L = \frac{-m c_p \ln (\Delta T_i / \Delta T_f)}{\pi D h} = \frac{2 \text{ kg/s} (4181 \text{ J/kg·K}) \ln (25^\circ \text{C}/75^\circ \text{C})}{\pi (0.04 \text{ m}) 6919 \text{ W/m}^2·\text{K}} = 10.6 \text{ m}.
\]

(b) Using the IHT Correlations Tool, Internal Flow, for fully developed Turbulent Flow, along with appropriate energy balance and rate equations, the required length L as a function of flow rate is computed and plotted on the right.
PROBLEM 8.33 (Cont.)

(c) From Eq. 8.22a the pressure drop is
\[ \frac{\Delta p}{\Delta x} = f \frac{\rho u_m^2}{2D} \]  \hspace{1cm} (4)

The friction factor, \( f \), for the smooth surface condition, Eq. 8.21 with \( 3000 \leq Re_D \leq 5 \times 10^6 \), is
\[ f = \left( 0.790/n \left( Re_D - 1.64 \right) \right)^{-2} \]  \hspace{1cm} (5)

Using IHT with these equations and Eq. (1), the pressure gradient as a function of diameter for the selected flow rates is computed and plotted on the right.

**COMMENTS:**
1. Since \( L/D = (10.6/0.040) = 265 \), the assumption of fully developed conditions throughout is justified.
2. The IHT Workspace used to generate the graphical results are shown below.
**Problem 8.34**

**Known:** Flow rate and inlet temperature of water passing through a tube of prescribed length, diameter and surface temperature.

**Find:** (a) Outlet water temperature and rate of heat transfer to water for prescribed conditions, and (b) Compute and plot the required tube length \( L \) to achieve \( T_{m,o} \) found in part (a) as a function of the surface temperature for the range \( 85 \leq T_s \leq 95^\circ C \).

**Schematic:**

![Schematic Diagram](image)

**Assumptions:** (1) Steady-state conditions, (2) Constant properties, (3) Negligible kinetic energy, potential energy and flow work effects, (4) Fully developed flow conditions.

**Properties:** Table A.6, Water (\( T_m = 325 \) K): \( c_p = 4182 \text{ J/kg} \cdot \text{K} \), \( \mu = 528 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 \), \( k = 0.645 \text{ W/m-K} \), \( Pr = 3.42 \).

**Analysis:** (a) From Eq. 8.6, the Reynolds number is

\[
Re_D = \frac{4 \dot{m}}{\pi D \mu} = \frac{4 \times 2 \text{ kg/s}}{\pi (0.04 \text{ m}) 528 \times 10^{-6} \text{ N} \cdot \text{s/m}^2} = 1.21 	imes 10^5.
\]

Hence the flow is turbulent, and assuming fully developed conditions throughout the tube, it follows from the Dittus-Boelter correlation, Eq. 8.60,

\[
\overline{h} = \frac{k}{D} 0.023 Re_D^{4/5} Pr^{0.4} = \frac{0.645 \text{ W/m-K}}{0.04 \text{ m}} 0.023 \left(1.21 \times 10^5\right)^{4/5} (3.42)^{0.4} = 7064 \text{ W/m}^2 \cdot \text{K}.
\]

From the energy balance relation, Eq. 8.42b,

\[
T_{m,o} = T_s - \left(T_s - T_{m,i}\right) \exp \left(-\frac{\pi D L \overline{h}}{mc_p}\right)
\]

\[
T_{m,o} = 90^\circ C - \left(90^\circ C - 25^\circ C\right) \exp \left(-\frac{\pi \times 0.04 m \times 4 m}{2 \text{ kg/s} \times 4182 \text{ J/kg} \cdot \text{K}} \frac{7064 \text{ W/m}^2 \cdot \text{K}}{7064 \text{ W/m}^2 \cdot \text{K}}\right) = 47.5^\circ C
\]

From the overall energy balance, Eq. 8.37,

\[
q = \dot{m} c_p \left(T_{m,o} - T_{m,i}\right) = 2 \text{ kg/s} \times 4182 \text{ J/kg} \cdot \text{K} \left(47.5 - 25\right) ^\circ \text{C} = 188 \text{ kW}.
\]

(b) Using the IHT Correlations Tool, Internal Flow, for fully developed Turbulent Flow, along with the energy balance and rate equations used above, the required length, \( L \), to achieve \( T_{m,o} = 44.9^\circ C \) (see comment 1 below) as a function of tube surface temperature is computed and plotted below.
From the plot, the outlet temperature increases nearly linearly with the surface temperature. The convection coefficient and heat rate show similar behavior for this range of conditions.

**COMMENTS:** (1) The mean temperature $T_m = 325$ K was overestimated in part (a). Another iteration is recommended and the results with $T_m = 309$ K are: $h = 6091$ W/m$^2$K, $T_{m,o} = 44.9^\circ C$ and $q = 167$ kW.

(2) The *IHT Workspace* used to generate the graphical results are shown below.
PROBLEM 8.35

FIND: Daily cost of heat loss per unit length of pipe.

SCHEMATIC:

ASSUMPTIONS: (1) Steady state, (2) Constant properties, (3) Negligible radiation from outer surface, (4) Fully-developed flow in pipe.

PROPERTIES: Table A-4, air (p = 1 atm, T\text{f} \approx 300K): \( k_a = 0.0263 \text{ W/m} \cdot \text{K} \), \( \nu_a = 15.89 \times 10^{-6} \text{ m}^2/\text{s} \), \( Pr_a = 0.707 \).

Table A-6, water (\( T_m = 323 \text{ K} \)): \( \rho_w = 988 \text{ kg/m}^3 \), \( \mu_w = 548 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 \), \( k_w = 0.643 \text{ W/m} \cdot \text{K} \), \( Pr_w = 3.56 \).

ANALYSIS: The heat loss per unit length of pipe is

\[
q' = \frac{T_m - T_\infty}{R_{\text{cnv,w}} + R_{\text{cnv,a}} + R_{\text{cnv,d}}} = \frac{T_m - T_\infty}{(h_w \pi D_i)^{-1} + \frac{\ln(D_o / D_i)}{2\pi k_p} + (h_a \pi D_o)^{-1}}
\]

With \( Re_{D,w} = \frac{\rho_w u_m D_i}{\mu_w} = 988 \text{ kg/m}^3 \times 0.5 \text{ m/s} \times 0.084 \text{ m} / 548 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 = 75,700 \), flow is turbulent, and for fully developed conditions, the Dittus-Boelter correlation yields

\[
h_w = \frac{k_w}{D_i} \cdot 0.023 Re_{D,w}^{0.8} Pr_{w}^{0.3} = 0.023 \cdot \frac{0.643 \text{ W/m} \cdot \text{K}}{0.084 \text{ m}} \cdot (75,700)^{0.8} \cdot (3.56)^{0.3} = 2060 \text{ W/m}^2 \cdot \text{K}
\]

With \( Re_{D,a} = \frac{\nu_a D_o}{\nu_a} = 3 \text{ m/s} \times (0.1 \text{ m}) / 15.89 \times 10^{-6} \text{ m}^2/\text{s} = 18,880 \), the Churchill-Bernstein correlation yields

\[
h_a = \frac{k_a}{D_o} \cdot 0.3 + \frac{0.62 Re_{D,a}^{1/2} Pr_{a}^{1/3}}{1 + (0.4/Pr_{a})^{2/3}}^{1/4} \left[ 1 + \left( \frac{Re_{D,w}}{282,000} \right)^{5/8} \right]^{4/5} = 20.1 \text{ W/m}^2 \cdot \text{K}
\]

Hence,

\[
q' = \frac{50^\circ\text{C} - (-5^\circ\text{C})}{\left( 1.84 \times 10^{-3} + 0.46 \times 10^{-3} + 158.3610^{-3} \right) \text{ K/W}} = 342 \text{ W/m} = 0.342 \text{ kW/m}
\]

The daily energy loss is then

\[
Q' = 0.346 \text{ kW/m} \times 24 \text{ h/d} = 8.22 \text{ kW} \cdot \text{h/d} \cdot \text{m}
\]

and the associated cost is

\[
C' = (8.22 \text{ kW} \cdot \text{h/d} \cdot \text{m}) \cdot (0.05 / \text{kW} \cdot \text{h}) = 0.411 / \text{m} \cdot \text{d}
\]

COMMENTS: Because \( R_{\text{cnv,a}} \gg R_{\text{cnv,w}} \), the convection resistance for the water side of the pipe could have been neglected, with negligible error. The implication is that the temperature of the pipe’s inner surface closely approximates that of the water. If \( R_{\text{cnv,w}} \) is neglected, the heat loss is

\[
q' = 346 \text{ W/m}
\]
PROBLEM 8.36

KNOWN: Inner and outer diameter of a steel pipe insulated on the outside and experiencing uniform heat generation. Flow rate and inlet temperature of water flowing through the pipe.

FIND: (a) Pipe length required to achieve desired outlet temperature, (b) Location and value of maximum pipe temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Negligible kinetic energy, potential energy and flow work changes, (4) One-dimensional radial conduction in pipe wall, (5) Outer surface in adiabatic.

PROPERTIES: Table A-1, Stainless steel 316 ($T \approx 400 K$): $k = 15 \text{ W/m} \cdot \text{K}$; Table A-6, Water ($T_m = 303 K$): $c_p = 4178 \text{ J/kg} \cdot \text{K}$, $k = 0.617 \text{ W/m} \cdot \text{K}$, $\mu = 803 \times 10^{-6} \text{ N} \cdot \text{s/m}^2$, $Pr = 5.45$.

ANALYSIS: (a) Performing an energy balance for a control volume about the inner tube, it follows that

$$\dot{m} c_p (T_{m.o} - T_{m,i}) = q = \dot{q} \left( \frac{\pi}{4} \right) \left( D_o^2 - D_i^2 \right) L$$

$$L = \frac{\dot{m} c_p (T_{m.o} - T_{m,i})}{\dot{q} \left( \frac{\pi}{4} \right) \left( D_o^2 - D_i^2 \right)} = \frac{0.1 \text{ kg/s} \cdot 4178 \text{ J/kg} \cdot \text{K} \cdot 20^\circ \text{C}}{10^6 \text{ W/m}^3 \cdot \left( \frac{\pi}{4} \right) \left[ (0.04 \text{ m})^2 - (0.02 \text{ m})^2 \right]}$$

$$L = 8.87 \text{ m}.$$ 

(b) The maximum wall temperature exists at the pipe exit ($x = L$) and the insulated surface ($r = r_o$). From Eq. 3.50, the radial temperature distribution in the wall is of the form

$$T(r) = -\frac{\dot{q}}{4k} r^2 + C_1 r + C_2.$$ 

Considering the boundary conditions,

$$r = r_0 : \left( \frac{dT}{dr} \right)_{r=r_0} = 0 = -\frac{\dot{q}}{2k} r_0 + \frac{C_1}{r_0} \quad \quad C_1 = \frac{\dot{q} r_0^2}{2k}$$

Continued .....
PROBLEM 8.36 (Cont.)

\[ r = \eta : \quad T(\eta) = T_s = -\frac{q_0}{4k} r^2 - \frac{q_0}{2k} \ln r + C_2 \quad C_2 = \frac{q_0}{4k} r^2 - \frac{q_0}{2k} \ln r + T_s. \]

The temperature distribution and the maximum wall temperature \((r = r_o)\) are

\[ T(r) = -\frac{q_0}{4k} (r^2 - r_i^2) + \frac{q_0}{2k} \ln \frac{r}{r_i} + T_s \]

\[ T_{w,max} = T(r_o) = -\frac{q_0}{4k} (r_o^2 - r_i^2) + \frac{q_0}{2k} \ln \frac{r_o}{r_i} + T_s \]

where \(T_s\) is the inner surface temperature of the wall at the exit, follows from

\[ q_s^* = \frac{q (\pi/4)}{\pi D_i L} = \frac{q (D_o^2 - D_i^2)}{4 D_i} = h(T_s - T_{m,o}) \]

where \(h\) is the local convection coefficient at the exit. With

\[ \text{Re}_D = \frac{4 \frac{m}{m}}{\pi D_i \mu} = \frac{4 \times 0.1 \text{ kg/s}}{\pi (0.02 \text{ m}) 803 \times 10^{-6} \text{ N \cdot m/s}} = 7928 \]

the flow is turbulent and, with \((L/D_i) = (8.87 \text{ m/0.02m}) = 444 >> (x_{fd}/D) \approx 10\), it is also fully developed. Hence, from the Dittus-Boelter correlation, Eq. 8.60,

\[ h = \frac{k}{k} \left( \text{Re}_D^{4/5} \text{ Pr}^{0.4} \right) = \frac{0.617 \text{ W/m} \cdot \text{K}}{0.02 \text{ m}} = 0.023 (7928)^{4/5} 5.45^{0.4} = 1840 \text{ W/m}^2 \cdot \text{K}. \]

Hence, the inner surface temperature of the wall at the exit is

\[ T_s = \frac{q (D_o^2 - D_i^2)}{4 h D_i} + T_{m,o} = \frac{10^6 \text{ W/m}^3 \left[ (0.04 \text{ m})^2 - (0.02 \text{ m})^2 \right]}{4 \times 1840 \text{ W/m}^2 \cdot \text{K} (0.02 \text{ m})} + 40 \text{ } ^\circ \text{C} = 48.2 \text{ } ^\circ \text{C} \]

and \(T_{w,max} = -\frac{10^6 \text{ W/m}^3}{4 \times 15 \text{ W/m} \cdot \text{K}} \left[ (0.02 \text{ m})^2 - (0.01 \text{ m})^2 \right]

\[ + \frac{10^6 \text{ W/m}^3 (0.02 \text{ m})^2}{2 \times 15 \text{ W/m} \cdot \text{K}} \ln \frac{0.02}{0.01} + 48.2 \text{ } ^\circ \text{C} = 52.4 \text{ } ^\circ \text{C}. \]

**COMMENTS:** The physical situation corresponds to a uniform surface heat flux, and \(T_m\) increases linearly with \(x\). In the fully developed region, \(T_s\) also increases linearly with \(x\).
**PROBLEM 8.37**

**KNOWN:** Dimensions and thermal conductivity of concrete duct. Convection conditions of ambient air. Flow rate and inlet temperature of water flow through duct.

**FIND:** (a) Outlet temperature, (b) Pressure drop and pump power requirement, (c) Effect of flow rate and pipe diameter on outlet temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Fully developed flow throughout duct, (3) Negligible pipe wall conduction resistance, (4) Negligible potential energy, kinetic energy and flow work changes for water, (5) Constant properties.

**PROPERTIES:** Table A-6, water ($T_m = 360 \text{ K}$): $\rho = 967 \text{ kg/m}^3$, $c_p = 4203 \text{ J/kg} \cdot \text{K}$, $\mu = 324 \times 10^{-6} \text{ N} \cdot \text{s/m}^2$, $k_w = 0.674 \text{ W/m} \cdot \text{K}$, $Pr = 2.02$.

**ANALYSIS:** (a) The outlet temperature is given by

$$T_{m,o} = T_\infty + \left(T_{m,i} - T_\infty\right) \exp\left(-UA/\dot{m}c_p\right)$$

where

$$UA = \left(R_{tot}\right)^{-1} = \left(R_{cnv,w} + R_{cnd} + R_{cnv,a}\right)^{-1}$$

$$R_{cnd} = \frac{\ln \left(1.08w/D\right)}{2\pi kL} = \frac{\ln \left(1.08 \times 0.30m/0.15m\right)}{2\pi \left(1.4W/m \cdot K\right)100m} = 8.75 \times 10^{-4} \text{ K/W}$$

$$R_{cnv,a} = \left(4wLh\right)^{-1} = \left(4 \times 0.3m \times 100m \times 25W/m^2 \cdot K\right)^{-1} = 3.33 \times 10^{-4} \text{ K/W}$$

With

$$Re_D = 4 \dot{m}/\pi D \mu = \left(4 \times 2 \text{ kg/s}\right)/\left(\pi \times 0.15m \times 324 \times 10^{-6} \text{ N} \cdot \text{s/m}^2\right) = 52,400,$$

$$h_w = h_{fd} = \frac{k_w}{D} \frac{0.023 \cdot Re_D^{4/5} \cdot Pr^{0.3}}{0.15m} = \frac{0.674 \text{ W/m} \cdot \text{K} \times 0.023}{(52,400)^{4/5} (2.02)^{0.3}} = 761 \text{ W/m}^2 \cdot \text{K}$$

$$R_{cnv,w} = \left(\pi D L h_w\right)^{-1} = \left(\pi \times 0.15m \times 100m \times 761 \text{ W/m}^2 \cdot \text{K}\right)^{-1} = 2.79 \times 10^{-5} \text{ K/W}$$

$$UA = \left[\left(2.79 \times 10^{-5} + 8.75 \times 10^{-4} + 3.33 \times 10^{-4}\right)\text{K/W}\right]^{-1} = 809 \text{ W/K}$$

$$T_{m,o} = 0^\circ \text{C} + 90^\circ \text{C} \exp\left(-\frac{809 \text{ W/K}}{2 \text{ kg/s} \times 4203 \text{ J/kg} \cdot \text{K}}\right) = 81.7^\circ \text{C}$$

Continued …..
PROBLEM 8.37 (Cont.)

(b) With \( f = 0.0206 \) from Fig. 8.3 and \( u_m = \dot{m} / \rho \pi D^2 / 4 = 0.117 \, \text{m/s} \),

\[
\Delta p = f \frac{\rho u_m^2}{2D} L = 0.0206 \left( \frac{967 \, \text{kg/m}^3 \cdot (0.117 \, \text{m/s})^2}{2 \times 0.15 \, \text{m}} \right) 100 \, \text{m} = 91 \, \text{N/m}^2 = 8.98 \times 10^{-4} \, \text{bars}
\]

With \( \dot{V} = \dot{m} / \rho = 2.07 \times 10^{-3} \, \text{m}^3 / \text{s} \), the pump power requirement is

\[
P = \Delta p \dot{V} = \left( 91 \, \text{N/m}^2 \right) 2.07 \times 10^{-3} \, \text{m}^3 / \text{s} = 0.19 \, \text{W}
\]

(c) The effects of varying the flowrate and duct diameter were assessed using the IHT software, and results are shown below.

Although \( R_{\text{env,w}} \) and hence \( R_{\text{tot}} \), decreases with increasing \( \dot{m} \), thereby increasing UA, the effect is significantly less than that of \( \dot{m} \) to the first power, causing the exponential term, \( \exp \left( -UA / \dot{m} \, c_p \right) \), to approach unity and \( T_{m,o} \) to approach \( T_{m,i} \). The effect can alternatively be attributed to a reduction in the residence time of the water in the pipe (\( u_m \) increases with increasing \( \dot{m} \) for fixed \( D \)). With increasing \( D \) for fixed \( \dot{m} \) and \( w \), \( T_{m,o} \) decreases due to an increase in the residence time, as well as a reduction in the conduction resistance, \( R_{\text{end}} \).

COMMENTS: (1) Use of \( \bar{T}_m = 360 \, \text{K} \) to evaluate properties of the water for Parts (a) and (b) is reasonable, and iteration is not necessary. (2) The pressure drop and pump power requirement are small.
PROBLEM 8.38

KNOWN: Water flow through a thick-walled tube immersed in a well stirred, hot reaction tank maintained at 85°C; conduction thermal resistance of the tube wall based upon the inner surface area is $R_{cd}^* = 0.002 \text{ m}^2 \cdot \text{K} / \text{W}$.

FIND: (a) The outlet temperature of the process fluid, $T_{m,o}$; assume, and then justify, fully developed flow and thermal conditions within the tube; and (b) Do you expect $T_{m,o}$ to increase or decrease if the combined thermal entry condition exists within the tube? Estimate the outlet temperature of the process fluid for this condition.

SCHEMATIC:

ASSUMPTIONS: (1) Flow is fully developed, part (a), (2) Constant properties, (3) Negligible kinetic and potential energy changes and flow work, and (4) Constant wall temperature heating.

PROPERTIES: Table A-6, Water ($T_m = (T_{m,o} + T_{m,i})/2 = 337$ K): $c_p = 4187 \text{ J/kg} \cdot \text{K}$, $\mu = 4.415 \times 10^{-4} \text{ N} \cdot \text{s/m}^2$, $k = 0.6574 \text{ W/m} \cdot \text{K}$, $Pr = 2.80$; (T$_s$ = 358 K): $\mu_s = 3.316 \times 10^{-4} \text{ N} \cdot \text{s/m}^2$.

ANALYSIS: (a) The outlet temperature is determined from the rate equation, Eq. 8.46a, written as

$$\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp \left( - \frac{\overline{U} A_s}{m c_p} \right)$$

(1)

where the overall coefficient, based upon the inner surface area of the tube is expressed in terms of the convection and conduction thermal resistances,

$$\frac{1}{\overline{U}} = \frac{1}{h} + R_{cd,i}^*$$

(2)

To estimate $\overline{h}$, begin by characterizing the flow

$$Re_D = 4 \frac{m}{\pi D \mu}$$

$$Re_D = 4 \left( \frac{33}{3600} \text{ kg/s} \right) / \pi \times 0.012 \text{ m} \times 4.415 \times 10^{-4} \text{ N} \cdot \text{s/m}^2 = 2210$$

Consider the flow as laminar, and assuming fully developed conditions, estimate $\overline{h}$ with the correlation of Eq. 8.55,

$$Nu_D = \overline{h} D / k = 3.66$$

$$\overline{h} = 3.66 \times 0.6574 \text{ W/m} \cdot \text{K} / 0.012 \text{ m} = 201 \text{ W/m}^2 \cdot \text{K}$$

From Eq. (2),

$$\overline{U} = \left[ \frac{1}{201 \text{ W/m}^2 \cdot \text{K}} + 0.002 \text{ m}^2 \cdot \text{K} / \text{W} \right]^{-1} = 143.1 \text{ W/m}^2 \cdot \text{K}$$

and from Eq. (1), with $A_s = \pi DL$, calculate $T_{m,o}$.

Continued …..
PROBLEM 8.38 (Cont.)

\[
\frac{85 - T_{m,o}}{85 - 20} = \exp\left(-\frac{143.1 \text{ W/m}^2\cdot\text{K}\times\pi\times0.012 \text{ m}\times8 \text{ m}}{33/3600 \text{ kg/s}\times4187 \text{ J/kg}\cdot\text{K}}\right)
\]

\[T_{m,o} = 64^\circ\text{C}\]

Fully developed flow and thermal conditions are justified if the tube length is much greater than the fully developed length \(x_{fd,t}\). From Eq. 8.23,

\[
\frac{x_{fd,t}}{D} = 0.05 \text{ Re}_D \text{ Pr}
\]

\[x_{fd,t} = 0.012 \text{ m}\times0.05\times221.0\times2.41 = 3.20 \text{ m}\]

That is, the length is only twice that required to reach fully developed conditions.

(b) Considering combined entry length conditions, estimate the convection coefficient using the Sieder-Tate correlation, Eq. 8.56,

\[
\bar{N}u_D = 3.66 + \frac{0.0668(D/L)\text{ Re}_D \text{ Pr}}{1+0.04[(D/L)\text{ Re}_D \text{ Pr}]^{2/3}}
\]

(5)

substituting numerical values, find

\[\bar{N}u_D = 4.05 \quad \bar{h} = 222 \text{ W/m}^2\cdot\text{K}\]

which is a 10% increase over the fully developed analysis result. Using the foregoing relations, find

\[U = 154 \text{ W/m}^2\cdot\text{K} \quad T_{m,o} = 65.5^\circ\text{C}\]

COMMENTS:  (1) The thermophysical properties for the fully developed correlation are evaluated at the mean fluid temperature \(T_m = (T_{m,o} + T_{m,i})/2\). The values are shown above in the properties section.

(2) For the Sieder-Tate correlation, the properties are also evaluated at \(T_m\) except for \(\mu_s\), which is evaluated at \(T_s\).

(3) For this case where the tube length is about twice \(x_{fd,t}\), the average heat transfer coefficient is larger as we would expect, but amounts to only a 10% increase.
PROBLEM 8.39

KNOWN: Flow rate and temperature of atmospheric air entering a duct of prescribed diameter, length and surface temperature.

FIND: (a) Air outlet temperature and duct heat loss for the prescribed conditions and (b) Calculate and plot q and $\Delta p$ for the range of diameters, $0.1 \leq D \leq 0.2$ m, maintaining the total surface area, $A_s = \pi DL$, at the same value as part (a). Explain the trade off between the heat transfer rate and pressure drop.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Negligible kinetic energy and potential energy changes, (4) Uniform surface temperature, (5) Fully developed flow conditions.

PROPERTIES: Table A.4, Air ($T_m \approx 310$ K, 1 atm): $\rho = 1.128$ kg/m$^3$, $c_p = 1007$ J/kg·K, $\mu = 189 \times 10^{-7}$ N·s/m$^2$, $k = 0.027$ W/m·K, Pr = 0.706.

ANALYSIS: (a) With 
$$Re_D = \frac{4m}{\pi D \mu} = \frac{4 \times 0.04 \text{ kg/s}}{\pi (0.15 \text{ m}) (189 \times 10^{-7} \text{ N·s/m}^2)} = 17,965$$
the flow is turbulent. Assuming fully developed conditions throughout the tube, it follows from the Dittus-Boelter correlation, Eq. 8.60, that
$$h = \frac{k}{D} \frac{0.023 Re_D^{4/5} Pr^{0.4}}{0.15 m} = \frac{0.027 \text{ W/m·K}}{0.15 m} \frac{0.023 (17,965)^{4/5} (0.706)^{0.4}}{1007 \text{ J/kg·K}} = 9.44 \text{ W/m}^2\cdot\text{K}.$$ 
Hence, from the energy balance relation, Eq. 8.42b,
$$T_{m,o} = T_s - (T_s - T_{m,i}) \exp \left( - \frac{\pi DL}{mc_p h} \right)$$
$$T_{m,o} = 15^\circ C + 45^\circ C \exp \left( - \frac{\pi (0.15 \text{ m}) 10 \text{ m} (9.44 \text{ W/m}^2\cdot\text{K})}{0.04 \text{ kg/s} (1007 \text{ J/kg·K})} \right) = 29.9^\circ C$$
From the overall energy balance, Eq. 8.37, it follows that
$$q = mc_p (T_{m,o} - T_{m,i}) = 0.04 \text{ kg/s} \times 1007 \text{ J/kg·K} (29.9 - 60) ^\circ C = -1212 \text{ W}.$$ 
From Eq. 8.22a, the pressure drop is
$$\Delta p = \frac{\rho u_m^2}{2D}$$
Continued...
and for the smooth surface conditions, Eq. 8.21 can be used to evaluate the friction factor,
\[
f = \left(0.790 \ln \left(Re_D \right) - 1.64 \right)^{-2} = \left(0.790 \ln \left(17,965 \right) - 1.64 \right)^{-2} = 0.0269
\]
Hence, the pressure drop is
\[
\Delta p = 0.0269 \frac{1.128 \text{ kg/m}^3 \left(2.0 \text{ m/s} \right)^2}{2 \times 0.15 \text{ m}} \times 10 \text{ m} = 4.03 \text{ N/m}^2
\]
where \( u_m = \frac{\dot{m}}{\rho A_c} = 0.04 \text{ kg/s} / \left(1.128 \text{ kg/m}^3 \right) \times \left(\pi 0.15^2 \text{ m}^2 / 4 \right) = 2.0 \text{ m/s} \).

(b) For the prescribed conditions of part (a), \( A_s = \pi DL = \pi (0.15 \text{ m}) \times 10 \text{ m} = 4.712 \text{ m}^2 \), using the IHT Correlations Tool, Internal Flow for fully developed Turbulent Flow along with the energy balance equation, rate equation and pressure drop equations used above, the heat rate \( q \) and \( \Delta p \) are calculated and plotted below.

From above, as \( D \) increases, \( L \) decreases so that \( A_s \) remains unchanged. The decrease in heat rate with increasing diameter is nearly linear, while the pressure drop decreases markedly. This is the trade off: increased heat rate requires a more significant increase in pressure drop, and hence fan blower power requirements.

**COMMENTS:**

1. To check the calculations, compute \( q \) from Eq. 8.44, where \( \Delta T_{\ell/m} \) is given by Eq. 8.45. It follows that \( \Delta T_{\ell/m} = -27.1 \text{°C} \) and \( q = -1206 \text{ W} \). The small difference in results may be attributed to round-off error.

2. For part (a), a slight improvement in accuracy may be obtained by evaluating the properties at \( T_m = 318 \text{ K} \): \( \bar{h} = 9.42 \text{ W/m}^2\text{-K} \), \( T_{m,o} = 303 \text{ K} = 30 \text{°C} \), \( q = -1211 \text{ W} \), \( f = 0.0271 \) and \( \Delta p = 4.20 \text{ N/m}^2 \).
**PROBLEM 8.40**

**KNOWN:** Inlet temperature, pressure and flow rate of air. Tube diameter and length. Pressure of saturated steam.

**FIND:** Outlet temperature and pressure of air. Mass rate of steam condensation.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Outer surface of annulus is adiabatic, (3) Negligible potential energy, kinetic energy and flow work changes for air, (4) Fully-developed flow throughout the tube, (5) Smooth tube surface, (6) Constant properties.

**PROPERTIES:** *Table A-4*, air ($T_m = 325 \text{ K, } p = 5 \text{ atm}$): $\rho = 5 \times \rho \left(1 \text{ atm}\right) = 5.391 \text{ kg/m}^3$, $c_p = 1008 \text{ J/kg \cdot K}$, $\mu = 196.4 \times 10^{-7} \text{ N \cdot s/m}^2$, $k = 0.0281 \text{ W/m \cdot K}$, $Pr = 0.703$. *Table A-6*, sat. steam ($p = 2.455 \text{ bars}$): $T_s = 400 \text{ K}$, $h_{fg} = 2183 \text{ kJ/kg}$.

**ANALYSIS:** With a uniform surface temperature, the air outlet temperature is

$$T_{m,o} = T_s - \left(T_s - T_{m,i}\right) \exp \left(-\frac{\pi D_i L}{\dot{m} c_p} h\right)$$

With $Re_D = 4\dot{m}/\pi D_i \mu = 0.12 \text{ kg/s/\pi \left(0.05 \text{ m}\right)}196.4 \times 10^{-7} \text{ kg/s \cdot m} = 38,980$, the flow is turbulent, and the Dittus-Boelter correlation yields

$$h = h_{fd} = \left(\frac{k}{D_i}\right) 0.023 \left(\frac{0.0281 \text{ W/m \cdot K}}{0.05 \text{ m}}\right) 0.023 (38,980)^{4/5} (0.703)^{0.4} = 52.8 \text{ W/m}^2 \cdot \text{K}$$

$$T_{m,o} = 127^\circ \text{C} - (110^\circ \text{C}) \exp \left(-\frac{\pi \times 0.05 \text{m} \times 5 \text{m} 	imes 52.8 \text{ W/m}^2 \cdot \text{K}}{0.03 \text{kg/s \times 1008 J/kg \cdot K}}\right) = 99^\circ \text{C}$$

The pressure drop is $\Delta p = f \left(\rho u_m^2 / 2 D_i\right) L$, where, with $A_c = \pi D_i^2 / 4 = 1.963 \times 10^{-3} \text{ m}^2$, $u_m = \dot{m} / \rho A_c = 2.83 \text{ m/s}$, and with $Re_D = 38,980$, Fig. 8.3 yields $f \approx 0.022$. Hence,

$$\Delta p = 0.022 \times 5.391 \text{ kg/m}^3 \left(\frac{2.83 \text{ m/s}}{2 \times 0.05 \text{m}}\right)^2 5 \text{m} = 95 \text{ N/m}^2 = 9.4 \times 10^{-4} \text{ atm}$$

The rate of heat transfer to the air is

$$q = \dot{m} c_p \left(T_{m,o} - T_{m,i}\right) = 0.03 \text{ kg/s \times 1008 J/kg \cdot K} \left(82^\circ \text{C}\right) = 2480 \text{ W}$$

and the rate of condensation is then

$$\dot{m}_c = \frac{q}{h_{fg}} = \frac{2480 \text{ W}}{2.183 \times 10^6 \text{ J/kg}} = 1.14 \times 10^{-3} \text{ kg/s}$$

**COMMENTS:** (1) With $T_m = \left(T_{m,i} + T_{m,o}\right)/2 = 331 \text{ K}$, the initial estimate of 325 K is reasonable and iteration is not necessary. (2) For a steam flow rate of 0.01 kg/s, approximately 10% of the outflow would be in the form of saturated liquid, (3) With $L/D_i = 100$, it is reasonable to assume fully developed flow throughout the tube.
**PROBLEM 8.41**

**KNOWN:** Duct diameter and length. Thermal conductivity of insulation. Gas inlet temperature and velocity and minimum allowable outlet temperature. Temperature and velocity of air in cross flow.

**FIND:** Minimum allowable insulation thickness.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible potential and kinetic energy and flow work changes for gas flow through duct, (2) Fully developed flow throughout duct, (3) Negligible duct wall conduction resistance, (4) Negligible effect of insulation thickness on outer convection coefficient and thermal resistance, (5) Properties of gas may be approximated as those of air.

**PROPERTIES:** Table A-4, air (p = 1 atm). \( T_{m,i} = 1600\text{K} \): \( \rho_i = 0.218 \text{ kg/m}^3 \).

\[ mT = \left( T_{m,i} + T_{m,o} \right) / 2 = 1500\text{K} \]: \( \rho = 0.232 \text{ kg/m}^3 \), \( c_p = 1230 \text{ J/kg K} \), \( \mu = 557 \times 10^{-7} \text{ N s/m}^2 \), \( k = 0.100 \text{ W/m K} \), \( Pr = 0.685 \).

\( T_f = 300\text{K} \) (assumed): \( \nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s} \), \( k = 0.0263 \text{ W/m K} \), \( Pr = 0.707 \).

**ANALYSIS:** From Eqs. (8.46a) and (3.19),

\[
\frac{T_\infty - T_{m,o}}{T_\infty - T_{m,i}} = \frac{-1150\text{K}}{-1350\text{K}} = 0.852 = \exp \left( -\frac{\Bar{U}A_s}{\bar{m}c_p} \right) = \exp \left( -\frac{1}{R_{tot}\bar{m}c_p} \right)
\]

Hence, with \( \bar{m} = \left( \rho u_m A_c \right)_i = 0.218 \text{ kg/m}^3 \times 10\text{ m/s} \times \pi \left( 1\text{m} \right)^2 / 4 = 1.712 \text{ kg/s} \),

\[
R_{tot} = -\left[ \bar{m}c_p \ln (0.852) \right]^{-1} = -\left[ 1.712 \text{ kg/s} \times 1230 \text{ J/kg K} \times (0.160) \right]^{-1} = 2.96 \times 10^{-3} \text{ K/W}
\]

The total thermal resistance is

\[
R_{tot} = R_{conv,i} + R_{cond,ins} + R_{conv,o} = \left( h_i \pi D_i L \right)^{-1} + \left( \ln \left( \frac{D_o}{D_i} \right) / 2\pi k_{ins} L \right) + \left( h_o \pi D_o L \right)^{-1} \quad (1)
\]

With \( Re_{D,i} = 4\bar{m} / \pi D_i \mu = \left( 4 \times 1.712 \text{ kg/s} \right) / \left( \pi \times 1\text{m} \times 557 \times 10^{-7} \text{ N s/m}^2 \right) = 39.130 \), the Dittus-Boelter correlation yields

\[
h_i = \left( \frac{k}{D} \right) 0.023 \left( \frac{Re_{D}}{5} \right)^{4/5} Pr^{1/3} \left( \frac{0.100 \text{ W/m K}}{1\text{m}} \right) 0.023 \left( 39.130 \right)^{4/5} \left( 0.685 \right)^{1/3} = 9.57 \text{ W/m}^2 \cdot \text{K}
\]

The internal resistance is then

\[
R_{conv,i} = \left( h_i \pi D_i L \right)^{-1} = \left( 9.57 \text{ W/m}^2 \cdot \text{K} \times \pi \times 1\text{m} \times 100\text{m} \right)^{-1} = 3.33 \times 10^{-4} \text{ K/W}
\]

With \( Re_D = VD_i / \nu = 15 \text{ m/s} \times 1\text{m} / 15.89 \times 10^{-6} \text{ m}^2/\text{s} = 9.44 \times 10^5 \), the Churchill-Bernstein correlation yields

\[
\text{Continued} \ldots
dots
PROBLEM 8.41 (Cont.)

\[
\begin{align*}
    h_0 &= \left( \frac{k}{D} \right) \left[ 0.3 + \frac{0.62 \text{Re}_{D}^{1/2} \text{Pr}^{1/3}}{1 + (0.4/\text{Pr})^{2/3}} \right]^{1/4} \left[ 1 + \left( \frac{\text{Re}_{D}}{282,000} \right)^{5/8} \right]^{4/5} \\
    &\approx 30.9 \text{ W/m} \cdot \text{K}
\end{align*}
\]

\[
R_{\text{conv,o}} = (h_0 \pi D_1 L)^{-1} = \left( 30.9 \text{ W/m}^2 \cdot \text{K} \times \pi \times 1 \text{m} \times 100 \text{m} \right)^{-1} = 1.03 \times 10^{-4} \text{ K/W}
\]

Hence, from Eq. (1)

\[
\ln \left( \frac{D_0}{D_i} \right) = \left( 2.96 \times 10^{-3} - 3.33 \times 10^{-4} - 1.03 \times 10^{-4} \right) \text{ K/W} = 2.52 \times 10^{-3} \text{ K/W}
\]

\[
D_0 = D_i \exp \left( 2\pi k_{\text{ins}} L \times 2.52 \times 10^{-3} \text{ K/W} \right) = 1 \text{m} \times \exp \left( 1.58 \times 10^{-2} \text{ K/W} \times 0.125 \text{ W/m} \cdot \text{K} \times 100 \text{m} \right) = 1.22 \text{m}
\]

Hence, the minimum insulation thickness is

\[
t_{\text{min}} = (D_0 - D_i) / 2 = 0.11 \text{m}
\]

COMMENTS: With \(D_0 = 1.22\text{m}\), use of \(D_i = 1\text{m}\) to evaluate the outer convection coefficient and thermal resistance is a reasonable approximation. However, improved accuracy may be obtained by using the calculated value of \(D_o\) to determine conditions at the outer surface and iterating on the solution.
PROBLEM 8.42

KNOWN: Flow rate, inlet temperature and desired outlet temperature of liquid mercury flowing through a tube of prescribed diameter and surface temperature.

FIND: Required tube length and error associated with use of a correlation for moderate to large Pr fluids.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Negligible kinetic energy, potential energy and flow work effects, (4) Fully developed flow.

PROPERTIES: Table A-5, Mercury \( c_m = 350 \text{K} \) \( c_p = 137.7 \text{ J/kg} \cdot \text{K}, \mu = 0.1309 \times 10^{-2} \text{ N} \cdot \text{s/m}^2 \), \( k = 9.18 \text{ W/m} \cdot \text{K}, \text{Pr} = 0.0196 \).

ANALYSIS: The Reynolds and Peclet numbers are

\[
\text{Re}_D = \frac{4 \dot{m}}{\pi D \mu} = \frac{4 \times 0.5 \text{ kg/s}}{\pi (0.05 \text{ m}) 0.1309 \times 10^{-2} \text{ N} \cdot \text{s/m}^2} = 9727
\]

\[
\text{Pe}_D = \text{Re}_D \text{Pr} = 9727 (0.0196) = 191.
\]

Hence, assuming fully developed turbulent flow throughout the tube, it follows from Eq. 8.66 that

\[
\bar{h} = \frac{k}{D} (5.0 + 0.025 \text{Pe}^{0.8}_D) = \frac{9.18 \text{ W/m} \cdot \text{K}}{0.05 \text{ m}} (5.0 + 0.025 \times 191^{0.8}) = 1224 \text{ W/m}^2 \cdot \text{K}.
\]

From Eq. 8.42a, it follows that

\[
L = -\frac{\dot{m} c_p}{\pi D h} \frac{\Delta T_o}{\ell n} = -\frac{(0.5 \text{ kg/s}) 137.7 \text{ J/kg} \cdot \text{K}}{\pi (0.05 \text{ m}) 1224 \text{ W/m}^2 \cdot \text{K}} \frac{450 - 400}{450 - 300} = 0.39 \text{ m}. \quad <
\]

If the Dittus-Boelter correlation, Eq. 8.60, is used in place of Eq. 8.66,

\[
\bar{h} = \frac{k}{D} 0.023 \text{Re}^{4/5}_D \text{Pr}^{0.4} = \frac{9.18 \text{ W/m}^2 \cdot \text{K}}{0.05 \text{ m}} 0.023 (9727)^{4/5} (0.0196)^{0.4} = 1358 \text{ W/m}^2 \cdot \text{K}
\]

and the required tube length is

\[
L = -\frac{\dot{m} c_p}{\pi D h} \frac{\Delta T_o}{\ell n} = -\frac{(0.5 \text{ kg/s}) 137.7 \text{ J/kg} \cdot \text{K}}{\pi (0.05 \text{ m}) 1358 \text{ W/m}^2 \cdot \text{K}} \frac{450 - 400}{450 - 300} = 0.35 \text{ m}. \quad <
\]

COMMENTS: Such good agreement between results does not occur in general. For example, if \( \text{Re}_D = 2 \times 10^4 \), \( \bar{h} = 1463 \) from Eq. 8.66 and 2417 from Eq. 8.60. Large errors are usually associated with using conventional (moderate to large Pr) correlations with liquid metals.
PROBLEM 8.43

KNOWN: Surface temperature and diameter of a tube. Velocity and temperature of air in cross flow. Velocity and temperature of air in fully developed internal flow.

FIND: Convection heat flux associated with the external and internal flows.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform cylinder surface temperature, (3) Fully developed internal flow.

PROPERTIES: Table A-4, Air (298K): \( \nu = 15.71 \times 10^{-6} \text{ m}^2/\text{s} \), \( k = 0.0261 \text{ W/m} \cdot \text{K} \), Pr = 0.71.

ANALYSIS: For the external and internal flows,

\[
\text{Re}_D = \frac{VD}{v} = \frac{u_m D}{v} = \frac{30 \text{ m/s} \times 0.05 \text{ m}}{15.71 \times 10^{-6} \text{ m}^2/\text{s}} = 9.55 \times 10^4.
\]

From the Zhukauskas relation for the external flow, with \( C = 0.26 \) and \( m = 0.6 \),

\[
\overline{\text{Nu}}_D = C \frac{\text{Re}_D^{m} \text{Pr}^{n}}{\text{Pr}^{m} / \text{Pr}^{n}} = 0.26 \left( 9.55 \times 10^4 \right)^{0.6} \left( 0.71 \right)^{0.37} \left( 1 \right)^{1/4} = 223.
\]

Hence, the convection coefficient and heat flux are

\[
\bar{h} = \frac{k}{D} \overline{\text{Nu}}_D = \frac{0.0261 \text{ W/m} \cdot \text{K}}{0.05 \text{ m}} \times 223 = 116.4 \text{ W/m}^2 \cdot \text{K}
\]

\[
q^* = h (T_s - T_\infty) = 116.4 \text{ W/m}^2 \cdot \text{K} \cdot (100 - 25) \text{ K} = 8.73 \times 10^3 \text{ W/m}^2.
\]

Using the Dittus-Boelter correlation, Eq. 8.60, for the internal flow, which is turbulent,

\[
\overline{\text{Nu}}_D = 0.023 \text{ Re}_D^{4/5} \text{ Pr}^{0.4} = 0.023 \left( 9.55 \times 10^4 \right)^{4/5} \left( 0.71 \right)^{0.4} = 193
\]

\[
\bar{h} = \frac{k}{D} \overline{\text{Nu}}_D = \frac{0.0261 \text{ W/m} \cdot \text{K}}{0.05 \text{ m}} \times 193 = 101 \text{ W/m}^2 \cdot \text{K}
\]

and the heat flux is

\[
q^* = h (T_s - T_m) = 101 \text{ W/m}^2 \cdot \text{K} \cdot (100 - 25) \text{ K} = 7.58 \times 10^3 \text{ W/m}^2.
\]

COMMENTS: Convection effects associated with the two flow conditions are comparable.
PROBLEM 8.44

KNOWN: Diameter, length and surface temperature of condenser tubes. Water velocity and inlet temperature.

FIND: (a) Water outlet temperature evaluating properties at \( T_m = 300 \text{ K} \), (b) Repeat calculations using properties evaluated at the appropriate temperature, \( \bar{T}_m = (T_{m,i} + T_{m,o})/2 \), and (c) Coolant mean velocities for the range \( 4 \leq L \leq 7 \text{ m} \) which provide the same \( T_{m,o} \) as found in part (b).

SCHEMATIC:

![Diagram of condenser tubes with dimensions](image)

ASSUMPTIONS: (1) Negligible tube wall conduction resistance, (2) Negligible kinetic energy, potential energy and flow work changes.

PROPERTIES: Table A.6. Water (\( \bar{T}_m = 300 \text{ K} \)): \( \rho = 997 \text{ kg/m}^3, c_p = 4179 \text{ J/kg} \cdot \text{K}, \mu = 855 \times 10^{-6} \text{ kg/s} \cdot \text{m}, k = 0.613 \text{ W/m} \cdot \text{K}, Pr = 5.83. \)

ANALYSIS: (a) From Equation 8.42b

\[
T_{m,o} = T_s - (T_s - T_{m,i}) \exp\left[-\left(\frac{\pi D L}{\mu c_p} \right) \frac{1}{h}\right].
\]

and evaluating properties at \( \bar{T}_m = 300 \text{ K} \), find

\[
Re_D = \frac{\rho u_m D}{\mu} = \frac{997 \text{ kg/m}^3 (1 \text{ m/s}) 0.0254 \text{ m}}{855 \times 10^{-6} \text{ kg/s} \cdot \text{m}} = 29,618
\]

The flow is turbulent, and since \( L/D = 197 \), it is reasonable to assume fully developed flow throughout the tube. Hence, \( h = h_d \). From the Dittus-Boelter equation,

\[
Nu_D = 0.023 \left(\frac{4}{5}\right) Re_D^{4/5} Pr^{0.4} = 0.023 (29,618)^{4/5} (5.83)^{0.4} = 176
\]

\[
h = Nu_D \left(\frac{k}{D}\right) = 176 (0.613 \text{ W/m} \cdot \text{K}/0.0254 \text{ m}) = 4248 \text{ W/m}^2 \cdot \text{K}.
\]

With

\[
m = \rho u_m \left(\frac{\pi D^2}{4}\right) = 997 \text{ kg/m}^3 (1 \text{ m/s}) (0.0254 \text{ m})^2 = 0.505 \text{ kg/s}.
\]

Equation 8.42b yields

\[
T_{m,o} = 350 \text{ K} - (60 \text{ K}) \exp\left[-\left(\frac{\pi (0.0254 \text{ m}) 5 \text{ m} (4248 \text{ W/m}^2 \cdot \text{K})}{0.505 \text{ kg/s} (4179 \text{ J/kg} \cdot \text{K})}\right]\right] = 323 \text{ K} = 50^\circ \text{C}<
\]

(b) Using the IHT Correlations Tool, Internal Flow, for fully developed Turbulent Flow, along with the energy balance and rate equations above, the calculation of part (a) is repeated with \( \bar{T}_m = (T_{m,i} + T_{m,o})/2 \) giving these results:

\[
\bar{T}_m = 307.3 \text{ K} \quad T_{m,o} = 51.7^\circ \text{C} = 324.7 \text{ K}<
\]

(c) Using the IHT model developed for the part (b) analysis, the coolant mean velocity, \( u_m \), as a function of tube length \( L \) with \( T_{m,o} = 51.7^\circ \text{C} \) is calculated and the results plotted below.

Continued...
PROBLEM 8.44 (Cont.)

**COMMENTS:**

1. Using $\bar{T}_m = 300 \text{ K}$ vs. $\bar{T}_m = \frac{T_{m,i} + T_{m,o}}{2} = 307 \text{ K}$ for this application resulted in a difference of $T_{m,o} = 50^\circ \text{C}$ vs. $T_{m,o} = 51.7^\circ \text{C}$. While the difference is only $1.7^\circ \text{C}$, it is good practice to use the proper value for $\bar{T}_m$.

2. Note that $u_m$ must be increased markedly with increasing length in order that $T_{m,o}$ remain fixed.
PROBLEM 8.45

KNOWN: Gas turbine vane approximated as a tube of prescribed diameter and length maintained at a known surface temperature. Air inlet temperature and flowrate.

FIND: (a) Outlet temperature of the air coolant for the prescribed conditions and (b) Compute and plot the air outlet temperature $T_{m,o}$ as a function of flow rate, $0.1 \leq \dot{m} \leq 0.6$ kg/h. Compare this result with those for vanes having passage diameters of 2 and 4 mm.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible kinetic and potential energy changes.

PROPERTIES: Table A.4, Air (assume $T_m = 780$ K, 1 atm): $c_p = 1094 \text{ J/kg} \cdot \text{K}$, $k = 0.0563 \text{ W/m} \cdot \text{K}$, $\mu = 363.7 \times 10^{-7} \text{ N} \cdot \text{s/m}^2$, $Pr = 0.706$; (T = 650°C = 923 K, 1 atm): $\mu = 404.2 \times 10^{-7} \text{ N} \cdot \text{s/m}^2$.

ANALYSIS: (a) For constant wall temperature heating, from Eq. 8.43,

$$\frac{T_{m,0} - T_s}{T_{m,i} - T_s} = \exp \left( - \frac{PLh}{\dot{m}c_p} \right) \tag{1}$$

where $P = \pi D$. For flow in circular passage,

$$Re_D = \frac{4 \dot{m}}{\pi D \mu} = \frac{4 \times 0.18 \text{ kg/h}(1/3600 \text{s/h})}{\pi (0.003 \text{ m})363.7 \times 10^{-7} \text{ N} \cdot \text{s/m}^2} = 584. \tag{2}$$

The flow is laminar, and since $L/D = 75 \text{ mm}/3 \text{ mm} = 25$, the Sieder-Tate correlation including combined entry length yields

$$Nu_D = \frac{h D}{\mu} = 1.86 \left( \frac{Re_D Pr}{L/D} \right)^{1/3} \left( \frac{\mu}{\mu_s} \right)^{0.14} \tag{3}$$

$$h = \frac{0.0563 \text{ W/m} \cdot \text{K}}{0.003 \text{ m}} \times 1.86 \left( \frac{584 \times 0.706}{25} \right)^{1/3} \left( \frac{363.7 \times 10^{-7}}{404.2 \times 10^{-7}} \right)^{0.14} = 87.5 \text{ W/m}^2 \cdot \text{K}.$$ 

Hence, the air outlet temperature is

$$\frac{650 - T_{m,o}}{(650 - 427) \degree C} = \exp \left( - \frac{\pi (0.003 \text{ m}) \times 0.075 \text{ m} \times 87.5 \text{ W/m}^2 \cdot \text{K}}{(0.18/3600) \text{ kg/s} \times 1094 \text{ J/kg} \cdot \text{K}} \right)$$

$$T_{m,o} = 578 \degree C \quad <$$

(b) Using the IHT Correlations Tool, Internal Flow, for Laminar Flow with combined entry length, along with the energy balance and rate equations above, the outlet temperature $T_{m,o}$ was calculated as a function of flow rate for diameters of $D = 2, 3$ and 4 mm. The plot below shows that $T_{m,o}$ decreases nearly linearly with increasing flow rate, but is independent of passage diameter.

Continued...
COMMENTS: (1) Based upon the calculation for $T_{m,o} = 578^\circ C$, $\bar{T}_m = 775$ K which is in good agreement with our assumption to evaluate the thermophysical properties.

(2) Why is $T_{m,o}$ independent of $D$? From Eq. (3), note that $\bar{h}$ is inversely proportional to $D$, $\bar{h} \sim D^{-1}$. From Eq. (1), note that on the right-hand side the product $P \cdot \bar{h}$ will be independent of $D$. Hence, $T_{m,o}$ will depend only on $\dot{m}$. This is, of course, a consequence of the laminar flow condition and will not be the same for turbulent flow.
PROBLEM 8.46

KNOWN: Gas-cooled nuclear reactor tube of 20 mm diameter and 780 mm length with helium heated from 600 K to 1000 K at $8 \times 10^{-3}$ kg/s.

FIND: (a) Uniform tube wall temperature required to heat the helium, (b) Outlet temperature and required flow rate to achieve same removal rate and wall temperature if the coolant gas is air.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible kinetic energy and potential energy changes, (3) Fully developed conditions.

PROPERTIES: Table A-4, Helium ($T_m = 800$K, 1 atm): $\rho = 0.06272 \text{ kg/m}^3$, $c_p = 5193 \text{ J/kg} \cdot \text{K}$, $k = 0.304 \text{ W/m}\cdot\text{K}$, $\mu = 382 \times 10^{-7} \text{ Ns/m}^2$, $\nu = 6.09 \times 10^{-4} \text{ m}^2/\text{s}$, $Pr = 0.654$; Air ($T_m = 800$K, 1 atm): $\rho = 0.4354 \text{ kg/m}^3$, $c_p = 1099 \text{ J/kg} \cdot \text{K}$, $k = 57.3 \times 10^{-3} \text{ W/m}\cdot\text{K}$, $\nu = 84.93 \times 10^{-6} \text{ m}^2/\text{s}$, $Pr = 0.709$.

ANALYSIS: (a) For helium and a constant wall temperature, from Eq. 8.46,

$$\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp \left( -\frac{PLh}{\dot{m} c_p} \right)$$

where $P = \pi D$. For the circular tube,

$$Re_D = \frac{4\dot{m}}{\pi \mu} = \frac{4 \times 8 \times 10^{-3} \text{ kg/s}}{\pi \times 0.020 \text{ m} \times 382 \times 10^{-7} \text{ Ns/m}^2} = 1.333 \times 10^4$$

and using the Colburn correlation for turbulent, fully developed flow,

$$Nu = 0.023 \left( \frac{Re_D^{4/5}}{Pr^{1/3}} \right) = 0.023 \left( 1.333 \times 10^4 \right)^{4/5} \left( 0.654 \right)^{1/3} = 39.83$$

$$h = Nu \cdot k/D = 39.83 \times 0.304 \text{ W/m} \cdot \text{K}/0.02 \text{ m} = 605 \text{ W/m}^2 \cdot \text{K}$$

Hence, the surface temperature is

$$\frac{T_s - 1000 \text{ K}}{T_s - 600 \text{ K}} = \exp \left[ -\pi \left( 0.020 \text{ m} \cdot 0.780 \text{ m} \cdot 605 \text{ W/m}^2 \cdot \text{K} \right) \right] = 0.4898$$

$$T_s = 1384 \text{ K}.$$ 

The heat rate with helium coolant is

$$q = \dot{m} c_p \left( T_{m,o} - T_{m,i} \right) = 8 \times 10^{-3} \text{ kg/s} \times 5193 \text{ J/kg} \cdot \text{K} \left( 1000 - 600 \right) \text{ K} = 16.62 \text{ kW}.$$ 

Continued …..
(b) For the same heat removal rate \( (q) \) and wall temperature \( (T_s) \) with air supplied at \( T_{m,i} \), the relevant relations are

\[
q = 16,620 \text{ W} = \dot{m}_a \cdot c_p \left( T_{m,o} - T_{m,i} \right) \tag{1}
\]

\[
\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp \left[ -\frac{P L \bar{h}_a}{\dot{m}_a c_p} \right] \tag{2}
\]

\[
\text{Re} = \frac{4\dot{m}_a}{\pi D \mu} \quad \frac{\bar{h} D}{k} = 0.023 \frac{\text{Re}^{4/5}}{\text{Pr}^{1/3}} \tag{3,4}
\]

where \( T_{m,o} \) and \( \dot{m}_a \) are unknown. An iterative solution is required: assume a value of \( T_{m,o} \) and find \( \dot{m}_a \) from Eq. (1); use \( \dot{m}_a \) in Eqs. (3) and (4) to find \( \bar{h}_a \) and then Eq. (2) to evaluate \( T_{m,o} \); compare results and iterate. Using thermophysical properties of air evaluated at \( T_m = 800\text{K} \), the above relations, written in the order they would be used in the iteration, become

\[
\dot{m}_a = \frac{15.123}{T_{m,o} - 600} \tag{5}
\]

\[
\bar{h}_a = 5.725 \times 10^3 \cdot \dot{m}_a^{4/5} \tag{6}
\]

\[
T_{m,o} = 1384 - 784 \exp \left[ -4.459 \times 10^{-5} \left( \frac{\bar{h}_a}{\dot{m}_a} \right) \right] \tag{7}
\]

Results of the iterative solution are

<table>
<thead>
<tr>
<th>Trial</th>
<th>( T_{m,o} ) (K) ( (\text{Assumed}) )</th>
<th>( \dot{m}_a ) (kg/s)</th>
<th>( \bar{h}_a ) (W/m(^2) \cdot K)</th>
<th>( T_{m,o} ) (K)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1000</td>
<td>3.025 \times 10^{-2}</td>
<td>348.6</td>
<td>915.0</td>
</tr>
<tr>
<td>2</td>
<td>950</td>
<td>4.321 \times 10^{-2}</td>
<td>463.7</td>
<td>898.0</td>
</tr>
<tr>

<tr>
<td>4</td>
<td>890</td>
<td>5.215 \times 10^{-2}</td>
<td>539.0</td>
<td>889.5</td>
</tr>
</tbody>
</table>

Hence, we find

\[
\dot{m}_a = 5.22 \times 10^{-2} \text{ kg/s} \quad T_{m,o} = 890 \text{ K.}
\]

**COMMENTS:** To achieve the same cooling rate with air, the required mass rate is 6.5 times that obtained with helium.
**PROBLEM 8.47**

**KNOWN:** Air at prescribed inlet temperature and mean velocity heated by condensing steam on its outer surface.

**FIND:** (a) Air outlet temperature, pressure drop and heat transfer rate and (b) Effect on parameters of part (a) if pressure were doubled.

**SCHEMATIC:**

![Diagram](image)

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible kinetic and potential energy changes, (3) Thermal resistance of tube wall and condensate film are negligible.

**PROPERTIES:** Table A-4, Air (assume $T_m = 450 \text{K}$, 1 atm = 101.3 kPa): $\rho = 0.7740 \text{kg/m}^3$, $c_p = 1021 \text{J/kg} \cdot \text{K}$, $\mu = 250.7 \times 10^{-7} \text{N} \cdot \text{s/m}^2$, $k = 0.0373 \text{W/m} \cdot \text{K}$, $Pr = \mu c_p / k = 0.686$. Note that only $\rho$ is pressure dependent; i.e., $\rho \propto P$; Table A-6, Saturated water (20 bar): $T_{sat} = T_s = 485 \text{K}$.

**ANALYSIS:** (a) For constant wall temperature heating, from Eq. 8.46 but with $U = \overline{h_i}$ since $\overline{h_o} >> \overline{h_i}$, where $\overline{h_o}$ is the convection coefficient for the condensing steam,

$$\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp \left( - \frac{P L}{\bar{m} c_p \overline{h_i}} \right)$$

where $P = \pi D$. For the air flow, find the mass rate and Reynolds number,

\[
\bar{m} = \rho A_c u_m = 0.7740 \text{kg/m}^3 (200 \text{kPa}/101.3 \text{kPa}) \left( \pi (0.025 \text{m})^2 / 4 \right) \times 6 \text{ m/s}
\]

\[
\bar{m} = 4.501 \times 10^{-3} \text{kg/s}.
\]

\[
Re_D = \frac{4 \bar{m} \mu} {\pi D} = \frac{4 \times 4.501 \times 10^{-3} \text{ kg/s}} {250.7 \times 10^{-7} \text{ N} \cdot \text{s/m}^2 \times \pi (0.025 \text{ m})} = 9.143 \times 10^3.
\]

Using the Dittus-Boelter correlation for fully-developed turbulent flow,

\[
Nu_D = 0.023 Re^{4/5} Pr^{0.4} = 0.023 \left( 9.143 \times 10^3 \right)^{4/5} \left( 0.682 \right)^{0.4} = 29.12
\]

$h_i = Nu \cdot k / D = 29.12 \times 0.0373 \text{ W/m} \cdot \text{K} / 0.025 \text{ m} = 43.4 \text{ W/m}^2 \cdot \text{K}.$

Hence, the outlet temperature is

\[
\frac{212 - T_{m,o}}{(212 - 150) \circ C} = \exp \left[ - \frac{\pi (0.025 \text{ m}) \times 2 \times 43.4 \text{ W/m}^2 \cdot \text{K}} {4.501 \times 10^{-3} \text{ kg/s} \times 1021 \text{ J/kg} \cdot \text{K}} \right]
\]

$T_{m,o} = 198 \circ C.$

Continued …..
PROBLEM 8.47 (Cont.)

The pressure drop follows from Eqs. 8.20 and 8.22,

\[
f = 0.316 \text{Re}_{D}^{-1/4} = 0.316 \left(9.143 \times 10^{3}\right)^{-1/4} = 0.0323
\]

\[
\Delta p = f \frac{\rho u_{m}^{2} L}{2D}
\]

\[
\Delta p = 0.0323 \frac{0.774 \text{kg/m}^{3} (200/101.3)(6 \text{ m/s})^{2} \times 2 \text{ m}}{2 \times 0.025 \text{ m}} = 71.1 \text{ N/m}^{2}.
\]

The heat transfer rate is

\[
q = \dot{m} c_{p} (T_{m,o} - T_{m,i}) = 4.501 \times 10^{-3} \text{ kg/s} \times 1021 \text{ J/kg} \cdot \text{K} (198 - 150) \text{K} = 221 \text{ W.}
\]

(b) If the pressure were doubled, we can see from the above relations, that \(\dot{m} \propto \rho\), hence

\[
\dot{m} = 2\dot{m}_{o}
\]

\[
\text{Re}_{D} = 2\text{Re}_{D,o},
\]

since

\[
h_{i} \propto (\text{Re})^{4/5} \rightarrow \left(\frac{h_{i}}{h_{i,o}}\right) = 2^{4/5},
\]

\[
h_{i} = 1.74h_{i,o}.
\]

It follows that \(T_{m,o} = 195^\circ\text{C}\), so that the effect on temperature is slight. However, the pressure drop increases by the factor \(2(2)^{-1/4} = 1.68\) and the heat rate by \(2(195 - 150)/(198 - 150) = 1.88\).

In summary:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>p = 200 kPa</th>
<th>p = 400 kPa</th>
<th>Increase, %</th>
</tr>
</thead>
<tbody>
<tr>
<td>(\dot{m}), kg/s \times 10^{3}</td>
<td>4.501</td>
<td>9.002</td>
<td>100</td>
</tr>
<tr>
<td>(h_{i}), W/m^{2}K</td>
<td>43.4</td>
<td>86.8</td>
<td>100</td>
</tr>
<tr>
<td>(T_{m,o} - T_{m,i})°C</td>
<td>48</td>
<td>45</td>
<td>-6</td>
</tr>
<tr>
<td>(\Delta p), N/m^{2}</td>
<td>71.1</td>
<td>119</td>
<td>68</td>
</tr>
<tr>
<td>(q), W</td>
<td>221</td>
<td>415</td>
<td>88</td>
</tr>
</tbody>
</table>

**COMMENTS:** (1) Note that \(T_{m} = (198 + 150)\text{°C}/2 = 447\text{ K}\) agrees well with the assumed value (450 K) used to evaluate the thermophysical properties.
PROBLEM 8.48

KNOWN: Diameter, length and surface temperature of tubes used to heat ambient air. Flowrate and inlet temperature of air.

FIND: (a) Air outlet temperature and heat rate per tube, (b) Effect of flowrate on outlet temperature. Design and operating conditions suitable for providing 1 kg/s of air at 75°C.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Negligible kinetic/potential energy and flow work changes, (3) Negligible tube wall thermal resistance.

PROPERTIES: Table A.4, air (assume \( \overline{T_m} = 330 \) K): \( c_p = 1008 \, J/kg \cdot K, \mu = 198.8 \times 10^{-7} \, N \cdot s/m^2, k = 0.0285 \, W/m \cdot K, Pr = 0.703 \).

ANALYSIS: (a) For \( \dot{m} = 0.01 \, kg/s \), \( Re_D = 4 \dot{m} \pi D \mu = 0.04 \, kg/s/(\pi(0.05 \, m)198.8 \times 10^{-7} \, N \cdot s/m^2 = 12,810 \). Hence, the flow is turbulent. If fully developed flow is assumed throughout the tube, the Dittus-Boelter correlation may be used to obtain the average Nusselt number.

\[
\overline{Nu_D} = Nu_D = 0.023 Re_D^{4/5} Pr^{0.4} = 0.023(12,810)^{0.8}(0.703)^{0.4} = 38.6
\]

Hence, \( \overline{h} = \overline{Nu_D}(k/D) = 38.6(0.0285 \, W/m \cdot K/0.05 \, m) = 22.0 \, W/m^2 \cdot K \)

From Eq. 8.42b,

\[
\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp \left( -\frac{\pi D L h}{mc_p} \right) = \exp \left( -\frac{\pi \times 0.05 \times 5 \times 22 \, W/m^2 \cdot K}{0.01 \, kg/s \times 1008 \, J/kg \cdot K} \right) = 0.180
\]

\[
T_{m,o} = T_s - 0.180(T_s - T_{m,i}) = 100^\circ C - 0.180(80^\circ C) = 85.6^\circ C
\]

Hence, \( q = mc_p(T_{m,o} - T_{m,i}) = 0.01 \, kg/s \times (1008 \, J/kg \cdot K) \times 65.6 \, K = 661 \, W \)

(b) The effect of flowrate on the outlet temperature was determined by using the IHT Correlations and Properties Toolpads.

Continued...
Although $\overline{h}$ and hence the heat rate increase with increasing $\overline{\dot{m}}$, the increase in $q$ is not linearly proportional to the increase in $\overline{\dot{m}}$ and $T_{m,o}$ decreases with increasing $\overline{\dot{m}}$.

A flowrate of $\dot{m} = 0.05 \text{ kg/s}$ is not large enough to provide the desired outlet temperature of $75^\circ\text{C}$, and to achieve this value, a flowrate of $0.0678 \text{ kg/s}$ would be needed. At such a flowrate, $N = 1 \text{ kg/s}/0.0678 \text{ kg/s} = 14.75 = 15$ tubes would be needed to satisfy the process air requirement. Alternatively, a lower flowrate could be supplied to a larger number of tubes and the discharge mixed with ambient air to satisfy the desired conditions. Requirements of this option are that

\[
N\dot{m} + \dot{m}_{\text{amb}} = 1 \text{ kg/s}
\]

\[
(N\dot{m} + \dot{m}_{\text{amb}})c_p(T_{m,o} - T_{m,i}) = 1 \text{ kg/s} \times 1008 \text{ J/kg} \cdot \text{K} \times (75 - 20) \text{ K} = 55,400 \text{ W}
\]

where $\dot{m}$ is the flowrate per tube. Using a larger number of tubes with a smaller flowrate per tube would reduce flow pressure losses and hence provide for reduced operating costs.

**COMMENTS:** With $L/D = 5 \text{ m}/0.05 \text{ m} = 100$, the assumption of fully developed conditions throughout the tube is reasonable.
PROBLEM 8.49

KNOWN: Length and diameter of tube submerged in paraffin of prescribed dimensions. Inlet temperature and flow rate of water flowing through tube.

FIND: (a) Outlet temperature, heat rate, and time required for complete melting, and (b) Effect of flowrate on operating conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible KE/PE and flowwork changes for water, (2) Constant water properties, (3) Negligible tube wall conduction resistance, (4) Negligible convection resistance in melt \(T_s = T_m = T_{mp}\), (5) Fully developed flow, (6) No heat loss to the surroundings.

PROPERTIES: Water (given): \(c_p = 4.185 \text{ kJ/kg} \cdot \text{K}, k = 0.653 \text{ W/m} \cdot \text{K}, \mu = 467 \times 10^{-6} \text{ kg/s} \cdot \text{m}, \text{Pr} = 2.99;\)
Paraffin (given): \(T_{mp} = 27.4^\circ \text{C}, h_{sf} = 244 \text{ kJ/kg}, \rho = 770 \text{ kg/m}^3\).

ANALYSIS: (a) From Eq. 8.42b, \(\frac{m_o}{m_i} p = \frac{T_{m,o} - T_{m,i}}{T_{m,o} - T_{m,i}} = \exp\left(-\frac{\pi DL h}{m c_p}\right)\). With \(Re_D = \frac{4m}{\pi \mu D} = 10,906\), the flow is turbulent. Assuming fully developed conditions,

\[
h = \frac{Nu_D k}{D} = \frac{k}{D} \cdot 0.023 \cdot \text{Re}_D^{4/5} \cdot \text{Pr}^{0.3} = \frac{0.653 \text{ W/m} \cdot \text{K}}{0.025 \text{ m}} \cdot 0.023 \cdot (10,906)^{4/5} \cdot (2.99)^{0.3} = 1418 \text{ W/m}^2 \cdot \text{K}
\]

\(T_{m,o} = 27.4^\circ \text{C} - (27.4 - 60)^\circ \text{C} \exp\left(-\frac{\pi \times 0.025 \text{ m} \times 3 \text{ m}}{0.1 \text{ kg/s} \times 4185 \text{ J/kg} \cdot \text{K}} \cdot 1418 \text{ W/m}^2 \cdot \text{K}\right) = 42.17^\circ \text{C}\)

From the overall energy balance,

\[q = m c_p (T_{m,o} - T_{m,i}) = 0.1 \text{ kg/s} \times 4185 \text{ J/kg} \cdot \text{K} \times (60 - 42.17)^\circ \text{C} = 7500 \text{ W}\]

Applying an energy balance to a control volume about the paraffin, \(E_{in} = \Delta E_{st}\), the time \(t_m\) required to melt the paraffin is

\[qt_m = \rho V h_{sf} = \rho L \left(WH - \rho D^2 /4\right) h_{sf}
\]

\[t_m = \frac{770 \text{ kg/m}^3 \times 3 \text{ m} \times 0.25 \times 0.25 \text{ m}^2 - \pi (0.025 \text{ m})^2 /4}{7500 \text{ W} \times 2.44 \times 10^5 \text{ J/kg} = 4660 \text{ s} = 1.29 \text{h}}
\]

Continued...
PROBLEM 8.49 (Cont.)

(b) The effect of $\dot{m}$ on $q$ and $T_{m,o}$ was determined by accessing the Correlations Toolpad of IHT, and the results are plotted as follows.

Although $q$ increases with increasing $\dot{m}$ due to the attendant increase in $Re_D$, and therefore $\overline{h}$, the increase is not linearly proportional to the change in $\dot{m}$. Hence, from the overall energy balance, $q = \dot{m} c_p (T_{m,i} - T_{m,o})$, there is a reduction in $(T_{m,i} - T_{m,o})$, which corresponds to an increase in $T_{m,o}$. With the increase in $q$, there is a reduction in $t_m$, and for $\dot{m} = 0.5$ kg/s,

$$t_m = 1167 \text{ s} = 0.324 \text{ h}$$

COMMENTS: Heat transfer from the water to the paraffin is also affected by free convection in the melt region around the tube. The effect is to decrease $U$, increase $T_s$, and decrease $q$ with increasing time. The actual time to achieve complete melting would exceed values computed in the foregoing analysis.
PROBLEM 8.50

KNOWN: Configuration of microchannel heat sink.

FIND: (a) Expressions for longitudinal distributions of fluid mean and surface temperatures, (b) Coolant and channel surface temperature distributions for prescribed conditions, (c) Effect of heat sink design and operating conditions on the chip heat flux for a prescribed maximum allowable surface temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Negligible PE, KE and flow work changes, (3) All of the chip power dissipation is transferred to the coolant, with a uniform surface heat flux, \( q_s^* \), (4) Laminar, fully developed flow, (5) Constant properties.

PROPERTIES: Table A.6, Water (assume \( T_m = T_{m,i} = 290 \) K): \( c_p = 4184 \) J/kg-K, \( \mu = 1080 \times 10^{-6} \) N-s/m², \( k = 0.598 \) W/m-K, \( Pr = 7.56 \).

ANALYSIS: (a) The number of channels passing through the heat sink is \( N = L/S = L/C_1 D \), and conservation of energy dictates that

\[
q_c^*L^2 = N(\pi DL)q_s^* = \pi L^2 q_s^*/C_1
\]

which yields

\[
q_s^* = \frac{C_1 q_c^*}{\pi} \quad (1)
\]

With the mass flowrate per channel designated as \( \dot{m}_c = \dot{m}/N \), Eqs. 8.41 and 8.28 yield

\[
T_m(x) = T_{m,i} + \frac{q_s^* \pi D}{\dot{m}_c c_p} x = T_{m,i} + \frac{L q_c^*}{\dot{m}_c c_p} x \quad (2)
\]

\[
T_s(x) = T_m(x) + \frac{q_s^*}{h} = T_m(x) + \frac{C_1 q_c^*}{\pi h} \quad (3)
\]

where, for laminar, fully developed flow with uniform \( q_s^* \), Eq. 8.53 yields \( h = 4.36 \) k/D.

(b) With \( L = 12 \) mm, \( D = 1 \) mm, \( C_1 = 2 \) and \( \dot{m} = 0.01 \) kg/s, it follows that \( S = 2 \) mm, \( N = 6 \) and \( Re_D = 4\dot{m}/\pi D u = 4(0.01 \text{ kg/s}) / 6\pi (0.001 \text{ m})1.08 \times 10^{-3} \text{ N·s/m}^2 = 1965 \). Hence, the flow is laminar, as assumed, and \( h = 4.36(0.598 \text{ W/m·K}/0.001 \text{ m}) = 2607 \text{ W/m}^2·\text{K} \). From Eqs. (2) and (3) the outlet mean and surface temperatures are

\[
T_{m,o} = 290 \text{ K} + \frac{(0.012 \text{ m})^2 20 \times 10^4 \text{ W/m}^2}{0.01 \text{ kg/s}(4184 \text{ J/kg·K})} = 290.7 \text{ K} = 177^\circ \text{C}
\]

\[
T_{s,o} = T_{m,o} + \frac{2 \times 20 \times 10^4 \text{ W/m}^2}{2607 \text{ W/m}^2·\text{K}} = 339.5 \text{ K} = 66.5^\circ \text{C}
\]

Continued...
PROBLEM 8.50 (Cont.)

The axial temperature distributions are as follows

![Temperature Distribution Graph]

The flowrate is sufficiently large (and the convection coefficient sufficiently low) to render the increase in $T_m$ and $T_s$ with increasing $x$ extremely small.

(c) The desired constraint of $T_s,max \leq 50^\circ C$ is not met by the foregoing conditions. An obvious and logical approach to achieving improved performance would involve increasing $\dot{m}$ such that turbulent flow is maintained in each channel. A value of $\dot{m} > 0.002$ kg/s would provide $Re_D > 2300$ for $D = 0.001$. Using Eq. 8.60 with $n = 0.4$ to evaluate $Nu_D$ and accessing the Correlations Toolpad of IHT to explore the effect of variations in $\dot{m}$ for different combinations of $D$ and $C_1$, the following results were obtained.

![Chip heat flux vs Mass flowrate Graph]

We first note that a significant increase in $q_{C1}$ may be obtained by operating the channels in turbulent flow. In addition, there is an obvious advantage to reducing $C_1$, thereby increasing the number of channels for a fixed channel diameter. The biggest enhancement is associated with reducing the channel diameter, which significantly increases the convection coefficient, as well as the number of channels for fixed $C_1$. For $\dot{m}_1 = 0.005$ kg/s, $h$ increases from 32,400 to 81,600 W/m$^2$·K with decreasing $D$ from 1.0 to 0.6 mm. However, for fixed $\dot{m}_1$, the mean velocity in a channel increases with decreasing $D$ and care must be taken to maintain the flow pressure drop within acceptable limits.

**COMMENTS:** Although the distribution computed for $T_m(x)$ in part (b) is correct, the distribution for $T_s(x)$ represents an upper limit to actual conditions due to the assumption of fully developed flow throughout the channel.
PROBLEM 8.51

KNOWN: Cold plate geometry and temperature. Inlet temperature and flow rate of water. Number of circuit boards and temperature and velocity of air in parallel flow over boards.

FIND: (a) Heat dissipation by cold plates, (b) Heat dissipation by air flow.

SCHEMATIC:

ASSUMPTIONS: (1) Isothermal cold plate, (2) All heated generated by circuit boards is dissipated by cold plates (Part (a)), (3) Circuit boards may be represented as isothermal at an average surface temperature, (4) Air flow over circuit boards approximates that over a flat plate in parallel flow, (5) Steady operation, (6) Constant properties.

PROPERTIES: Table A-6, Water \( (T_m = 290\)K\): \( c_p = 4184 \)J/kg·K, \( \mu = 1080 \times 10^{-6} \)N·s/m², \( k = 0.598 \)W/m·K, \( Pr = 7.56. \) Table A-4, Air (\( p = 1 \)atm, \( T_f = 300\)K): \( \nu = 15.89 \times 10^{-6} \)m²/s, \( k = 0.0263 \)W/m·K, \( Pr = 0.707. \)

ANALYSIS: (a) With \( Re_D = 4 \frac{m_1}{\mu \pi} = \frac{4 \times 0.2 \text{ kg/s}}{\pi \times 0.01 \text{ m} \times 1080 \times 10^{-6} \text{ N·s/m}^2} = 23,600, \) the flow is turbulent, and from Eq. (8.60),

\[
h = -\frac{k}{D} Nu_D = 0.023 \frac{k}{D} Re_D^{4/5} Pr^{0.4} = 0.023 \times 0.598 \frac{W}{m \cdot K} \left( \frac{23,600}{0.01} \right)^{4/5} (7.56)^{0.4} = 9,730 \frac{W}{m \cdot K}
\]

With \( H/D = 0.75/0.01 = 75, \) it is reasonable to assume fully developed flow throughout the tube. Hence, from Eqs. (8.42b) and (8.37)

\[
\frac{T_{s,cp} - T_{m,o}}{T_{s,cp} - T_{m,i}} = \exp \left( -\frac{\pi DH}{m_1 c_p h} \right) = \exp \left( -\frac{\pi \times 0.01 \text{ m} \times 0.75 \text{ m} \times 9730 \text{ W/m}^2 \cdot \text{K}}{0.2 \text{ kg/s} \times 4184 \text{ J/kg} \cdot \text{K}} \right) = 0.760
\]

\[
T_{m,o} = T_{s,cp} - 0.76 \left( T_{s,cp} - T_{m,i} \right) = 13\text{°C}
\]

\[
q_1 = m_1 c_p \left( T_{m,o} - T_{m,i} \right) = 0.2 \text{ kg/s} \times 4184 \text{ J/kg} \cdot \text{K} \times 6\text{°C} = 5021 \text{ W}
\]

With a total of \( 2N = 20 \) passages, the total heat dissipation is

\[
q = 2Nq_1 = 20 \times 5021 \text{ W} = 100 \text{ kW}
\]

(b) For the air flow, \( Re_D = u_{\infty}L/\nu = 10 \text{ m/s} \times 0.60 \text{ m}/15.89 \times 10^{-6} \text{ m}^2/\text{s} = 378,000, \) and the flow is laminar. From Eq. (7.31),

\[
\bar{h} = -\frac{k}{L} Nu_L = 0.664 \frac{k}{L} Re_L^{1/2} Pr^{1/3} = 0.664 \times 0.0263 \frac{W}{m \cdot K} \left( \frac{378,000}{0.60} \right)^{1/2} (0.707)^{1/3} = 15.9 \frac{W}{m \cdot K}
\]

Heat dissipation to the air from both sides of 10 circuit boards is then

\[
q = 2N_{cb} \bar{h} (WL) \left( T_{s,cb} - T_{\infty} \right) = 20 \times 15.9 \frac{W}{m^2 \cdot K} \times 0.2 \text{ m}^2 \times 40\text{°C} = 2,670 \text{ W}
\]

COMMENTS: The cooling capacity of the cold plates far exceeds that of the air flow. However, the challenge would be one of efficiently transferring such a large amount of energy to the cold plates without incurring excessive temperatures on the circuit boards.
PROBLEM 8.52

KNOWN: Flow rate and temperature of Freon passing through a Teflon tube of prescribed inner and outer diameter. Velocity and temperature of air in cross flow over tube.

FIND: Heat transfer per unit tube length.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional radial conduction, (3) Constant properties, (4) Fully developed flow.

PROPERTIES: Table A-4, Air (T = 300K, 1 atm): \( \nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}, k = 0.0263 \text{ W/m} \cdot \text{K}, \text{Pr} = 0.707; \) Table A-5, Freon (T = 240K): \( \mu = 3.85 \times 10^{-4} \text{ N} \cdot \text{s/m}^2, k = 0.069 \text{ W/m} \cdot \text{K}, \text{Pr} = 5.0; \) Table A-3, Teflon (T \( \approx \) 300K): \( k = 0.35 \text{ W/m} \cdot \text{K}. \)

ANALYSIS: Considering the thermal circuit shown above, the heat rate is

\[
q' = \frac{T_\infty - T_m}{(1/h_o \pi D_o) + \left[ \ln \left(D_o / D_i \right)/2\pi k \right] + (1/h_i \pi D_i)}.
\]

\[
\text{Re}_{D,i} = \frac{4 \text{ m}}{\pi D_i \mu} = \frac{0.4 \text{ kg/s}}{\pi (0.025 \text{ m}) 3.85 \times 10^{-4} \text{ N} \cdot \text{s/m}^2} = 13,228
\]

and the flow is turbulent. Hence, from the Dittus-Boelter correlation

\[
h_i = \frac{k}{D_i} 0.023 \text{Re}^{4/5}_{D,i} \text{Pr}^{0.4} = \frac{0.069 \text{ W/m} \cdot \text{K}}{0.025 \text{ m}} 0.023(13,228)^{4/5} (5)^{0.4} = 240 \text{ W/m}^2 \cdot \text{K}.
\]

With \( \text{Re}_{D,o} = \frac{VD_o}{\nu} = \frac{(25 \text{ m/s})0.028 \text{ m}}{15.89 \times 10^{-6} \text{ m}^2/\text{s}} = 4.405 \times 10^4 \)

it follows from Eq. 7.56 and Table 7.4 that

\[
\bar{h}_o = \frac{k}{D} 0.26 \text{Re}^{0.6}_{D,o} \text{Pr}^{0.37} = \frac{0.0263 \text{ W/m} \cdot \text{K}}{0.028 \text{ m}} 0.26 \left(4.405 \times 10^4\right)^{0.6} (0.707)^{0.37} = 131 \text{ W/m}^2 \cdot \text{K}.
\]

Hence

\[
q' = \frac{T_\infty - T_m}{\left(131 \text{ W/m}^2 \cdot \text{K} \pi 0.028 \text{ m}\right)^{-1} + \ln (28/25)/2\pi (0.350 \text{ W/m} \cdot \text{K}) + \left(240 \text{ W/m}^2 \cdot \text{K} \pi 0.025 \text{ m}\right)^{-1}}^{1}
\]

\[
q' = \frac{(300 - 240) \text{K}}{(0.087 + 0.052 + 0.053) \text{ K} \cdot \text{m/W}^2} = 312 \text{ W/m}.
\]

COMMENTS: The three thermal resistances are comparable. Note that \( T_{s,o} = T_\infty - q'/h_o \pi D_o = 300 \text{K} - 312 \text{ W/m}/131 \text{ W/m}^2 \cdot \text{K} \pi 0.028 \text{ m} = 273 \text{ K}. \)
**PROBLEM 8.53**

**KNOWN:** Oil flowing slowly through a long, thin-walled pipe suspended in a room.

**FIND:** Heat loss per unit length of the pipe, \( q'_{\text{conv}} \).

**SCHEMATIC:**

![Schematic Diagram](Image)

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Tube wall thermal resistance negligible, (3) Fully developed flow, (4) Radiation exchange between pipe and room negligible.

**PROPERTIES:** Table A-5, Unused engine oil \( (T_m = 150^\circ\text{C} = 423\text{K}) \): \( k = 0.133 \text{ W/m-K} \).

**ANALYSIS:** The rate equation, for a unit length of the pipe, can be written as

\[
q'_{\text{conv}} = \frac{(T_m - T_\infty)}{R'_t}
\]

where the thermal resistance is comprised of two elements,

\[
R'_t = \frac{1}{h_i \pi D} + \frac{1}{h_o \pi D} = \frac{1}{\pi D} \left( \frac{1}{h_i} + \frac{1}{h_o} \right)
\]

The convection coefficient for internal flow, \( h_i \), must be estimated from an appropriate correlation. From practical considerations, we recognize that the oil flow rate cannot be large enough to achieve turbulent flow conditions. Hence, the flow is *laminar*, and if the pipe is very long, the flow will be *fully developed*. The appropriate correlation is

\[
\frac{N_u D}{k} = 3.66
\]

\[
h_i = \frac{N_u D}{k/D} = 3.66 \times 0.133 \frac{\text{W}}{\text{m} \cdot \text{K}} / 0.030 \text{ m} = 16.2 \text{ W/m}^2 \cdot \text{K}.
\]

The heat rate per unit length of the pipe is

\[
q'_{\text{conv}} = \frac{(150 - 20) \text{ } ^\circ\text{C}}{\pi (0.030 \text{ m}) \left( \frac{1}{16.2} + \frac{1}{11} \right) \text{m}^2 \cdot \text{K}} = 80.3 \text{ W/m}.
\]

**COMMENTS:** This problem requires making a judgment that the oil flow will be laminar rather than turbulent. Why is this a reasonable assumption? Recognize that the correlation applies to a constant surface temperature condition.
PROBLEM 8.54

KNOWN: Thin-walled, tall stack discharging exhaust gases from an oven into the environment.

FIND: (a) Outlet gas and stack surface temperatures, $T_{m,o}$ and $T_{s,o}$, and (b) Effect of wind temperature and velocity on $T_{m,o}$.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Wall thermal resistance negligible, (3) Exhaust gas properties approximated as those of atmospheric air, (4) Radiative exchange with surroundings negligible, (5) PE, KE, and flow work changes negligible, (6) Fully developed flow, (7) Constant properties.

PROPERTIES: Table A.4, air (assume $T_{m,o} = 773$ K, $T_{m} = 823$ K, 1 atm): $c_p = 1104$ J/kg K, $\mu = 376.4 \times 10^{-7}$ N s/m, $k = 0.0584$ W/m K, $Pr = 0.712$; Table A.4, air (assume $T_s = 523$ K, $T_f = 400$ K, 1 atm): $\nu = 26.41 \times 10^{-6}$ m$^2$/s, $k = 0.0338$ W/m K, $Pr = 0.690$.

ANALYSIS: (a) From Eq. 8.46a,

$$T_{m,o} = T_{\infty} - \left( T_{\infty} - T_{m,i} \right) \exp \left[ - \frac{PLT}{T_c p_m} \right] \quad U = \frac{1}{h_{i} + h_{o}}$$

where $h_{i}$ and $h_{o}$ are average coefficients for internal and external flow, respectively.

Internal flow: With a Reynolds number of

$$\text{Re}_{D_{i}} = \frac{4 m}{\pi \mu D} = \frac{4 \times 0.5 \text{ kg/s}}{\pi \times 0.5 \text{ m} \times 376.4 \times 10^{-7} \text{ N.s/m}^2} = 33,827$$

and the flow is turbulent. Considering the flow to be fully developed throughout the stack ($L/D = 12$) and with $T_s < T_m$, the Dittus-Boelter correlation has the form

$$\text{Nu}_{D} = \frac{h_{D} D}{k} = 0.023 \text{Re}_{D_{i}}^{4/5} \text{Pr}^{0.3} \quad (4)$$

$$h_{i} = \frac{58.4 \times 10^{-3} \text{ W/m.K}}{0.5 \text{ m}} \times 0.023 \left( 33,827 \right)^{4/5} (0.712)^{0.3} = 10.2 \text{ W/m}^2 \cdot \text{K}.$$ 

External flow: Working with the Churchill/Bernstein correlation, the Reynolds and Nusselt numbers are

$$\text{Re}_{D_{o}} = \frac{VD}{\nu} = \frac{5 \text{ m/s} \times 0.5 \text{ m}}{26.41 \times 10^{-6} \text{ m}^2/\text{s}} = 94,660$$

Continued...
\[
\overline{\text{Nu}}_D = 0.3 + \frac{0.62 \Re_D^{1/2} \Pr^{1/3}}{1 + (0.4/\Pr)^{2/3}} \left[1 + \left(\frac{\Re_D}{282,000}\right)^{5/8}\right]^{4/5} = 205
\]

Hence,
\[
h_o = (0.0338 \text{ W/m·K}/0.5 \text{ m}) \times 205 = 13.9 \text{ W/m}^2 \cdot \text{K}
\]

The outlet gas temperature is then
\[
T_{m,o} = 4^\circ \text{C} - (4 - 600)^\circ \text{C exp}\left[-\frac{\pi \times 0.5 \text{ m} \times 6 \text{ m}}{0.5 \text{ kg/s} \times 1104 \text{ J/kg·K} \left(\frac{1}{1/10.2 + 1/13.9}\right) \text{ W/m}^2 \cdot \text{K}}\right] = 543^\circ \text{C}
\]

(b) Using the Correlations and Properties Toolpads of IHT, with a surface temperature of \(T_s = 523 \text{ K}\) assumed solely for the purpose of evaluating properties associated with airflow over the cylinder, the following results were generated.

Due to the elevated temperatures of the gas, the variation in ambient temperature has only a small effect on the gas exit temperature. However, the effect of the freestream velocity is more pronounced. Discharge temperatures of approximately 530 and 560°C would be representative of cold/windy and warm/still atmospheric conditions, respectively.

**COMMENTS:** If there are constituents in the discharge gas flow that condense or precipitate out at temperatures below \(T_{s,o}\), this operating condition should be avoided.
PROBLEM 8.55

KNOWN: Hot fluid passing through a thin-walled tube with coolant in cross flow over the tube. Fluid flow rate and inlet and outlet temperatures.

FIND: Outlet temperature, $T_{m,o}$, if the flow rate is increased by a factor of 2 with all other conditions the same.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible kinetic and potential energy changes and axial conduction, (3) Constant properties, (4) Fully developed flow and thermal conditions, (5) Convection coefficients, $\bar{h}_o$ and $\bar{h}_i$, independent of temperature, and (6) Negligible wall thermal resistance.

PROPERTIES: Hot fluid (Given): $\rho = 1079 \text{ kg/m}^3$, $c_p = 2637 \text{ J/kg} \cdot \text{K}$, $\mu = 0.0034 \text{ N} \cdot \text{s/m}^2$, $k = 0.261 \text{ W/m} \cdot \text{K}$.

ANALYSIS: For conditions prescribed in the Schematic, Eq 8.46a can be used to evaluate the overall convection coefficient with $P = \pi D$,

$$\frac{T_{\infty} - T_{m,o}}{T_{\infty} - T_{m,i}} = \exp \left( -\frac{PL}{m_o c_p} \bar{U} \right) \tag{1}$$

$$\left( \frac{25 - 78}{25 - 85} \right) ^{\circ} \text{C} = \exp \left( -\frac{\pi \times 0.010 \text{m} \times 1 \text{m}}{(18/3600) \text{kg/s} \times 2637 \text{J/kg} \cdot \text{K}} \bar{U} \right)$$

$$U = 52.1 \text{ W/m}^2 \cdot \text{K}$$

The overall coefficient can be expressed in terms of the inside and outside coefficients,

$$U = \left( \frac{1}{\bar{h}_i} + \frac{1}{\bar{h}_o} \right)^{-1} \tag{2}$$

Characterize the internal flow with the Reynolds number, Eq. 8.6,

$$Re_D = \frac{4m_o}{\pi D \mu} = \frac{4 \times (18/3600) \text{kg/s}}{\pi \times 0.010 \text{m} \times 0.0034 \text{ N} \cdot \text{s/m}^2} = 187$$

and since the flow is laminar, and assumed to be fully developed, $\bar{h}_i$ will not change when the flow rate is doubled. That is, $U = 52.1 \text{ W/m}^2 \cdot \text{K}$ when $m = 2m_o$. Using Eq. (1) again, but with $T_{m,o}$ unknown,

$$\left( \frac{25 - T_{m,o}}{25 - 85} \right) ^{\circ} \text{C} = \exp \left( -\frac{\pi \times 0.010 \text{m} \times 1 \text{m}}{2 \times (18/3600) \text{kg/s} \times 2637 \text{J/kg} \cdot \text{K}} \times 52.1 \text{ W/m}^2 \cdot \text{K} \right)$$

$$T_{m,o} = 81.4 ^{\circ} \text{C}$$

COMMENTS: Examine the assumptions and explain why they were necessary in order to affect the solution.
PROBLEM 8.56

KNOWN: Thin walled tube of prescribed diameter and length. Water inlet temperature and flow rate.

FIND: (a) Outlet temperature of the water when the tube surface is maintained at a uniform temperature $T_s = 27^\circ C$ assuming $T_m = 300$ K for evaluating water properties, (b) Outlet temperature of the water when the tube is heated by cross flow of air with $V = 10$ m/s and $T_{\infty} = 100^\circ C$ assuming $T_f = 350$ K for evaluating air properties, and (c) Outlet temperature of the water for the conditions of part (b) using properly evaluated properties.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible kinetic and potential energy changes and axial conduction, (3) Fully developed flow and thermal conditions for internal flow, and (4) Negligible tube wall thermal resistance.

PROPERTIES: Table A.6, Water ($T_m = 300$ K): $\rho = 997$ kg/m$^3$, $c_p = 4179$ J/kg·K, $\mu = 855 \times 10^{-6}$ N·s/m$^2$, $k = 0.613$ W/m·K, $Pr = 5.83$; Table A.4, Air ($T_f = 350$ K, 1 atm): $v = 20.92 \times 10^{-6}$ m$^2$/s, $k = 0.030$ W/m·K, $Pr = 0.700$.

ANALYSIS: (a) For the constant wall temperature cooling process, $T_s = 27^\circ C$, the water outlet temperature can be determined from Eq. 8.42b, with $P = \pi D$,

$$\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp \left(-\frac{PL}{m_c p} \frac{h_i}{\rho c_p} \right) \quad (1)$$

To estimate the convection coefficient, characterize the flow evaluating properties at $T_m = 300$ K

$$Re_D = \frac{4 \dot{m}}{\pi D \mu} = \frac{4 \times 0.2 \text{ kg/s}}{\pi \times 0.010 \text{ m} \times 855 \times 10^{-6} \text{ N} \cdot \text{s} / \text{m}^2} = 29,783$$

Hence, the flow is turbulent and assuming fully developed ($L/D = 200$), and using the Dittus-Boelter correlation, Eq. 8.60, find $h_i$:

$$Nu_D = \frac{\frac{h_i D}{k}}{0.023Re_D^{0.8} Pr^{0.3}} \quad h_i = \frac{0.613 \text{ W/m} \cdot \text{K}}{0.010 \text{ m}} \times \frac{0.023(29,783)^{0.8}(5.83)^{0.3}}{9080 \text{ W/m}^2 \cdot \text{K}} = 9080 \text{ W/m}^2 \cdot \text{K} \quad (2)$$

Substituting this value for $h_i$ into Eq. (1), find

$$\frac{(27 - T_{m,o})}{(27 - 47) ^\circ \text{C}} = \exp \left(-\frac{\pi \times 0.010 \text{ m} \times 2 \text{ m}}{0.2 \text{ kg/s} \times 4179 \text{ J/kg} \cdot \text{K} \times 9080 \text{ W/m}^2 \cdot \text{K}} \times 9080 \text{ W/m}^2 \cdot \text{K} \right) \quad T_{m,o} = 37.1^\circ \text{C} <$$

(b) For the air heating process, $T_{\infty} = 100^\circ C$, the water outlet temperature follows from Eq. 8.46a,

$$\frac{T_{\infty} - T_{m,o}}{T_{\infty} - T_{m,i}} = \exp \left(-\frac{\pi D L}{m_c p} \frac{U}{U} \right) \quad (3)$$

Continued...
Problem 8.56 (Cont.)

where the overall coefficient is

$$\bar{U} = \left( \frac{1}{\bar{h}_i} + \frac{1}{\bar{h}_o} \right) \quad (4)$$

To estimate $\bar{h}_o$, use the Churchill-Bernstein correlation, Eq. 7.57, for cross flow over a cylinder using properties evaluated at $T_f = 350$ K.

$$\text{Re}_D = \frac{VD}{\nu} = \frac{10 \text{m/s} \times 0.010 \text{m}}{20.92 \times 10^{-6} \text{ m}^2/\text{s}} = 4780 \quad (5)$$

$$\bar{\text{Nu}}_D = 0.3 + \frac{0.62 \left( \frac{1}{2} \text{ Pr}^{1/3} \right)}{1 + (0.4/\text{Pr})^{2/3}} \left[ 1 + \left( \frac{\text{Re}_D}{282,000} \right)^{5/8} \right]^{4/5} \quad (6)$$

$$\bar{\text{Nu}}_D = 0.3 + \frac{0.62 \left( 4780 \right)^{1/2} \left( \frac{0.700}{10^4} \right)^{1/3}}{1 + (0.4/0.700)^{2/3}} \left[ 1 + \left( \frac{4780}{282,000} \right)^{5/8} \right]^{4/5} = 35.76$$

$$\bar{h}_o = \frac{\bar{\text{Nu}}_D k}{D} = \frac{0.030 \text{ W/m} \cdot \text{K}}{0.010 \text{ m}} \times 35.76 = 107 \text{ W/m}^2 \cdot \text{K} \quad (7,8)$$

Assuming $\bar{h}_i = 9080 \text{ W/m}^2 \cdot \text{K}$ as calculated from part (a), find $\bar{U}$ then $T_{m,o}$,

$$\bar{U} = \left( \frac{1}{9080} + \frac{1}{107} \right)^{-1} \text{ W/m}^2 \cdot \text{K} = 106 \text{ W/m}^2 \cdot \text{K}$$

$$\frac{100 - T_{m,o}}{100 - 47} \times 4179 \text{ J/kg} \cdot \text{K} \times 106 \text{ W/m}^2 \cdot \text{K} = 47.4^\circ \text{C}$$

(c) Using the IHT Correlation Tools for Internal Flow (Turbulent Flow) and External Flow (over a Cylinder) the analyses of part (b) were performed considering the appropriate temperatures to evaluate the thermophysical properties. For internal and external flow, respectively,

$$T_m = \left( T_{m,i} + T_{m,o} \right)/2 \quad \bar{T}_f = \left( T_s + T_\infty \right)/2 \quad (7,8)$$

where the average tube wall temperature is evaluated from the thermal circuit,

$$\frac{T_m - T_s}{1/\bar{h}_i} = \frac{T_\infty - T_s}{1/\bar{h}_o} \quad (9)$$

The results of the analyses are summarized in the table along with the results from parts (a) and (b).

<table>

Note that since $\bar{h}_o \ll \bar{h}_i$, $\bar{U}$ is controlled by the value of $\bar{h}_o$ which was evaluated near 350 K for both parts (b) and (c). Hence, it follows that $T_{m,o}$ is not very sensitive to $\bar{h}_i$ which, as seen above, is sensitive to the value of $T_m$. 

PROBLEM 8.57

KNOWN: Diameter of tube through which water of prescribed flow rate and inlet and outlet temperatures flows. Temperature of fluid in cross flow over the tube.

FIND: (a) Required tube length for air in cross flow at prescribed velocity, (b) Required tube length for water in cross flow at a prescribed velocity.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Constant properties, (3) Negligible tube wall conduction resistance, (4) Negligible KE, PE and flow work changes.

PROPERTIES: Table A.6, water (\(T_m = 50^\circ\text{C} = 323\text{ K}\)): \(c_p = 4181\text{ J/kg·K}, \mu = 548 \times 10^{-6}\text{ N·s/m}^2, k = 0.643\text{ W/m·K}, \text{Pr} = 3.46\). Table A.4, air (assume \(T_f = 300\text{ K}\)): \(\nu = 15.89 \times 10^{-6}\text{ m}^2/\text{s}, k = 0.0263\text{ W/m·K}, \text{Pr} = 0.707\). Table A.6, water (assume \(T_i = 300\text{ K}\)): \(\nu = 0.858 \times 10^{-6}\text{ m}^2/\text{s}, k = 0.613\text{ W/m·K}, \text{Pr} = 5.83\).

ANALYSIS: The required heat rate may be determined from the overall energy balance,

\[
q = \dot{m}c_p(T_{m,i} - T_{m,o}) = 0.215\text{ kg/s}(4181\text{ J/kg·K})(40^\circ\text{C}) = 35,960\text{ W}
\]

and the required tube length may be determined from the rate equation, Eq. 8.47a,

\[
L = \frac{q}{U\pi D A \Delta T_{\ell m}}
\]

where

\[
\Delta T_{\ell m} = \frac{T_{m,i} - T_{\infty}}{\ln \left( \frac{T_{m,i} - T_{\infty}}{T_{m,o} - T_{\infty}} \right)} = 30.8^\circ\text{C}
\]

and \(1/U = 1/h_i + 1/h_o\).

With

\[
\text{Re}_{Di} = 4\dot{m}/\pi D \mu = 0.860\text{ kg/s}/\pi (0.05\text{ m})548 \times 10^{-6}\text{ N·s/m}^2 = 9991
\]

the flow is turbulent and, assuming fully developed flow throughout the tube, the inside convection coefficient is determined from Eq. 8.60

\[
\text{Nu}_{Di} = 0.023 \text{Re}_{Di}^{4/5} \text{Pr}^{0.3} = 0.023(9991)^{0.8}(3.46)^{0.3} = 52.9
\]

\[
h_i = \text{Nu}_{Di}k/D = 52.9(0.643\text{ W/m·K})/0.05\text{ m} = 680\text{ W/m}^2\cdot\text{K}
\]

Continued...
PROBLEM 8.57 (Cont.)

(a) For water in cross flow at 20 m/s, \( \text{Re}_{D_o} = \frac{VD_o}{\nu} = 20 \text{ m/s}(0.05 \text{ m})/15.89 \times 10^{-6} \text{ m}^2/\text{s} = 62,933 \). From the Churchill/Bernstein correlation, it follows that

\[
\text{Nu}_{D_o} = 0.3 + \frac{0.62 \text{Re}_{D_o}^{1/2} \text{Pr}^{1/3}}{1 + (0.4/\text{Pr})^{2/3}} \left[ 1 + \left( \frac{\text{Re}_{D_o}}{282,000} \right)^{5/8} \right]^{4/5} = 158.7
\]

\[
h_o = \text{Nu}_{D_o} \frac{k}{D} = 158.7 \left( \frac{0.0263 \text{ W/m} \cdot \text{K}}{0.05 \text{ m}} \right) = 83.5 \text{ W/m}^2 \cdot \text{K}
\]

Hence, \( U = \left( \frac{1}{h_1} + \frac{1}{h_o} \right)^{-1} = 74.4 \text{ W/m}^2 \cdot \text{K} \) and

\[
L = \frac{35,960 \text{ W}}{(74.4 \text{ W/m}^2 \cdot \text{K}) \pi (0.05 \text{ m}) 30.8^\circ \text{C}} = 100 \text{ m}
\]

(b) For water in cross flow at 2 m/s, \( \text{Re}_{D_o} = 2 \text{ m/s}(0.05 \text{ m})/0.858 \times 10^{-6} \text{ m}^2/\text{s} = 116,550 \), and the correlation yields \( \text{Nu}_{D_o} = 527.3 \). Hence,

\[
h_o = \text{Nu}_{D_o} \frac{k}{D} = 527.3 \left( \frac{0.613 \text{ W/m} \cdot \text{K}}{0.05 \text{ m}} \right) = 6,465 \text{ W/m}^2 \cdot \text{K}
\]

\[
U = \left( \frac{1}{h_1} + \frac{1}{h_o} \right)^{-1} = 615.3 \text{ W/m}^2 \cdot \text{K}
\]

Hence,

\[
L = \frac{35,960 \text{ W}}{(615.3 \text{ W/m}^2 \cdot \text{K}) \pi (0.05 \text{ m}) 30.8^\circ \text{C}} = 12 \text{ m}
\]

COMMENTS: The foregoing results clearly indicate the superiority of water (relative to air) as a heat transfer fluid. Note the dominant contribution made by the smaller convection coefficient to the value of \( U \) in each of the two cases.
**PROBLEM 8.58**

**KNOWN:** Water flow rate and inlet temperature for a thin-walled tube of prescribed length and diameter.

**FIND:** Water outlet temperature for each of the following conditions: (a) Tube surface maintained at 27°C, (b) Insulation applied and outer surface maintained at 27°C, (c) Insulation applied and outer surface exposed to ambient air at 27°C.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Fully developed flow throughout the tube, (3) Negligible tube wall conduction resistance, (4) Negligible contact resistance between tube wall and insulation, (5) Uniform outside convection coefficient.

**PROPERTIES:** Assume water cools to $T_{m,o} = 27°C$ with no insulation but that cooling is negligible ($T_{m,o} = 97°C$) with insulation. Table A-4, Water ($T_m = 335K$): $c_p = 4186 \text{ J/kg-K}$, $\mu = 453 \times 10^{-6} \text{ N-s/m}^2$, $k = 0.656 \text{ W/m-K}$, $Pr = 2.88$; Table A-4, Water ($T_{m,i} = 370K$): $c_p = 4214 \text{ J/kg-K}$, $\mu = 289 \times 10^{-6} \text{ N-s/m}^2$, $k = 0.679 \text{ W/m-K}$, $Pr = 1.80$.

**ANALYSIS:** For each of the three cases, heat is transferred from the warm water to a surface (or the air) which is at a fixed temperature (27°C). Accordingly, an expression of the form given by Eq. 8.42b may be used to determine the outlet temperature of the water, so long as the appropriate heat transfer coefficient is used. In particular, each of the cases can be described by Eq. 8.46.

$$\frac{\Delta T_o}{\Delta T_i} = \exp \left( -\frac{\Delta}{c_p} \right)$$

Referring to the thermal circuit associated with heat transfer from the water,

$$\frac{1}{h_i \pi D_i L} + \frac{\ln (D_o/D_i)}{2 \pi k L} + \frac{1}{h_o \pi D_o L} = \frac{Q}{q}$$

and using Eq. 3.32, the UA product may be evaluated as

$$UA = (\Sigma R_t)^{-1}.$$

(a) For the first case: $T_{s,i} = 27°C$ $\Delta T_i = T_{m,i} - T_{s,i} = 70°C$ $UA = h_i \pi D_i L$.

$$Re_D = \frac{4m}{\pi D_i \mu} = \frac{4 \times 0.015 \text{ kg/s}}{\pi (0.003m) 453 \times 10^{-6} \text{ N-s/m}^2} = 14,053.$$
PROBLEM 8.58 (Cont.)

From Eq. 8.60,
\[
h_i = \frac{k}{D_i} 0.023 \text{Re}^{4/5} \text{Pr}^{0.3} = \frac{0.656 \text{W/m-K}}{0.003m} (0.023) \left(14,053\right)^{4/5} (2.88)^{0.3} = 14,373 \text{ W/m}^2 \cdot \text{K}.\]

\[
\Delta T_o = \Delta T_{\text{exp}} \left(-\frac{h_i \pi D_i L}{m c_p}\right) = 70^\circ \text{C} \exp \left(-\frac{14,373 \pi \times 0.003m \times 1m}{0.015 \text{ kg/s} \times 4186 \text{ J/kg-K}}\right) = 8.1^\circ \text{C}\]

\[
T_{m,o} = \Delta T_o + T_{s,i} = 8.1^\circ \text{C} + 27^\circ \text{C} = 35.1^\circ \text{C}.
\]

(b) For the second case: \(T_{s,o} = 27^\circ \text{C}\) with

\[
\Delta T_i = T_{m,i} - T_{s,o} = 70^\circ \text{C} \quad \text{UA} = \left[\left(1/h_i \pi D_i L\right) + \ell n \left(D_o / D_i\right) / 2\pi \text{ kL}\right]^{-1}.
\]

With \(\text{Re}_D = \frac{4 \text{ m}}{\pi D_i \mu} = \frac{4 \times 0.015 \text{ kg/s}}{\pi \left(0.003m\right) 289 \times 10^{-6} \text{ N} \cdot \text{s/m}^2} = 22,028\)

\[
h_i = \frac{k}{D_i} 0.023 \text{Re}^{4/5} \text{Pr}^{0.3} = \frac{0.679 \text{ W/m-K}}{0.003m} (0.023) \left(22,028\right)^{4/5} (1.80)^{0.3} = 18,511 \text{ W/m}^2 \cdot \text{K}.
\]

It follows that

\[
UA = \left[1 \frac{18,511 \pi \times 0.003}{\ell n \left(0.004/0.003\right)} \frac{1}{2\pi \left(0.05\right)}\right]^{-1} = \left[5.73 \times 10^{-3} + 0.916\right]^{-1} = 1.085 \text{ W/K}
\]

and the outlet temperature is

\[
\Delta T_o = 70^\circ \text{C} \exp \left(-\frac{1.085 \text{ W/K}}{0.015 \text{ kg/s} \times 4214 \text{ J/kg-K}}\right) = 68.8^\circ \text{C}
\]

\[
T_{m,o} = \Delta T_o + T_{s,o} = 68.8^\circ \text{C} + 27^\circ \text{C} = 95.8^\circ \text{C}.
\]

(c) For the third case: \(T_{\infty} = 27^\circ \text{C}, \Delta T_i = T_{m,i} - T_{\infty} = 70^\circ \text{C}\) and

\[
UA = \left[(1/h_i \pi D_i L) + \ell n \left(D_o / D_i\right) / 2\pi \text{ kL} + (1/h_o \pi D_o L)\right]^{-1}
\]

\[
UA = \left[5.73 \times 10^{-3} + 0.916 + \frac{1}{5\pi \left(0.004\right)}\right]^{-1} = \left[5.73 \times 10^{-3} + 0.916 + 15.92\right]^{-1} = 0.0594 \text{ W/K}
\]

\[
\Delta T_o = 70^\circ \text{C} \exp \left(-\frac{0.0594 \text{ W/K}}{0.015 \text{ kg/s} \times 4214 \text{ J/kg-K}}\right) = 69.9^\circ \text{C}
\]

\[
T_{m,o} = \Delta T_o + T_{\infty} = 69.9^\circ \text{C} + 27^\circ \text{C} = 96.9^\circ \text{C}.
\]

COMMENTS: Note that \(R_{\text{conv,o}} >> R_{\text{cond,insul}} >> R_{\text{conv,i}}\).
**PROBLEM 8.59**

**KNOWN:** Thick-walled pipe of thermal conductivity 60 W/m·K passing hot water with \( \text{Re}_D = 20,000 \), a mean temperature of 80°C, and cooled externally by air in cross-flow at 20 m/s and 25°C.

**FIND:** Heat transfer rate per unit pipe length, \( q' \).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Internal flow is turbulent and fully developed.

**PROPERTIES:** Table A-6, Water (\( T_m = 80^\circ \text{C} = 353 \text{K} \)) \( k = 0.670 \text{ W/m·K}, \text{Pr} = 2.20 \); Table A-4, Air (\( T_\infty = 25^\circ \text{C} = 300 \text{K}, 1 \text{ atm} \)) \( \nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s} \), \( k = 0.0263 \text{ W/m·K}, \text{Pr} = 0.707 \).

**ANALYSIS:** The heat rate per unit length, considering thermal resistances to internal flow, wall conduction (Eq. 3.28) and external flow, with \( A = \pi D_L \), is

\[
q' = \left[ \frac{1}{h_i D_i} \ln \left( \frac{D_O}{D_i} \right) + \frac{1}{h_O D_O} \right]^{-1} \left( T_m - T_\infty \right).
\]

Internal Flow: Using the Dittus-Boelter correlation with \( n = 1/3 \) for turbulent, fully developed flow, where \( \text{Re}_D = 20,000 \)

\[
h_i = \left( \frac{k}{D_i} \right) N_u_D = (k/D_i) 0.023 \text{Re}^{4/5} \text{Pr}^{1/3}
\]

\[
h_i = (0.670 \text{ W/m·K}/0.020 \text{ m}) 0.023 (20,000)^{4/5} 2.20^{1/3} = 2765 \text{ W/m}^2·\text{K}.
\]

External Flow: Using the Zhukauskas correlation for cross-flow over a circular cylinder with \( \text{Pr}/\text{Pr}_s = 1 \), find first

\[
\text{Re}_D = \frac{\upsilon D_O}{\nu} = \frac{20 \text{ m/s} \times 0.025 \text{ m}}{15.89 \times 10^{-6} \text{ m}^2/\text{s}} = 31,466
\]

and from Table 7.4, \( C = 0.26 \) and \( m = 0.6 \), where \( n = 0.37 \),

\[
\text{Nu}_D = \frac{h_O D}{k} = C \text{Re}_D^m \text{Pr}^n \left( \text{Pr}/\text{Pr}_s \right)^{1/4}
\]

\[
h_O = (0.0263 \text{ W/m·K}/0.025 \text{ m}) 0.26 (31,466)^{0.6} (0.707)^{0.37} = 120 \text{ W/m}^2·\text{K}.
\]

Hence, the heat rate is

\[
q' = \left[ \frac{1}{2765 \text{ W/m}^2·\text{K} \times \pi 0.020 \text{ m}} + (1/2\pi 60 \text{ W/m·K}) \ln (25/20) \right. \left. + \left( \frac{1}{120 \text{ W/m}^2·\text{K} \times \pi 0.025 \text{ m}} \right) \right]^{-1} (80 - 25)^\circ \text{C}
\]

\[
q' = \left[ 5.756 \times 10^{-3} + 5.919 \times 10^{-4} + 1.061 \times 10^{-1} \right]^{-1} \text{ W/m·K} (80 - 25)^\circ \text{C}
\]

\[
q' = 489 \text{ W/m}.
\]

**COMMENTS:** Note that the external flow represents the major thermal resistance to heat transfer.
PROBLEM 8.60

KNOWN: Reaction vessel with process fluid at 75°C cooled by water at 27°C and 0.12 kg/s through 15 mm tube. High convection coefficient on outside of tube (3000 W/m²⋅K) created by vigorous stirring.

FIND: (a) Maximum heat transfer rate if outlet temperature of water cannot exceed Tₘₒ = 47°C, and (b) Required tube length.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible kinetic and potential energy changes, (3) Negligible thermal resistance of tube wall.

PROPERTIES: Table A-6, Water \( \left( \bar{T}_m = (47 + 27)°C/2 = 310K \right) \): \( \rho = \frac{1}{\nu_f} = 993.1 \text{ kg/m}^3 \), \( c_p = 4178 \text{ J/kg} \cdot \text{K} \), \( \mu = 695 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 \), \( k = 0.628 \text{ W/m} \cdot \text{K} \), \( Pr = 4.62 \).

ANALYSIS: (a) From an overall energy balance on the tube with Tₘₒ = 47°C,
\[ q_{\text{max}} = \dot{m} c_p (T_{m,o} - T_{m,i}) = 0.12 \text{ kg/s} \times 4178 \text{ J/kg} \cdot \text{K} (47 - 27)°C = 10,027 \text{ W}. \]

(b) For the constant surface temperature heating condition, from Eq. 8.46,
\[ \frac{T_{\infty} - T_{m,o}}{T_{\infty} - T_{m,i}} = \exp \left( -\frac{PL}{\dot{m} c_p \bar{U}} \right) \quad \text{where} \quad 1/U = 1/h_o + 1/h_l. \]

For internal flow in the tube, find
\[ \text{Re}_D = \frac{4\dot{m}}{\pi D \mu} = \frac{4 \times 0.12 \text{ kg/s}}{\pi \times 0.015 \text{ m} \times 695 \times 10^{-6} \text{ N} \cdot \text{s/m}^2} = 14,656 \]
and the flow is turbulent. Assuming fully developed flow, use the Dittus-Boelter correlation with \( n = 0.4 \) (heating),
\[ \text{Nu}_D = h_i D/k = 0.23 \text{Re}_D^{4/5} Pr^{0.4} \]
\[ h_i = [0.628 \text{ W/m} \cdot \text{K}/0.015 \text{ m}] \times 0.023 (14,656)^{4/5} (4.62)^{0.4} = 3822 \text{ W/m}^2 \cdot \text{K}. \]
Hence, \( 1/U = [1/3000 + 1/3822] \text{ m}^2 \cdot \text{K/W} \) or \( U = 1680 \text{ W/m}^2 \cdot \text{K} \). From the energy balance relation with \( P = \pi D \), find
\[ \frac{(75 - 47)°C}{(75 - 27)°C} = \exp \left( -\frac{\pi \left( 0.015 \text{ m} \right) L \times 1680 \text{ W/m}^2 \cdot \text{K}}{0.12 \text{ kg/s} \times 4178 \text{ J/kg} \cdot \text{K}} \right) \quad \text{L} = 3.4 \text{ m}. \]

COMMENTS: Note that L/D = 227 and the fully developed flow assumption is appropriate.
PROBLEM 8.61

KNOWN: Water flowing through a tube heated by cross flow of a hot gas. Required to heat water from 15 to 35°C with a flow rate of 0.2 kg/s.

FIND: Design graphs to demonstrate acceptable combinations of tube diameter (D = 20, 30 or 40 mm), tube length (L = 3, 4 or 6 m) and hot gas velocity (20 ≤ V ≤ 40 m/s) and temperature (T_∞ = 250, 375 or 500°C).

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible kinetic and potential energy changes and axial conduction, (3) Fully developed flow and thermal conditions for internal flow, (4) Properties of the hot gas are those of atmospheric air, and (5) Negligible tube wall thermal resistance.

PROPERTIES: Table A.6, Water \( (T_m = (15 + 35) \frac{C}{2} = 298K) \); Table A.4, Air \( (T_f = \frac{T_s + T_∞}{2}, 1 \text{ atm}) \).

ANALYSIS: Method of Analysis: The tube having internal flow of water with cross flow of hot gas can be analyzed by the energy balance relation, Eq. 4.86a

\[
\frac{T_∞ - T_{m,o}}{T_∞ - T_{m,i}} = \exp \left( \frac{\pi DL}{mc_p} \bar{U} \right)
\]

(1)

where the overall coefficient \( \bar{U} \) is

\[
\bar{U} = \left( \frac{1}{\bar{h}_i} + \frac{1}{\bar{h}_0} \right)^{-1}
\]

(2)

Estimation of the internal flow coefficient, \( \bar{h}_i \): Evaluating water properties at the average mean fluid

\[
\bar{T}_m = \left( T_{m,i} + T_{m,o} \right) / 2,
\]

(3)

characterize the flow with the Reynolds number,

\[
Re_{D,i} = \frac{4m}{\pi D \mu}
\]

(4)

and assuming the flow to be both turbulent and fully developed (L/D > 3m/0.07m = 42), use the Dittus-Boelter correlation, Eq. 8.60, to evaluate \( \bar{h}_i \).

Continued...
PROBLEM 8.61 (Cont.)

\[ \overline{\text{Nu}}_{D,i} = \frac{\overline{h}_i D}{k_i} = 0.023 \text{Re}_{D,i}^{0.8} \text{Pr}_{D,i}^{0.4} \quad (5) \]

Estimation of the external flow coefficient, \( \overline{h}_o \): Evaluating gas (air) properties at the average film temperature

\[ \overline{T}_f = \frac{\overline{T}_s + T_\infty}{2} \quad (6) \]

where \( \overline{T}_s \) is the average tube wall temperature (see Eq. (9)), characterize the flow

\[ \text{Re}_{D,o} = \frac{VD}{\nu} \quad (7) \]

and use the Churchill-Bernstein correlation, Eq. 7.57, for cross-flow over a cylinder,

\[ \overline{\text{Nu}}_{D,o} = \frac{\overline{h}_o D}{k_o} = 0.3 + \frac{0.62 \text{Re}_{D,o}^{1/2} \text{Pr}_o^{1/3}}{\left[ 1 + (0.4/\text{Pr}_o)^{2/3} \right]^{1/4}} \left[ 1 + \left( \frac{\text{Re}_{D,o}}{282,000} \right)^{5/8} \right]^{4/5} \quad (8) \]

The average tube wall temperature, \( \overline{T}_s \), follows from the thermal circuit

\[ \frac{\overline{T}_m - \overline{T}_s}{1/\overline{h}_i} = \frac{\overline{T}_s - T_\infty}{1/\overline{h}_o} \quad (9) \]

The IHT Workspace: Using the Correlation Tools for Internal Flow (Turbulent flow), and External Flow (Flow over a Cylinder) and Properties for Air and Water, along with the appropriate energy balances and rate equations, the heater-tube system can be analyzed.

The Design Strategy: We have chosen to generate the design information in the following manner: for a specified gas temperature, \( T_\infty \), plot the required length \( L \) (limiting the scale to \( 3 \leq L \leq 6 \)m) as a function of gas velocity \( V \) (\( 20 \leq V \leq 40 \) m/s) for tube diameters of \( D = 20, 30 \) and \( 40 \) mm. Three design graphs corresponding to \( T_\infty = 250, 375 \) and \( 500 \)°C were generated and are shown on the next page.

COMMENTS: (1) The collection of design graphs will allow the contractor to select appropriate combinations of tube \( D \) and \( L \) and gas stream parameters (\( T_\infty \) and \( V \)) to achieve the required water heating.

(2) Note from the design graphs that with \( T_\infty = 250 \)°C, the required heating of the water can be achieved only with a 40-mm diameter by 6 m length tube with gas velocities greater than 32 m/s. This configuration represents a worst case condition of largest tube parameters and highest gas velocity.

(3) Which operating conditions, \( T_\infty = 375 \) or \( 500 \)°C, provides the contractor with more options in selecting combinations of tube parameters and gas velocities? What are the trade-offs in operating at 375 or \( 500 \)°C? Consider such features as tube life, tubing costs and fan requirements.

(4) The Reynolds numbers for the internal flow are approximately \( 7,100, 9,460 \) and \( 14,200 \) for the tube diameters of 20, 30 and 40 mm. For the larger tube sizes, the Reynolds numbers are below 10,000, the usual lower limit for turbulent flow.

Continued...
PROBLEM 8.61 (Cont.)

Gas temperature, $T_{\text{inf}} = 250 \, ^{\circ}\text{C}$

![Graph showing tube length vs. gas velocity for $T_{\text{inf}} = 250 \, ^{\circ}\text{C}$ with different tube diameters.]

Gas temperature, $T_{\text{inf}} = 375 \, ^{\circ}\text{C}$

![Graph showing tube length vs. gas velocity for $T_{\text{inf}} = 375 \, ^{\circ}\text{C}$ with different tube diameters.]

Gas temperature, $T_{\text{inf}} = 500 \, ^{\circ}\text{C}$

![Graph showing tube length vs. gas velocity for $T_{\text{inf}} = 500 \, ^{\circ}\text{C}$ with different tube diameters.]
PROBLEM 8.62

KNOWN: Exhaust gasses at 200°C and mass rate 0.03 kg/s enter tube of diameter 6 mm and length 20 m. Tube experiences cross-flow of autumn winds at 15°C and 5 m/s.

FIND: Average heat transfer coefficients for (a) exhaust gas inside tube and (b) air flowing across outside of tube, (c) Estimate overall coefficient and exhaust gas temperature at outlet of tube.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible kinetic and potential energy changes, (3) Negligible tube wall resistance, (4) Exhaust gas properties are those of air, (5) Negligible radiation effects.

PROPERTIES: *Table A-4*, Air (assume $T_{m,o} = 15^\circ$C, hence $T_{m} = 380 K$, 1 atm): $c_p = 1012$ J/kg·K, $k = 0.0323 W/m·K$, $\mu = 221.6 \times 10^{-7} N\cdot s/m^2$, $Pr = 0.694$; Air ($T_\infty = 15^\circ$C = 288 K, 1 atm): $k = 0.0253 W/m·K$, $\nu = 14.82 \times 10^{-6} m^2/s$, $Pr = 0.710$; Air ($T_s = 90^\circ$C = 363 K, 1 atm): $Pr = 0.698$.

ANALYSIS: (a) For the internal flow through the tube assuming a value for $T_{m,o} = 15^\circ$C, find

$$Re_D = \frac{4m}{\pi \mu} = \frac{4 \times 0.003 \text{ kg/s}}{\pi \times 0.006 \text{ m} \times 221.6 \times 10^{-7} \text{ N} \cdot \text{s/m}^2} = 2.873 \times 10^4.$$ 

Hence the flow is turbulent and, since $L/D >> 10$, fully developed. Using the Dittus-Doelter correlation with $n = 0.3$,

$$\begin{align*}
Nu_D &= 0.023Re_D^{0.8}Pr^{0.3} = 0.023 \left(2.873 \times 10^4\right)^{0.8}(0.694)^{0.3} = 76.0 \\
h_i &= Nu \cdot k/D = 76.0 \times 0.0323 \text{ W/m·K}/0.006 \text{ m} = 409 \text{ W/m}^2\cdot\text{K}. \quad \langle \text{Continued} \rangle
\end{align*}$$

(b) For cross-flow over the circular tube, find using thermophysical properties at $T_\infty$,

$$Re_D = \frac{VD}{V} = \frac{5 \text{ m/s} \times 0.006 \text{ m}}{14.82 \times 10^{-6} \text{ m}^2/s} = 2024$$ 

and using the Zhukauskus correlation with $C = 0.26$, $m = 0.6$, and $n = 0.37$,

$$\begin{align*}
Nu_D &= CRe_D^{m}Pr^n \left(Pr/Pr_s\right)^{1/4} = 0.26(2024)^{0.6}0.710^{0.37}(0.710/0.698)^{0.25} = 23.1 \\
h_o &= Nu_D \cdot k/D = 23.1 \times 0.0253 \text{ W/m·K}/0.006 \text{ m} = 97.5 \text{ W/m}^2\cdot\text{K}. \quad \langle \text{Continued} \rangle
\end{align*}$$

Continued …..
PROBLEM 8.62 (Cont.)

(c) Assuming the thermal resistance of the tube wall is negligible,

\[
\frac{1}{U} = \frac{1}{h_o} + \frac{1}{h_i} = \left( \frac{1}{97.5} + \frac{1}{409} \right) \text{m}^2 \cdot \text{K/W} \quad U = 78.8 \text{ W/m}^2 \cdot \text{K}.
\]

The gas outlet temperature can be determined from the expression where \( P = \pi D \).

\[
\frac{T_\infty - T_{m,o}}{T_\infty - T_{m,i}} = \exp \left( -\frac{PUL}{m c_p} \right) = \exp \left( -\frac{\pi \times 0.006 \text{ m} \times 78.8 \text{ W/m}^2 \cdot \text{K} \times 20 \text{ m}}{0.003 \text{ kg/s} \times 1012 \text{ J/kg} \cdot \text{K}} \right)
\]

\[
\frac{15 - T_{m,o}}{(15 - 200)^\circ \text{C}} = 0.999
\]

\[T_{m,o} = 15^\circ \text{C}.\]

**COMMENTS:** (1) With \( T_{m,o} = 15^\circ \text{C} \), find \( \bar{T}_m = 380 \text{ K} \); hence thermophysical properties for the internal flow correlation were evaluated at a reasonable temperature. Note that the gas is cooled from \( 200^\circ \text{C} \) to the ambient air temperature, \( T_{m,o} = T_\infty \), over the 20-m length!

(2) The average wall surface temperature, \( T_s \), follows from an energy balance on the wall surface,

\[
\frac{\bar{T}_m - \bar{T}_s}{\bar{T}_s - T_{\inf}} = \frac{h_i}{h_o}
\]

and substituting numerical values, find \( \bar{T}_s = 90^\circ \text{C} = 363 \text{ K} \), the value we assumed for evaluating \( Pr_s \). Can you draw a thermal circuit to represent this energy balance relation?

(3) When using the Zhukauskus correlation, it is reasonable to evaluate \( Pr_s \) at the \( \bar{T}_m \) for the first trial. For gases the assumption is a safe one, but for liquids, especially oils, additional trials will be required since the Prandtl number may be strongly dependent upon temperature.
**PROBLEM 8.63**

**KNOWN:** Superheated steam passing through thin-walled pipe covered with insulation and suspended in a quiescent air.

**FIND:** Point along pipe surface where steam will begin condensing ($x_1$).

**SCHEMATIC:**

- Insulation, $k = 0.085$ W/m·K, $t = 25$ mm
- Superheated steam, $p = 1$ atm, $u_m = 10$ m/s, $D_i = 0.05$ m, $T_m,i = 120$ °C
- Quiescent air, $T_\infty = 20$ °C, $h_o = 10$ W/m²·K
- $T_s(x_1) = 100$ °C

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible KE, PE and flow work changes, (3) Steam properties may be approximated as those corresponding to saturated conditions.

**PROPERTIES:** Table A.6, Saturated steam ($T_m = (100 + 120)/2 = 110$ °C $= 385$ K): $\rho_g = 0.876$ kg/m³, $c_p,g = 2080$ J/kg·K, $\mu_g = 12.49 \times 10^{-6}$ N·s/m², $k_g = 0.0258$ W/m·K, $Pr_g = 1.004$.

**ANALYSIS:** From Eq. 8.46a, where $T_{m,x}$ is the mean temperature at any distance $x$,

$$\frac{T_\infty - T_{m,x}}{T_\infty - T_{m,i}} = \exp \left( - \frac{P_x}{\dot{m} c_p} U \right)$$

The mass flow rate, with $A_c = \pi D_i^2/4$, is

$$\dot{m} = \rho_g A_c u_m = 0.876 \text{kg/m}^3 \left( \pi (0.050 \text{m})^2 / 4 \right) \times 10 \text{m/s} = 0.0172 \text{kg/s}$$

and for the internal flow,

$$\text{Re}_D = \frac{4\dot{m}}{\pi D_i \mu} = \frac{4 \times 0.0172 \text{kg/s}}{\pi (0.050 \text{m}) \times 12.49 \times 10^{-6} \text{N·s/m}^2} = 35,068.$$ 

Assuming the flow is fully developed, the Dittus-Boelter correlation yields

$$\text{Nu}_D = \frac{h_i D_i}{k} = 0.023 \left( 35,068 \right)^{4/5} (1.004)^{0.3} = 99.58$$

$$h_i = \frac{0.0258 \text{W/m·K}}{0.050 \text{m}} \times 99.58 = 51.4 \text{W/m}^2 \cdot \text{K}$$

Hence, from Eq. 3.31, the overall coefficient for the inner surface is

$$U_i = \left[ \frac{1}{h_i} + \frac{D_i \ln (D_o/D_i)}{2k} + \frac{D_i}{D_o} \frac{1}{h_o} \right]^{-1} = \left[ \frac{1}{51.4} + \frac{(0.050) \ln (0.100/0.050)}{2 \times 0.085} + \frac{0.050}{0.100} \right]^{-1} \text{W/m}^2 \cdot \text{K}$$

$$U_i = \left[ 1.946 \times 10^{-2} + 2.039 \times 10^{-1} + 5.000 \times 10^{-2} \right]^{-1} = 3.66 \text{W/m}^2 \cdot \text{K}.$$ 

Continued...
PROBLEM 8.63 (Cont.)

With condensation occurring when the surface temperature reaches 100°C, the corresponding value of $T_m$ may be determined from the local ($x = x_1$) requirement that

$$U_i \left( \pi D_i \right) \left[ T_m (x_1) - T_\infty \right] = h_i \left( \pi D_i \right) \left[ T_m (x_1) - T_s \right].$$

Hence,

$$T_m (x_1) = \frac{T_\infty - (h_i/U_i) T_s}{1 - (h_i/U_i)} = \frac{20 - (51.4/3.66) 100^\circ C}{1 - (51.4/3.66)} = 107.7^\circ C$$

The distance at which the mean steam temperature is 107.7°C can then be estimated from Eq. (1), where $P = \pi D_i$ and $U = U_i$,

$$\frac{(20 - 107.7)^\circ C}{(20 - 120)^\circ C} = \exp \left( -\frac{\pi (0.050 m) 3.66 W/m^2 \cdot K (x_1)}{0.0172 kg/s \times 2080 J/kg \cdot K} \right)$$

$$x_1 = 8.15 \text{ m}$$

COMMENTS: Note that condensation first occurs at the location for which the surface, and not the mean, temperature reaches 100°C.
PROBLEM 8.64

KNOWN: Length and diameter of air conditioning duct. Inlet temperature of chilled air. Temperature and convection coefficient associated with outer air. Chilled air flowrate.

FIND: Chilled air exit temperature and heat flow rate.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible tube wall conduction resistance, (3) Negligible kinetic and potential energy changes and axial conduction.

PROPERTIES: Table A-4, Air (300K, 1 atm): \( c_p = 1007 \text{ J/kg} \cdot \text{K}, \mu = 184.6 \times 10^{-7} \text{ kg/s} \cdot \text{m}, k = 0.0263 \text{ W/m} \cdot \text{K}, Pr = 0.707. \)

ANALYSIS: The exit temperature may be obtained from Eq. 8.46, where

\[
\bar{U} = \left( h_i^{-1} + h_o^{-1} \right)^{-1}
\]

With \( \text{Re}_D = \left( \frac{4m}{\pi D \mu} \right) = \left( \frac{4 \times 0.05 \text{ kg/s}}{\pi \times 0.3 \text{ m} \times 184.6 \times 10^{-7} \text{ kg/s} \cdot \text{m}} \right) = 11,495 \)

the flow is turbulent and, assuming fully developed conditions over the entire length, the Dittus-Boelter correlation yields

\[
\text{Nu}_D = 0.023 \text{Re}_D^{4/5} \text{Pr}^{0.4} = 0.023 \left( 11,495 \right)^{4/5} \left( 0.707 \right)^{0.4} = 35.5
\]

\[
h_i = \text{Nu}_D \left( k/D \right) = 35.5 \left( 0.0263 \text{ W/m} \cdot \text{K}/0.3 \text{ m} \right) = 31.1 \text{ W/m}^2 \cdot \text{K}
\]

and \( \bar{U} = \left( 3.11^{-1} + 2.0^{-1} \right)^{-1} \left( \text{W/m}^2 \cdot \text{K} \right) = 1.22 \text{ W/m}^2 \cdot \text{K}. \)

Eq. 8.46 yields

\[
T_{m,o} = T_\infty - \left( T_\infty - T_{m,i} \right) \exp \left[ - \left( \pi DL/m c_p \right) \bar{U} \right]
\]

\[
T_{m,o} = 37^\circ\text{C} - 30^\circ\text{C} \exp \left[ - \left( \frac{\pi \times 0.3 \text{ m} \times 15 \text{ m} \times 1.22 \text{ W/m}^2 \cdot \text{K}}{0.05 \text{ kg/s} \times 1007 \text{ J/kg} \cdot \text{K}} \right) \right] = 15.7^\circ\text{C}
\]

and the heat rate is

\[
q = m c_p \left( T_{m,o} - T_{m,i} \right) = 0.05 \text{ kg/s} \times 1007 \text{ J/kg} \cdot \text{K} \times \left( 8.7^\circ\text{C} \right) = 438 \text{ W.}
\]

COMMENTS: The temperature rise of the chilled air is excessive, and the outer surface of the duct should be insulated to reduce \( \bar{U} \) and thereby \( T_{m,o} \) and \( q \).
PROBLEM 8.65

KNOWN: Length, diameter, insulation characteristics and burial depth of a pipe. Ground surface temperature. Inlet temperature, flow rate and properties of oil flowing through pipe.

FIND: (a) An expression for the oil outlet temperature, (b) Oil outlet temperature and pipe heat transfer rate for prescribed conditions, and (c) Design information for trade off between burial depth of pipe (z) and pipe insulation thickness (t) on the heat loss.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Two-dimensional conduction in soil, (4) Negligible pipe wall thermal resistance, (5) Total resistance to heat loss is independent of x.

PROPERTIES: Oil (given): \( \rho_o = 900 \, \text{kg/m}^3, \ c_{p,o} = 2000 \, \text{J/kg} \cdot \text{K}, \nu_o = 8.5 \times 10^{-4} \, \text{m}^2/\text{s}, \ k_o = 0.140 \, \text{W/m} \cdot \text{K}, \ Pr_o = 10^4; \) Soil (given): \( k_s = 0.50 \, \text{W/m} \cdot \text{K}; \) Insulation (given): \( k_i = 0.05 \, \text{W/m} \cdot \text{K}. \)

ANALYSIS: (a) From Eq. 8.36 for a differential control volume in the oil and the rate equation

\[
dq_{\text{conv}} = \dot{m}_o c_{p,o} \, dT_m = dq = (T_s - T_m) / R_{\text{tot}}
\]

where the total resistance is expressed as

\[
R_{\text{tot}} = R_{\text{conv}} + R_{\text{cond},i} + R_{\text{cond},s} = \left( \frac{1}{h \pi D_i} + \frac{\ln(D_0/D_i)}{2 \pi k_i} \right) + \frac{1}{k_s S}
\]

\[
R_{\text{tot}} = \frac{1}{h \pi D_i} + \frac{\ln(D_0/D_i)}{2 \pi k_i} + \frac{\cosh^{-1}(2z/D_0)}{2 \pi k_s}
\]

where, from Table 4.1,

\[
S = 2\pi dx / \cosh^{-1}(2z/D_0)
\]

It follows that

\[
\frac{(T_s - T_m) \, dx}{R_{\text{tot}}} = \dot{m}_o c_{p,o} \, dT_m \quad \quad \quad \quad \frac{dT_m}{T_s - T_m} = \frac{dx}{\dot{m}_o c_{p,o} R'_{\text{tot}}}
\]

Integrating between inlet and outlet conditions

\[
\int_{T_{m,i}}^{T_{m,o}} \frac{dT_m}{T_m - T_s} = \int_0^L \frac{dx}{\dot{m}_o c_{p,o} R'_{\text{tot}}}
\]

Assuming \( R'_{\text{tot}} \) to be independent of x and integrating,

\[
\frac{T_{m,o} - T_s}{T_{m,i} - T_s} = \exp \left( -\frac{L}{\dot{m}_o c_{p,o} R'_{\text{tot}}} \right).
\]

Continued...
(b) To calculate $T_{m,o}$ for the prescribed conditions, begin by evaluating $\bar{h}$, where

$$\text{Re}_D = \frac{4m_o}{\pi D_i \rho \nu} = \frac{4 \times 500 \text{ kg/s}}{\pi (1.2 \text{ m}) 900 \text{ kg/m}^3 \times 8.5 \times 10^{-4} \text{ m}^2/\text{s}} = 694 \quad (4)$$

Hence, the flow is laminar, and with a thermal entry length,

$$\overline{\text{Nu}}_D = 3.66 + \frac{0.0668 (D_i/L) \text{Re}_D \text{Pr}}{1 + 0.04 [(D_i/L) \text{Re}_D \text{Pr}]^{2/3}} \quad (5)$$

$$\text{(D}_i/L) \text{Re}_D \text{Pr} = \left( \frac{1.2}{10^5} \right) (694) 10^4 = 83.3 \quad \overline{\text{Nu}}_D = 6.82$$

$$\bar{h} = \frac{k}{D_i} \frac{6.82}{1.2} = \frac{0.14 \text{ W/m} \cdot \text{K}}{6.82} = 0.80 \text{ W/m}^2 \cdot \text{K}$$

From Eq. (2), the overall thermal resistance is

$$R'_{\text{tot}} = \frac{1}{0.8 \text{ W/m}^2 \cdot \text{K} \pi (1.2 \text{ m})} + \frac{\ln(1.5/1.2)}{2\pi (0.05 \text{ W/m} \cdot \text{K})} + \frac{\cosh^{-1}(4)}{2\pi (0.5 \text{ W/m} \cdot \text{K})}$$

$$R'_{\text{tot}} = (0.33 + 0.71 + 0.66) \text{ K \cdot m/W} = 1.70 \text{ K \cdot m/W}$$

and the oil outlet temperature can be calculated as

$$\frac{T_{m,o} - T_s}{T_{m,i} - T_s} = \exp\left( -\frac{10^5 \text{ m}}{500 \text{ kg/s} \times 2000 \text{ J/kg} \cdot \text{K} \times 1.7 \text{ K} \cdot \text{m/W}} \right) = 0.943$$

$$T_{m,o} = 110.9 \degree \text{C} \quad \text{<}$$

The total rate of heat transfer from the pipeline is then

$$q = \dot{m}_o c_{p,o} \left( T_{m,i} - T_{m,o} \right) \quad (6)$$

$$q = 500 \text{ kg/s} \times 2000 \text{ J/kg} \cdot \text{K} (120 - 110.9)^\circ \text{C} = 9.1 \times 10^6 \text{ W.} \quad \text{<}$$

(c) Using the IHT Workspace with the foregoing equations, an analysis was performed to determine the heat loss, $q$, as a function of burial depth for the range, $1 \leq z \leq 6$ m, for thicknesses of insulation which are -25%, +25%, +50% and 100% that of the base case, $t = r_o - r_1 = 150$ mm.

![Graph showing heat loss as a function of burial depth for different insulation thicknesses.](image-url)
PROBLEM 8.65 (Cont.)

From this information, the operations manager can compare the costs associated with burial depth and insulation thickness with respect to acceptable heat loss.

COMMENTS: (1) Since the thermal entry region is very long, \( x_{\text{fd,t}} \approx 0.05DRe_{\text{p}}, \Pr = 4.16 \times 10^5 \) m, \( h_x \) will be changing with \( x \) throughout the pipe. A more accurate solution would therefore be one in which Eq. (1) is integrated numerically, in a step-by-step fashion. For example, the integration could involve a step width of \( \Delta x = 10^3 \) m, with \( h \) and \( R'_t \) evaluated at each step.

(2) The three contributions to the total thermal resistance are comparable.

(3) IHT version 1.0 doesn’t support inverse hyperbolic functions. To determine the shape factor from Eq. (3), use this approach:

```
// Shape factor:
S = 2 * pi / yy // Eq (2); Table 4.1
cosh (yy) = 2 * z / Do // Inverse hyperbolic function representation
\[
cosh (yy) = 0.5 \times (\exp (yy) + \exp (-yy)) \]
\[
R'conds = 1 / (ks * S) // Thermal resistance
```
**PROBLEM 8.66**

**KNOWN:** Length, diameter, insulation characteristics and burial depth of pipe. Ground surface temperature. Inlet temperature, minimum allowable exit temperature, flow rate and properties of oil flow through pipe.

**FIND:** Effect of soil thermal conductivity and flowrate on heat rate and outlet temperature.

**SCHEMATIC:**

![Diagram](image)

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties, (3) Two-dimensional conduction in soil, (4) Negligible pipe wall thermal resistance, (5) Total resistance to heat loss is independent of x.

**PROPERTIES:** Oil (given):

\[
\begin{align*}
\rho_o &= 900 \text{ kg/m}^3, \\
c_{p,o} &= 2000 \text{ J/kg} \cdot \text{K}, \\
\nu_o &= 8.5 \times 10^{-4} \text{ m}^2/\text{s}, \\
k_o &= 0.140 \text{ W/m} \cdot \text{K}, \\
Pr_o &= 10^4.
\end{align*}
\]

**ANALYSIS:** From the analysis of Problem 8.60, the outlet temperature may be computed from the expression

\[
\frac{T_{m,o} - T_s}{T_{m,i} - T_s} = \exp \left( - \frac{L}{\dot{m}c_p,o R_{tot}'} \right)
\]

where

\[
R_{tot}' = \frac{1}{\bar{h} \pi D_i} + \frac{\ln \left( \frac{D_o}{D_i} \right)}{2 \pi k_i} + \frac{\cosh^{-1} \left( \frac{2z}{D_o} \right)}{2 \pi k_s}
\]

and \(\bar{h}\) is determined from Eq. 8.56. The heat rate may then be obtained from the overall energy balance

\[
q = \dot{m}c_p \left( T_{m,i} - T_{m,o} \right)
\]

Using the *Correlations* Toolpad of IHT to perform the parametric calculations, the following results were obtained.

![Graphs](image)
Due to a reduction in the thermal conduction resistance of the soil with increasing $k_s$, there is a corresponding increase in the heat rate $q$ from the pipe and a reduction in the oil outlet temperature. The heat rate also increases with increasing $\dot{m}$ (due to an increase in $\bar{h}$ and hence a decrease in the convection resistance), but the increase lags that of the flow rate, causing the outlet temperature to increase with increasing $\dot{m}$. Conditions for which $T_{m,o} \geq 110^\circ C$ cannot be achieved for $\dot{m} = 250$ kg/s, but can be achieved for $k_s \leq 0.33$ W/m$\cdot$K and $k_s \leq 0.65$ W/m$\cdot$K for $\dot{m} = 375$ kg/s and 500 kg/s, respectively. The worst case condition corresponds to the smallest value of $\dot{m}$ and the largest value of $k_s$.

Measures to maintain $T_{m,o} \geq 110^\circ C$ could include increasing the burial depth, increasing the insulation thickness, and/or using an insulation of lower thermal conductivity.

**COMMENTS:** The thermophysical properties of oil depend strongly on temperature, and a more accurate solution would account for the effect of variations in $\bar{T}_m$ on the properties.
PROBLEM 8.67

KNOWN: Water flowing through a thin-walled tube is heated by hot gases moving in cross flow over the tube.

FIND: Outlet temperature of the water, T_{m,o}.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Tube wall thermal resistance negligible, (3) Exhaust gas properties those of atmospheric air, (4) KE, PE, flow work changes negligible, (5) Fully developed internal flow, (6) Constant properties.

PROPERTIES: Table A-6, Water \( (\text{assume } T_{m,o} = 50^\circ \text{C}, T_m = (50+30)^\circ \text{C}/2 = 315 \text{ K}) \): \( \rho = 1/\nu_f = 991.1 \text{ kg/m}^3, c_p = 4179 \text{ J/kg} \cdot \text{K}, \mu = 631 \times 10^{-6} \text{ N} \cdot \text{s/m}^2, k = 0.634 \text{ W/m} \cdot \text{K}, \text{Pr} = 4.16; \) Table A-4, Air \( (T_\infty = 225^\circ \text{C} \approx 500 \text{ K}, 1 \text{ atm}) \): \( \nu = 38.79 \times 10^{-6} \text{ m}^2/\text{s}, k = 40.7 \times 10^{-3} \text{ W/m} \cdot \text{K}, \text{Pr} = 0.684. \)

ANALYSIS: This situation may be analyzed using Eq. 8.46 with \( \bar{h}_i + \bar{h}_o \) and \( h_i, h_o \) correspond to coefficients for internal and external flows, respectively. **Internal flow:**

With properties evaluated at \( T_m, \) assuming \( T_{m,o} = 50^\circ \text{C}, \) \( \text{Re}_D = 4m/\pi D \mu = 4 \times 0.25 \text{ kg/s} / \pi \times 0.040 \text{ m} \times 631 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 = 12,611. \) The internal flow is turbulent and fully developed \( (L/D = 100), \) and the Dittus-Boelter correlation for heating conditions \( (T_s > T_m) \) is appropriate,

\[
\bar{h}_i = \frac{k}{D} 0.023 \frac{Re_D^{4/5} Pr^{0.4}}{Pr^{0.6}} = \frac{0.634 \text{ W/m} \cdot \text{K}}{0.040 \text{ m}} \frac{0.023(12,611)^{4/5} (4.16)^{0.4}}{1230 \text{ W/m}^2 \cdot \text{K}}.
\]

For the external flow,

\[
\text{Re}_D = \frac{VD}{\nu} = 100 \text{ m/s} \times 0.040 \text{ m} / 38.79 \times 10^{-6} \text{ m}^2/\text{s} = 1.031 \times 10^5
\]

and from Table 7.4, \( C = 0.26 \) and \( n = 0.6; \) \( \text{Pr} \leq 10, n = 0.37, \) and \( \text{Pr} \approx \text{Pr}_s, \)

\[
\bar{h}_o = \frac{(k/D) C \text{Re}_D^m \text{Pr}^n}{0.040 \text{ m}} \left( \frac{\text{Pr}}{\text{Pr}_s} \right)^{1/4}
\]

\[
\bar{h}_o = \frac{40.7 \times 10^{-3} \text{ W/m} \cdot \text{K}}{0.040 \text{ m}} \times 0.26 \left( 1.031 \times 10^5 \right)^{0.6} \left( 0.684 \right)^{0.37} \left( 1 \right)^{1/4} = 234 \text{ W/m}^2 \cdot \text{K}.
\]

Substituting numerical values into Eq. 8.46 with \( P = \pi D \) and \( U = 197 \text{ W/m}^2 \cdot \text{K}, \)

\[
\frac{T_\infty - T_{m,o}}{T_\infty - T_{m,i}} = \exp \left( -P \frac{L \U}{m \rho c_p} \right) \tag{1}
\]

\[
T_{m,o} = 225^\circ \text{C} - (225 - 30)^\circ \text{C} \exp \left[ -\frac{\pi \times 0.040 \text{ m} \times 4 \text{ m}}{0.25 \text{ kg/s} \times 4179 \text{ J/kg} \cdot \text{K}} \times 197 \text{ W/m}^2 \cdot \text{K} \right] = 47.6^\circ \text{C} \tag{1}
\]

COMMENTS: Note the assumed value of \( T_{m,o} \) to evaluate water properties was reasonable.

Using Eq. (1), replacing \( T_\infty \) and \( U \) with \( T_s \) and \( \bar{h}_i, \) respectively, find \( T_s = 63.2^\circ \text{C}; \) hence, \( \text{Pr}_s(T_s) \approx 0.687. \) The assumption that \( \text{Pr} \approx \text{Pr}_s \) in the Zhukauskas relation is reasonable.
PROBLEM 8.68

KNOWN: Single tube heat exchanger for cooling blood.

FIND: (a) Temperature at which properties are evaluated in estimating $\overline{h}$, (b) Prandtl number for the blood, $\text{Pr}$, (c) Flow condition: laminar or turbulent, (d) Average heat transfer coefficient, $\overline{h}$, for blood flow, (e) Total heat rate, $q$, (f) Required length of tube, $L$, when $U$ is known.

SCHEMATIC:

PROPERTIES: Blood (Given, $\overline{T_m}$): $\rho = 1000 \text{ kg/m}^3$, $\nu = 7 \times 10^{-7} \text{ m}^2/\text{s}$, $k = 0.5 \text{ W/m}\cdot\text{K}$, $c_p = 4000 \text{ J/kg}\cdot\text{K}$.

ASSUMPTIONS: (1) Flow and thermal conditions fully developed, (2) Thermal resistance of tube material is negligible, (3) Overall heat transfer coefficient between blood and water-ice mixture is $U = 300 \text{ W/m}^2\cdot\text{K}$, (4) Constant properties, (5) Negligible heat transfer enhancement associated with coiling.

ANALYSIS: (a) Evaluate properties at $\overline{T_m} = (T_o + T_i)/2 = (40 + 30)\degree\text{C}/2 = 35\degree\text{C}$. <

(b) The Prandtl number is

$$\text{Pr} = \frac{c_p \mu}{k} = \frac{c_p \nu \rho}{k} = \frac{\left( 4000 \text{ J/kg} \cdot \text{K} \times 7 \times 10^{-7} \text{ m}^2/\text{s} \times 1000 \text{ kg/m}^3 \right)}{0.5 \text{ W/m} \cdot \text{K}} = 5.60.$$ <

(c) Calculate Reynolds number as

$$\text{Re}_D = \frac{4 \overline{V}}{\pi D \mu} = \frac{4 \overline{V} \rho}{\pi D \nu} = \frac{4 \overline{V}}{\pi \times 2.5 \times 10^{-3} \text{ m/s} \times 7 \times 10^{-7} \text{ m}^2/\text{s}} = 1213.$$<

Hence, the flow is laminar,

(d) For laminar and fully developed conditions, Eq. 8.55 is the proper correlation,

$$\text{Nu}_D = \overline{h} D/k = 3.66 \quad \overline{h} = 3.66 \times 0.5 \text{ W/m} \cdot \text{K}/2.5 \times 10^{-3} \text{ m} = 732 \text{ W/m}^2\cdot\text{K},$$<

(e) The total heat rate follows from an overall energy balance, Eq. 8.37,

$$q = \dot{m} c_p (T_o - T_i) = \rho \overline{V} c_p (T_o - T_i)$$

$$q = 1000 \text{ kg/m}^3 \left( 10^{-4} \text{ m}^3/\text{min} \times 60 \text{ s/min} \right) 4000 \text{ J/kg} \cdot \text{K} \times (30 - 40)\degree\text{C} = -66.7 \text{ W}.$$<

(f) Using the rate equation, Eq. 8.47, solve for $L$,

$$L = \frac{q}{U \pi D \Delta T_{\overline{h}m}} = \frac{66.7 \text{ W}}{300 \text{ W/m}^2\cdot\text{K} \left( \pi \times 2.5 \times 10^{-3} \text{ m} \right) \times 34.8 \degree\text{C}} = 0.81 \text{ m}$$

where $A = \pi DL$ and $\Delta T_{\overline{h}m} = [(40 - 0)\degree\text{C} - (30 - 0)\degree\text{C}] / \ell n(40/30) = 34.8\degree\text{C}$. <
**PROBLEM 8.69**

**KNOWN:** Flow conditions associated with water passing through a pipe and air flowing over the pipe.

**FIND:** (a) Differential equation which determines the variation of the mixed-mean temperature of the water, (b) Heat transfer per unit length of pipe at the inlet and outlet temperature of the water.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible temperature drop across the pipe wall, (2) Negligible radiation exchange between outer surface of insulation and surroundings, (3) Fully developed flow throughout pipe, (4) Negligible potential and kinetic energy and flow work effects.

**PROPERTIES:** Table A-6, Water \((T_{m,i} = 200^\circ C)\): \(c_{p,w} = 4500 \text{ J/kg} \cdot \text{K}, \mu_w = 134 \times 10^{-6} \text{ N} \cdot \text{s/m}^2,\) \(k_w = 0.665 \text{ W/m} \cdot \text{K}, \text{Pr}_w = 0.91;\) Table A-4, Air \((T_{\infty} = -10^\circ C)\): \(\nu_a = 12.6 \times 10^{-6} \text{ m}^2/\text{s}, k_a = 0.023 \text{ W/m} \cdot \text{K}, \text{Pr}_a = 0.71, \text{Pr}_s \approx 0.7.

**ANALYSIS:** (a) Following the development of Section 8.3.1 and applying an energy balance to a differential element in the water, we obtain

\[ \dot{m} c_{p,w} T_m - \dot{d}q - \dot{m} c_{p,w} (T_m + dT_m) = 0. \]

Hence

\[ \dot{d}q = -\dot{m} c_{p,w} dT_m \]

where

\[ \dot{d}q = U_i dA_i (T_m - T_\infty) = U_i \pi D dx (T_m - T_{\infty}). \]

Substituting into the energy balance, it follows that

\[ \frac{d T_m}{dx} = -\frac{U_i \pi D}{\dot{m} c_p} (T_m - T_{\infty}). \quad (1) \]

The overall heat transfer coefficient based on the inside surface area may be evaluated from Eq. 3.30 which, for the present conditions, reduces to

\[ U_i = \frac{1}{1 + \frac{D}{h_i} + \frac{D}{2k} \left( \frac{D}{D + 2t} \right) + \frac{D}{D + 2t} \frac{1}{h_0}. \quad (2) \]

For the *inner water flow*, Eq. 8.6 gives

\[ \text{Re}_D = \frac{4 \dot{m}}{\pi D \mu_w} = \frac{4 \times 2 \text{ kg/s}}{\pi (1 \text{ m}) \times 134 \times 10^{-6} \text{ kg/s} \cdot \text{m}} = 19,004. \]

Continued …..
PROBLEM 8.69 (Cont.)

Hence, the flow is turbulent. With the assumption of fully developed conditions, it follows from Eq.
8.60 that
\[ h_1 = \frac{k_w}{D} \times 0.023 \frac{Re^{4/5}_D}{Pr^{0.3}_w}. \]  
(3)

For the \textit{external air flow}
\[ Re_D = \frac{V(D+2t)}{v} = \frac{4 \text{ m/s} (1.3 \text{ m})}{12.6 \times 10^{-6} \text{ m}^2/\text{s}} = 4.13 \times 10^5. \]

Using Eq. 7.31 to obtain the outside convection coefficient,
\[ h_o = \frac{k_a}{(D+2t)} \times 0.076 \frac{Re^{0.7}_D}{Pr^{0.37}_a} \left(Pr_a/Pr_s\right)^{1/4}. \]  
(4)

(b) The heat transfer per unit length of pipe at the inlet is
\[ q' = \pi \cdot D \cdot U_i \left(T_{m,i} - T_\infty\right). \]  
(5)

From Eqs. (3 and 4),
\[ h_1 = \frac{0.665 \text{ W/m} \cdot \text{K}}{1 \text{ m}} \times 0.023 (19,004)^{4/5} (0.91)^{0.3} = 39.4 \text{ W/m}^2 \cdot \text{K} \]
\[ h_o = \frac{0.023 \text{ W/m} \cdot \text{K}}{(1.3 \text{ m})} \times 0.076 (4.13 \times 10^5)^{0.7} (0.71)^{0.37} (1)^{1/4} = 10.1 \text{ W/m}^2 \cdot \text{K}. \]

Hence, from Eq. (2)
\[ U_i = \left[ \frac{1}{39.4 \text{ W/m}^2 \cdot \text{K}} + \frac{1 \text{ m}}{0.1 \text{ W/m} \cdot \text{K}} / \ln \left(1.3 \circ \frac{1}{1.3} \times \frac{1}{10.1 \text{ W/m}^2 \cdot \text{K}}\right) \right]^{-1} = 0.37 \text{ W/m}^2 \cdot \text{K} \]

and from Eq. (5)
\[ q' = \pi (1 \text{ m}) \left(0.37 \text{ W/m}^2 \cdot \text{K}\right) (200+10)\circ \text{C} = 244 \text{ W/m}. \]

Since $U_i$ is a constant, independent of $x$, Eq. (1) may be integrated from $x = 0$ to $x = L$. The result is analogous to Eq. 8.42b and may be expressed as
\[ \frac{T_\infty - T_{m,o}}{T_\infty - T_{m,i}} = \exp \left( -\frac{\pi DL}{m c_{p,w} U_i} \right) = \exp \left( -\frac{\pi \times 1 \text{ m} \times 500 \text{ m}}{2 \text{ kg/s} \times 4500 \text{ J/kg} \cdot \text{K}} \times 0.37 \text{ W/m}^2 \cdot \text{K} \right) \]
Hence
\[ \frac{T_\infty - T_{m,o}}{T_\infty - T_{m,i}} = 0.937. \]
\[ T_{m,o} = T_\infty + 0.937 \left(T_{m,i} - T_\infty\right) = 187\circ \text{C}. \]

\textbf{COMMENTS:} The largest contribution to the denominator on the right-hand side of Eq. (2) is made
by the conduction term (the insulation provides 96% of the total resistance to heat transfer). For this
reason the assumption of fully developed conditions throughout the pipe has a negligible effect on the
calculations. Since the reduction in $T_m$ is small (13\circ C), little error is incurred by evaluating all
properties of water at $T_{m,i}$. 
PROBLEM 8.70

KNOWN: Inner and outer radii and thermal conductivity of a teflon tube. Flowrate and temperature of confined water. Heat flux at outer surface and temperature and convection coefficient of ambient air.

FIND: Fraction of heat transfer to water and temperature of tube outer surface.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Fully-developed flow, (3) One-dimensional conduction, (4) Negligible tape contact and conduction resistances.

PROPERTIES: Table A-6, Water (T_m = 290K): µ = 1080 × 10^{-6} kg/s·m, k = 0.598 W/m·K, Pr = 7.56.

ANALYSIS: The outer surface temperature follows from a surface energy balance

\[
q^* = \frac{T_{s,o} - T_\infty}{(h_0/2\pi r_0) - 1} - \left(\ln\left(\frac{r_0}{\eta}\right) + \frac{1}{2\pi \eta} L h_1\right)
\]

\[
q^* = h_0 (T_{s,o} - T_\infty) + \frac{T_{s,o} - T_m}{(r_0/k) \ln(r_0/\eta) + (r_0/\eta) / h_1}.
\]

With \( \text{Re}_D = 4 \dot{m} / (\pi D \mu) = 4 (0.2 \text{kg/s}) / \left[ \pi (0.02 \text{ m}) 1080 \times 10^{-6} \text{ kg/s·m} \right] = 11.789 \)
the flow is turbulent and Eq. 8.60 yields

\[ h_i = (k/D_1) 0.023 \text{Re}_D^{4/5} \text{Pr}^{0.4} = (0.598 \text{ W/m·K}/0.02 \text{ m})(0.023)(11.789)^{4/5} (7.56)^{0.4} = 2792 \text{ W/m}^2·\text{K}. \]

Hence

\[
2000 \text{ W/m}^2 = 25 \text{ W/m}^2·\text{K} (T_{s,o} - 300 \text{ K}) + \frac{T_{s,o} - 290 \text{ K}}{(0.013 \text{ m}/0.35 \text{ W/m·K}) \ln(1.3) + (1.3) / (2792 \text{ W/m}^2·\text{K})}
\]

and solving for \( T_{s,o} \), \( T_{s,o} = 308.3 \text{ K}. \) \( < \)

The heat flux to the air is

\[ q^*_o = h_0 (T_{s,o} - T_\infty) = 25 \text{ W/m}^2·\text{K} (308.3 - 300 \text{ K}) = 207.5 \text{ W/m}^2. \]

Hence, \( q^*_o / q^* = (2000 - 207.5) / 2000 = 0.90. \) \( < \)

COMMENTS: The resistance to heat transfer by convection to the air substantially exceeds that due to conduction in the teflon and convection in the water. Hence, most of the heat is transferred to the water.
**PROBLEM 8.71**

**KNOWN:** Temperature recorded by a thermocouple inserted in a stack containing flue gases with a prescribed flow rate. Diameters and emissivities of thermocouple tube and gas stack. Conditions associated with stack surroundings.

**FIND:** Equations for predicting thermocouple error and error associated with prescribed conditions.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Flue gas has properties of air at $T_g \approx 327^\circ C$, (3) Stack forms a large enclosure about the thermocouple tube and surroundings form a large enclosure around the stack, (4) Stack surface energy balance is unaffected by heat loss to tube, (5) Gas flow is fully developed, (6) Negligible conduction along thermocouple tube, (7) Stack wall is thin.

**PROPERTIES:** Table A-4, Air ($T_g = 600K$, $p_g = 1$ atm): $\rho = 0.58 \text{ kg/m}^3$, $\mu = 305.8 \times 10^{-7} \text{ N} \cdot \text{s/m}^2$, $\nu = 52.7 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 0.0469 \text{ W/mK}$, $Pr = 0.685$.

**ANALYSIS:** Determination of the thermocouple error necessitates determining the gas temperature $T_g$ and relating it to the thermocouple temperature $T_t$. From an energy balance applied to a control surface about the thermocouple,

$$q_{\text{conv}} = q_{\text{rad}} \quad \text{or} \quad h_t A_t (T_g - T_t) = \varepsilon_t \sigma A_t (T_t^4 - T_s^4).$$

Hence

$$T_g = T_t + \frac{\varepsilon_t \sigma}{h_t} (T_t^4 - T_s^4). \quad (1)$$

However, $T_s$ is unknown and must be determined from an energy balance on the stack wall.

$$q_{\text{conv,i}} = q_{\text{conv,o}} + q_{\text{rad}}$$

$$h_i A_s (T_g - T_s) = h_o A_s (T_s - T_{\infty}) + \varepsilon_s \sigma A_s (T_s^4 - T_{\text{sur}}^4)$$

or

$$T_g = T_s + \frac{h_o}{h_i} (T_s - T_{\infty}) + \frac{\varepsilon_s \sigma}{h_i} (T_s^4 - T_{\text{sur}}^4). \quad (2)$$

$T_g$ and $T_s$ may be determined by simultaneously solving Eqs. (1) and (2). For the prescribed conditions

$$Re = \frac{\rho V D_t}{\mu} = \frac{\rho (m_g / \rho \pi D_t^2 / 4) D_t}{\mu} = \frac{4 m_g D_t}{\pi \mu D_t^2} = \frac{4 \times 1 \text{ kg/s} \times 0.01 \text{ m}}{\pi \times 305.8 \times 10^{-7} \text{ N} \cdot \text{s/m}^2 (0.6 \text{ m})^2} = 1157.$$
PROBLEM 8.71 (Cont.)

Assuming \( \frac{Pr}{Pr_s} = 1 \), it follows from the Zhukauskus correlation

\[
\overline{Nu_D} = 0.26Re^{0.6}Pr^{0.37}
\]

where \( C = 0.26 \) and \( m = 0.6 \) from Table 7.4. Hence

\[
h_t = \frac{0.0469 \text{ W/m} \cdot \text{K}}{0.01 \text{ m}} = (1157)^{0.6} (0.685)^{0.87} \times 0.26 = 73 \text{ W/m}^2 \cdot \text{K}.
\]

Hence, from Eq. (1)

\[
T_g = 573 \text{ K} + \frac{0.8 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4}{73 \text{ W/m}^2 \cdot \text{K}} \left( 573^4 - T_s^4 \right) K^4
\]

\[
T_g = 573 \text{ K} + 67 \text{ K} - 6.214 \times 10^{-10} T_s^4 = 640 - 6.214 \times 10^{-10} T_s^4.
\] (1a)

Also,

\[
Re_{Ds} = \frac{4 \dot{m}_g}{\pi D_s \mu} = \frac{4 \times 1 \text{ kg/s}}{\pi (0.6 \text{ m}) 305.8 \times 10^{-7} \text{ N} \cdot \text{s/m}^2} = 6.94 \times 10^4
\]

and the gas flow is turbulent. Hence from the Dittus-Boelter correlation,

\[
h_i = \frac{k}{D_s} Re^{4/5}_{Ds} Pr^{0.3} = \frac{0.0469 \text{ W/m} \cdot \text{K}}{0.6 \text{ m}} \times 0.023 \left( 6.94 \times 10^4 \right)^{4/5} \times (0.685)^{0.3} = 12 \text{ W/m}^2 \cdot \text{K}.
\]

Hence from Eq. (2)

\[
T_g = T_s + \frac{25}{12} (T_s - 300 \text{ K}) + \frac{0.8 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4}{12 \text{ W/m}^2 \cdot \text{K}} \left[ T_s^4 - 300^4 \right] K^4
\]

\[
T_g = T_s + 2.083 T_s - 625 \text{ K} + 3.78 \times 10^{-9} T_s^4 - 30.6 \text{ K} = -655.6 \text{ K} + 3.083 T_s + 3.78 \times 10^{-9} T_s^4.
\] (2a)

Solve Eqs. (1a) and (2a) by trial-and-error. Assume values for \( T_s \) and determine \( T_g \) from (1a) and (2a). Continue until values of \( T_g \) agree.

<table>
<thead>
<tr>
<th>( T_s ) (K)</th>
<th>( T_g ) (K) → (1a)</th>
<th>( T_g ) (K) → (2a)</th>
</tr>
</thead>
<tbody>
<tr>
<td>400</td>
<td>624</td>
<td>674</td>
</tr>
<tr>
<td>375</td>
<td>628</td>
<td>575</td>
</tr>
<tr>
<td>387</td>
<td>626</td>
<td>622</td>
</tr>
<tr>
<td>388</td>
<td>626</td>
<td>626</td>
</tr>
</tbody>
</table>

Hence \( T_s = 388 \text{ K} \), \( T_g = 626 \text{ K} \)

and the thermocouple error is \( T_g - T_1 = 626 \text{ K} - 573 \text{ K} = 53^\circ \text{C} \).

**COMMENTS:** The thermocouple error results from radiation exchange between the thermocouple tube and the cooler stack wall. Anything done to \( \uparrow T_s \) would \( \downarrow \) this error (e.g., \( \downarrow h_o \) or \( \uparrow T_{\infty} \) and \( T_{\text{sur}} \)). The error also \( \downarrow \) with \( \uparrow h_t \). The error could be reduced by installing a radiation shield around the tube.
**PROBLEM 8.72**

**KNOWN:** Platen heated by hot ethylene glycol flowing through tubing arrangement with spacing S soldered to lower surface. Top surface exposed to convection process.

**FIND:** Tube spacing S and heating fluid temperature \( T_m \) which will maintain the top surface at 45 ± 0.25°C.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions; (2) Lower surface is insulated, all heat transfer from hot fluid is into platen; (3) Copper tube is thick-walled such that interface between solder and platen is isothermal; (4) Fully developed flow conditions in tube.

**PROPERTIES:** *Table A.4*, Ethylene glycol (\( T_m = 60^\circ \text{C} \)): \( \mu = 0.00522 \text{ N}\cdot\text{s}/\text{m}^2 \), \( k = 0.2603 \text{ W}/\text{m}\cdot\text{K} \).

**ANALYSIS:** Begin the analysis by setting up a nodal mesh (9 × 6) to represent the platen experiencing convection on the top surface (\( T_{\infty}, h \)) while the two side boundaries are symmetry adiabats. On the lower surface, nodes 46 and 47 represent the isothermal platen-solder interface maintained at \( T_o \) by the hot fluid. The remaining nodes (49-54) are insulated on their lower boundary.

The heat rate supplied by the tube to the platen can be expressed as

\[
q_{cv} = 0.5h_o \left( \pi D_i \right) \left( T_m - T_o \right)
\]  

(1)

From energy balances about nodes 46 and 47, the heat rate into the platen by conduction can be expressed as

\[
q_{cd} = q'_a + q'_b + q'_c
\]

(2)

\[
q'_a = k \left( \Delta x / 2 \right) \left( T_{46} - T_{37} \right) / \Delta y
\]

(3)

Continued...
PROBLEM 8.72 (Cont.)

\[
q'_b = k \left( \Delta x \right) \left( T_{47} - T_{38} \right) / \Delta y
\]
(4)

\[
q'_c = k \left( \Delta y / 2 \right) \left( T_{47} - T_{48} \right) / \Delta x
\]
(5)

and we require that

\[
q'_{cd} = q'_{cv}
\]
(6)

The convection coefficient for internal flow can be estimated from a correlation assuming fully developed flow. First, characterize the flow with

\[
Re_D = \frac{4m}{\pi D_i \mu} = \frac{4 \times 0.06 \text{ kg/s}}{\pi \left( 0.008 \text{ m} \right) 0.00522 \text{ N.s/m}^2} = 1829
\]

and since it is laminar,

\[
Nu_D = \frac{h_o D_i}{k} = 3.66
\]

\[
h_o = 3.66 \times 0.2603 \text{ W/m.K} / 0.008 \text{ m} = 119.1 \text{ W/m.K}
\]

where properties are evaluated at \( T_m \). Using the \textit{IHT Finite-Difference Tool for Two-Dimensional Steady-State Conditions} and the \textit{Properties Tool} for Ethylene Glycol, along with the foregoing rate equations and energy balances, Eqs. (1-6), a model was developed to solve for the temperature distribution in the platen. In the solution, we determined what hot fluid temperature was required to maintain \( T_1 = 45 \degree C \). Two trials were run. In the first, the nodal arrangement was as shown above \((9 \times 6)\) for which \( S/2 = (9 - 1) \Delta x = 42.67 \text{ mm} \) with \( \Delta x = 2D_i / 3 = 5.33 \text{ mm} \) and \( \Delta y = w / 5 = 5 \text{ mm} \). In the second trial, we repositioned the right-hand symmetry adiabat to pass vertically through the nodes 6-51 so that now the nodal mesh is \((6 \times 6)\) and \( S/2 = (6 - 1) \Delta x = 26.65 \text{ mm} \) with \( \Delta x \) and \( \Delta y \) remaining the same. The results of the trials are tabulated below.

<table>
<thead>
<tr>
<th>Trial</th>

</tbody>
</table>

From the trial 2 results, the surface temperature uniformity is \( (T_1 - T_6) = 0.5 \degree C \) which satisfies the \( \pm 0.25 \degree C \) requirement. So that suitable tube spacing and fluid temperature are

\[
S = 53 \text{ mm} \quad \quad T_m = 85 \degree C
\]

**COMMENTS:**

1. Recognize that the grid spacing is quite coarse and good practice demands that we repeat the analysis decreasing the nodal spacing until no further changes are seen in \( T_m \).

2. In the first trial, note that \( T_m = 105 \degree C \) which of course, is not possible.
PROBLEM 8.73

KNOWN: Features of tubing used in a ground source heat pump. Temperature of surrounding soil. Fluid inlet temperature and flowrate.

FIND: (a) Effect of tube length on outlet temperature, (b) Recommended tube length and the effect of variations in the flowrate.

SCHEMATIC:

Polyethylene tubing
(\( t = 8 \text{ mm}, k_f = 0.47 \text{ W/m-K} \))

\( T_s = 10 ^\circ \text{C} \)

\( T_{m,o} \)

\( D_i = 25 \text{ mm} \)

\( T_{m,i} = 0 ^\circ \text{C} \)

\( m = 0.03 \text{ kg/s} \)

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Negligible conduction resistance in soil, (4) Negligible KE, PE and flow work changes, (5) Fluid properties correspond to those of water.

PROPERTIES: Table A.6 (assume \( T_m = 277 \text{ K} \)): \( c_p = 4206 \text{ J/kg-K}, \mu = 1560 \times 10^{-6} \text{ N-s/m}^2, k = 0.577 \text{ W/m-K}, Pr = 11.44. \)

ANALYSIS: (a) For the prescribed conditions, \( Re_D = 4\bar{m}/\pi D_i \mu = 4(0.03 \text{ kg/s})/\pi (0.025 \text{ m})1560 \times 10^{-6} \text{ N-s/m}^2 = 980 \) and the flow is laminar. Assuming thermal entry length conditions, which is reasonable for \( Pr = 11.44 \), Eq. 8.56 may be used to determine the average convection coefficient

\[
\overline{Nu_D} = 3.66 + \frac{0.0668(D/L)Re_D Pr}{1 + 0.04[(D/L)Re_D Pr]^{2/3}}
\]

With \( T_s \) used in lieu of \( T_m \), Eq. 8.46b may be used to determine \( T_{m,o} \),

\[
\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp \left( -\frac{L}{mc_pR_{tot}'} \right)
\]

where \( R_{tot}' \) accounts for the convection and tube wall conduction resistances,

\[
R_{tot}' = R_{cvn}' + R_{cnd}' = \left(1/\pi D_i h\right) + \ln \left(D_o/D_i\right)/2\pi k_f
\]

and

\( D_o = D_i + 2t = 41 \text{ mm} \).

Using the Correlations and Properties Toolpads of IHT, the following results were obtained for the effect of the tube length \( L \) on \( T_{m,o} \).

Continued...
The longer the tube the larger the rate of heat extraction from the soil, and for \( \dot{m} = 0.030 \text{ kg/s} \), the temperature rise of \( \Delta T = (T_{m,o} - T_{m,i}) = 6^\circ\text{C} \) is well below the maximum possible value of \( \Delta T_{\text{max}} = 10^\circ\text{C} \).

(b) The length should be at least 50 m long. If the flowrate were reduced by 50\% (\( \dot{m} = 0.015 \text{ kg/s} \)), the corresponding temperature rise would be close to \( \Delta T_{\text{max}} \) and \( L = 50 \text{ m} \) would be close to optimal. However, for the nominal flowrate and a 50\% increase from the nominal, the length should exceed 50 m to recover more heat and provide a heat pump inlet temperature which is closer to the maximum possible value.

**COMMENTS:** In practice, the tube surface temperature would be less than 10\(^\circ\text{C} \) (if the temperature of the soil well removed from the tube were at 10\(^\circ\text{C} \)), thereby reducing the heat extraction rate and \( T_{m,o} \).
PROBLEM 8.74

KNOWN: Reynolds numbers for fully developed turbulent flow of water in a smooth circular tube.

FIND: Nusselt numbers based on the Colburn, Petukhov and Gnielinski correlations.

SCHEMATIC:

ANALYSIS: The correlations are

\textit{Colburn}, Equation 8.59,
\[ \text{Nu}_D = 0.023 \text{Re}_D^{4/5} \text{Pr}^{1/3} \]

\textit{Petukhov}, Equation 8.62,
\[ \text{Nu}_D = \frac{(f/8) \text{Re}_D \text{Pr}}{1.07 + 12.7 (f/8)^{1/2} \left( \text{Pr}^{2/3} - 1 \right)} \]
\[ f = (1.82 \log_{10} \text{Re}_D - 1.64)^{-2} \]

\textit{Gnielinski}, Equation 8.63,
\[ \text{Nu}_D = \frac{(f/8)(\text{Re}_D - 1000)\text{Pr}}{1 + 12.7 (f/8)^{1/2} \left( \text{Pr}^{2/3} - 1 \right)} \]
\[ f = (0.79 \ln \text{Re}_D - 1.64)^{-2} \]

It follows that:

<table>
<thead>
<tr>
<th>Correlation</th>
<th>\text{Re}_D</th>
<th>4000</th>
<th>\text{10}^4</th>
<th>\text{10}^5</th>
</tr>
</thead>
<tbody>
<tr>
<td>Colburn</td>
<td></td>
<td>31.8</td>
<td>66.2</td>
<td>417.9</td>
</tr>
<tr>
<td>Petukhov</td>
<td></td>
<td>40.0</td>
<td>81.2</td>
<td>549.5</td>
</tr>
<tr>
<td>Gnielinski</td>
<td></td>
<td>30.0</td>
<td>75.0</td>
<td>560.0</td>
</tr>
</tbody>
</table>

\textbf{COMMENTS:} The Colburn equation does well in the transitional region (\text{Re}_D \leq \text{10}^4), where the Gnielinski equation provides the best predictions, but can significantly underpredict the Nusselt number under fully turbulent conditions.
PROBLEM 8.75

KNOWN: Effect of entry length on average Nusselt number for turbulent flow in a tube.

FIND: Ratio of average to fully developed Nusselt numbers for prescribed conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Sharp edged inlet, (2) Combined entry region.

ANALYSIS: From Eq. 8.64,

\[
\frac{\overline{Nu_D}}{Nu_{D,fd}} = 1 + \frac{C}{(x/D)^m}
\]

and with \( C = 24R_e^D - 0.23 \) and \( m = 0.815 - 2.08 \times 10^{-6}R_eD \),

\[
\frac{\overline{Nu_D}}{Nu_{D,fd}} = 1 + \frac{24R_e^D - 0.23}{(x/D)(0.815 - 2.08 \times 10^{-6}R_eD)}
\]

It follows that

<table>
<thead>
<tr>
<th>( \frac{\overline{Nu_D}}{Nu_{D,fd}} )</th>
<th>( R_eD )</th>
<th>( \frac{D}{D\zeta} )</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.464</td>
<td>( 10^4 )</td>
<td>10</td>
</tr>
<tr>
<td>1.112</td>
<td>( 10^4 )</td>
<td>60</td>
</tr>
<tr>
<td>1.420</td>
<td>( 10^5 )</td>
<td>10</td>
</tr>
<tr>
<td>1.142</td>
<td>( 10^5 )</td>
<td>60</td>
</tr>
</tbody>
</table>

COMMENTS: The assumption \( \overline{Nu_D} = Nu_{fd} \) for \( x/D = 10 \) would result in underprediction of \( \overline{Nu_D} \) by approximately 45%. The underprediction is only approximately 10% for \( x/D = 60 \).
PROBLEM 8.76

KNOWN: Fluid enters a thin-walled tube of 5-mm diameter and 2-m length with a flow rate of 0.04 kg/s and temperature of \( T_{m,i} = 85^\circ C \); tube surface temperature is maintained at \( T_s = 25^\circ C \); and, for this base operating condition, the outlet temperature is \( T_{m,o} = 31.1^\circ C \).

FIND: The outlet temperature if the flow rate is doubled?

SCHEMATIC:

ASSUMPTIONS: (1) Flow is fully developed and turbulent, (2) Fluid properties are independent of temperature, and (3) Constant surface temperature cooling conditions.

ANALYSIS: For the base operating condition (b), the rate equation, Eq. 8.42b, with \( C = \dot{m} \cdot c_p \), the capacity rate, is

\[
\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp \left( -\frac{PL \cdot h_b}{C_b} \right)
\]

Substituting numerical values, with \( P = \pi D \), find the ratio, \( h_b / C_b \),

\[
\frac{25 - 31.1}{25 - 85} = \exp \left[ \pi \times 0.005 \times 2 \times 2 \left( h_b / C_b \right) \right]
\]

\[
h_b / C_b = 72.77 \text{ m}^{-2}
\]

For the new operating condition (n), the flow rate is doubled, \( C_n = 2C_b \), and the convection coefficient scales according to the Dittus-Boelter relation, Eq. 8.60,

\[
\bar{h} \propto \text{Re}^{0.8} \cdot D^{0.8}
\]

\[
\bar{h}_n = 2^{0.8} \bar{h}_b \quad \text{and} \quad \left( \frac{h_n}{C_n} \right) = 2^{0.8} / 2 \left( h_b / C_b \right)
\]

Using the rate equation for the new operating condition, find

\[
\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp \left( -\frac{PL \cdot h_n}{C_n} \right) = \exp \left[ -\pi \times 0.005 \times 2 \times 0.871 \left( h_b / C_b \right) \right]
\]

\[
\frac{25 - T_{m,o}}{25 - 85} = \exp \left[ -\pi \times 0.005 \times 2 \times 0.871 \times 72.77 \text{ m}^{-2} \right]
\]

\[
T_{m,o} = 33.2^\circ C
\]
PROBLEM 8.77

KNOWN: Flow rate and inlet temperature of air passing through a rectangular duct of prescribed dimensions and surface heat flux.

FIND: Air and duct surface temperatures at outlet.

SCHEMATIC:

![Diagram of air flow through a duct with dimensions and heat flux](image)

ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform surface heat flux, (3) Constant properties, (4) Atmospheric pressure, (3) Fully developed conditions at duct exit, (6) Negligible KE, PE and flow work effects.

PROPERTIES: Table A-4, Air \( \bar{T}_m = 300\text{K}, 1\text{ atm} \): \( c_p = 1007\text{ J/kg K}, \mu = 184.6 \times 10^{-7}\text{ N s/m}^2 \), \( k = 0.0263\text{ W/m K}, \text{Pr} = 0.707 \).

ANALYSIS: For this uniform heat flux condition, the heat rate is

\[
q = q^* A_s = q^* \left[ 2(L \times W) + 2(L \times H) \right]
\]

\[
q = 600\text{ W/m}^2 \left[ 2(1\text{m} \times 0.016\text{m}) + 2(1\text{m} \times 0.004\text{m}) \right] = 24\text{ W}.
\]

From an overall energy balance

\[
\frac{\bar{T}_{m,o} - \bar{T}_{m,i}}{m} = \frac{24\text{ W}}{3 \times 10^{-4}\text{ kg/s} \times 1007\text{ J/kg K}} = 379\text{ K}.
\]

The surface temperature at the outlet may be determined from Newton’s law of cooling, where

\[
T_{s,o} = \bar{T}_{m,o} + \frac{q^*}{h}.
\]

From Eqs. 8.67 and 8.1

\[
D_h = \frac{4A_c}{P} = \frac{4(0.016\text{m} \times 0.004\text{m})}{2(0.016\text{m} + 0.004\text{m})} = 0.0064\text{ m}
\]

\[
Re_D = \frac{\rho u_m D_h}{\mu} = \frac{\bar{m} D_h}{A_c \mu} = \frac{3 \times 10^{-4}\text{ kg/s} (0.0064\text{m})}{64 \times 10^{-6}\text{ m}^2 \left( 184.6 \times 10^{-7}\text{ N s/m}^2 \right)} = 1625.
\]

Hence the flow is laminar, and from Table 8.1

\[
h = \frac{k}{D_h} \left( \frac{0.0263\text{ W/m K}}{0.0064\text{ m}} \right) = 5.33 = 22\text{ W/m}^2 \cdot \text{K}
\]

\[
T_{s,o} = 379\text{ K} + \frac{600\text{ W/m}^2}{22\text{ W/m}^2 \cdot \text{K}} = 406\text{ K}.
\]

COMMENTS: The calculations should be reperformed with properties evaluated at \( \bar{T}_m = 340\text{ K} \). The change in \( \bar{T}_{m,o} \) would be negligible, and \( T_{s,o} \) would decrease slightly.
**PROBLEM 8.78**

**KNOWN:** Flow rate and temperature of air entering a triangular duct of prescribed dimensions and surface temperature.

**FIND:** Air outlet temperature.

**SCHEMATIC:**

![Diagram of air flow through a triangular duct with specified dimensions and temperatures]

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties, (3) Uniform surface temperature, (4) Fully developed conditions throughout, (5) Air is at atmospheric pressure, (6) Negligible potential and kinetic energy and flow work effects.

**PROPERTIES:** Table A-4, Air (assume $\bar{T}_{m} = 325$K, 1 atm): $c_p = 1008$ J/kg·K, $\mu = 196.4 \times 10^{-7}$ N·s/m$^2$, $k = 0.0282$ W/m·K, $Pr = 0.707$.

**ANALYSIS:** From Eqs. 8.67 and 8.1

\[
\frac{D_h}{P} = 4 \left( \frac{A_c}{3(0.02m)} \right) = 0.0115 \text{ m}
\]

\[
Re_D = \frac{\rho u_m D_h}{\mu} = \frac{m D_h}{A_c \mu} = \frac{4 \times 10^{-4} \text{ kg/s}(0.0115 \text{ m})}{1.73 \times 10^{-4} \text{ m}^2 \left( 196.4 \times 10^{-7} \text{ N·s/m}^2 \right)} = 1354.
\]

Hence the flow is laminar and from Table 8.1,

\[
h = \frac{k}{D_h} = 2.47 = \frac{0.0282 \text{ W/m·K}}{0.0115 \text{ m}} = 6.1 \text{ W/m}^2·\text{K}.
\]

From Eq. 8.42b it follows that, with $P = 3$ W,

\[
T_{m,o} = T_s - (T_s - T_{m,i}) \exp \left( -\frac{PL}{m c_p h} \right)
\]

\[
T_{m,o} = 100^\circ \text{C} - (100^\circ \text{C} - 27^\circ \text{C}) \exp \left( -\frac{3 \times 0.02m \times 2m \times 6.1 \text{ W/m}^2·\text{K}}{4 \times 10^{-4} \text{ kg/s} \times 1008 \text{ J/kg·K}} \right)
\]

\[
T_{m,o} = 88^\circ \text{C}.
\]

**COMMENTS:** With $T_{m,o} = 88^\circ \text{C}$, $T_m = 330$K and there is no need to re-evaluate the properties.
PROBLEM 8.79

KNOWN: Temperature and velocity of gas flow between parallel plates of prescribed surface temperature and separation. Thickness and location of plate insert.

FIND: Heat flux to the plates (a) without and (b) with the insert.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible radiation, (3) Gas has properties of atmospheric air, (4) Plates are of infinite width W, (5) Fully developed flow.

PROPERTIES: Table A-4, Air (1 atm, \(T_m = 1000K\)): \(\rho = 0.348 \text{ kg/m}^3\), \(\mu = 424.4 \times 10^{-7} \text{ kg/s \cdot m}\), \(k = 0.0667 \text{ W/mK}\), \(Pr = 0.726\).

ANALYSIS: (a) Based upon the hydraulic diameter \(D_h\), the Reynolds number is

\[
Re_{D_h} = \frac{\rho \ u_m \ D_h}{\mu} = \frac{0.348 \text{ kg/m}^3 \times (60 \text{ m/s}) \times 0.08 \text{ m}}{424.4 \times 10^{-7} \text{ kg/s \cdot m}} = 39,360.
\]

Since the flow is fully developed and turbulent, use the Dittus-Boelter correlation,

\[
Nu_D = 0.023 \left( \frac{Re_{D_h}^{4/5}}{Pr^{0.3}} \right) = 0.023 \left( \frac{39,360^{4/5}}{(0.726)^{0.3}} \right) = 99.1
\]

\[
h = \frac{k}{Nu_D} \frac{h}{D_h} = \frac{0.0667 \text{ W/mK}}{0.08 \text{ m}} = 82.6 \text{ W/m}^2 \cdot \text{K}
\]

\[
q^* = h(T_m - T_s) = 82.6 \text{ W/m}^2 \cdot \text{K}\left(1000 - 350\right) \text{K} = 53,700 \text{ W/m}^2.
\]

(b) From continuity,

\[
\dot{m} = (\rho \ u_m A_a) = (\rho \ u_m A_b) = \frac{u_m}{u_m} = \frac{u_m}{A} = \frac{60 \text{ m/s}}{40/20} = 120 \text{ m/s}.
\]

For each of the resulting channels, \(D_h = 0.02 \text{ m}\) and

\[
Re_{D_h} = \frac{\rho \ u_m \ D_h}{\mu} = \frac{0.348 \text{ kg/m}^3 \times (120 \text{ m/s}) \times 0.02 \text{ m}}{424.4 \times 10^{-7} \text{ kg/s \cdot m}} = 19,680.
\]

Since the flow is still turbulent,

\[
Nu_D = 0.023\left(19,680\right)^{4/5} (0.726)^{0.3} = 56.9
\]

\[
h = \frac{56.9 \left(0.0667 \text{ W/mK}\right)}{0.02 \text{ m}} = 189.8 \text{ W/m}^2 \cdot \text{K}
\]

\[
q^* = 189.8 \text{ W/m}^2 \cdot \text{K}\left(1000 - 350\right) \text{K} = 123,400 \text{ W/m}^2.
\]

COMMENTS: From the Dittus-Boelter equation,

\[
h_b/h_a = \left(\frac{u_{m,b}}{u_{m,a}}\right)^{0.8} \left(\frac{D_{h,a}}{D_{h,b}}\right)^{0.2} = (2)^{0.8} \left(4\right)^{0.2} = 1.74 \times 1.32 = 2.30.
\]

Hence, heat transfer enhancement due to the insert is primarily a result of the increase in \(u_m\) and secondarily a result of the decrease in \(D_h\).
**PROBLEM 8.80**

**KNOWN:** Temperature, pressure and flow rate of air entering a rectangular duct of prescribed dimensions and surface temperature.

**FIND:** Air outlet temperature and duct heat transfer rate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties, (3) Uniform surface temperature, (4) Fully developed flow throughout, (5) Negligible potential and kinetic energy and flow work effects.

**PROPERTIES:** Table A-4, Air (assume $T_m = 325$ K, 1 atm): $c_p = 1008$ J/kg·K, $\mu = 196.4 \times 10^{-7}$ N·s/m$^2$, $k = 0.0282$ W/m·K, $Pr = 0.707$.

**ANALYSIS:** From Eqs. 8.67 and 8.1,

$$D_h = \frac{4 A_c}{P} = \frac{4 \times (0.15 \times 0.075) \text{m}^2}{2(0.15 + 0.075) \text{m}} = 0.10 \text{ m}$$

$$Re_D = \frac{\rho \frac{u_m D_h}{\mu}}{\mu} = \frac{\dot{m} D_h}{A_c \mu} = \frac{0.1 \text{ kg/s}(0.1 \text{ m})}{(0.15 \text{m} \times 0.075 \text{m})196.4 \times 10^{-7} \text{ N·s/m}^2} = 45,260.$$ 

Hence the flow is turbulent, and from Eq. 8.60

$$h = \frac{k}{D_h} Re_D^{4/5} \frac{Pr^{0.4}}{0.1 \text{ m}} = 0.0282 \text{ W/m·K} \frac{0.023(45,260)^{4/5} (0.707)^{0.4}}{0.1 \text{ m}} = 30 \text{ W/m}^2 \cdot \text{K}.$$ 

From Eq. 8.42b, with $P = 2(W + H)$,

$$T_{m,o} = T_s + (T_s - T_{m,i}) \exp \left( -\frac{PL}{\dot{m} c_p h} \right)$$

$$T_{m,o} = 400 \text{ K} - (400 - 285) \text{ K} \exp \left[ -\frac{2(0.15 \text{m} + 0.075 \text{m})2 \text{m}(30 \text{W/m}^2 \cdot \text{K})}{0.1 \text{ kg/s} \times 1008 \text{ J/kg·K}} \right]$$

$$T_{m,o} = 312 \text{ K}$$

and from Eq. 8.37

$$q = \dot{m} c_p \left( T_{m,o} - T_{m,i} \right) = 0.1 \text{ kg/s} \times 1008 \text{ J/kg·K} (312 - 285) \text{ K} = 2724 \text{ W}.$$ 

**COMMENTS:** (1) The calculations may be checked by determining $q$ from Eqs. 8.44 and 8.45. We obtain $\Delta T_{m} = 101^\circ$C and $q = 2724$ W.

(2) $\bar{T}_m$ has been over-estimated. The calculations should be repeated with properties evaluated at $\bar{T}_m = 299$ K.
PROBLEM 8.81

KNOWN: Dimensions of semi-circular copper tubes in contact at plane surfaces. Thermal contact resistance. Tube flow conditions.

FIND: (a) Heat rate per unit tube length, and (b) The effect on the heat rate when the fluids are ethylene glycol, the exchanger tube is fabricated from an aluminum alloy, or the exchanger tube thickness is increased.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Adiabatic outer surface, (4) Fully developed flow, (5) Negligible heat loss to surroundings.

PROPERTIES: Table A.1, Copper (T ≈ 300 K): k = 400 W/m·K; Table A.6, Water (290 K): µ = 1080 × 10^-6 N·s/m², k = 0.598 W/m·K, Pr = 7.56; (330 K): µ = 489 × 10^-6 N·s/m², k = 0.65 W/m·K, Pr = 3.15; (given): µ = 800 × 10^-6 kg/s·m, k = 0.625 W/m·K, Pr = 5.35.

ANALYSIS: (a,b) Heat transfer from the hot to cold fluids is enhanced by conduction through the semi-circular portions of the tube walls. The walls may be approximated as straight fins with an insulated tip, and the thermal circuit is shown below.

Note that, since each semi-circular surface is insulated on one side, surfaces may be combined to yield a single fin of thickness 2t with convection on both sides. Also, due to the equivalent geometry and the assumption of constant properties, there is symmetry on opposite sides of the contact resistance. From the thermal circuit, the heat rate is

\[ q' = \frac{T_{h,m} - T_{c,m}}{R'_{tot}} \]  

(1)

For flow through the semi-circular tube,

\[ \text{Re}_D = \frac{\rho u_m D_h}{\mu} = \frac{\dot{m}D_h}{A_c \mu} = \frac{4\dot{m}A_c}{A_c \mu} = \frac{4\dot{m}}{(2\pi + \pi r_i)\mu} \]  

(2)

\[ \text{Re}_D = \frac{4 \times 0.2 \text{ kg/s}}{(2 + \pi)0.02 \text{ m} \times 800 \times 10^{-6} \text{ kg/s·m}} = 9725 \]

the flow is turbulent. Using the Colburn correlation,

\[ \text{Nu}_D = 0.023 \text{Re}_D^{4/5} \text{Pr}^{1/3} = 0.023(9725)^{4/5}(5.35)^{1/3} = 62.4 \]  

(3)

Continued...
PROBLEM 8.81 (Cont.)

\[ D_h = \frac{\frac{4A_c}{P}}{\frac{4\left(\pi r_i^2/2\right)}{(\pi + 2) \bar{r}_i}} = \frac{2\pi}{\pi + 2} \quad 0.02 \text{ m} = 0.0244 \text{ m} \quad (4) \]

\[ h = \frac{k}{D_h} \frac{1}{\frac{0.02}{0.0244}} = 62.4 \quad 0.625 \quad 1600 \frac{\text{W}}{\text{m}^2 \cdot \text{K}}. \quad (5) \]

Find now values for the thermal resistance of the circuit.

\[ R_\text{conv} = \frac{1}{2\theta_h} = \frac{1}{(0.04 \text{ m})(1600 \frac{\text{W}}{\text{m}^2 \cdot \text{K}})} = 0.0156 \text{ m} \cdot \text{K/W} \quad (6) \]

\[ R_\text{fin} = \frac{\theta_b}{qf} = \frac{1}{(hP'kA_c')^{1/2} \tanh (hP/kA_c)L} \quad (7) \]

\[ L = \pi r_i/2 = \pi (0.01 \text{ m}) = 0.0314 \text{ m} \quad A_c = 2t \cdot 1 \text{ m} = 0.006 \text{ m}^2 \quad P \approx 2.1 \text{ m} \quad (8,9,10) \]

\[ (hP'kA_c')^{1/2} = \left(1600 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} \cdot \text{K} \times 2 \text{ m} / \text{m} \times 400 \frac{\text{W}}{\text{m} \cdot \text{K}} \times 0.006 \text{ m}^2 / \text{s} \right)^{1/2} = 87.6 \frac{\text{W}}{\text{K} \cdot \text{m}} \]

\[ (hP/kA_c)^{1/2} L = \left(1600 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} \cdot \text{K} \times 2 \text{ m} / \text{m} \times 400 \frac{\text{W}}{\text{m} \cdot \text{K}} \times 0.006 \text{ m}^2 \right)^{1/2} \quad 0.0314 \text{ m} = 1.15 \]

\[ R_\text{fin} = \frac{1}{87.6 \frac{\text{W}}{\text{m} \cdot \text{K}} (0.817)} = 0.0140 \text{ m} \cdot \text{K/W} \quad (11) \]

\[ R_\text{cond} = \frac{t}{2kr_i} = \frac{0.003 \text{ m}}{2(400 \frac{\text{W}}{\text{m} \cdot \text{K}})(0.02 \text{ m})} = 1.875 \times 10^{-4} \text{ m} \cdot \text{K/W} \quad (12) \]

\[ R_{t,c} = \frac{R_{t,c}'}{2\theta_i} = \frac{10^{-5} \text{ m}^2 \cdot \text{K/W}}{2(0.02 \text{ m})} = 2.5 \times 10^{-4} \text{ m} \cdot \text{K/W} \quad (13) \]

The equivalent resistance of the parallel circuit is

\[ R'_\text{eq} = \left( R_{\text{fin}}^{-1} + R_{\text{conv}}^{-1} \right)^{-1} = \left(71.4 \frac{\text{W}}{\text{m} \cdot \text{K}} + 64.1 \frac{\text{W}}{\text{m} \cdot \text{K}} \right)^{-1} = 7.38 \times 10^{-3} \text{ m} \cdot \text{K/W} \quad (14) \]

Hence

\[ R'_\text{tot} = 2 \left( R'_\text{eq} + R'_\text{cond} \right) + R'_{t,c} \quad (15) \]

\[ R'_\text{tot} = \left[ 2 \left( 7.38 \times 10^{-3} + 1.875 \times 10^{-4} \right) + 2.5 \times 10^{-4} \right] \text{m} \cdot \text{K/W} = 0.0154 \text{ m} \cdot \text{K/W} \]

\[ q' = \frac{(330 - 290) \text{K}}{0.0154 \text{ m} \cdot \text{K/W}} = 2600 \frac{\text{W}}{\text{m}}. \quad < \]

(c) Using the IHT Workspace with the foregoing equations, analyses were performed and the results summarized in the table below. The “Conditions” are described below; the “Change” is relative to the base case condition.

*Conditions: change from base case
- Base case - water, copper ($k = 400$ W/m·K), $t = 3$ mm
- Ethylene glycol - ethylene glycol instead of water
- Aluminum alloy - alloy ($k = 177$ W/m·K) instead of copper
- Thicker tube - $t = 4$ mm instead of 3 mm

As expected, using ethylene glycol as the working fluid would decrease the heat rate. Note that $R'_{\text{conv}}$ is the dominate resistance since the convection coefficient is considerably reduced compared to that with water. Using aluminum alloy, rather than copper, as the tube material reduces the heat rate by 14%. Conduction-convection (fin) in the tube wall is important as can be seen by examining the change in $R'_{\text{fin}}$ relative to the base condition. Increasing the tube wall thickness for the copper tube exchanger from 3 to 4 mm had only a marginal positive effect on the heat rate.

**COMMENTS:** A more accurate calculation would account for the absence of symmetry about the contact plane. Evaluation of water properties at $T_{h,m} = 330$ K and $T_{c,m} = 290$ K yields $h_h = 2060$ W/m²·K and $h_c = W/m²·K$. 
PROBLEM 8.82

KNOWN: Heat exchanger to warm blood from a storage temperature 10° to 37° at 200 ml/min. Tubing has rectangular cross-section 6.4 mm × 1.6 mm sandwiched between plates maintained at 40°C.

FIND: (a) Length of tubing and (b) Assessment of assumptions to indicate whether analysis under- or over-estimates length.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible kinetic and potential energy changes, (3) Blood flow is fully developed, (4) Blood has properties of water, and (5) Negligible tube wall and contact resistance.

PROPERTIES: Table A-6, Water (√Tm = 300 K): cp,f = 4179 J/kg·K, ρf = 1/νf = 997 kg/m³, νf = µf/νf = 8.58 × 10⁻⁷ m²/s, k = 0.613 W/m·K, Pr = 5.83.

ANALYSIS: (a) From an overall energy balance and the rate equation,

\[ q = \dot{m} c_p (T_{m,o} - T_{m,i}) = \bar{h} A_s \Delta T_{LMTD} \tag{1} \]

where

\[ \Delta T_{LMTD} = \frac{\Delta T_1 - \Delta T_2}{\ln (\Delta T_1 / \Delta T_2)} = \frac{(40 - 15) - (40 - 37)}{\ln (2.5/3)} = 10°C. \]

To estimate \( \bar{h} \), find the Reynolds number for the rectangular tube,

\[ \text{Re}_D = \frac{\dot{m} D_h}{\nu} \frac{0.326 \text{ m/s} \times 0.00256 \text{ m}}{8.58 \times 10^{-7} \text{ m}^2 / \text{s}} = 973 \]

where

\[ D_h = 4 A_c / P = 4 \left( 6.4 \text{ mm} \times 1.6 \text{ mm} \right) / 2 \left( 6.4 + 1.6 \right) \text{ mm} = 2.56 \text{ mm} \]

\[ A_c = (6.4 \text{ mm} \times 1.6 \text{ mm}) = 1.024 \times 10^{-5} \text{ m}^2 \]

\[ \nu = \dot{m} / \rho A_c = \dot{\nu} / A_c = 200 \text{ m} / 60 \text{ s} \left( 10^{-6} \text{ m}^3 / \text{ m} / \text{s} \right) / 1.024 \times 10^{-5} \text{ m}^2 = 0.326 \text{ m/s}. \]

Hence the flow is laminar, but assuming fully developed flow with an isothermal surface from Table 8.1 with b/a = 6.4/1.6 = 4,

\[ \text{Nu}_D = \frac{h D_h}{k} = 4.4 \quad h = \frac{4.4 \times 0.613 \text{ W/m} \cdot \text{K}}{0.00256 \text{ m}} = 1054 \text{ W/m}^2 \cdot \text{K}. \]

Continued …..
PROBLEM 8.82 (Cont.)

From Eq. (1) with

\[ A_s = PL = 2(6.4 + 1.6) \times 10^{-3} \text{m} \times L = 1.6 \times 10^{-2} \text{L} \]

\[ \dot{m} = \rho A_c u_m = 997 \text{kg/m}^3 \times 1.024 \times 10^{-5} \text{m}^2 \times 0.326 \text{m/s} = 3.328 \times 10^{-3} \text{kg/s} \]

the length of the rectangular tubing can be found as

\[ 3.328 \times 10^{-3} \text{kg/s} \times 4179 \text{J/kg} \cdot \text{K} (37 - 15) \text{K} = 1054 \text{W/m}^2 \cdot \text{K} \times 1.6 \times 10^{-2} \text{L} \text{m}^2 \times 10 \text{K} \]

\[ L = 1.8 \text{ m}. \]

(b) Consider these comments with regard to whether the analysis under- or over-estimates the length,

⇒ fully-developed flow - \( L/D_R = 1.8 \text{ m/0.00256} = 700 \); not likely to have any effect,

⇒ negligible tube wall resistance - depends upon materials of construction; if plastic, analysis under predicts length,

⇒ negligible thermal contact resistance between tube and heating plate - if present, analysis under predicts length.
PROBLEM 8.83

KNOWN: Coolant flowing through a rectangular channel (gallery) within the body of a mold.

FIND: Convection coefficient when the coolant is process water or ethylene glycol.

SCHEMATIC:

ASSUMPTIONS: (1) Gallery can be approximated as a rectangular channel with a uniform surface temperature, (2) Fully developed flow conditions.

PROPERTIES: Table A.6, Water (\( T_m = (140 + 15)°C/2 = 350 \) K): \( \rho = 974 \text{ kg/m}^3, \mu = 365 \times 10^{-6} \text{n⋅s/m}^2, v = \mu/\rho = 3.749 \times 10^{-7} \text{ m}^2/\text{s}, k = 0.668 \text{ W/m⋅K}, Pr = 2.29; \) Table A.5, Ethylene glycol (\( T_m = 350 \) K): \( \rho = 1079 \text{ kg/m}^3, v = 3.17 \times 10^{-6} \text{ m}^2/\text{s}, k = 0.261 \text{ W/m⋅K}, Pr = 34.6. \)

ANALYSIS: The characteristic length of the channel, the hydraulic diameter, Eq. 8.67, is

\[
D_h = \frac{4(a \times b)}{2(a + b)} = \frac{4 \times 0.090 \times 0.0095}{2(0.090 + 0.0095)} \text{ m} = 0.0172 \text{ m}
\]

For the water coolant, from the continuity equation, find the Reynolds number to characterize the flow

\[
u_m = \frac{\dot{V}}{A_c} = \frac{1.3 \times 10^{-3} \text{ m}^3/\text{s}}{0.090 \times 0.0095} = 1.52 \text{ m/s}
\]

\[
Re_{D_h} = \frac{\nu_m D_h}{v} = \frac{1.52 \text{ m/s} \times 0.0172 \text{ m}}{3.749 \times 10^{-7} \text{ m}^2/\text{s}} = 69,736
\]

Since the flow is turbulent, and assuming fully developed conditions, use the Dittus-Boelter correlation, Eq. 8.60, to estimate the convection coefficient,

\[
Nu_{D_h} = \frac{h D_h}{k} = 0.023 Re^{0.8} Pr^{0.4} = 0.023 (69,736)^{0.8} (2.29)^{0.4} = 240
\]

\[
h_w = \frac{0.668 \text{ W/m⋅K}}{0.0172 \text{ m}} \times 240 = 9326 \text{ W/m}^2 \cdot \text{K}
\]

Repeating the calculations using properties for the ethylene glycol coolant, find

\[
Re_{D_h} = 8,247 \quad Nu_{D_h} = 128 \quad h_{eg} = 1957 \text{ W/m}^2 \cdot \text{K}
\]

Continued...
COMMENTS:  (1) The convection coefficient for the water coolant is more than 4 times greater than that with the ethylene glycol coolant. The corrosion protection afforded by the latter coolant greatly compromises the thermal performance of the gallery. In such situations, it is useful to explore a compromise between corrosion protection and thermal performance by using an aqueous solution of ethylene glycol (50%-50%, for example).

(2) Recognize that for the ethylene glycol coolant calculation the Reynolds number is slightly below the lower limit of applicability of the Dittus-Boelter correlation.
PROBLEM 8.84

KNOWN: Dimensions, surface temperature and thermal conductivity of a cold plate. Velocity, inlet temperature, and properties of coolant.

FIND: (a) Model for determining the heat rate q and outlet temperature, $T_{m,o}$, (b) Values of q and $T_{m,o}$ for prescribed conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible KE, PE and flow work changes, (3) Constant properties, (4) Symmetry about the midplane (horizontal) of the cold plate and the midplane (vertical) of each cooling channel, (5) Negligible heat transfer at sidewalls of cold plate, (6) One-dimensional conduction from outer surface of cold plate to base surface of channel and within the channel side walls, which act as extended surfaces.

PROPERTIES: Water (prescribed): $\rho = 984 \text{ kg/m}^3$, $c_p = 4184 \text{ J/kg} \cdot \text{K}$, $\mu = 489 \times 10^{-6} \text{ N} \cdot \text{s/m}^2$, $k = 0.65 \text{ W/m} \cdot \text{K}$, $Pr = 3.15$.

ANALYSIS: (a) The outlet temperature, $T_{m,o}$, may be determined from the energy balance prescribed by Eq. 8.46b,

$$\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp \left( -\frac{1}{\bar{m}_1 c_p R_{tot}} \right)$$

where $\bar{m}_1 = \rho u_n A_c$ is the flowrate for a single channel and $R_{tot}$ is the total resistance to heat transfer between the cold plate surface and the coolant for a particular channel. This resistance may be determined from the symmetrical section shown schematically, which represents one-half of the cell associated with a full channel. With the number of channels (and cells) corresponding to $N = W/S$, there are $2N = 2(W/S)$ symmetrical sections, and the total resistance $R_{tot}$ of a cell is one-half that of a symmetrical section. Hence, $R_{tot} = R_{ss}/2$, where the resistance of the symmetrical section includes the effect of conduction through the outer wall of the cold plate and convection from the inner surfaces. Hence,

$$R_{ss} = \frac{(H-h)/2}{k_{cp} (SW)} + \frac{1}{\eta_0 h A_t}$$

where $A_t = A_f + A_b = 2(h/2 \times W) + (w \times W)$, $\bar{h}$ is the average convection coefficient for the channel flow, and $\eta_0$ is the overall surface efficiency.

$$\eta_0 = 1 - \frac{A_f}{A_t} (1 - \eta_f)$$

Continued...
PROBLEM 8.84 (Cont.)

The efficiency $\eta_f$ corresponds to that of a straight, rectangular fin with an adiabatic tip, Eq. 3.89, and $L_c = w/2$. With $D_h = 4A_c/p = 4w^2/4w = w = 0.006 m$, $\text{Re}_{D_h} = \rho u_m D_h/\mu = 984 kg/m^3 \times 2 m/s \times 0.006 m/489 \times 10^6 N \cdot s/m^2 = 24,150$ and the channel flow is turbulent. Assuming fully-developed flow throughout the channel, the Dittus-Boelter correlation, Eq. 8.60, may therefore be used to evaluate $\overline{h}$, where

$$\overline{\text{Nu}_D} = \text{Nu}_{D,fd} = 0.023 \text{Re}_D^{4/5} \text{Pr}^{0.4}$$

The total heat rate for the cold plate may be expressed as

$$q = Nq_1 = N\eta_\text{f} c_p \left( T_{m,o} - T_{m,i} \right)$$

(b) For the prescribed conditions,

$$\dot{m}_1 = \rho u_m A_c = 984 kg/m^3 \left( 2 m/s \right) \left( 0.006 m \right)^2 = 0.0708 kg/s$$

$$\overline{\text{Nu}_D} = 0.023 \left( 24,150 \right)^{4/5} \left( 3.15 \right)^{0.4} = 116.8$$

$$\overline{h} = 116.8 k/D_h = 116.8 \left( 0.65 W/m \cdot K \right)/(0.006 m) = 12,650 W/m^2 \cdot K$$

$$A_f = 2 (h/2 \times W) = 2 \left( 0.003 m \times 0.1 m \right) = 6 \times 10^{-4} m^2$$

$$A_t = A_f + A_b = 6 \times 10^{-4} m^2 + (0.006 m \times 0.1 m) = 1.2 \times 10^{-3} m^2$$

With $m = \left( \overline{h} \delta_{f} / k_{cp} A_{cf} \right)^{1/2} = \left[ \overline{h} \left( 2 \delta + 2W \right) / k_{cp} \left( \delta W \right) \right]^{1/2} = \left[ 12,650 W/m^2 \cdot K \left( 0.008 + 0.200 \right) m/400 W/m \cdot K (0.004 \times 0.100) \right] m^{1/2} = 128.2 m^{-1}$.

$$\eta_f = \frac{\tanh m \left( h/2 \right)}{m \left( h/2 \right)} = \frac{\tanh \left( 128.2 \times 0.003 \right)}{128.2 \times 0.003} = 0.366 = 0.952$$

$$\eta_o = 1 - 0.5 \left( 1 - 0.952 \right) = 0.976$$

$$R_{ss} = \frac{\left( 0.010 - 0.006 \right)m/2}{400 W/m \cdot K (0.01 m \times 0.1 m)} + \frac{1}{0.976 \left( 12650 W/m^2 \cdot K \right) 1.2 \times 10^{-3} m^2}$$

$$R_{ss} = \left( 0.005 + 0.0675 \right) K/W = 0.0725 K/W$$

With $R_{ss} = R_{ss}/2 = 0.0362 K/W$,

$$T_{s} = T_{m,o} = \exp \left( - \frac{1}{0.0708 kg/s \times 4184 J/kg \cdot K \times 0.0362 K/W} \right) = 0.911$$

$$T_{m,o} = T_{s} - 0.911 \left( T_{s} - T_{m,i} \right) = 360 K - 0.911 \left( 360 - 300 \right) K = 305.3 K$$

The total heat rate is

$$q = N\eta_\text{f} c_p \left( T_{m,o} - T_{m,i} \right) = 10 \times 0.0708 kg/s \times 4184 J/kg \cdot K \left( 305.3 - 300 \right) K = 15,700 W$$

COMMENTS: The prescribed properties correspond to a value of $T_m$ which significantly exceeds that obtained from the foregoing solution ($T_m = 302.6 K$). Hence, the calculations should be repeated using more appropriate thermophysical properties (see next problem). From Eq. 3.85, the effectiveness of the extended surface is

$$\varepsilon = \frac{R_{ss}}{R_{ss}} = \left( \overline{h} \delta W \right)^{-1}/\left( \overline{h} A_f \eta_f \right)^{-1} = \left( A_f \eta_f / \delta W \right) = \left( 6 \times 10^{-4} m^2 \times 0.954 \right)/(0.004 m \times 0.10 m) = 1.43.$$  

Hence, the ribs are only marginally effective in enhancing heat transfer to the coolant.
**PROBLEM 8.85**

**KNOWN:** Geometry, surface temperature and thermal conductivity of a cold plate. Velocity and inlet temperature of coolant.

**FIND:** Effect of channel width on total heat rate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible KE, PE and flow work changes, (3) Constant properties, (4) Symmetry about midplane (horizontal) of the cold plate and the midplane (vertical) of each channel, (5) Negligible heat transfer at sidewalls of cold plate, (6) One-dimensional conduction from outer surface of cold plate to base surface of channel and within the channel side walls, which act as extended surfaces.

**PROPERTIES:** Water: Evaluated at \( T_m \) using the *Properties* Toolpad of IHT.

**ANALYSIS:** The model developed for the preceding problem was entered into the workspace of IHT, with the Dittus-Boelter equation and exponential relation accessed from the *Correlations* Toolpad and modified to account for the hydraulic diameter and the total resistance to heat transfer. Calculations were performed for

<table>

</tbody>
</table>

It is clearly beneficial to increase the number of channels, with the total heat rate increasing by approximately a factor of 5 as \( N \) increases from 1 to 20. The heat rate may be increased further by increasing \( u_m \) and hence the flowrate per channel, although an upper limit would be associated with the pressure drop, which would increase with decreasing \( D_h \). Could additional heat transfer enhancement be achieved by altering the thickness \( \delta \) of the channel walls?

**COMMENTS:** Note that results obtained for Case 4 differ from those of the preceding problem due to different fluid properties. In this case the properties were evaluated at the actual value of \( T_m = 302.6 \) K, rather than at an assumed (significantly larger) value.
PROBLEM 8.86

KNOWN: Heat sink with 24 passages for air flow removes power dissipation from circuit board.

FIND: Operating temperature of the board and pressure drop across the sink.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible kinetic and potential energy changes, (3) Negligible thermal resistance between the circuit boards and air passages, (4) Sink surface and board are isothermal at $T_s$.

PROPERTIES: Table A-4, Air ($T = 310$ K, 1 atm): $\rho = 1.1281$ kg/m$^3$, $c_p = 1008$ J/kg·K, $\nu = 16.89 \times 10^{-6}$ m$^2$/s, $k = 0.0270$ W/m·K, $Pr = 0.706$.

ANALYSIS: The air outlet temperature follows from Eq. 8.43,

$$T_s - T_{m,o} = \exp \left( - \frac{PLh}{m c_p} \right).$$

The mass flow rate for the entire sink is

$$\dot{m} = \rho \dot{V} = 1.1281 \text{ kg/m}^3 \times 0.060 \text{ m}^3/s = 6.77 \times 10^{-2} \text{ kg/s}$$

and the Reynolds number for a rectangular passage is

$$Re_D = \frac{u_m D_h}{\nu}$$

where

$$D_h = 4A_c / P = 4(6 \text{ mm} \times 25 \text{ mm}) / 2(6 + 25) \text{ mm} = 9.68 \text{ mm}$$

$$u_m = \frac{\dot{m}/24}{\rho A_c} = \frac{6.77 \times 10^{-2} \text{ kg/s/24}}{1.1281 \text{ kg/m}^3 (6 \times 25) \times 10^{-6} \text{ m}^2} = 16.7 \text{ m/s}$$

giving

$$Re_D = \frac{16.7 \text{ m/s} \times 9.68 \times 10^{-3} \text{ m}}{16.89 \times 10^{-6} \text{ m}^2 / \text{s}} = 9571.$$ Assume the flow is turbulent and fully developed and using the Dittus-Boelter correlation find

$$Nu_D = 0.023Re^{4/5}Pr^{0.4} = 0.023(9571)^{4/5}(0.706)^{0.4} = 30.6$$

$$h = \frac{Nu \cdot k}{D_h} = \frac{30.6 \times 0.027 \text{ W/m} \cdot \text{K}}{0.00968 \text{ m}} = 85.4 \text{ W/m}^2 \cdot \text{K.}$$

Continued .....
PROBLEM 8.86 (Cont.)

From an overall energy balance on the sink,

\[ q = m \cdot c_p \left( T_{m,o} - T_{m,i} \right) \quad T_{m,o} = T_{m,i} + \frac{q}{m \cdot c_p} \]

\[ T_{m,o} = 27^\circ C + 50 \text{ W}/6.77 \times 10^{-2} \text{ kg/s} \times 1008 \text{ J/kg} \cdot \text{K} = 27.73^\circ C \]

Hence, the operating temperature of the circuit board for these conditions is

\[ T_s = 30^\circ C. \]

The pressure drop in the rectangular passage for the smooth surface condition follows from Eqs. 8.22 and 8.20

\[ \Delta p = f \cdot \frac{\rho \cdot u_m^2 \cdot L}{D_h} \]

where

\[ f = 0.31 \cdot \text{Re}^{1/4} = 0.316 \cdot (9554)^{-1/4} = 0.0320. \]

\[ \Delta p = 0.0320 \cdot \frac{1.1281 \text{ kg/m}^3 \cdot (16.7 \text{ m/s})^2}{0.00968 \text{ m}} \times 0.150 \text{ m} = 156 \text{ N/m}^2. \]

COMMENTS: (1) The analysis has been simplified by assuming the channel is rectangular and all four sides experience heat transfer. Since the insulated surface is a small portion of the total passage surface area, the effect can’t be very large.

(2) The power required to move the air through the heat sink is \( P_{\text{elec}} = \dot{V} \cdot \Delta p = 0.060 \text{ m}^3/\text{s} \times 156 \text{ N/m}^2 = 9.4 \text{ W}. \)
**PROBLEM 8.87**

**KNOWN:** Channel formed between metallic blades dissipating heat by internal volumetric generation.

**FIND:** (a) The heat removal rate per blade for the prescribed thermal conditions and (b) Time required to slow a train of mass 10^6 kg from 120 km/h to 50 km/h.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions for channel blades and air flow, (2) The blades form a channel of rectangular \((a \times b)\) cross-section and length \(L\), (3) Negligible kinetic energy changes and axial conduction inside the channel, and (4) Fully developed flow conditions in the channel.

**PROPERTIES:** Table A.4, Air \((T_m = 350 \text{ K}, 1 \text{ atm})\): \(\rho = 0.995 \text{ kg/m}^3\), \(c_p = 1009 \text{ J/kg} \cdot \text{K}\), \(\nu = 20.92 \times 10^{-6} \text{ m}^2/\text{s}\), \(k = 0.030 \text{ W/m} \cdot \text{K}\), \(Pr = 0.700\).

**ANALYSIS:** (a) The heat removal rate by the air from a single channel (one blade) follows from an overall energy balance,

\[
q = \dot{m}c_p \left( T_{m,o} - T_{m,i} \right) \tag{1}
\]

where the outlet temperature can be determined from Eq. 8.42b,

\[
\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp\left( -\frac{PL}{\dot{m}c_p} \bar{h} \right) \tag{2}
\]

The hydraulic diameter, \(D_h\), flows from Eq. 8.67,

\[
D_h = \frac{4Ac}{P} = \frac{4(a+b)}{2(a+b)} = \frac{4(0.220 \times 0.004)m^2}{2(0.220 + 0.004)m} = 0.0079m \tag{3}
\]

Assuming \(T_m = 350\text{K}\), the Reynolds number is

\[
Re_{Dh} = \frac{u_mD_h}{\nu} = \frac{50 \text{ m/s} \times 0.0079m}{20.92 \times 10^{-6} \text{ m}^2/\text{s}} = 18,779 \tag{4}
\]

Using the Dittus-Boelter correlation, Eq. 8.60,

\[
Nu_{Dh} = \frac{hD_h}{k} = 0.023 \text{Re}^{0.8} \text{Pr}^{0.4} = 0.023(18,779)^{0.8}(0.700)^{0.4} = 52.37 \tag{5}
\]

Continued...
PROBLEM 8.87 (Cont.)

\[
\bar{h} = \frac{0.030 \text{ W/m} \cdot \text{K}}{0.0079 \text{ m}} \times 52.37 = 199 \text{ W/m}^2 \cdot \text{K}
\]

Hence, the outlet temperature is

\[
\frac{600 - T_{m,o}}{(600 - 25) \degree \text{C}} = \exp \left( \frac{2(0.220 + 0.004) \text{ m} \times 0.070 \text{ m}}{0.0438 \text{ kg/s} \times 1009 \text{ J/kg} \cdot \text{K}} \cdot 199 \text{ W/m}^2 \cdot \text{K} \right)
\]

\[
T_{m,o} = 100.7 \degree \text{C}
\]

where

\[
\dot{m} = \rho A_c u_m = 0.995 \text{ kg/m}^3 \times (0.220 \times 0.004) \text{ m}^2 \times 50 \text{ m/s} = 0.0438 \text{ kg/s}
\]

and the rate of heat removal per blade, from Eq. (1), is

\[
q = 0.0438 \text{ kg/s} \times 1009 \text{ J/kg} \cdot \text{K} \times (100.7 - 25) \degree \text{C} = 3.346 \text{ kW}
\]

(b) From an energy balance on the locomotive over an interval of time, \( \Delta t \), the heat energy transferred to the air stream results in a change in kinetic energy of the train,

\[
-E_{\text{out}} = \Delta E = KE_f - KE_i
\]

\[
-(q \times N) \times \Delta t = \frac{1}{2} M \left( V_f^2 - V_i^2 \right)
\]

\[
-3346 \text{ W/blade} \times 2000 \text{ blades} \times \Delta t (s) = \frac{1}{2} \times 10^{-6} \text{ kg} \left[ \left( \frac{50,000}{3600} \right)^2 - \left( \frac{120,000}{3600} \right)^2 \right] \text{ m}^2/\text{s}^2
\]

\[
\Delta t = 69 \text{s}
\]

COMMENTS: (1) For the channel, \( L/D_h = 0.070 \text{ m}/0.0079 \text{ m} = 8.9 < 10 \) so that the assumption of fully developed conditions may not be satisfied. Recognize that the flow at the channel entrance may be highly turbulent because of the upstream fan swirl and ducting.

(2) What benefits could be realized by increasing the heat transfer coefficient? Aside from increasing velocity, what design changes would you make to increase \( h \)?

(3) Our assumption for \( T_m = 350 \text{ K} \) at which to evaluate properties is reasonable considering \( T_m = (100.7 + 25) \degree \text{C}/2 = 335 \text{ K} \).
PROBLEM 8.88

KNOWN: Chip and cooling channel dimensions. Channel flowrate and inlet temperature. Chip temperature.

FIND: Water outlet temperature and chip power.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible kinetic and potential energy changes for water, (2) Uniform channel surface temperature, (3) $T_m = 300$ K, (4) Fully developed flow.

PROPERTIES: Table A-6, Water ($T_m = 300$ K): $c_p = 4179$ J/kg·K, $\mu = 855 \times 10^{-6}$ kg/s·m, $k = 0.613$ W/m·K, Pr = 583.

ANALYSIS: Using the hydraulic diameter, find the Reynolds number,

$$D_h = \frac{4(H \times W)}{2(H + W)} = \frac{2(50\times200)\mu m^2}{250 \mu m} = 8 \times 10^{-5} \text{ m}$$

$$Re_D = \frac{\rho u_m D_h}{\mu} = \frac{\dot{m}_D h}{A_c \mu} = \frac{10^{-4} \text{ kg/s} \left(8 \times 10^{-5} \text{ m} \right)}{(50 \times 200) \times 10^{-12} \text{ m}^2 \left(855 \times 10^{-6} \text{ kg/s·m} \right)} = 936.$$ 

Hence, the flow is laminar and, from Table 8.1, $Nu_D = 4.44$, so that

$$h = Nu_D \frac{k}{D_h} = \frac{4.44 \left(0.613 \text{ W/m·K} \right)}{8 \times 10^{-5} \text{ m}} = 34,022 \text{ W/m}^2 \cdot \text{K}.$$ 

With $P = 2(H + W) = 2(250 \mu m) \times 10^{-6} \text{ m/\mu m} = 5 \times 10^{-4} \text{ m}$, Eq. 8.42b yields

$$\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp \left(-\frac{PL}{\dot{m}_s c_p} h \right) = \exp \left(-\frac{5 \times 10^{-6} \text{ m}^2 \times 34,022 \text{ W/m}^2 \cdot \text{K}}{10^{-4} \text{ kg/s} \times 4179 \text{ J/kg·K}} \right).$$

$$T_{m,o} = 350 \text{ K} - 60 \text{ K} \exp (-0.407) = 310 \text{ K}.$$  

Hence, from Eq. 8.37,

$$q = \dot{m} c_p \left(T_{m,o} - T_{m,i} \right) = \dot{m} c_p \left(T_{m,o} - T_{m,i} \right) = 50 \times 10^{-4} \text{ kg/s} (4179 \text{ J/kg·K}) (20 \text{ K}) = 418 \text{ W}.$$  

COMMENTS: (1) The chip heat flux of 418 W/cm$^2$ is extremely large and the method provides a very efficient means of heat removal from high power chips. However, clogging of the microchannels is a potential problem which could seriously compromise reliability. (2) $L/D_h = 125$ and 0.05 $Re_D Pr = 272$. Hence, fully developed conditions are not realized and $\overline{h} > 34,022$. The actual power dissipation is therefore greater than 418 W.
**PROBLEM 8.89**

**KNOWN:** Chip and cooling channel dimensions. Channel flow rate and inlet temperature. Temperature of chip at base of channel.

**FIND:** (a) Water outlet temperature and chip power, (b) Effect of channel width and pitch on power dissipation.

**SCHEMATIC:**

![Schematic](image)

**ASSUMPTIONS:** (1) Negligible flow work and kinetic and potential energy changes for water, (2) Flow may be approximated as fully developed and channel walls as isothermal for purposes of estimating the convection coefficient, (3) One-dimensional conduction along channel side walls, (4) Adiabatic condition at end of side walls, (5) Heat dissipation is exclusively through fluid flow in channels, (6) Constant properties.

**PROPERTIES:** *Table A-6, Water (T_m = 300K):* \( c_p = 4179 \text{ J/kg} \cdot \text{K}, \mu = 855 \times 10^{-6} \text{ kg/s} \cdot \text{m}, k = 0.613 \text{ W/m} \cdot \text{K}, \text{Pr} = 5.83.\)

**ANALYSIS:** (a) The channel sidewalls act as fins, and a *unit* channel/sidewall combination is shown in schematic (a), where the total number of unit cells corresponds to \( N = L/S. \) With \( N = 50 \) and \( L = 10 \text{ mm}, S = 200 \mu\text{m} \) and \( \delta = S – W = 150 \mu\text{m}. \) Alternatively, the unit cell may be represented in terms of a single fin of thickness \( \delta, \) as shown in schematic (b). The thermal resistance of the unit cell may be obtained from the expression for a fin array, Eq. (3.103), \( R_{t,o} = (\eta_o hA_t)^{-1}, \) where \( A_t = A_f + A_b = L (2H + W) = 0.01 \text{m} \times (4 \times 10^{-4} + 0.5 \times 10^{-4}) \text{ m} = 4.5 \times 10^{-6} \text{ m}^2. \) With \( D_h = 4 \text{(H} \times \text{W)/2 (H} + \text{W)} = 4 \times 2 \times 10^{-4} \times 0.5 \times 10^{-4} / 2 \times 2.5 \times 10^{-4} \text{ m} = 8 \times 10^{-5} \text{ m}, \) the Reynolds number is \( Re_D = \rho u m D_h / \mu = \dot{m}_l D_h / A_c \mu = 10^{-4} \text{ kg/s} \times 8 \times 10^{-5} \text{ m/(2} \times \text{10}^{-4} \times 0.5 \times 10^{-4} \text{ m) 855} \times \text{10}^{-6} \text{ kg/s} \cdot \text{m} = 936. \) Hence, the flow is laminar, and assuming fully developed conditions throughout a channel with uniform surface temperature, Table 8.1 yields \( \text{Nu}_D = 4.44. \) Hence,

\[
h = \frac{k}{D_h} \frac{\text{Nu}_D}{\text{Nu}_D} = \frac{0.613 \text{ W/m} \cdot \text{K} \times 4.44}{8 \times 10^{-5} \text{ m}} = 34,022 \text{ W/m}^2 \cdot \text{K}
\]

With \( m = (2h/k_{ch})^{1/2} = (68,044 \text{ W/m}^2 \cdot \text{K}/140 \text{ W/m} \cdot \text{K} \times 1.5 \times 10^{-4} \text{ m})^{1/2} = 1800 \text{ m}^{-1} \) and \( mH = 0.36, \) the fin efficiency is

\[
\eta_f = \frac{\tanh mH}{mH} = \frac{0.345}{0.36} = 0.958
\]

and the overall surface efficiency is

\[
\eta_o = 1 - \frac{A_f}{A_t} (1 - \eta_f) = 1 - \frac{4.0 \times 10^{-6}}{4.5 \times 10^{-6}} (1 - 0.958) = 0.963
\]

The thermal resistance of the unit cell is then Continued …..
PROBLEM 8.89 (Cont.)

\[ R_{t,o} = (\eta_A h A_t)^{-1} = \left(0.963 \times 34,022 \text{ W} / \text{m}^2 \cdot \text{K} \times 4.5 \times 10^{-6} \text{ m}^2 \right)^{-1} = 6.78 \text{ K/W} \]

The outlet temperature follows from Eq. (8.46b),

\[ T_{m,o} = T_s - \left( T_s - T_{m,i} \right) \exp \left( -\frac{1}{m c_p R_{t,o}} \right) = 350 \text{ K} - (60 \text{ K}) \times \]

\[ \exp \left( -\frac{1}{10^{-4} \text{ kg/s} \times 4179 \text{ J/kg} \cdot \text{K} \times 6.78 \text{ K/W}} \right) = 307.8 \text{ K} \]

The heat rate per channel is then

\[ q_l = m c_p \left( T_{m,o} - T_{m,i} \right) = 10^{-4} \text{ kg/s} \times 4179 \text{ J/kg} \cdot \text{K} (17.8 \text{ K}) = 7.46 \text{ W} \]

and the chip power dissipation is

\[ q = N q_l = 50 \times 7.46 \text{ W} = 373 \text{ W} \]

(b) The foregoing result indicates significant heat transfer from the channel side walls due to the large value of \( \eta_f \). If the pitch is reduced by a factor of 2 (\( S = 100 \mu\text{m} \)), we obtain

\[ S = 100 \mu\text{m}, \ W = 50 \mu\text{m}, \ \delta = 50 \mu\text{m}, \ N = 100; \ q_l = 7.04 \text{ W}, \ q = 704 \text{ W} \]

Hence, although there is a reduction in \( \eta_f \) due to the reduction in \( \delta (\eta_f = 0.89) \) and therefore a slight reduction in the value of \( q_l \), the effect is more than compensated by the increase in the number of channels. Additional benefit may be derived by further reducing the pitch to whatever minimum value of \( \delta \) is imposed by manufacturing or structural limitations. There would also be an advantage to increasing the channel hydraulic diameter and or flowrate, such that turbulent flow is achieved with a correspondingly larger value of \( h \).

**COMMENTS:** (1) Because electronic devices fail by contact with a polar fluid such as water, great care would have to be taken to hermetically seal the devices from the coolant channels. In lieu of water, a dielectric fluid could be used, thereby permitting contact between the fluid and the electronics. However, all such fluids, such as air, are less effective as coolants. (2) With \( L/D_h = 125 \) and \( L/D_h)_{fd} = 0.05 \text{ Re} \text{D \ Pr} = 273 \), fully developed flow is not achieved and the value of \( h = h_{fd} \) underestimates the actual value of \( h \) in the channel. The coefficient is also underestimated by using a Nusselt number that presumes heat transfer from all four (rather than three) surfaces of a channel.
PROBLEM 8.90

KNOWN: Chip and cooling channel dimensions. Channel flow rate and inlet temperature. Temperature of chip at base of channel.

FIND: (a) Outlet temperature and chip power dissipation for dielectric liquid, (b) Outlet temperature and chip power dissipation for air.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible flow work and kinetic and potential energy changes, (2) Flow may be approximated as fully developed and channel walls as isothermal for purposes of estimating the convection coefficient, (3) One-dimensional conduction along the channel side walls, (4) Adiabatic condition at end of side walls, (5) Heat dissipation is exclusively through fluid flow in channels, (6) Constant properties.

PROPERTIES: Prescribed. Dielectric liquid: \( c_p = 1050 \text{ J/kg} \cdot \text{K}, k = 0.065 \text{ W/m} \cdot \text{K}, \mu = 0.0012 \text{ N} \cdot \text{s/m}^2, \text{Pr} = 15 \). Air: \( c_p = 1007 \text{ J/kg} \cdot \text{K}, k = 0.0263 \text{ W/m} \cdot \text{K}, \mu = 185 \times 10^{-7} \text{ N} \cdot \text{s/m}^2, \text{Pr} = 0.707 \).

ANALYSIS: (a) The channel side walls act as fins, and a unit channel/sidewall combination is shown in schematic (a), where \( \delta = S - W = 150 \mu\text{m} \). Alternatively, the unit cell may be represented in terms of a single fin of thickness \( \delta \), as shown in schematic (b). The thermal resistance of the unit cell may be obtained from the expression for a fin array, Eq. (3.103), \( R_{t,o} = (\eta_o h A_t)^{-1} \), where \( A_t = A_f + A_h = L(2H + W) = 4.5 \times 10^{-6} \text{ m}^2 \). With \( A_c = H \times W = 10^{-8} \text{ m}^2 \) and \( D_h = 4A_c/(H + W) = 8 \times 10^{-5} \text{ m} \), the Reynolds number is \( Re_D = \rho u m D_h / \mu = mH D_h/A_c \mu = 667 \). Hence, the flow is laminar, and assuming fully developed conditions throughout a channel with uniform surface temperature, Table 8.1 yields \( Nu_D = 4.44 \). Hence, \( h = \frac{k}{D_h} \frac{Nu_D}{8 \times 10^{-5} \text{ m}} = 3608 \text{ W/m}^2 \cdot \text{K} \).

With \( m = (2 h/k_{ch} \delta)^{1/2} = 586 \text{ m}^{-1} \) and \( mH = 0.117 \), the fin efficiency is
\[
\eta_f = \frac{\tanh mH}{mH} = \frac{0.1167}{0.117} = 0.995
\]

and the overall surface efficiency is
\[
\eta_o = 1 - \frac{A_f}{A_t} (1 - \eta_f) = 1 - \frac{4.0 \times 10^{-6}}{4.5 \times 10^{-6}} (1 - 0.995) = 0.996.
\]

The thermal resistance of the unit cell is then
\[
R_{t,o} = (\eta_o h A_t)^{-1} = \left(0.996 \times 3608 \text{ W/m}^2 \cdot \text{K} \times 4.5 \times 10^{-6} \text{ m}^2 \right)^{-1} = 61.9 \text{ K/W}
\]

The outlet temperature follows from Eq. (8.46b),
\[
T_{m,o} = T_s - \left( T_s - T_{m,i} \right) \exp \left( -\frac{1}{\dot{m}_l c_p R_{t,o}} \right) = 350 \text{K}
\]

Continued ….
PROBLEM 8.90 (Cont.)

\[-(60K)\exp\left(-\frac{1}{10^{-4} \text{ kg/s} \times 1050 \text{ J/kg} \cdot \text{K} \times 61.9 \text{ K/W}}\right) = 298.6K\]

The heat rate per channel is then

\[q_1 = \dot{m}_1 c_p \left(T_{m,o} - T_{m,i}\right) = 10^{-4} \text{ kg/s} \times 1050 \text{ J/kg} \cdot \text{K} \times 8.6 \text{ K} = 0.899 \text{ W}\]

and the chip power dissipation is

\[q = Nq_1 = 50 \times 0.899 \text{ W} = 45.0 \text{ W}\]

(b) With \(\dot{m}_1 = 10^{-6} \text{ kg/s}\). \(\text{Re}_D = \dot{m}_1 D_h / A_c \mu = 432\) and the flow is laminar. Hence, with \(\text{Nu}_D = 4.44\),

\[h = \frac{k}{D_h} \text{Nu}_D = \frac{0.0263 \text{ W/m} \cdot \text{K} \times 4.44}{8 \times 10^{-5} \text{ m}} = 1460 \text{ W/m}^2 \cdot \text{K}\]

With \(m = (2 h/k_c \delta)^{1/2} = 373 \text{ m}^{-1}\) and \(mH = 0.0746\), the fin efficiency is

\[\eta_f = \frac{\tanh mH}{mH} = \frac{0.0744}{0.0746} = 0.998\]

and the overall surface efficiency is

\[\eta_o = 1 - \frac{A_f}{A_t}(1 - \eta_f) = 1 - \frac{4.0 \times 10^{-6}}{4.5 \times 10^{-6}}(1 - 0.998) = 0.998\]

Hence,

\[R_{t,o} = (\eta_o h A_t)^{-1} = \left(0.998 \times 1460 \text{ W/m}^2 \cdot \text{K} \times 4.5 \times 10^{-6} \text{ m}^2\right)^{-1} = 153 \text{ K/W}\]

The outlet temperature is then

\[T_{m,o} = T_s - \left(T_s - T_{m,i}\right)\exp\left(-\frac{1}{\dot{m}_1 c_p R_{t,o}}\right) = 350 \text{ K}\]

\[-(60K)\exp\left(-\frac{1}{10^{-6} \text{ kg/s} \times 1007 \text{ J/kg} \cdot \text{K} \times 153 \text{ K/W}}\right) = 349.9 \text{ K}\]

\[q_1 = \dot{m}_1 c_p \left(T_{m,o} - T_{m,i}\right) = 10^{-6} \text{ kg/s} \times 1007 \text{ J/kg} \cdot \text{K} \times 59.9 \text{ K} = 0.060 \text{ W}\]

\[q = Nq_1 = 3.02 \text{ W}\]

**COMMENTS:** (1) For laminar flow in the channels, there is a clear advantage to using the dielectric liquid instead of air. (2) The prescribed channel geometry is by no means optimized, and the number of fins should be increased by reducing \(S\). Also, channel dimensions and/or flow rates could be increased to achieve turbulent flow and hence much larger values of \(h\). (3) With \(L/D_h = 125\) and \(L/D_h)_{\text{fd}} = 0.05 \text{ Re}_D \text{ Pr} = 500\) for the dielectric liquid, fully developed flow is not achieved and its assumption yields a conservative (under) estimate of the convection coefficient. The coefficient is also underestimated by using a Nusselt number that presumes heat transfer from all four (rather than three) surfaces of a channel.
PROBLEM 8.91

KNOWN: Arrangement of chips and cooling channels for a substrate. Contact and conduction resistances. Coolant velocity and inlet temperature.

FIND: (a) Coolant temperature rise, (b) Chip and substrate temperatures.

SCHEMATIC:

ASSUMPTIONS: (1) Constant properties, (2) Fully-developed flow, (3) Negligible kinetic and potential energy changes, (4) Heat transfer exclusively to water, (5) Steady-state conditions.

PROPERTIES: Water (given): \( \rho = 1000 \text{ kg/m}^3 \), \( c_p = 4180 \text{ J/kg\cdot K} \), \( k = 0.610 \text{ W/m\cdot K} \), \( Pr = 5.8 \), \( \mu = 855 \times 10^{-6} \text{ kg/s} \).

ANALYSIS: (a) For a single flow channel, the overall energy balance yields

\[
T_{m,o} - T_{m,i} = \frac{q}{m c_p} = \frac{N_L P}{\rho u m^4 c_p} = \frac{10 \times 5 \text{ W}}{1000 \text{ kg/m}^3 \left( \frac{1 \text{ m/s}}{1 \text{ m/s}} \right) \left( \frac{0.005 \text{ m}}{0.005 \text{ m}} \right)^2 4180 \text{ J/kg\cdot K}} = 0.48^\circ \text{C}.
\]

From the thermal circuit,

\[
q = \frac{T_0 - T_m}{R_{t,c} + R_{\text{cond}} + R_{\text{conv}}} \quad R_{t,c} = \frac{R_{t,c}^*}{A_s} = \left( \frac{0.5 \times 10^{-4} \text{ m}^2 \cdot \text{K}}{10 \left( \frac{0.005 \text{ m}}{0.005 \text{ m}} \right)^2} \right) = 0.2 \text{ K/W}.
\]

With \( D_h = 4A_c/P = 4(0.005 \text{ m})^2 /4(0.005 \text{ m}) = 0.005 \text{ m} \),

\[
Re_D = \frac{\rho u m D_h}{\mu} = \frac{1000 \text{ kg/m}^3 \left( \frac{1 \text{ m/s}}{1 \text{ m/s}} \right) \times 0.005 \text{ m}}{855 \times 10^{-6} \text{ kg/s\cdot m}} = 5848.
\]

With turbulent flow, the Dittus-Boelter correlation yields

\[
h = \frac{k}{D} 0.023 Re_D^{4/5} Pr^{0.4} = \left( \frac{0.61 \text{ W/m\cdot K}}{0.005 \text{ m}} \right) 0.023 \left( 5848 \right)^{4/5} \left( 5.8 \right)^{0.4} = 5849 \text{ W/m}^2 \cdot \text{K}
\]

\[
R_{\text{conv}} = \left( hA_s \right)^{-1} = \left( \frac{5849 \text{ W/m}^2 \cdot \text{K}}{4 \times 0.005 \text{ m} \times 0.2 \text{ m}} \right)^{-1} = 0.043 \text{ K/W}.
\]

Approximating \( T_m \) as \( (T_{m,i} + T_{m,o})/2 = 25.24^\circ \text{C} \),

\[
T_c = T_m + q \left( R_{t,c} + R_{\text{cond}} + R_{\text{conv}} \right) = 25.24^\circ \text{C} + 50 \text{ W} \left( 0.2 + 0.12 + 0.043 \right) \text{ K/W} = 43.3^\circ \text{C}.
\]

Similarly, from the thermal circuits,

\[
T_s = T_m + q \times R_{\text{conv}} = 25.24^\circ \text{C} + 50 \text{ W} \times 0.043 \text{ K/W} = 27.4^\circ \text{C}
\]

COMMENTS: (1) Since the coolant temperature rise is less than \( 0.5^\circ \text{C} \), all chip temperatures will be within \( 0.5^\circ \text{C} \) of each other. (2) The channel surface temperature may also be obtained from Eq. 8.42b, yielding the same result.
**PROBLEM 8.92**

**KNOWN:** Power dissipation of components on each side of a hollow core PCB. Dimensions of PCB. Inlet temperature and flow rate of air.

**FIND:** Outlet air temperature and inlet and outlet surface temperatures for prescribed flow rates.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady flow, (2) Negligible flow work and potential and kinetic energy changes, (3) Channel may be approximated as infinite parallel plates, (4) Uniform surface heat flux, (5) Fully developed flow at exit, (6) Constant properties.

**PROPERTIES:** Table A-4, Air ($T_m = 310K$): $\rho = 1.128 \text{ kg/m}^3$, $c_p = 1007 \text{ J/kg K}$, $\mu = 189.3 \times 10^{-7} \text{ N s/m}^2$, $k = 0.0270 \text{ W/m K}$, $Pr = 0.706$.

**ANALYSIS:** Performing an energy balance for a control surface about the hollow core, $2q = \dot{m} c_p (T_{m,o} - T_{m,i})$, in which case

$$T_{m,o} = \frac{2q}{\dot{m} c_p} + T_{m,i} = \frac{80 \text{ W}}{0.002 \text{ kg/s} \times 1007 \text{ J/kg K}} + 20^\circ \text{C} = 59.7^\circ \text{C}$$

The surface temperatures may be obtained from Newton’s law of cooling, $q_s^* = h(T_s - T_m)$. Hence, with $h \rightarrow \infty$ at the entrance, where the thermal boundary layer thickness is zero,

$$T_{s,i} = T_{m,i} = 20^\circ \text{C}$$

With $Re_D = \rho \dot{m} D_h / \mu = \dot{m} D_h / A_c \mu$, where $D_h = 2H = 0.008 \text{ m}$ and $A_c = H \times W = 0.004 \text{ m} \times 0.3 \text{ m} = 0.0012 \text{ m}^2$, $Re_D = (0.002 \text{ kg/s} \times 0.008 \text{ m})/(0.0012 \text{ m}^2 \times 189.3 \times 10^{-7} \text{ N s/m}^2) = 704$ and the flow is laminar. With a uniform surface heat flux, $q_s^* = q/(W \times L) = 40 \text{ W}/(0.3 \text{ m})^2 = 444 \text{ W/m}^2$, Table 8.3 yields $Nu_D = 8.23$. Hence,

$$h = \frac{Nu_D k}{D_h} = \frac{8.23 \times 0.027 \text{ W/m K}}{0.008 \text{ m}} = 27.8 \text{ W/m}^2 \cdot \text{K}$$

$$T_{s,o} = T_{m,o} + \frac{q_s^*}{h} = 59.7^\circ \text{C} + \frac{444 \text{ W/m}^2}{27.8 \text{ W/m}^2 \cdot \text{K}} = 75.7^\circ \text{C}$$

If the flowrate is increased by a factor of 5,

$$T_{m,o} = \frac{2q}{\dot{m} c_p} + T_{m,i} = \frac{80 \text{ W}}{0.01 \text{ kg/s} \times 1007 \text{ J/kg K}} + 20^\circ \text{C} = 27.9^\circ \text{C}$$

The surface temperature at the inlet is unchanged, Continued …..
PROBLEM 8.92 (Cont.)

\[ T_{s,i} = 20^\circ C \]

but with \( \text{Re}_D = 3520 \), flow in the channel is now turbulent. Using Eq. (8.60) as a first approximation,

\[
h = \left( \frac{k}{\text{D}_h} \right) 0.023 \text{Re}_D^{4/5} \text{Pr}^{0.4} = \left( \frac{0.027 \text{ W/m·K}}{0.008 \text{ m}} \right) 0.023 (3520)^{4/5} (0.706)^{0.4} = 46.4 \text{ W/m}^2 \cdot \text{K}
\]

\[
T_{s,o} = T_{m,o} + \frac{q_s}{h} = 27.9^\circ C + \frac{444 \text{ W/m}^2}{46.4 \text{ W/m}^2 \cdot \text{K}} = 37.5^\circ C
\]

COMMENTS: (1) With \( \text{L/D}_h = 37.5 \) and \( \text{L/D}_h)_{fd} = 0.05 \text{ Re}_D \text{ Pr} = 25 \) for the laminar flow, it is reasonable to assume fully developed conditions at the exit. The same may be said for the turbulent flow condition. (2) The temperature difference, \( T_s - T_m \), increases from approximately 0 at the entrance to a maximum value associated with fully developed conditions.
**PROBLEM 8.93**

**KNOWN:** Printed-circuit board (PCB) with uniform temperature $T_s$ cooled by laminar, fully developed flow in a parallel-plate channel. The air flow with an inlet temperature of $T_{m,i}$ is driven by a pressure difference, $\Delta p$.

**FIND:** The average heat removal rate per unit area, $q_s^*\left(\text{W/m}^2\right)$, from the PCB.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Laminar, fully developed flow, (2) Upper and lower walls of the channel are insulated and of infinite extent in the transverse direction, (3) PCB has uniform surface temperature, (4) Constant properties, (5) Negligible kinetic and potential energy changes and flow work.

**PROPERTIES:** Table A-4, Air ($T_m = 293$ K, 1 atm): $\rho = 1.192$ kg/m$^3$, $c_p = 1007$ J/kg$\cdot$K, $\nu = 1.531 \times 10^{-5}$ m$^2$/s, $k = 0.0258$ W/m$\cdot$K, $Pr = 0.709$.

**ANALYSIS:** The energy equations for determining the heat rate from one surface of the board are Eqs. 8.37 and 8.42b

$$q = \dot{m}c_p(T_{m,o} - T_{m,i}) = q_s^*A_s$$  \hspace{1cm} (1)

$$\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp\left(-\frac{PLh}{\dot{m}c_p}\right)$$  \hspace{1cm} (2)

where $A_s = Lw$ and $P = 2(w + a)$ where $w$ is the width in the transverse direction. For the fully developed flow condition, the velocity is estimated from the friction pressure drop relation, Eq. 8.22a,

$$\Delta p = f\left(\rho u_m^2 / 2\right)(L/D_h)$$  \hspace{1cm} (3)

where the hydraulic diameter for the channel cross section is

$$D_h = \frac{4A_c}{P} = \frac{4(wa)}{2(w+a)} = 2a \quad a \ll w$$

The friction factor $f$ from Table 8.1 for the cross section $b/a = \infty$ is

$$f \cdot Re_{D_h} = 96$$  \hspace{1cm} (4)

where the Reynolds number is

$$Re_{D_h} = u_mD_h / \nu$$  \hspace{1cm} (5)

Continued …..
PROBLEM 8.93 (Cont.)

and the flow rate through one channel is

\[ \dot{m} = \rho A_c u_m = \rho (w a) u_m \]  

For fully developed laminar flow from Table 8.1.

\[ \overline{Nu}_D = \frac{\overline{h} D_h}{k} = 7.54 \]  

The above system of equations needs to be solved simultaneously for the unknowns: \( q, \dot{m}, T_{m,o}, \)
\( \text{Re}_{Dh}, f, u_m, \overline{h} \). Using IHT with \( w = 1 \) m, find these results:

<table>
<thead>
<tr>
<th>( u_m ) (m/s)</th>
<th>( \text{Re}_{Dh} )</th>
<th>( f )</th>
<th>( \overline{h} ) (W/m(^2)K)</th>
<th>( T_{m,o} ) (°C)</th>
<th>( q ) (W)</th>
<th>( \overline{q_s} ) (W/m(^2))</th>
</tr>
</thead>
<tbody>
<tr>
<td>6.0</td>
<td>7578</td>
<td>0.0127</td>
<td>9.9</td>
<td>20.9</td>
<td>66</td>
<td>442</td>
</tr>
</tbody>
</table>

From Eq. (1), the average heat removal per unit area of the board is

\[ \overline{q_s} = 442 \text{ W/m}^2 \]

**COMMENTS:**  
(1) The thermophysical properties of the air are evaluated at the average mean temperature, \( T_m = (T_{m,i} + T_{m,o})/2 \).

(2) The fully developed flow length, \( x_{fd,t} \), for the channel follows from Eq. 8.23,

\[ x_{fd,t} = D_h \times 0.05 \text{Re}_{Dh} \text{Pr} \]

\[ x_{fd,t} = 2 \times 0.010 \text{ m} \times 0.05 \times 7578 \times 0.707 = 5.4 \text{ m} \]

Since \( L << x_{fd,t} \), we conclude that the flow is not likely to be fully developed.

(3) Recognize also that the Reynolds number is larger than the critical value indicating that appreciable turbulence could be present. Considering that \( L << x_{fd,t} \) and \( \text{Re}_{Dh} > 2300 \), do you conclude that our estimate for the average heat flux is a conservative or an optimistic one?
PROBLEM 8.94

KNOWN: Inner and outer tube surface conditions for an annulus.

FIND: (a) Velocity profile, (b) Temperature profile and expression for inner surface Nusselt number.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Laminar, fully developed flow, (3) Uniform heat flux at inner surface, (4) Adiabatic outer surface, (5) Constant properties, (6) Negligible potential and kinetic energy changes, flow work, and viscous dissipation.

ANALYSIS: (a) From Section 8.1.3, the general solution to Eq. 8.12, which also applies to annular flow as represented in Figure 8.10, is

\[ u(r) = \frac{1}{\mu} \left( \frac{dp}{dx} \right) \left( \frac{r^2}{4} \right) + C_1 \frac{ln r}{r} + C_2. \]

Applying the boundary conditions,

\[ u(r_1) = 0 \quad 0 = \frac{1}{\mu} \left( \frac{dp}{dx} \right) \left( \frac{r_1^2}{4} \right) + C_1 \frac{ln r_1}{r_1} + C_2 \]

\[ u(r_0) = 0 \quad 0 = \frac{1}{\mu} \left( \frac{dp}{dx} \right) \left( \frac{r_0^2}{4} \right) + C_1 \frac{ln r_0}{r_0} + C_2. \]

Hence,

\[ C_1 = \frac{1}{\mu} \left( \frac{dp}{dx} \right) \left( \frac{r_0^2 - r_1^2}{4} \right) \quad C_2 = -\frac{1}{\mu} \left( \frac{dp}{dx} \right) \left( \frac{r_1^2}{4} \right) - \frac{1}{\mu} \left( \frac{dp}{dx} \right) \left( \frac{r_0^2}{4} \right) \frac{ln r_0}{ln (r_1/r_0)} \]

and the velocity distribution is

\[ u(r) = \frac{1}{\mu} \left( \frac{dp}{dx} \right) \left( \frac{r^2}{4} - \frac{r_1^2}{4} \right) + \frac{1}{\mu} \left( \frac{dp}{dx} \right) \left( \frac{r_0^2}{4} - \frac{r_1^2}{4} \right) \frac{ln r}{ln (r_1/r_0)} \]

\[ -\frac{1}{\mu} \left( \frac{dp}{dx} \right) \left( \frac{r_0^2}{4} - \frac{r_1^2}{4} \right) \frac{ln r_0}{ln (r_1/r_0)} \]

\[ u(r) = -\frac{r_0^2}{4\mu} \left( \frac{dp}{dx} \right) \left[ 1 - (r/r_0)^2 + \frac{(r_1/r_0)^2 - 1}{\ln (r_1/r_0)} \right]. \]

(b) For fully developed conditions with uniform surface heat flux,

\[ v = 0 \quad \frac{\partial T}{\partial x} = \frac{dT_m}{dx} = \text{const.} \]

Continued …..
Hence, from Eq. 8.48, which also applies for laminar flow,
\[
\frac{1}{r} \frac{\partial}{\partial r} \left( r \frac{\partial T}{\partial r} \right) = \frac{u}{\alpha} \frac{dT_m}{dx} - k \rho c_p \left( \frac{T_m}{T_s,i} - T_m \right)
\]
Substituting the velocity distribution, with
\[
C_1 = -\frac{r_0^2}{4\mu} \left( \frac{dp}{dx} \right) \quad \quad \quad \quad C_2 = \frac{(\eta / r_0)^2 - 1}{\ln (\eta / r_0)}
\]
Eq. (2)

it follows that
\[
\frac{1}{r} \frac{\partial}{\partial r} \left( r \frac{\partial T}{\partial r} \right) = \frac{C_1}{\alpha} \frac{dT_m}{dx} \left[ 1 - \left( \frac{r}{r_0} \right)^2 + C_2 \ln \left( \frac{r}{r_0} \right) \right]
\]
and the temperature distribution is
\[
T(r) = \frac{C_1}{\alpha} \frac{dT_m}{dx} \left[ \frac{r^2}{4} - \frac{r^4}{16 r_0^2} + C_2 \left( \frac{r}{2} \ln \frac{r}{r_0} - \frac{r^2}{4} \right) \right] + C_3 \ln r + C_4.
\]
Eq. (3)

From the requirement that \( q_i^\sigma = 0 \), it follows that \( \frac{\partial}{\partial r} \frac{T}{r} \bigg|_{r_0} = 0 \). Hence,
\[
\frac{C_1}{\alpha} \frac{dT_m}{dx} \left[ \frac{r_0}{2} - \frac{r_0}{4} + C_2 \left( -\frac{r_0}{4} \right) \right] + \frac{C_3}{r_0} = 0
\]
Eq. (4)

From the condition that \( T(r_i) = T_{s,i} \), it follows that
\[
C_4 = T_{s,i} - \frac{C_1}{\alpha} \frac{dT_m}{dx} \left[ \frac{r_i^2}{4} - \frac{r_i^4}{16 r_0^2} + C_2 \left( \frac{r_i^2}{4} \ln \frac{r_i}{r_0} - \frac{r_i^2}{4} \right) \right] + C_3 \ln r_i.
\]
Eq. (5)

From Eqs. 8.68 and 8.70, the inner surface Nusselt number is
\[
Nu_i = \frac{h_i D_h}{k} = \frac{q_i^\sigma D_h}{k (T_{s,i} - T_m)}
\]
where \( D_h = 2(r_o - r_i) \). To obtain a workable form of \( Nu_i \), the mean temperature \( T_m \) must be evaluated. This may be done by substituting Eqs. (1) and (3) into Eq. 8.27 and evaluating \( u_m \) by substituting Eq. (1) into Eq. 8.8. Since the integrations are long and tedious, they are not provided.

**COMMENTS:** From an energy balance performed for a differential control volume in the annular region, \( dT_m / dx = 2\pi q_i^\sigma / \rho \ c_p \ u_m \left( \frac{r_o^2 - r_i^2}{r_o} \right) \).
**PROBLEM 8.95**

**KNOWN:** Inlet temperature, pressure and flow rate of air. Annulus length and tube diameters. Pressure of saturated steam.

**FIND:** Outlet temperature and pressure drop of air. Mass rate of steam condensation.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Outer surface of annulus is adiabatic, (3) Negligible potential energy, kinetic energy and flow work changes for air, (4) Fully developed flow throughout annulus, (5) Smooth annulus surfaces, (6) Constant properties.

**PROPERTIES:** Table A-4, air \( \bar{T}_m \approx 325K, p = 5 \text{ atm} \):
\[ \rho = 5 \times \rho (1 \text{ atm}) = 5.391 \text{ kg/m}^3, \ c_p = 1008 \text{ J/kg\cdotK}, \ \mu = 196.4 \times 10^{-7} \text{ N\cdots/m}^2, k = 0.0281 \text{ W/m\cdotK}, \ Pr = 0.703. \]
Table A-6, sat. steam (\( p = 2.455 \text{ bars} \)):
\[ T_s = 400K, h_{fg} = 2183 \text{ kJ/kg}. \]

**ANALYSIS:** With a uniform surface temperature, the air outlet temperature is
\[
T_{m,o} = T_s - (T_s - T_{m,i}) \exp \left( -\frac{\pi D_i L}{m c_p} \right)
\]
With \( A_c = \pi \left( \frac{D_o^2 - D_t^2}{4} \right) = 1.355 \times 10^{-3} \text{ m}^2, \ D_h = D_o - D_t = 0.015 \text{ m} \) and \( \text{Re}_D = \rho u_m D_h / \mu = \dot{m}D_h / A_c \mu = 16,900 \), the flow is turbulent and the Dittus-Boelter correlation yields
\[
\bar{h} = h_{fd} = \left( \frac{k}{D_h} \right) 0.023 \text{Re}^{4/5} \text{Pr}^{0.4} \left( \frac{0.0281 \text{ W/m\cdotK}}{0.015} \right) 0.023 \left( 16,900 \right)^{4/5} \left( 0.703 \right)^{0.4} = 90.3 \text{ W/m}^2\cdot\text{K}
\]
\[
T_{m,o} = 127^\circ\text{C} - (110^\circ\text{C}) \exp \left( -\frac{\pi \times 0.05 \times 5 \times 90.3 \text{ W/m}^2\cdot\text{K}}{0.03 \text{ kg/s} \times 1008 \text{ J/kg\cdotK}} \right) = 116.5^\circ\text{C} <
\]
The pressure drop is
\[
\Delta p = f \left( \rho u_m^2 / 2D_h \right) L, \text{ where, with } u_m = \dot{m} / \rho A_c = 0.03 \text{ kg/s} / \left( 5.391 \text{ kg/m}^3 \times 1.355 \times 10^{-3} \text{ m}^2 \right) = 4.11 \text{ m/s}, \ \text{and with } \text{Re}_D = 16,900, \ \text{Fig. 8.3 yields } f = 0.026. \ \text{Hence,}
\]
\[
\Delta p = 0.026 \times 5.391 \text{ kJ/m}^3 \times \left( \frac{4.11 \text{ m/s}}{2 \times 0.015} \right)^2 \times 5 \text{ m} = 395 \text{ N/m}^2 = 3.9 \times 10^{-3} \text{ atm} <
\]
The rate of heat transfer to the air is
\[
q = \dot{m} c_p (T_{m,o} - T_{m,i}) = 0.03 \text{ kg/s} \times 1008 \text{ J/kg\cdotK} (99.5^\circ\text{C}) = 3009 \text{ W}
\]
and the rate of condensation is then
\[
\dot{m}_c = \frac{q}{h_{fg}} = \frac{3009 \text{ W}}{2.183 \times 10^6 \text{ J/kg}} = 1.38 \times 10^{-3} \text{ kg/s} <
\]

**COMMENTS:** (1) With \( \bar{T}_m = (T_{m,i} + T_{m,o}) / 2 = 340K \), the initial estimate of 325K is too low and an iterative solution should be obtained, (2) For a steam flow rate of 0.01 kg/s, approximately 14% of the outflow would be in the form of saturated liquid, (3) With \( L/D_h = 333 \), the assumption of fully developed flow throughout the tube is excellent.
PROBLEM 8.96

KNOWN: Dimensions and surface thermal conditions for a concentric tube annulus. Water flow rate and inlet temperature.

FIND: (a) Tube length required to achieve desired outlet temperature, (b) Inner tube surface temperature at outlet.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform heat flux at inner surface, (3) Adiabatic outer surface, (4) Fully developed flow at exit, (5) Constant properties.

PROPERTIES: Table A-6, Water (\( \bar{T}_m = 328K \)): \( c_p = 4183 \text{ J/kg} \cdot \text{K} \); \( T_{m,o} = 358K \): \( \mu = 332 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 \), \( k = 0.673 \text{ W/m} \cdot \text{K} \), \( Pr = 2.07 \).

ANALYSIS: (a) From the overall energy balance, Eq. 8.37,

\[
q = q_i L = \dot{m} c_p (T_{m,o} - T_{m,i})
\]

\[
L = \frac{\dot{m} c_p}{q_i} \left( T_{m,o} - T_{m,i} \right) = \frac{(0.04 \text{ kg/s}) \cdot 4183 \text{ J/kg} \cdot \text{K} \cdot (85 - 25) \text{ C}}{4000 \text{ W/m}} = 2.51 \text{ m}.
\]

(b) From Eqs. 8.1 and 8.5,

\[
\text{Re}_D = \frac{\rho \dot{m} D_h}{\mu} = \frac{\dot{m} D_h}{A_c \mu} = \frac{\dot{m} (D_o - D_i)}{(\pi/4) \left( D_o^2 - D_i^2 \right) \mu} = \frac{4 \dot{m}}{\pi (D_o + D_i) \mu}
\]

\[
\text{Re}_D = \frac{4 \times 0.04 \text{ kg/s}}{\pi (0.075 \text{ m}) 332 \times 10^{-6} \text{ kg/s} \cdot \text{m}} = 2045.
\]

Hence the flow is laminar, and with \( D_i/D_o = 0.5 \), it follows from Eq. 8.73 and Table 8.3

\[ Nu_i = Nu_{ii} = 6.24 \]

\[ h_i = 6.24 \frac{k}{D_h} = 6.24 \frac{0.673 \text{ W/m} \cdot \text{K}}{0.025 \text{ m}} = 168 \text{ W/m}^2 \cdot \text{K}. \]

From Eq. 8.68,

\[
T_{s,i} (L) = T_{m,o} + \frac{q'_i}{h_i} = T_{m,o} + \frac{q'_i}{\pi D_i}
\]

\[
T_{s,i} (L) = 85^\circ C + \frac{4000 \text{ W/m}}{\pi (0.025 \text{ m}) 168 \text{ W/m}^2 \cdot \text{K}} = 388^\circ C.
\]

COMMENTS: Unless the water is pressurized, local boiling would occur at the tube surface, causing \( h_i \) to be larger.
**PROBLEM 8.97**

**KNOWN:** Heat rate per unit length at the inner surface of an annular recuperator of prescribed dimensions. Flow rate and inlet temperature of air passing through annular region.

**FIND:** (a) Temperature of air leaving the recuperator, (b) Inner pipe temperature at inlet and outlet and outer pipe temperature at inlet.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties, (3) Uniform heating of recuperator inner surface, (4) Adiabatic outer surface, (5) Negligible kinetic and potential energy changes for air, (6) Fully developed air flow throughout.

**PROPERTIES:** Table A-4, Air \((T_m = 500K)\): \(c_p = 1030 \text{ J/kg K}, \mu = 270 \times 10^{-7} \text{ N s/m}^2, k = 0.041 \text{ W/m K}, \text{Pr} = 0.68.\)

**ANALYSIS:**

(a) From an energy balance on the air

\[
q_1^* = \dot{m}_a \, c_p \left( T_{a,2} - T_{a,1} \right)
\]

\[
T_{a,2} = T_{a,1} + \frac{q_1^* \, L}{\dot{m}_a \, c_p} = 300K + \frac{1.25 \times 10^5 \text{ W/m} \times 7 \text{ m}}{2.1 \text{ kg/s} \times 1030 \text{ J/kg K}} = 704.5K.
\]

(b) The surface temperatures may be evaluated from Eqs. 8.68 and 8.69 with

\[
\text{Re}_D = \frac{\rho \, u_m \, D_h}{\mu} = \frac{\dot{m}_a \, (D_0 - D_1)}{(\pi/4) \, (D_0^2 - D_1^2) \, \mu} = \frac{4 \, \dot{m}_a}{\pi \, (4.05 \text{ m}) \, 270 \times 10^{-7} \text{ N s/m}^2} \approx 24,452
\]

the flow is turbulent and from Eq. 8.60

\[
h = \frac{k}{\rho \, u_m \, D_h} = \frac{1}{0.023 \, \text{ Re}^{4/5}_D \, \text{ Pr}^{0.4}} = \frac{0.041 \text{ W/m K}}{0.05 \text{ m}} \times 0.023 \times (24,452)^{4/5} \times (0.68)^{0.4} = 52 \text{ W/m}^2 \text{ K}.
\]

With \(q_1^* = q_1^* \, /\pi \, D_1 = 1.25 \times 10^5 \text{ W/m} \times \pi \times 2 \text{ m} = 19,900 \text{ W/m}^2\)

Eq. 8.68 gives

\[
(T_{s,i} - T_m) = \frac{q_1^*}{h} = 19,900 \text{ W/m}^2 / 52 \text{ W/m}^2 \text{ K} = 383K
\]

\[
T_{s,i,1} = 683K \quad T_{s,i,2} = 1087K.
\]

From Eq. 8.69, with \(q_0^* = 0, \quad (T_{s,o} - T_m) = 0.\) Hence

\[
T_{s,o,1} = T_{a,1} = 300K.
\]
PROBLEM 8.98

KNOWN: A concentric tube arrangement for removing heat generated from a biochemical reaction in a settling tank. Water is supplied to the annular region at rate of 0.2 kg/s.

FIND: (a) The inlet temperature of the supply water that will provide for an average tank surface temperature of 37°C; assume and then justify fully developed flow and thermal conditions; and (b) Sketch the water and surface temperatures along the flow direction for two cases: the fully developed conditions of part (a), and when entrance effects are important. Comment on the features of the temperature distributions, with particular attention to the longitudinal gradient on the tank surface. What change to the system or operating conditions would you make to reduce the gradient?

SCHEMATIC:

ASSUMPTIONS: (1) Fully developed flow and thermal conditions, (2) Inner annulus surface has uniform heat flux, while outer surface is insulated, (3) Constant properties, (4) Negligible kinetic and potential energy changes and flow work.

PROPERTIES: Table A-6, Water (Tm = 304 K): ρ = 995.6 kg/m³, cp = 4178 J/kg·K, ν = 7.987 × 10⁻⁷ m²/s, k = 0.618 W/m·K, Pr = 5.39.

ANALYSIS: (a) The overall energy balance on the fluid passing through the concentric tube is

\[ q = \dot{m} c_p \left( T_{m,i} - T_{m,o} \right) \]  

and from an energy balance on the reaction tank,

\[ q = q_{s,i} A_{s,i} = \dot{q} (\pi D_i) L. \]  

The convection rate equation applied to the inner surface \( A_{s,i} \) is

\[ q_{c,v} = q_{s,i} = h_i \left( \bar{T}_s - T_m \right) \]  

where \( \bar{T}_s \) is the average inner surface temperature and

\[ T_m = \left( T_{m,i} + T_{m,o} \right) / 2. \]

To estimate \( h_i \), begin by characterizing the flow with

\[ \text{Re}_{Dh} = u_m D_h / \nu \quad \text{D}_h = D_o - D_i \quad \dot{m} = \rho A_c u_m \]

where \( A_c = \pi \left( D_o^2 - D_i^4 \right) / 4 \). Substituting numerical values find

\[ \text{Re}_{Dh} = 1779 \]

Assuming fully developed conditions for laminar flow through an annulus, it follows from Table 8.3 and Eq. 8.73 with \( D_i/D_o = 0.8 \),

\[ \bar{N}_{ui} = \bar{h}_i D_h / k = 5.58 \quad \bar{h}_i = 172 \text{ W/m}^2\cdot\text{K} \]

Continued .....
PROBLEM 8.98 (Cont.)

Using Eq. (3) with \( \bar{T}_i \), and \( T_s = 37^\circ C \), and \( q'_{S,i} \) from Eq. (2), find

\[ T_m = 30.5^\circ C \]

From Eqs. (1) and (4), calculate

\[ T_{m,i} = 30.3^\circ C \quad T_{m,o} = 30.6^\circ C \]

For this annulus, the thermal entry length from Eq. 8.23 is

\[ x_{fd,t} = D_h \times 0.05 \ Re D_h \ Pr \]

\[ x_{fd,t} = (0.100 - 0.080) m \times 0.05 \times 1779 \times 5.39 = 9.59 m \]

Since \( L = 1 m \), we conclude that entry length effects are significant, and the fully developed flow assumption is approximate.

(b) Since the fluid is being heated by flow over a surface with uniform heat flux, the mean fluid temperature, \( T_m(x) \), will increase linearly with longitudinal distance \( x \). Assuming fully developed conditions, the surface temperature \( T_s(x) \) will likewise increase linearly with distance as shown in the schematic below. Note that the longitudinal temperature difference is about \( 0.3^\circ C \), and that the inlet mean temperature is \( 30.3^\circ C \).

Considering now entrance length effects, the convection coefficient is no longer uniform, and will be largest near the entrance, and larger than for the fully developed flow everywhere. Hence, we expect the surface temperature near the entrance to be closer to the mean fluid temperature than elsewhere. We also expect the average mean temperature of the fluid will be higher so that the average surface temperature, \( T_s \), remains at \( 37^\circ C \). However, the rise in temperature of the fluid \( (T_{m,o} - T_{m,i}) \) will remain the same, about \( 0.3^\circ C \), since the heat removal rate is the same. Increasing the flow rate will tend to minimize the longitudinal gradient by reducing \( (T_{m,o} - T_{m,i}) \) and increasing \( h(x) \). The graph below illustrates the distinctive features of the fully developed flow and entrance length effects.

**COMMENTS:** The thermophysical properties required in the convection correlation and the energy equations were evaluated at \( T_m = (T_{m,i} + T_{m,o})/2 \).
PROBLEM 8.99

KNOWN: Surface thermal conditions and diameters associated with a concentric tube annulus. Water flow rate and inlet temperature.

FIND: (a) Length required to achieve desired outlet temperature, (b) Heat flux from inner tube at outlet.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Fully developed conditions throughout, (3) Adiabatic outer surface, (4) Uniform temperature at inner surface, (5) Constant properties.

PROPERTIES: Table A-6, Water \( (T_m = 320K) \): \( c_p = 4180 \text{ J/kg} \cdot \text{K}, \mu = 577 \times 10^{-6} \text{ N} \cdot \text{s/m}^2, k = 0.640 \text{ W/m} \cdot \text{K}, \) \( Pr = 3.77. \)

ANALYSIS: (a) From Eq. 8.42a,

\[
L = -\frac{m c_p}{\text{Pr}} \frac{\Delta T_o}{\Delta T_i} = -\frac{m c_p}{\pi D_i h} \frac{T_s - T_{m,o}}{T_s - T_{m,i}}.
\]

With \( \text{Re}_D = \frac{\rho u_m D_h}{\mu} = \frac{m \left( D_o - D_i \right)}{(\pi/4) \left( D_o^2 - D_i^2 \right) \mu} = \frac{4 m}{\pi \left( D_o + D_i \right) \mu} \)

\[
\text{Re}_D = \frac{4 \times 0.02 \text{ kg/s}}{\pi \left( 0.125 \text{m} \right) 577 \times 10^{-6} \text{N} \cdot \text{s/m}^2} = 353
\]

the flow is laminar. Hence, from Eq. 8.70 and Table 8.2,

\[
\bar{h} = h_i = \frac{k}{D_h} \text{Nu}_i = \frac{0.64 \text{ W/m} \cdot \text{K}}{(0.100 - 0.025) \text{ m}} 7.37 = 63 \text{ W/m}^2 \cdot \text{K}
\]

and \( L = -\frac{0.02 \text{ kg/s} \left( 4180 \text{ J/kg} \cdot \text{K} \right)}{\pi \left( 0.025 \text{m} \right) 63 \text{ W/m}^2 \cdot \text{K}} \left( 100 - 75 \right) \text{°C} = 19.7 \text{ m}. \)

(b) From Eq. 8.69

\[
q_i^\prime (L) = h_i \left( T_{s,i} - T_{m,o} \right) = 63 \frac{W}{m^2} \left( 100 - 75 \right) \text{°C} = 1575 \text{ W/m}^2.
\]

COMMENTS: The total heat rate to the water is

\[
q = m c_p \left( T_{m,o} - T_{m,i} \right) = 0.02 \text{ kg/s} \times 4180 \text{ J/kg} \cdot \text{K} \left( 55 \text{°C} \right) = 4598 \text{ W}.
\]
PROBLEM 8.100

KNOWN: Surface thermal conditions and diameters associated with a concentric tube annulus. Water flow rate and inlet temperature.

FIND: Length required to achieve desired outlet temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Fully developed conditions throughout, (3) Adiabatic outer surface, (4) Uniform temperature at inner surface, (5) Constant properties.

PROPERTIES: Table A-6, Water \( (T_m = 320\, \text{K}) \): \( c_p = 4180 \, \text{J/kg}\cdot\text{K}, \mu = 577 \times 10^{-6} \, \text{N}\cdot\text{s}/\text{m}^2, \) \( k = 0.640 \, \text{W/m}\cdot\text{K}, \) \( Pr = 3.77. \)

ANALYSIS: From Eq. 8.42a,

\[
L = -\frac{\dot{m} c_p}{\mu h} \Delta T_0 = \frac{\dot{m} c_p}{\mu D_l h} \Delta T_i = \frac{\dot{m}}{\pi D_l h} T_s - T_{m,o}.
\]

With

\[
\operatorname{Re}_D = \frac{\rho u_m D_h}{\mu} = \frac{\dot{m} (D_o - D_i)}{(\pi/4) \left( \frac{D_o^2 - D_i^2}{D_o} \right) \mu} = \frac{4 \dot{m}}{\pi (D_o + D_i) \mu}
\]

\[
\operatorname{Re}_D = \frac{4 \times 0.30 \, \text{kg/s}}{\pi (0.125\, \text{m}) 577 \times 10^{-6} \, \text{N}\cdot\text{s}/\text{m}^2} = 5296
\]

and the flow is turbulent. Hence, from Eq. 8.60,

\[
\bar{h} = \frac{k}{D_h} \frac{\operatorname{Nu}_D}{D_h} = 0.023 \frac{k}{D_h} \frac{\operatorname{Re}_D^{4/5} \, Pr^{0.4}}{D_h}
\]

\[
\bar{h} = 0.023 \frac{0.640 \, \text{W/m}\cdot\text{K}}{0.075 \, \text{m}} (5296)^{4/5} (3.77)^{0.4} = 318 \, \text{W/m}^2\cdot\text{K}
\]

and hence the required length is

\[
L = -\frac{0.30 \, \text{kg/s} \times (4180 \, \text{J/kg}\cdot\text{K})}{\pi (0.025\, \text{m}) 318 \, \text{W/m}^2\cdot\text{K}} (100 - 75) \, ^\circ\text{C} = 58.4 \, \text{m}.
\]

COMMENTS: Increasing \( \dot{m} \) by a factor of 15 increases \( \operatorname{Re}_D \) accordingly, and the flow is turbulent. However, \( \bar{h} \) increases by a factor of only 5, from the result of Problem 8.99, in which case the tube length must be a factor of 3 larger than that of Problem 8.99.
PROBLEM 8.101

FIND: (a) Air outlet temperature and fan power requirement without coating and coiled spring, (b) Effect of coiled spring on air outlet temperature and fan power, (c) Effect of coating on outlet temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Negligible heat transfer from air in vertical pipe sections, (3) Negligible flow work and potential and kinetic energy changes for air flow through pipe, (4) Smooth interior surface without spring, (5) Negligible coating thickness, (6) Constant properties.

PROPERTIES: Table A-4, Air (T_{m,i} = 29°C): \( \rho_i = 1.155 \text{ kg/m}^3 \). Air (\( \bar{T}_m = 25°C \)): \( c_p = 1007 \ J/kg \cdot K, \mu = 183.6 \times 10^{-7} \ N \cdot s/m^2, k_a = 0.0261 \ W/m \cdot K, \text{Pr} = 0.707. \)

ANALYSIS: (a) From Eq. (8.46a),
\[
\frac{T_{\infty} - T_{m,o}}{T_{\infty} - T_{m,i}} = \exp \left( -\frac{\bar{U}A_S}{m c_p} \right)
\]
where, from Eq. (3.32),
\[
\left( \frac{\bar{U}A_S}{m c_p} \right)^{-1} = R_{tot} = \frac{1}{\bar{h_i} \pi D_i L} + \frac{\ln(D_o/D_i)}{2 \pi L k} + \frac{1}{h_o \pi D_o L}
\]
With \( m = \rho_i \bar{V}_i = 0.0289 \text{ kg/s} \) and \( \text{Re}_D = 4m/\pi D_i \mu = 13,350, \) the pipe flow is turbulent. With \( L/D_i = 100, \) we may assume fully developed flow throughout the pipe, and from Eq. (8.60),
\[
\bar{h}_i = \frac{ka}{D_i} 0.023 \text{ Re}_D^{4/5} \text{ Pr}^{0.3} = 0.0261 \text{ W/m} \cdot \text{K} \cdot 0.023(13,350)^{4/5} (0.707)^{0.3} = 7.20 \text{ W/m}^2 \cdot \text{K}
\]
Hence,
\[
R_{tot} = \left( \frac{1}{7.20 \times \pi \times 0.15 \times 15} + \ln(0.17/0.15) + \frac{1}{1500 \times \pi \times 0.17 \times 15} \right) \text{K/W}
\]
\[
R_{tot} = (0.0196 + 0.0089 + 0.0001) \text{K/W} = 0.0286 \text{ K/W}
\]
Hence, \( \bar{U}A_S = R_{tot}^{-1} = 35.0 \text{ W/K} \) and
\[
T_{m,o} = T_{\infty} + (T_{m,i} - T_{\infty}) \exp \left( -\frac{\bar{U}A_S}{m c_p} \right) = 17°C + (12°C) \exp \left( -\frac{35.0 \text{ W/K}}{0.0289 \text{ kg/s} \times 1007 \text{ J/kg} \cdot \text{K}} \right) = 20.6°C
\]
Continued …..
From Eq. (8.20a), \( f = 0.316 \) \( \frac{Re^{-1/4}}{Re} = 0.0294 \). Hence, from Eqs. (8.22a) and (8.22b), with \( u_{m,i} = \dot{V}_i / A_c = 1.415 \text{ m/s} \),

\[
P = f \frac{\rho u_{m,i}^2}{2D_i} L \dot{V}_i = 0.0294 \frac{1.155 \text{ kg/m}^3 (1.415 \text{ m/s})^2}{2(0.15 \text{ m})} 15 \text{ m} \times 0.025 \text{ m}^3 / \text{s} = 0.085 \text{ W}
\]

(b) With \( h_{cp} = 2h_i = 14.4 \text{ W/m}^2 \cdot \text{K} \), the inner convection resistance is reduced from 0.0196 K/W to 0.0098 K/W and hence the total resistance from 0.0286 K/W to 0.0188 K/W. It follows that \( \bar{U}A_s = 53.2 \text{ W/K} \) and

\[
T_{m,o} = 18.9^\circ \text{C}
\]

With \( f_{cp} = 1.5f \),

\[
P = 0.128 \text{ W}
\]

(c) With the coating of organic matter, there is an additional thermal resistance of the form \( R_{t,c} = \frac{R_{t,c}^*}{(\pi D_o L)} = \left(0.05 \text{ m}^2 \cdot \text{K/W}\right) / (\pi \times 0.17\text{m} \times 15\text{m}) = 0.0062 \text{ K/W} \). The total resistance is then \( R_{tot} = 0.0348 \text{ K/W} \) and \( \bar{U}A_s = 28.7 \text{ W/K} \). Hence,

\[
T_{m,o} = 21.5^\circ \text{C}
\]

**COMMENTS:** (1) The fan power requirement is small, and the process is economical, with or without the coiled spring. (2) Heat transfer enhancement associated with the coiled spring is manifested by a 34% reduction in the total thermal resistance and a 1.7°C reduction in the outlet temperature. (3) Fouling of the outer surface increases the total resistance by 22% and the outlet temperature by 0.9°C. The penalty is not severe but could be ameliorated by periodic cleaning of the surface.
PROBLEM 8.102

KNOWN: Air flow through a plastic tube in which evaporation occurs.

FIND: Convection mass transfer coefficient, \( h_m \).

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Heat-mass transfer analogy applicable, (4) Fully-developed flow and mass transfer conditions.

PROPERTIES: Plastic-air (given, 400K): \( \text{Sc} = \frac{v}{D_{AB}} = 2.0 \); Table A-4, Air (400K, 1 atm): \( v = 26.41 \times 10^{-6} \text{ m}^2/\text{s} \).

ANALYSIS: For fully-developed flow and thermal conditions with laminar flow and a uniform surface temperature,

\[
\frac{Nu_D}{k} = \frac{h D}{k} = 3.66
\]

This situation is analogous to the evaporation of plastic vapor into the air stream with the inner surface remaining at a constant concentration of plastic vapor, \( C_{A,s} \), along the length of the tube. Invoking the heat-mass transfer analogy,

\[
\frac{Sh_D}{D_{AB}} = \frac{h_m D}{D_{AB}} = 3.66.
\]

Recognizing that \( \text{Sc} = \frac{v}{D_{AB}} \),

\[
h_m = 3.66 \left( \frac{v}{\text{Sc}} \right) \frac{1}{D} = 3.66 \times \frac{26.4 \times 10^{-6} \text{ m}^2/\text{s}}{2.0} \times \frac{1}{2 \times 10^{-3} \text{ m}} = 2.42 \times 10^{-2} \text{ m/s}. \]

COMMENTS: (1) The heat-mass transfer analogy requires that the vapor (A) have a negligible effect on the flow. Hence, the flow is that of air (B) and \( v = v_B \).

(2) Only the mixture property \( D_{AB} \) is required to characterize the plastic vapor for this evaporation process.
PROBLEM 8.103

KNOWN: Air passing upward through a tube having a thin water film on its inside surface.

FIND: Convection mass transfer coefficient.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Heat-mass analogy applicable, and (4) Fully developed flow and thermal conditions.

PROPERTIES: Table A.4, Air (300 K, 1 atm): $\mu = 184.6 \times 10^{-7}$ N⋅s/m², $k = 0.0263$ W/m⋅K; Table A.8, Water vapor-air (300 K, 1 atm): $D_{AB} = 0.26 \times 10^{-4}$ m²/s.

ANALYSIS: Begin by characterizing the air flow with the Reynolds number,

$$Re_D = \frac{4\dot{m}}{\pi D\mu} = \frac{4 \times (3/3600) \text{kg/s}}{\pi \times 0.030 \text{m} \times 184.6 \times 10^{-7} \text{N/s} \cdot \text{m}^2} = 1916$$

Since the flow is laminar, and assuming fully developed flow and thermal conditions, Eq. 8.55 is appropriate for the uniform $T_s$ wall condition,

$$Nu_D = \frac{h D}{k} = 3.66$$

$$h = \frac{0.0263 \text{ W/m} \cdot \text{K}}{0.030 \text{ m}} \times 3.66 = 3.21 \text{ W/m}^2 \cdot \text{K}$$

Invoking the heat-mass analogy, for laminar flow conditions,

$$Sh_D = \frac{h_m D}{D_{AB}} = Nu_D$$

$$h_m = \frac{D_{AB}}{D} \left( \frac{0.26 \times 10^{-4} \text{ m}^2/\text{s}}{0.030 \text{ m}} \right) \times 3.66 = 0.0032 \text{ m/s}$$

COMMENTS: (1) The heat-mass analogy requires that the water vapor (A) have negligible effect on the velocity boundary layer. It is important to recognize that the vapor is species (A) and the air species (B). Hence the flow is that of air (B) and hence $\mu = \mu_B$.

(2) Note only the mixture property $D_{AB}$ is required to characterize the water vapor for this evaporation process.
PROBLEM 8.104

KNOWN: Temperature and flow rate of air in a tube with a naphthalene coated inner surface.

FIND: Convection mass transfer coefficient under fully developed conditions and velocity and concentration entry lengths.

SCHEMATIC:

ASSUMPTIONS: (1) Heat and mass transfer analogy is applicable, (2) Uniform vapor concentration along inner surface.

PROPERTIES: Table A-4, Air (300K, 1 atm): \( \mu = 184.6 \times 10^{-7} \text{ N} \cdot \text{s/m}^2 \), \( \nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s} \); Table A-8, Naphthalene-air (300K, 1 atm): \( D_{AB} = 6.2 \times 10^{-6} \text{ m}^2/\text{s} \), \( Sc = \mu/D_{AB} = 2.56 \).

ANALYSIS: For air flow through the tube,
\[
Re_D = \frac{4 \dot{m}}{\pi D \mu} = \frac{4 \times 0.04 \text{ kg/s}}{\pi (0.05 \text{ m}) 184.6 \times 10^{-7} \text{ N} \cdot \text{s/m}^2} = 55,178.
\]
Hence the flow is turbulent and from the Colburn equation, Eq. 8.59,
\[
Sh_D = 0.023 \frac{Re_D^{4/5} Sc^{1/3}}{= 0.023(55,178)^{4/5}(2.56)^{1/3} = 196}
\]
\[
h_m = \frac{D_{AB}}{D} \frac{Sh_D}{0.05 \text{ m}} = \frac{6.2 \times 10^{-6} \text{ m}^2/\text{s}}{0.05 \text{ m}} = 0.024 \text{ m/s}.
\]
From Eq. 8.4, it follows that
\[
10D \leq x_{fd,h} = x_{fd,c} \leq 60D
\]
or
\[
0.5 \text{ m} \leq x_{fd,h} = x_{fd,c} \leq 3 \text{ m}.
\]
An entry length of 0.5m is assumed.

COMMENTS: Note that the flow properties are taken to be those of the air, with the contribution of the naphthalene vapor assumed to be negligible.
PROBLEM 8.105

KNOWN: Air flow over roughened section of tube constructed from naphthalene.

FIND: Mass and heat transfer convection coefficients associated with the roughened section; contrast these results with those for a smooth section.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Heat-mass transfer analogy applicable, (3) Negligible naphthalene vapor in airstream, $\rho_{A,m} = 0$, (4) Constant properties, (5) Naphthalene vapor behaves as perfect gas.

PROPERTIES: 
- Table A-4, Air (300K, 1 atm): $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 0.0263 \text{ W/mK}$, $Pr = 0.707$; 
- Table A-8, Naphthalene-air mixture (300K, 1 atm): $D_{AB} = 0.62 \times 10^{-5} \text{ m}^2/\text{s}$, $Sc = \nu_B/D_{AB} = 2.563$; 
- Naphthalene (given, 300K): $p_{sat,A} = 1.31 \times 10^{-4} \text{ bar}$, $M_A = 128.16 \text{ kg/kmol}$.

ANALYSIS: Using the rate equation with the experimentally observed sublimination rate of naphthalene vapor, the average mass transfer coefficient for the section is

$$h_m = \frac{m_A}{(\pi DL)} \left( \rho_{A,s} - \rho_{A,m} \right)$$

$$\rho_{A,m} = 0 \quad \rho_{A,s} = \rho_{A,sat (300K)} = M_A \frac{p_{sat,A}}{RT}$$

$$\rho_{A,s} = 128.16 \text{ kg/kmol} \times \frac{1.31 \times 10^{-4} \text{ bar}}{8.314 \times 10^{-2} \text{ m}^3/\text{mol} \cdot \text{K} \times 300 \text{ K}} = 6.731 \times 10^{-4} \text{ kg/m}^3$$

$$h_m = \frac{0.010 \text{ kg}}{(\pi \times 0.075 \text{ m} \times 0.150 \text{ m})} \left( 6.731 \times 10^{-4} - 0 \right) \text{ kg/m}^3 = 3.89 \times 10^{-2} \text{ m/s}.$$  

Invoking the heat-mass transfer analogy, the associated heat transfer coefficient is

$$h = h_m \frac{k}{D_{AB}} \left( \frac{Pr}{Sc} \right)^{1/3} = 3.89 \times 10^{-2} \text{ m/s} \left( \frac{0.0263 \text{ W/mK}}{0.62 \times 10^{-5} \text{ m}^2/\text{s}} \left( \frac{0.707}{2.563} \right)^{1/3} \right) = 107 \text{ W/m}^2 \cdot \text{K}.$$  

The corresponding convection coefficients for a smooth section can be estimated using the Colburn relation,

$$h = \frac{k}{D} 0.023 \text{ Re}_D^{4/5} Pr^{1/3} = \left( 0.0263 \text{ W/mK} / 0.075 \text{ m} \right) \times 0.023 \left( 35,000 \right)^{4/5} (0.707)^{1/3} = 31 \text{ W/m}^2 \cdot \text{K}.$$  

Invoking the heat-mass transfer analogy,

$$h_m = (D_{AB}/D) 0.023 \text{ Re}_D^{4/5} Sc^{1/3} = \left( 0.62 \times 10^{-5} \text{ m}^2 / \text{s} / 0.075 \text{ m} \right) \times 0.023 \left( 35,000 \right)^{4/5} (2.563)^{1/3}$$

$$h_m = 1.12 \times 10^{-2} \text{ m/s}$$  

COMMENTS: The effect of roughening is to increase the convection coefficients over the corresponding value for the smooth condition; in this case, by a factor of approximately 3.5.
PROBLEM 8.106

KNOWN: Dry air with prescribed velocity and temperature flowing over a thin-walled tube with a water-saturated fibrous coating. Water passes at a prescribed rate through the tube to maintain an approximately uniform surface temperature $T_s = 27^\circ C$.

FIND: (a) Heat rate from the external surface of the tube considering heat and mass transfer processes and (b) For a flow rate of $m = 0.025$ kg/s, the inlet temperature, $T_{m,i}$, of the water that must be supplied to the tube.

SCHEMATIC:

\[ T_{\infty} = 35^\circ C \]
\[ V = 10 \text{ m/s} \]

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Heat-mass analogy applicable, and (4) Negligible kinetic energy and axial conduction in the tube flow.

PROPERTIES: Table A.4, Air ($\bar{T_f} = (T_s + T_w)/2 = 304$ K): $\rho = 1.148$ kg/m$^3$, $c_p = 1007$ J/kg$\cdot$K, $\nu = 16.29 \times 10^{-6}$ m$^2$/s, $k = 0.0266$ W/m$\cdot$K, $\alpha = 23.09 \times 10^{-6}$ m$^2$/s, Pr = 0.706; Table A.6, Water ($T_s = 300$ K): $\rho_{A,s} = 1/\gamma g = 0.02556$ kg/m$^3$, $h_{fg} = 2438$ kJ/kg, $\mu = 855 \times 10^{-6}$ N$\cdot$s/m$^2$; Table A.6, Water ($\bar{T_m} = 305$ K): $\rho = 995$ kg/m$^3$, $c_p = 4178$ J/kg$\cdot$K, $\mu = 769 \times 10^{-6}$ N$\cdot$s/m$^2$, $k = 0.620$ W/m$\cdot$K, Pr = 5.20; Table A.8, Water vapor-air ($T_s = 300$ K): $D_{AB} = 0.26 \times 10^{-4}$ m$^2$/s.

ANALYSIS: (a) On the Schematic above, the surface energy balance yields

\[ \dot{q}_{\text{out}} = \dot{q}_{\text{conv}} + \dot{q}_{\text{evap}} \quad (1) \]

and substituting the rate equations,

\[ \dot{q}_{\text{conv}} = \bar{h}_o A_s (T_s - T_{\infty}) \]
\[ \dot{q}_{\text{evap}} = n_A h_{fg} = \bar{h}_m A_s (\rho_{A,s} - \rho_{A,\infty}) h_{fg} \quad (2,3) \]

where $\bar{h}_o$ can be estimated from an appropriate correlation and $\bar{h}_m$ from the heat-mass analogy using $\bar{h}_o$.

Estimation of the heat transfer coefficient, $\bar{h}_o$: The Reynolds number, evaluated with properties at $\bar{T_f} = (T_s + T_w)/2 = 304$ K, is

\[ \text{Re}_{D_o} = \frac{VD}{\nu} = \frac{10 \text{ m/s} \times 0.020 \text{ m}}{1.629 \times 10^{-5} \text{ m}^2/\text{s}} = 12,277 \quad (4) \]

Using the Churchill-Bernstein correlation, Eq. 7.57, for cross flow over a cylinder, find $\bar{h}_o$

\[ \text{Nu}_{D_o} = 0.3 + \left[ \frac{0.62 \text{Re}^{1/2} \text{Pr}_{D_o}^{1/3}}{1 + (0.4/\text{Pr}_o)^{2/3}} \right]^{1/4} \left[ 1 + \left( \frac{\text{Re}_{D_o}}{282,000} \right)^{5/8} \right]^{4/5} \quad (5) \]

Continued...
**PROBLEM 8.106 (Cont.)**

\[
\begin{align*}
\text{Nu}_{D,o} &= 0.3 + \frac{0.62(12.277)^{1/2}(0.706)^{1/3}}{\left[1+(0.4/0.706)^{2/3}\right]^{1/4}} \left[1+\left(\frac{12.277}{282.000}\right)^{5/8}\right]^{4/5} \\
\bar{h}_o &= \frac{k}{D} \text{Nu}_{D,o} = \frac{0.0266 \text{ W/m·K}}{0.020 \text{ m}} \times 60.1 = 80.0 \text{ W/m}^2 \cdot \text{K}
\end{align*}
\]

The Heat-Mass Analogy: From Eq. 6.92, with \( n = 1/3 \),

\[
\frac{\bar{h}_o}{\bar{h}_m} = \rho c_p L e^{2/3} = \rho c_p \left( \frac{\alpha}{D AB} \right)^{2/3}
\]

\[
\bar{h}_m = 80.0 \text{ W/m}^2 \cdot \text{K} \left[1.148 \text{ kg/m}^3 \times 1007 \text{ J/kg·K} \left(23.09 \times 10^{-6} \text{ m}^2/\text{s}/0.26 \times 10^{-4} \text{ m}^2/\text{s}\right)^{2/3}\right] = 0.0749 \text{ m/s}
\]

Hence, the heat rate leaving the tube surface from Eq. (1) is,

\[
q_{\text{out}} = \left[80 \text{ W/m}^2 \cdot \text{K} \left(27 - 35\right) ^{5/8} + 0.0749 \text{ m/s}(0.02556 - 0) \text{ kg/m}^3 \times 2438 \times 10^3 \text{ J/kg}\right](\pi \times 0.020 \text{ m} \times 0.200 \text{ m})
\]

\[
q_{\text{out}} = -8.04 \text{ W} + 58.65 = 50.6 \text{ W}
\]

(b) For tube flow analysis, the heat rate and rate equations are

\[
q = \dot{m} c_p \left(T_{m,o} - T_{m,i}\right) \quad \frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp\left(-\frac{\pi D L}{\dot{m} c_p} \bar{h}_i\right)
\]

where \( T_s = 27^\circ \text{C} \), the uniform temperature of the tube surface, and \( q = -50.6 \text{ W} \) according to the analysis of part (a). To estimate \( \bar{h}_i \), first characterize the flow,

\[
\text{Re}_{D,i} = \frac{4 \dot{m}}{\pi D u_i} = \frac{4 \times 0.025 \text{ kg/s}}{\pi \times 0.020 \text{ m} \times 769 \times 10^{-6} \text{ N·s/m}^2} = 2070
\]

using properties evaluated at an assumed mean temperature, \( T_m = 305 \text{ K} \) (slightly above \( T_s \)). The flow is laminar, and assuming a combined entry region, use the Sieder-Tate correlation, Eq. 8.57,

\[
\text{Nu}_{D,i} = 1.86 \left(\text{Re}_{D,i} \text{ Pr}_l \right)^{1/3} \left(\frac{\mu}{\mu_s}\right)^{0.14}
\]

\[
\text{Nu}_{D,i} = 1.86 \left(\frac{2070 \times 5.20}{0.200/0.020}\right)^{1/3} \left(\frac{769 \times 10^{-6}}{855 \times 10^{-6}}\right)^{0.14}
\]

\[
\bar{h}_i = \frac{k_i}{D} \text{Nu}_{D,i} = \frac{0.620 \text{ W/m·K}}{0.020 \text{ m}} \times 18.78 = 582 \text{ W/m}^2 \cdot \text{K}
\]

Referring to Eqs. (7) and (8), recognize that there are two unknowns, \( T_{m,i} \) and \( T_{m,o} \), as we have evaluated both \( q \) and \( \bar{h}_i \). Using the IHT solver, we found

\[
T_{m,i} = 34.2^\circ \text{C} \quad T_{m,o} = 33.7^\circ \text{C}
\]

Continued...
COMMENTS: Using the IHT Rate Equation Tool, Rate Equation for a Tube, Constant Surface Temperature, and the Correlation, Internal Flow, Laminar, Combined Entry Length, a model to perform the analysis for part (b) was developed and is copied below.

// Rate Equation Tool - Tube, Constant Surface Temperature:
/* For flow through a tube with a uniform wall temperature, Fig 8.7b, the overall energy balance and heat rate equations are */
q = mdot*cp*(Tmo - Tmi)    // Heat rate, W; Eq 8.37
q = - 50.64 // Heat rate, W; required to sustain heat loss on outer surface
(Ts - Tmo) / (Ts - Tmi) = exp ( - P * L * h / (mdot * cp)) // Eq 8.42b
// where the fluid and constant tube wall temperatures are
Ts = 27 + 273 // Tube wall temperature, K
Tmi_C = Tmi - 273 // Inlet mean fluid temperature, K
Tmo_C = Tmo - 273 // Outlet mean fluid temperature, K
// The tube parameters are
P = pi * D // Perimeter, m
Ac = pi * (D^2) / 4 // Cross sectional area, m^2
D = 0.020 // Tube diameter, m
L = 0.20 // Tube length, m
// The tube mass flow rate and fluid thermophysical properties are
mdot = rho * um * Ac
mdot = 0.025

// Properties Tool - Water
// Water property functions : T dependence, From Table A.6
// Units: T(K), p(bars);
x = 0 // Quality (0=sat liquid or 1=sat vapor)
rho = rho_Tx("Water",Tm,x) // Density, kg/m^3
cp = cp_Tx("Water",Tm,x) // Specific heat, J/kg·K
mu = mu_Tx("Water",Tm,x) // Viscosity, N-s/m^2
mus = mu_Tx("Water",Ts,x) // Viscosity, N-s/m^2

PROBLEM 8.107

KNOWN: Density and flow rate of gas through a tube with evaporation or sublimination at the tube surface.

FIND: (a) Longitudinal distribution of mean vapor density, (b) Total rate of vapor transfer.

SCHEMATIC:

ASSUMPTIONS: (1) Steady, incompressible flow, (2) Flow rate is independent of x, (3) Negligible chemical reactions, (4) Uniform perimeter P.

ANALYSIS: (a) Applying conservation of species to a differential control volume

\[
\rho_{A,m} u_{m} A_{c} + d n_{A} = \left( \rho_{A,m} + \frac{d \rho_{A,m}}{d x} \right) u_{m} A_{c}
\]

or, with \( u_{m} A_{c} = \dot{m}/\rho \) and \( d n_{A} = h_{m} P \, dx \left( \rho_{A,s} - \rho_{A,m} \right) \),

\[
\frac{\dot{m}}{\rho} \frac{d \rho_{A,m}}{d x} \, dx = h_{m} P \, dx \left( \rho_{A,s} - \rho_{A,m} \right).
\]

Separating variables and integrating,

\[
\int_{\rho_{A,m,i}}^{\rho_{A,m}} \frac{d \rho_{A,m}}{\rho_{A,s} - \rho_{A,m}} = \int_{0}^{x} \frac{\rho_{A,s} h_{m}}{\dot{m}} \, dx = \frac{\rho_{A,s} P}{\dot{m}} \int_{0}^{x} h_{m} \, dx
\]

\[
\frac{\rho_{A,s} - \rho_{A,m}}{\rho_{A,s} - \rho_{A,m,i}} = \frac{\rho_{A,s} - \rho_{A,m}(x)}{\rho_{A,s} - \rho_{A,m,i}} = \exp \left( -\frac{\rho_{A,s} h_{m} x}{\dot{m}} \right).
\]  

(b) With \( \Delta \rho_{A} \equiv \rho_{A,s} - \rho_{A,m} \),

\[ n_{A} = \left( \dot{m}/\rho \right) \left( \rho_{A,m,o} - \rho_{A,m,i} \right) = -\left( \dot{m}/\rho \right) \left( \Delta \rho_{A,o} - \Delta \rho_{A,i} \right) \]

and from Eq. (1) with

\[
-\frac{\dot{m}}{\rho} = P L \bar{h}_{m} / \ell_{n} \frac{\Delta \rho_{A,o}}{\Delta \rho_{A,i}}
\]

it follows that

\[
n_{A} = \bar{h}_{m} P L / \ell_{n} \left( \Delta \rho_{A,o} / \Delta \rho_{A,i} \right).
\]

COMMENTS: Due to the addition of vapor, \( \dot{m} \) will actually increase with x. However, if the specific humidity of the saturated gas-vapor mixture is small (as is usually the case), the change in \( \dot{m} \) will be small.
PROBLEM 8.108

FIND: (a) Vapor density at tube outlet, (b) Evaporation rate.

SCHEMATIC:

ASSUMPTIONS: (1) Steady, incompressible flow, (2) Constant flow rate, (3) Isothermal system (water film maintained at 25°C), (4) Fully developed flow.

PROPERTIES: Table A-4, Air (1 atm, 298K): \( \rho = 1.1707 \text{ kg/m}^3 \), \( \mu = 183.6 \times 10^{-7} \text{ N} \cdot \text{s/m}^2 \), \( \nu = 15.71 \times 10^{-6} \text{ m}^2/\text{s} \); Table A-6, Water vapor (298K): \( \rho_{A, \text{sat}} = 1/\sqrt{g} = (1/44.25 \text{ m}^3/\text{kg}) = 0.0226 \text{ kg/m}^3 \); Table A-8, Air-vapor (298K): \( D_{AB} = 26 \times 10^{-6} \text{ m}^2/\text{s} \); Sc = \( \nu/D_{AB} = 0.60 \).

ANALYSIS: (a) From Equation 8.81, 
\[
\rho_{A,m,o} = \rho_{A,s} - \left( \rho_{A,s} - \rho_{A,m,i} \right) \exp \left( -\frac{\pi DL}{m} \bar{h}_m \right)
\]

\[
\text{Re}_D = \frac{4 \bar{m}}{\pi Du} = \frac{4 \times 3 \times 10^{-4} \text{ kg/s}}{\pi (0.01 \text{ m}) 183.6 \times 10^{-7} \text{ N} \cdot \text{s/m}^2} = 2080.
\]

Flow is laminar and from the mass transfer analogy to Eq. 8.57,
\[
\overline{Sh}_D = 1.86 \left( \frac{\text{Re}_D \text{Sc}}{L/D} \right)^{1/3} = 1.86 \left( \frac{2080 \times 0.60}{100} \right)^{1/3} = 4.31
\]

\[
\bar{h}_m = \frac{\overline{Sh}_D D_{AB}}{\bar{D}} = \frac{4.31 \times 26 \times 10^{-6} \text{ m}^2/\text{s}}{0.01 \text{ m}} = 0.0112 \text{ m/s}
\]

\[
\rho_{A,m,o} = 0.0226 \text{ kg/m}^3
\]

\[
-0.0226 \text{ kg/m}^3 \exp \left( -\frac{\pi \times 0.01 \text{ m} \times 1 \text{ m} \times 1.17 \text{ kg/m}^3 \times 0.0112 \text{ m/s}}{3 \times 10^{-4} \text{ kg/s}} \right) = 0.0169 \text{ kg/m}^3 \quad <\n\]

(b) The evaporation rate is

\[
n_A = \frac{u}{m} \lambda_{A,c} \left( \rho_{A,m,o} - \rho_{A,m,i} \right) = \frac{\bar{m}}{\rho} \left( \rho_{A,m,o} \right) = \frac{3 \times 10^{-4} \text{ kg/s}}{1.1707 \text{ kg/m}^3} = 0.0169 \text{ kg/m}^3 = 4.33 \times 10^{-6} \text{ kg/s}. \quad <\n\]

COMMENTS: With

\[
\Delta \rho_{A,o} = \Delta \rho_{A,i} \exp \left( -\frac{\pi DL \rho}{m} \bar{h}_m \right) = 0.0226 \exp \left( -\frac{\pi \times 0.01 \times 1 \times 1.17}{3 \times 10^{-4} \text{ kg/s}} \times 0.0112 \text{ m/s} \right) = 5.73 \times 10^{-3} \text{ kg/m}^3
\]

the evaporation rate is

\[
n_A = \bar{h}_m \pi \frac{\Delta \rho_{A,o} - \Delta \rho_{A,i}}{n (\Delta \rho_{A,o}/\Delta \rho_{A,i})} = 0.0112 \frac{m}{s} \pi \left( \frac{0.00573 - 0.0226}{0.00573/0.0226} \right) = 4.33 \times 10^{-6} \text{ kg/s}
\]

which agrees with the result of part (b).
PROBLEM 8.109

KNOWN: Flow rate and temperature of air in circular tube of prescribed diameter. Inner tube surface is wetted. Flow is fully developed and inlet air is dry.

FIND: Tube length required to reach 99% of saturation.

SCHEMATIC:

ASSUMPTIONS: (1) Steady, incompressible flow, (2) Constant flow rate, (3) Water film is also at 25°C.

PROPERTIES: Table A-4, Air (298K, 1 atm): \( \rho = 1.17 \text{ kg/m}^3, \mu = 183.6 \times 10^{-7} \text{ N·s/m}^2, \nu = 15.71 \times 10^{-6} \text{ m}^2/\text{s}; \) Table A-6, Water vapor (298K): \( \rho_A,\text{sat}= 1/\nu_g = (1/44.25 \text{ m}^3/\text{kg}) = 0.0226 \text{ kg/m}^3; \) Table A-8, Air-vapor (298K): \( D_{AB} = 26 \times 10^{-6} \text{ m}^2/\text{s}, Sc = \nu/D_{AB} = 0.60. \)

ANALYSIS: If \( \rho_{A,m,o} = 0.99 \rho_{A,s}, \) it follows from Problem 8.81 that
\[
\frac{\rho_{A,s} - 0.99 \rho_{A,s}}{\rho_{A,s}} = 0.01 = \exp\left( -\frac{\pi D \rho}{m} h_m \right).
\]

With
\[
Re_D = \frac{4 \dot{m}}{\pi D \mu} = \frac{4 \times 10^{-3} \text{ kg/s}}{\pi (0.01 \text{ m}) 183.6 \times 10^{-7} \text{ N·s/m}^2} = 6935
\]
the flow is turbulent and the mass transfer version of the Colburn equation is
\[
Sh_D = 0.023 Re_D^{4/5} Sc^{1/3} = 0.023(6935)^{4/5} (0.60)^{1/3} = 22.9
\]
\[
h_m = Sh_D \frac{D_{AB}}{D} = \frac{22.9 \times 26 \times 10^{-6} \text{ m}^2/\text{s}}{0.01 \text{ m}} = 0.0595 \text{ m/s}.
\]

Hence
\[
0.01 = \exp\left( -\frac{\pi \times 0.01 \text{ m} \times L \times 1.17 \text{ kg/m}^3}{10^{-3} \text{ kg/s}} \right) 0.0595 \text{ m/s}
\]
\[
0.01 = \exp(-2.188 L)
\]
\[
L = 2.1 \text{ m}. \]
PROBLEM 8.110

KNOWN: Flow rate and temperature of atmospheric air in circular tube of prescribed diameter. Flow is fully developed, and air is dry. Inner tube surface is wetted.

FIND: (a) Tube length required to reach 99% saturation, (b) Heat rate needed to maintain tube surface at air temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Steady, incompressible flow, (2) Constant flow rate.

PROPERTIES: Table A-4, Air (298K, 1 atm): \( \rho = 1.17 \text{ kg/m}^3 \), \( \mu = 183.6 \times 10^{-7} \text{ Ns/m}^2 \), \( \nu = 15.71 \times 10^{-6} \text{ m}^2/\text{s} \); Table A-6, Water vapor (298K): \( v_g = 44.25 \text{ m}^3/\text{kg} \), \( \rho_{A,sat} = 1/v_g = 0.0226 \text{ kg/m}^3 \), \( h_{fg} = 2443 \text{ kJ/kg} \); Table A-8, Air-vapor (298K): \( D_{AB} = 26 \times 10^{-6} \text{ m}^2/\text{s} \), \( Sc = \nu/D_{AB} = 0.60 \).

ANALYSIS: (a) If \( \rho_{A,m,o} = 0.99 \rho_{A,s} \), it follows from Problem 8.107 that
\[
\frac{\rho_{A,s} - 0.99 \rho_{A,s}}{\rho_{A,s}} = 0.01 = \exp\left( -\frac{\pi DL\rho}{m} h_m \right).
\]

With
\[
Re_D = \frac{4\dot{m}}{\pi D\mu} = \frac{4 \times 10^{-3} \text{ kg/s}}{\pi (0.02 \text{ m}) 183.6 \times 10^{-7} \text{ Ns/m}^2} = 3467,
\]

The flow is turbulent (weakly) and the mass transfer analog to the Colburn equation is
\[
Sh_D = 0.023 \left( \frac{D_{AB}}{D} \right)^{1/3} Sc^{1/3} = 0.023(3467)^{4/5} (0.60)^{1/3} = 13.2
\]
\[
h_m = \frac{Sh_D D_{AB}}{D} = \frac{13.2 \times 26 \times 10^{-6} \text{ m}^2/\text{s}}{0.02 \text{ m}} = 0.0172 \text{ m/s}.
\]

Hence,
\[
L = -\frac{\dot{m}}{D\pi D h_m} \ell n(0.01) = -\frac{10^{-3} \text{ kg/s} \times \ell n(0.01)}{\pi (0.02 \text{ m}) 1.17 \text{ kg/m}^3 (0.0172 \text{ m/s})} = 3.64 \text{ m}.
\]

(b) The required heat rate is
\[
q = n_A \ h_{fg} = n_A = \ell n(0.01) \frac{\Delta \rho_{A,o} - \Delta \rho_{A,i}}{\ell n(\Delta \rho_{A,o} / \Delta \rho_{A,i})} \Delta \rho_{A,o} \ - \Delta \rho_{A,i}
\]
\[
n_A = 0.0172 \text{ m/s} \times \pi (0.02 \text{ m}) 3.64 \text{ m} = 0.01 \rho_{A,s} - \rho_{A,s} \ell n(0.01)
\]
\[
n_A = -8.542 \times 10^{-4} \text{ m}^3/\text{s} \left( 0.99 \times 0.0226 \text{ kg/m}^3 \right) = 1.91 \times 10^{-5} \text{ kg/s}
\]
\[
q = n_A \ h_{fg} = 1.91 \times 10^{-5} \text{ kg/s} \times 2.443 \times 10^6 \text{ J/kg} = 46.7 \text{ W}.
\]

COMMENTS: The evaporation rate is low; hence the heat requirement is small.
PROBLEM 8.111

KNOWN: Tube length, diameter and temperature. Air temperature and velocity. Saturation pressure of thin liquid film and properties of vapor.

FIND: (a) Partial pressure and mass fraction of vapor at tube exit, (b) Mass rate at which liquid is removed from the tube.

SCHEMATIC:

ASSUMPTIONS: (1) System is isothermal at 300K, (2) Steady, incompressible flow, (3) Perfect gas behavior, (4) Mass flow rate is independent of x.

PROPERTIES: Table A-4, Air (300K, 1 atm): $\rho = 1.16 \text{ kg/m}^3$, $\nu = 15.9 \times 10^{-6} \text{ m}^2/\text{s}$. Prescribed, Vapor (300K): $p_{A,\text{sat}} = 15 \text{ mm Hg}$, $M_A = 70 \text{ kg/kmol}$, $D_{AB} = 10^{-5} \text{ m}^2/\text{s}$.

ANALYSIS: (a) With the vapor assumed to behave as an ideal gas, $p_A = C_A \Re T = \rho_A (\Re / M_A) T$, and isothermal conditions, the vapor pressure at the outlet may be obtained from the expression

$$\frac{p_{A,\text{sat}} - p_{A,o}}{p_{A,\text{sat}} - p_{A,i}} = \frac{\rho_{A,s} - \rho_{A,m,o}}{\rho_{A,s} - \rho_{A,m,i}} = \exp\left(\frac{-\rho \pi D L \bar{h}_m}{m}\right)$$

where $\bar{m} = \rho u_m A_c = 1.16 \text{ kg/m}^3 \times 0.5 \text{ m/s} \times \pi (0.05 \text{ m})^2 / 4 = 1.14 \times 10^{-3} \text{ kg/s}$. With $Re_D = u_m D / \nu = 0.5 \text{ m/s} \times 0.05 \text{ m}/15.9 \times 10^{-6} \text{ m}^2/\text{s} = 1570$, the flow is laminar and $\bar{h}_m$ may be determined from the mass transfer analog to Eq. 8.57. With $Sc = \nu / D_A = 1.59$ and $[Re_D Sc/(L/D)]^{1/3} = 2.92 > 2$.

$$\bar{h}_m = \frac{Sh_D D_{AB}}{D} = 1.86 \left(\frac{Re Sc}{L/D}\right)^{1/3} = 1.86 \times 2.92 \times \frac{10^{-5} \text{ m}^2/\text{s}}{0.05 \text{ m}} = 1.09 \times 10^{-3} \text{ m/s}$$

Hence, with $p_{A,i} = 0$

$$p_{A,o} = p_{A,\text{sat}} \left[1 - \exp\left(-\frac{\rho \pi D L \bar{h}_m}{m}\right)\right] = 15 \text{ mm Hg} \left[1 - \exp\left(-\frac{1.16 \text{ kg/m}^3 \times \pi \times 0.05 \text{ m} \times 5 \text{ m} \times 1.09 \times 10^{-3} \text{ m/s}}{1.14 \times 10^{-3} \text{ kg/s}}\right)\right] = 8.7 \text{ mm Hg}$$

The corresponding mass density of the vapor is

$$\rho_{A,m,o} = \frac{p_{A,o} M_A}{RT} = \frac{8.7 \text{ mm Hg} \times 70 \text{ kg/kmol}}{(760 \text{ mm Hg/atm}) (0.082 \text{ m}^3 \cdot \text{ atm/kg mol K}) 300 \text{ K}} = 0.0326 \text{ kg/m}^3$$

(b) The evaporation rate is

$$n_A = u_m A_c \left(\rho_{A,m,o} - \rho_{A,m,i}\right) = 0.5 \text{ m/s} \times 1.96 \times 10^{-3} \text{ m}^2 \times 0.0326 \text{ kg/m}^3 = 3.20 \times 10^{-5} \text{ kg/s}$$

COMMENTS: (1) Since the evaporation rate ($n_A = 3.2 \times 10^{-5} \text{ kg/s}$) is much less than the air flow rate ($\bar{m} = 1.14 \times 10^{-3} \text{ kg/s}$), the assumption of a fixed flow rate is reasonable. (2) The evaporation rate is also given by $n_A = \bar{h}_m \pi D L A \rho_{A,m} = \bar{h}_m \pi D L \rho_{A,m,o} / \ln \left[\left(p_{A,\text{sat}} - p_{A,o}\right)/p_{A,\text{sat}}\right] = 3.22 \times 10^{-5} \text{ kg/s}$, which agrees with the calculation of part (b).
**PROBLEM 8.112**

**KNOWN:** Air flow rate through trachea of diameter D and length L.

**FIND:** (a) Average mass transfer convection coefficient, $\overline{h}_m$, and (b) Rate of water loss per day (liter/day).

**SCHEMATIC:**

![Schematic diagram of air flow through trachea](image)

**ASSUMPTIONS:** (1) Trachea can be approximated as a smooth tube with uniform surface temperature, (2) Laminar, fully developed flow, (3) Trachea inner surface is saturated with water at body temperature, $T_s = 37^\circ C$, (4) Negligible water vapor in air at 310 K during inhalation, and (5) Heat-mass analogy is applicable.

**PROPERTIES:** Table A-4, Air (310 K, 1 atm): $\rho_B = 1.128 \text{ kg/m}^3$, $\mu = 1.893 \times 10^{-5} \text{ N} \cdot \text{s/m}^2$; Table A-6, Water ($T_s = 37^\circ C = 310 \text{ K}$): $\rho_{A,f} = 993 \text{ kg/m}^3$, $\rho_{A,g} = 0.04361 \text{ kg/m}^3$; Table A-8, Water-vapor air (310 K, 1 atm): $D_{AB} = 0.26 \times 10^{-4} (310/298)^{3/2} = 2.76 \times 10^{-5} \text{ m}^2/\text{s}$.

**ANALYSIS:** (a) Begin by characterizing the air (B) flow in the trachea modeled as a smooth tube, 

$$Re_D = \frac{4 \dot{V}_B}{\pi D \mu}$$

$$Re_D = \frac{4 \times 10 \text{ liter/min} \times 10^{-3} \text{ m}^3/\text{litrer} \times 1 \text{ min/60s} \times 1.128 \text{ kg/m}^3}{\pi \times 0.020 \text{ m} \times 1.893 \times 10^{-5} \text{ N} \cdot \text{s/m}^2} = 632$$

Hence, the flow is laminar, and for fully developed conditions and invoking the heat-mass analogy

$$Nu_D = Sh_D = 3.66 \quad Sh = \overline{h}_m D / D_{AB}$$

$$\overline{h}_m = 3.66 \frac{D_{AB}}{D} = 3.66 \times 2.76 \times 10^{-5} \text{ m}^2/\text{s}/0.020 \text{ m} = 0.0050 \text{ m/s}$$

(b) The species (A) transfer rate equation, Eq. 8.75, has the form

$$n_A = \overline{h}_m A_s \Delta \rho_A, \ell_m$$

$$\Delta \rho_A, \ell_m = \frac{(\rho_A,s - \rho_A,m,o) - (\rho_A,s - \rho_A,m,i)}{\ell_m (\rho_A,s - \rho_A,m,o) / (\rho_A,s - \rho_A,m,i)}$$

where the mean outlet species density, $\rho_{A,m,o}$, can be determined from Eq. 8.78

$$\frac{\rho_A,s - \rho_A,m,o}{\rho_A,s - \rho_A,m,i} = \exp \left( - \frac{\overline{h}_m P}{\dot{m}} \right)$$

where $\dot{m}/\rho = u_{m,A} = \dot{V}_B$. Substituting numerical values with $P = \pi D$,

$$\rho_{A,m,o} = 0.009233 \quad n_A = 1.54 \times 10^{-6} \text{ kg/s}$$

The volumetric rate of water loss on a daily basis, assuming a 12 hour inhalation period, is

$$\dot{V}_A = \left( 1.54 \times 10^{-6} \text{ kg/s} / 993 \text{ kg/m}^3 \right) \times 10^3 \text{ liter/m}^3 \times (3600 \text{ s/h} \times 12 \text{ h/day})$$

$$\dot{V}_A = 0.067 \text{ liter/day}$$
**PROBLEM 8.113**

**KNOWN:** Air (species B) is in fully developed, laminar flow as it enters a circular tube wetted with liquid A (water). Tube length and diameter. Flow rate of air and system temperature.

**FIND:** (a) Governing differential equation for species transfer, (b) Heat transfer analog and an expression for $\overline{Sh_D}$, (c) General expression for $\rho_{A,m,o}$, (d) Value of $\rho_{A,m,o}$ for prescribed conditions.

**SCHEMATIC:**

![Diagram](image)

**ASSUMPTIONS:** (1) Steady, incompressible flow, (2) Flow rate is independent of $x$, (3) Laminar, fully developed flow (hydrodynamically), (4) Isothermal conditions, (5) Dry air at inlet.

**PROPERTIES:** *Table A.4*, Air (298 K, 1 atm): $\rho = 1.1707 \text{ kg/m}^3$, $\mu = 183.6 \times 10^{-7} \text{ N} \cdot \text{s/m}^2$, $v = 15.71 \times 10^{-6} \text{ m}^2/\text{s}$; *Table A.6*, Water vapor (298 K): $\rho_{A,sat} = 1/\nu_6 = 0.0266 \text{ kg/m}^3$; *Table A.8*, Air-vapor (298 K): $D_{AB} = 26 \times 10^{-6} \text{ m}^2/\text{s}$, $Sc = \nu/D_{AB} = 0.60$.

**ANALYSIS:** (a) The governing differential equation may be inferred by analogy to Eq. 8.48. In this case, the dependent variable is the vapor mass density, $\rho_A(x,r)$, and the diffusivity is $D_{AB}$. With $v = 0$ for fully-developed flow, it follows that

$$
\frac{u}{d} \frac{\partial \rho_A}{\partial x} = \frac{D_{AB}}{r} \frac{\partial}{\partial r} \left( r \frac{\partial \rho_A}{\partial r} \right)
$$

The entrance condition is

$$
\rho_A(0, r) = 0
$$

and the boundary conditions are

$$
\rho_A(r, x) = \rho_{A,s} \quad \frac{\partial \rho_A}{\partial x}|_{r=0} = 0
$$

(b) The foregoing conditions are analogous to those of the thermal entry length condition associated with Eq. 8.56. Invoking this analogy the average Sherwood number for laminar, fully developed flow is

$$
\overline{Sh_D} = 3.66 \frac{0.0668(D/L)ReDSc}{1 + 0.04[(D/L)ReDSc]^{2/3}}
$$

(c) Applying conservation of species to the differential control volume,

$$
\rho_{A,m} u_m A_c + d n_A = \left\{ \rho_{A,m} + \frac{d \rho_{A,m}}{dx} \right\} u_m A_c
$$

or, with $u_m A_c = \dot{m}/\rho$ and $d n_A = h_m \pi D d x (\rho_{A,s} - \rho_{A,m})$

$$
\frac{\dot{m}}{\rho} \frac{d \rho_{A,m}}{dx} d x = h_m \pi D d x (\rho_{A,s} - \rho_{A,m})
$$

Continued...
PROBLEM 8.113 (Cont.)

\[ \int \rho_{A,m} \frac{d\rho_{A,m}}{\rho_{A,m,i} \rho_{A,s} - \rho_{A,m}} = \int_{x_0}^{x} \frac{\rho \pi Dh_m}{\bar{m}} \, dx \]

or

\[ \frac{\rho_{A,s} - \rho_{A,m}(x)}{\rho_{A,s} - \rho_{A,m,i}} = \exp \left( - \frac{\rho \pi D \bar{h}_m(x)}{\bar{m}} \right) \]

at \( x = L \),

\[ \frac{\rho_{A,s} - \rho_{A,m,o}}{\rho_{A,s} - \rho_{A,m,i}} = \exp \left( - \frac{\rho \pi D L \bar{h}_m}{\bar{m}} \right) \]

(d) For the prescribed conditions, \( \text{Re}_D = 4 \bar{m} / \pi D \mu = 4 \left( 2.5 \times 10^{-4} \text{ kg/s} / \pi (0.01 \text{ m}) \right) 183.6 \times 10^{-7} \text{ N} \cdot \text{s/m}^2 = 1734 \) and \( \left( \text{D/L} \right) \text{Re}_D \text{Sc} = (0.01 \text{ m/1 m})1734(0.6) = 10.4. \) Hence,

\[ \text{Sh}_D = 3.66 + \frac{0.0668 \left( 10.4 \right)}{1 + 0.04 \left( 10.4 \right)^{2/3}} = 4.24 \]

\[ \bar{h}_m = \text{Sh}_D \left( \text{D}_{AB}/D \right) = 4.24 \left( 2.6 \times 10^{-6} \text{ m}^2/\text{s}/0.01 \text{ m} \right) = 0.011 \text{ m/s} \]

Hence,

\[ \frac{\rho_{A,s} - \rho_{A,m,o}}{\rho_{A,s} - \rho_{A,m,i}} = \exp \left( - \frac{1.1707 \text{ kg/m}^3 \times \pi \times 0.01 \text{ m} \times 1 \text{ m} \times 0.011 \text{ m/s}}{2.5 \times 10^{-4} \text{ kg/s}} \right) = 0.198 \]

\[ \rho_{A,m,o} = \rho_{A,s} - 0.198 \left( \rho_{A,s} - \rho_{A,m,i} \right) = 0.0226 \text{ kg/m}^3 \left( 1 - 0.198 \right) = 0.0181 \text{ kg/m}^3 \]

COMMENTS: Due to evaporation, \( \bar{m} \) actually increases with increasing \( x \). However, the increase is small, and the assumption of fixed \( \bar{m} \) is good.
PROBLEM 9.1

**KNOWN:** Tabulated values of density for water and definition of the volumetric thermal expansion coefficient, $\beta$.

**FIND:** Value of the volumetric expansion coefficient at 300K; compare with tabulated values.

**PROPERTIES:** *Table A-6, Water (300K):* $\rho = 1/\nu_f = 1/1.003 \times 10^{-3} \text{ m}^3/\text{kg} = 997.0 \text{ kg/m}^3$, $\beta = 276.1 \times 10^{-6} \text{ K}^{-1}$; (295K): $\rho = 1/\nu_f = 1/1.002 \times 10^{-3} \text{ m}^3/\text{kg} = 998.0 \text{ kg/m}^3$; (305K): $\rho = 1/\nu_f = 1/1.005 \times 10^{-3} \text{ m}^3/\text{kg} = 995.0 \text{ kg/m}^3$.

**ANALYSIS:** The volumetric expansion coefficient is defined by Eq. 9.4 as

$$\beta = -\frac{1}{\rho} \left( \frac{\partial \rho}{\partial T} \right)_p .$$

The density change with temperature at constant pressure can be estimated as

$$\frac{\partial \rho}{\partial T}_p \approx \frac{\rho_1 - \rho_2}{T_1 - T_2} ,$$

where the subscripts (1,2) denote the property values just above and below, respectively, the condition for $T = 300K$ denoted by the subscript (o). That is,

$$\beta_o = -\frac{1}{\rho_o} \left( \frac{\rho_1 - \rho_2}{T_1 - T_2} \right)_p.$$

Substituting numerical values, find

$$\beta_o \approx \frac{-1}{997.0 \text{ kg/m}^3} \frac{(995.0 - 998.0) \text{ kg/m}^3}{(305 - 295) \text{ K}} = 300.9 \times 10^{-6} \text{ K}^{-1} .$$

Compare this value with the tabulation, $\beta = 276.1 \times 10^{-6} \text{ K}^{-1}$, to find our estimate is 8.7% high.

**COMMENTS:** (1) The poor agreement between our estimate and the tabulated value is due to the poor precision with which the density change with temperature is estimated. The tabulated values of $\beta$ were determined from accurate equation of state data.

(2) Note that $\beta$ is negative for $T < 275K$. Why? What is the implication for free convection?
PROBLEM 9.2

KNOWN: Object with specified characteristic length and temperature difference above ambient fluid.

FIND: Grashof number for air, hydrogen, water, ethylene glycol for a pressure of 1 atm.

SCHEMATIC:

ASSUMPTIONS: (1) Thermophysical properties evaluated at $T_f = 350K$, (2) Perfect gas behavior, ($\beta = 1/T_f$).

PROPERTIES: Evaluate at 1 atm, $T_f = 350K$:

*Table A-4*, Air: $\nu = 20.92 \times 10^{-6} m^2/s$; Hydrogen: $\nu = 143 \times 10^{-6} m^2/s$

*Table A-6*, Water (Sat. liquid): $\nu = \mu f v_f = 37.5 \times 10^{-6} m^2/s$, $\beta_f = 0.624 \times 10^{-3} K^{-1}$

*Table A-5*, Ethylene glycol: $\nu = 3.17 \times 10^{-6} m^2/s$, $\beta = 0.65 \times 10^{-3} K^{-1}$.

ANALYSIS: The Grashof number is given by Eq. 9.12,

$$Gr_L = \frac{g \beta (T_s - T_\infty) L^3}{\nu^2}.$$

Substituting numerical values for *air* with $\beta = 1/T_f$, find

$$Gr_{L,air} = \frac{9.8 m/s^2 \times (1/350K) \times (25K) \times (0.25m)^3}{(20.92 \times 10^{-6} m^2/s)^2} \approx 2.50 \times 10^7.$$  

Performing similar calculations for the other fluids, find

$$Gr_{L,hyd} = 5.35 \times 10^5$$  

$$Gr_{L,water} = 1.70 \times 10^6$$  

$$Gr_{L,eth} = 2.48 \times 10^8.$$

COMMENTS: Higher values of $Gr_L$ imply increased free convection flows. However, other properties affect the value of the heat transfer coefficient.
PROBLEM 9.3

KNOWN: Relation for the Rayleigh number.

FIND: Rayleigh number for four fluids for prescribed conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Perfect gas behavior for specified gases.

PROPERTIES: Table A-4, Air (400K, 1 atm): \( \nu = 26.41 \times 10^{-6} \text{ m}^2/\text{s}, \alpha = 38.3 \times 10^{-6} \text{ m}^2/\text{s}, \beta = 1/T = 1/400K = 2.50 \times 10^{-3} \text{ K}^{-1} \); Table A-4, Helium (400K, 1 atm): \( \nu = 199 \times 10^{-6} \text{ m}^2/\text{s}, \alpha = 295 \times 10^{-6} \text{ m}^2/\text{s}, \beta = 1/T = 2.50 \times 10^{-3} \text{ K}^{-1} \); Table A-5, Glycerin (12°C = 285K): \( \nu = 2830 \times 10^{-6} \text{ m}^2/\text{s}, \alpha = 0.964 \times 10^{-7} \text{ m}^2/\text{s}, \beta = 0.475 \times 10^{-3} \text{ K}^{-1} \); Table A-6, Water (37°C = 310K, sat. liq.): \( \nu = \mu_f \nu_f = 695 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 \times 1.007 \times 10^{-3} \text{ m}^3/\text{kg} = 0.700 \times 10^{-6} \text{ m}^2/\text{s}, \alpha = k_f \nu_f/c_{p,f} = 0.628 \text{ W/mK} \times 1.007 \times 10^{-3} \text{ m}^3/\text{kg} \times 4178 \text{ J/kg} \cdot \text{K} = 0.151 \times 10^{-6} \text{ m}^2/\text{s}, \beta_f = 361.9 \times 10^{-6} \text{ K}^{-1} \).

ANALYSIS: The Rayleigh number, a dimensionless parameter used in free convection analysis, is defined as the product of the Grashof and Prandtl numbers.

\[
Ra_L = Gr \cdot Pr = \frac{g \beta \Delta T L^3}{\nu^2} \frac{\mu c_p}{k} = \frac{g \beta \Delta T L^3}{\nu^2} \frac{(\nu \rho) c_p}{k} = \frac{g \beta \Delta T L^3}{\alpha}
\]

where \( \alpha = k/\rho c_p \) and \( \nu = \mu/\rho \). The numerical values for the four fluids follow:

**Air (400K, 1 atm)**

\[
Ra_L = 9.8 m/s^2 \left( \frac{1}{400K} \right) 30K (0.01 m)^3 / 26.41 \times 10^{-6} \text{ m}^2/\text{s} \times 38.3 \times 10^{-6} \text{ m}^2/\text{s} = 727
\]

**Helium (400K, 1 atm)**

\[
Ra_L = 9.8 m/s^2 \left( \frac{1}{400K} \right) 30K (0.01 m)^3 / 199 \times 10^{-6} \text{ m}^2/\text{s} \times 295 \times 10^{-6} \text{ m}^2/\text{s} = 12.5
\]

**Glycerin (285K)**

\[
Ra_L = 9.8 m/s^2 \left( 0.475 \times 10^{-3} \text{ K}^{-1} \right) 30K (0.01 m)^3 / 2830 \times 10^{-6} \text{ m}^2/\text{s} \times 0.964 \times 10^{-7} \text{ m}^2/\text{s} = 512
\]

**Water (310K)**

\[
Ra_L = 9.8 m/s^2 \left( 0.362 \times 10^{-3} \text{ K}^{-1} \right) 30K (0.01 m)^3 / 0.700 \times 10^{-6} \text{ m}^2/\text{s} \times 0.151 \times 10^{-6} \text{ m}^2/\text{s} = 9.35 \times 10^5
\]

COMMENTS: (1) Note the wide variation in values of Ra for the four fluids. A large value of Ra implies enhanced free convection, however, other properties affect the value of the heat transfer coefficient.
PROBLEM 9.4

KNOWN: Form of the Nusselt number correlation for natural convection and fluid properties.

FIND: Expression for figure of merit $F_N$ and values for air, water and a dielectric liquid.

PROPERTIES: Prescribed. Air: $k = 0.026 \text{ W/mK}, \beta = 0.0035 \text{ K}^{-1}, \nu = 1.5 \times 10^{-5} \text{ m}^2/\text{s}, \text{Pr} = 0.70$

Water: $k = 0.600 \text{ W/mK}, \beta = 2.7 \times 10^{-4} \text{ K}^{-1}, \nu = 10^{-6} \text{ m}^2/\text{s}, \text{Pr} = 5.0$

Dielectric liquid: $k = 0.064 \text{ W/mK}, \beta = 0.0014 \text{ K}^{-1}, \nu = 10^{-6} \text{ m}^2/\text{s}, \text{Pr} = 25$

ANALYSIS: With $Nu \sim Ra^n$, the convection coefficient may be expressed as

$$h \sim \frac{k (g \beta \Delta T L^3)^n}{\alpha \nu} \sim \frac{(g \Delta T L)^n}{(\alpha \nu)^n} \left( \frac{k \beta^n}{\alpha \nu^n} \right)$$

The figure of merit is therefore

$$F_N = \frac{k \beta^n}{\alpha \nu^n}$$

and for the three fluids, with $n = 0.33$ and $\alpha = \nu / \text{Pr}$,

$$F_N \left( \frac{\text{W} \cdot \text{s}^{2/3} \cdot \text{m}^{7/3} \cdot \text{K}^{4/3}}{\text{W} \cdot \text{s} / \text{m}^{2/3} \cdot \text{K}} \right) \begin{array}{ccc} \text{Air} & \text{Water} & \text{Dielectric} \\ 5.8 & 663 & 209 \end{array}$$

Water is clearly the superior heat transfer fluid, while air is the least effective.

COMMENTS: The figure of merit indicates that heat transfer is enhanced by fluids of large $k$, large $\beta$ and small values of $\alpha$ and $\nu$. 
PROBLEM 9.5

KNOWN:  Heat transfer rate by convection from a vertical surface, 1m high by 0.6m wide, to quiescent air that is 20K cooler.

FIND:  Ratio of the heat transfer rate for the above case to that for a vertical surface that is 0.6m high by 1m wide with quiescent air that is 20K warmer.

SCHEMATIC:

ASSUMPTIONS:  (1) Thermophysical properties independent of temperature; evaluate at 300K; (2) Negligible radiation exchange with surroundings, (3) Quiescent ambient air.

PROPERTIES:  Table A-4, Air (300K, 1 atm):  ν = 15.89 × 10^{-6} \text{ m}^2/\text{s}, \alpha = 22.5 \times 10^{-6} \text{ m}^2/\text{s}.

ANALYSIS:  The rate equation for convection between the plates and quiescent air is

\[ q = \overline{h}_L A_s \Delta T \]  \hspace{1cm} (1)

where \( \Delta T \) is either (\( T_s - T_\infty \)) or (\( T_\infty - T_s \)); for both cases, \( A_s = Lw \). The desired heat transfer ratio is then

\[ \frac{q_1}{q_2} = \frac{\overline{h}_{L1}}{\overline{h}_{L2}}. \]  \hspace{1cm} (2)

To determine the dependence of \( \overline{h}_L \) on geometry, first calculate the Rayleigh number,

\[ Ra_L = g \beta \Delta T L^3 / \nu \alpha \]  \hspace{1cm} (3)

and substituting property values at 300K, find,

Case 1: \( Ra_{L1} = 9.8 \text{ m/s}^2 (1/300K) 20K (1m)^3 / 15.89 \times 10^{-6} \text{ m}^2/\text{s} \times 22.5 \times 10^{-6} \text{ m}^2/\text{s} = 1.82 \times 10^9 \)

Case 2: \( Ra_{L2} = Ra_{L1} (L_2/L_1)^3 = 1.82 \times 10^4 (0.6m/1.0m)^3 = 3.94 \times 10^8 \).

Hence, Case 1 is turbulent and Case 2 is laminar. Using the correlation of Eq. 9.24,

\[ \overline{Nu}_L = \frac{\overline{h}_L L}{k} = C (Ra_L)^n \]  \hspace{1cm} (4)

where for Case 1: \( C_1 = 0.10, n_1 = 1/3 \) and for Case 2: \( C_2 = 0.59, n_2 = 1/4 \). Substituting Eq. (4) into the ratio of Eq. (2) with numerical values, find

\[ \frac{q_1}{q_2} = \frac{(C_1 / L_1) Ra_{L1}^{n_1}}{(C_2 / L_2) Ra_{L2}^{n_2}} \left( \frac{1.82 \times 10^9}{3.94 \times 10^8} \right)^{1/4} = 0.881 \]

COMMENTS:  Is this result to be expected? How do you explain this effect of plate orientation on the heat rates?
PROBLEM 9.6

KNOWN: Large vertical plate with uniform surface temperature of 130°C suspended in quiescent air at 25°C and atmospheric pressure.

FIND: (a) Boundary layer thickness at 0.25 m from lower edge, (b) Maximum velocity in boundary layer at this location and position of maximum, (c) Heat transfer coefficient at this location, (d) Location where boundary layer becomes turbulent.

SCHEMATIC:

ASSUMPTIONS: (1) Isothermal, vertical surface in an extensive, quiescent medium, (2) Boundary layer assumptions valid.

PROPERTIES: Table A-4, Air \( \left( T_f = (T_s + T_\infty) / 2 = 350 \text{K}, 1 \text{ atm} \right) \): \( v = 20.92 \times 10^{-6} \text{ m}^2/\text{s} \), \( k = 0.030 \text{ W/mK} \), \( Pr = 0.700 \).

ANALYSIS: (a) From the similarity solution results, Fig. 9.4 (see above right), the boundary layer thickness corresponds to a value of \( \eta \approx 5 \). From Eqs. 9.13 and 9.12,

\[
y = \eta x \left( \frac{Gr_x}{4} \right)^{-1/4} \tag{1}
\]

\[
Gr_x = g \beta \left( T_s - T_\infty \right) x^3 / v^2 = 9.8 \frac{m}{s^2} \times \frac{1}{350 \text{K}} \left( 130 - 25 \right) \text{K x}^3 / \left( 20.92 \times 10^{-6} \text{ m}^2 / \text{s} \right)^2 = 6.718 \times 10^9 x^3 \tag{2}
\]

\[
y \approx 5 (0.25 \text{m}) \left( 6.718 \times 10^9 \left( 0.25 \right)^3 / 4 \right)^{-1/4} = 1.746 \times 10^{-2} \text{m} = 17.5 \text{ mm}. \tag{3}
\]

(b) From the similarity solution shown above, the maximum velocity occurs at \( \eta = 1 \) with \( f' \left( \eta \right) = 0.275 \). From Eq. 9.15, find

\[
u = 2 \frac{2}{x} Gr_x^{1/2} f' \left( \eta \right) = \left( 2 \times 20.92 \times 10^{-6} \text{ m}^2 / \text{s} / 0.25 \text{m} \right) \left( 6.718 \times 10^9 \left( 0.25 \right)^3 \right)^{1/2} \times 0.275 = 0.47 \text{ m/s}. \tag{<}
\]

The maximum velocity occurs at a value of \( \eta = 1 \); using Eq. (3), it follows that this corresponds to a position in the boundary layer given as

\[
y_{\text{max}} = 1/5 \ (17.5 \ \text{mm}) = 3.5 \ \text{mm}. \tag{<}
\]

(c) From Eq. 9.19, the local heat transfer coefficient at \( x = 0.25 \text{ m} \) is

\[
Nu_x = h_x x / k = \left( Gr_x / 4 \right)^{1/4} \ g \left( Pr \right) = \left( 6.718 \times 10^9 \left( 0.25 \right)^3 / 4 \right)^{1/4} 0.586 = 41.9
\]

\[
h_x = Nu_x k / x = 41.9 \times 0.030 \text{ W/m} \cdot \text{K} / 0.25 \text{ m} = 5.0 \text{ W/m}^2 \cdot \text{K}. \tag{<}
\]

The value for \( g(Pr) \) is determined from Eq. 9.20 with \( Pr = 0.700 \).

(d) According to Eq. 9.23, the boundary layer becomes turbulent at \( x_c \) given as

\[
Ra_{x_c} = Gr_{x_c} Pr \approx 10^9 \quad x_c = \left[ \frac{10^9}{6.718 \times 10^9 \left( 0.700 \right)} \right]^{1/3} = 0.60 \text{ m}. \tag{<}
\]

COMMENTS: Note that \( \beta = 1/T_f \) is a suitable approximation for air.
PROBLEM 9.7

KNOWN: Thin, vertical plates of length 0.15 m at 54°C being cooled in a water bath at 20°C.

FIND: Minimum spacing between plates such that no interference will occur between free-convection boundary layers.

SCHEMATIC:

ASSUMPTIONS: (a) Water in bath is quiescent, (b) Plates are at uniform temperature.

PROPERTIES: Table A-6, Water \( (T_f = (T_s + T_\infty)/2 = (54 + 20)°C/2 = 310K) \): \( \rho = 1/\nu_f = 993.05 \) kg/m\(^3\), \( \mu = 695 \times 10^{-6} \) N s/m\(^2\), \( \nu = \mu/\rho = 6.998 \times 10^{-7} \) m\(^2\)/s, \( Pr = 4.62 \), \( \beta = 361.9 \times 10^{-6} \) K\(^{-1}\).

ANALYSIS: The minimum separation distance will be twice the thickness of the boundary layer at the trailing edge where \( x = 0.15 \) m. Assuming laminar, free convection boundary layer conditions, the similarity parameter, \( \eta \), given by Eq. 9.13, is

\[
\eta = \left(\frac{y}{x}\right)^{1/4} \left(\frac{Gr}{4xh}\right)
\]

where \( y \) is measured normal to the plate (see Fig. 9.3). According to Fig. 9.4, the boundary layer thickness occurs at a value \( \eta \approx 5 \).

It follows then that,

\[
y_{bl} = \eta x \left(\frac{Gr}{4x}\right)^{-1/4}
\]

where

\[
Gr_x = \frac{g \beta (T_s - T_\infty) x^3}{\nu^2}
\]

\[
Gr_x = 9.8 \text{ m/s}^2 \times 361.9 \times 10^{-6} \text{ K}^{-1} (54 - 20) \text{ K} \times (0.15 \text{ m})^3 / \left(6.998 \times 10^{-7} \text{ m}^2/\text{s}\right)^2 = 8.310 \times 10^8.
\]

Hence,

\[
y_{bl} = 5 \times 0.15 \text{ m} \left(8.310 \times 10^8 / 4\right)^{-1/4} = 6.247 \times 10^{-3} \text{ m} = 6.3 \text{ mm}
\]

and the minimum separation is

\[
d = 2 y_{bl} = 2 \times 6.3 \text{ mm} = 12.6 \text{ mm}.
\]

COMMENTS: According to Eq. 9.23, the critical Grashof number for the onset of turbulent conditions in the boundary layer is \( Gr_{xc} Pr = 10^9 \). For the conditions above, \( Gr_x Pr = 8.31 \times 10^8 \times 4.62 = 3.8 \times 10^9 \). We conclude that the boundary layer is indeed turbulent at \( x = 0.15 \text{ m} \) and our calculation is only an estimate which is likely to be low. Therefore, the plate separation should be greater than 12.6 mm.
**PROBLEM 9.8**

**KNOWN:** Square aluminum plate at 15°C suspended in quiescent air at 40°C.

**FIND:** Average heat transfer coefficient by two methods – using results of boundary layer similarity and results from an empirical correlation.

**SCHEMATIC:**

![Schematic Image]

**ASSUMPTIONS:** (1) Uniform plate surface temperature, (2) Quiescent room air, (3) Surface radiation exchange with surroundings negligible, (4) Perfect gas behavior for air, \( \beta = 1/T_f \).

**PROPERTIES:** Table A-4, Air \( (T_f = (T_s + T_\infty)/2 = (40 + 15)^\circ C/2 = 300K, 1 \text{ atm}) \): \( v = 15.89 \times 10^{-6} \text{ m}^2/\text{s}, k = 0.0263 \text{ W/m} \cdot \text{K}, \alpha = 22.5 \times 10^{-6} \text{ m}^2/\text{s}, \text{Pr} = 0.707 \).

**ANALYSIS:** Calculate the Rayleigh number to determine the boundary layer flow conditions,

\[
Ra_L = g \beta \Delta T L^3 / \nu \alpha
\]

\[
Ra_L = 9.8 \text{ m/s}^2 \left( \frac{1}{300K} \right) \left( 40 - 15 \right)^\circ \text{C}(0.2m)^3 / \left( 15.89 \times 10^{-6} \text{ m}^2/\text{s} \right) \left( 22.5 \times 10^{-6} \text{ m}^2/\text{s} \right) = 1.827 \times 10^7
\]

where \( \beta = 1/T_f \) and \( \Delta T = T_\infty - T_s \). Since \( Ra_L < 10^9 \), the flow is laminar and the similarity solution of Section 9.4 is applicable. From Eqs. 9.21 and 9.20,

\[
\overline{Nu_L} = \frac{\overline{h_L} L}{k} = \frac{4}{3} (Gr_L/4)^{1/4} g(Pr)
\]

\[
g(Pr) = \frac{0.75 \text{ Pr}^{1/2}}{\left[ 0.609 + 1.221 \text{ Pr}^{1/2} + 1.238 \text{ Pr} \right]^{1/4}}
\]

and substituting numerical values with \( Gr_L = Ra_L/Pr \), find

\[
g(Pr) = 0.75(0.707)^{1/2} / \left[ 0.609 + 1.22(0.707)^{1/2} + 1.238 \times 0.707 \right]^{1/4} = 0.501
\]

\[
\overline{h_L} = \left( \frac{0.0263 \text{ W/m} \cdot \text{K}}{0.20m} \right) \times \frac{4}{3} \left( \frac{1.827 \times 10^7 /0.707}{4} \right)^{1/4} \times 0.501 = 4.42 \text{ W/m}^2 \cdot \text{K}.
\]

The appropriate empirical correlation for estimating \( \overline{h_L} \) is given by Eq. 9.27,

\[
\overline{Nu_L} = \frac{\overline{h_L} L}{k} = 0.68 + \frac{0.670 \text{ Ra}_L^{1/4}}{\left[ 1 + (0.492/\text{Pr})^{9/16} \right]^{4/9}}
\]

\[
\overline{h_L} = \left( 0.0263 \text{ W/m} \cdot \text{K}/0.20m \right) \left[ 0.68 + 0.670 \left( 1.827 \times 10^7 \right)^{1/4} / \left[ 1 + (0.492/0.707)^{9/16} \right]^{4/9} \right]
\]

\[
\overline{h_L} = 4.42 \text{ W/m}^2 \cdot \text{K}.
\]

**COMMENTS:** The agreement of \( \overline{h_L} \) calculated by these two methods is excellent. Using the Churchill-Chu correlation, Eq. 9.26, find \( \overline{h_L} = 4.87 \text{ W/m} \cdot \text{K} \). This relation is not the most accurate for the laminar regime, but is suitable for both laminar and turbulent regions.
**PROBLEM 9.9**

**KNOWN:** Dimensions of vertical rectangular fins. Temperature of fins and quiescent air.

**FIND:** (a) Optimum fin spacing, (b) Rate of heat transfer from an array of fins at the optimal spacing.

**SCHEMATIC:**

![Schematic Diagram](image)

**ASSUMPTIONS:** (1) Fins are isothermal, (2) Radiation effects are negligible, (3) Air is quiescent.

**PROPERTIES:** *Table A-4, Air (T_f = 325K, 1 atm): v = 18.41 \times 10^{-6} \text{ m}^2/\text{s}, k = 0.0282 \text{ W/m}\cdot\text{K}, Pr = 0.703.*

**ANALYSIS:**

(a) If fins are too close, boundary layers on adjoining surfaces will coalesce and heat transfer will decrease. If fins are too far apart, the surface area becomes too small and heat transfer decreases. \( S_{op} \approx \delta_x = H. \) From Fig. 9.4, the edge of boundary layer corresponds to

\[
\eta = \left( \frac{\delta}{H} \right) \left( \frac{GrH}{4} \right)^{1/4} = 5.
\]

Hence, \( GrH = \frac{g \beta (T_s - T_\infty) H^3}{v H^2} = \frac{9.8 \text{ m/s}^2 (1/325 \text{K}) 50 \text{K} (0.15 \text{m})^3}{(18.41 \times 10^{-6} \text{ m}^2/\text{s})^2} = 1.5 \times 10^7 \)

\[
\delta(H) = 5(0.15 \text{m})/\left(1.5 \times 10^7 / 4\right)^{1/4} = 0.017 \text{m} = 17 \text{mm} \quad S_{op} \approx 34 \text{mm}. \left< \right.
\]

(b) The number of fins \( N \) can be found as

\[
N = \frac{W}{(S_{op} + t)} = 355/35.5 = 10
\]

and the rate is \( q = 2 N \bar{h} (H \cdot L) (T_s - T_\infty). \)

For laminar flow conditions

\[
\overline{Nu}_H = 0.68 + 0.67 \frac{Ra_L^{1/4}}{1 + (0.492/Pr)^{9/16}}^{4/9}
\]

\[
\overline{Nu}_H = 0.68 + 0.67 \left(1.5 \times 10^7 \times 0.703\right)^{1/4} / \left[1 + (0.492/0.703)^{9/16}\right]^{4/9} = 30
\]

\[\bar{h} = k \frac{\overline{Nu}_H}{H} = 0.0282 \text{ W/m}\cdot\text{K}(30)/0.15 \text{ m} = 5.6 \text{ W/m}^2\cdot\text{K}\]

\[
q = 2(10)5.6 \text{ W/m}^2\cdot\text{K}(0.15\text{m} \times 0.02\text{m}) (350 - 300)\text{K} = 16.8 \text{ W.} \left< \right.
\]

**COMMENTS:** Part (a) result is a conservative estimate of the optimum spacing. The increase in area resulting from a further reduction in \( S \) would more than compensate for the effect of fluid entrapment due to boundary layer merger. From a more rigorous treatment (see Section 9.7.1), \( S_{op} \approx 10 \text{ mm} \) is obtained for the prescribed conditions.
**PROBLEM 9.10**

**KNOWN:** Interior air and wall temperatures; wall height.

**FIND:** (a) Average heat transfer coefficient when $T_\infty = 20^\circ C$ and $T_s = 10^\circ C$, (b) Average heat transfer coefficient when $T_\infty = 27^\circ C$ and $T_s = 37^\circ C$.

**SCHEMATIC:**

**ASSUMPTIONS:** (a) Wall is at a uniform temperature, (b) Room air is quiescent.

**PROPERTIES:** Table A-4. Air ($T_f = 298K, 1 \text{ atm}$): $\beta = 1/T_f = 3.472 \times 10^{-3} \text{ K}^{-1}$, $\nu = 14.82 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 0.0253 \text{ W/mK}$, $\alpha = 20.9 \times 10^{-6} \text{ m}^2/\text{s}$, $Pr = 0.710$; (5) Air ($T_f = 305K, 1 \text{ atm}$): $\beta = 1/T_f = 3.279 \times 10^{-3} \text{ K}^{-1}$, $\nu = 16.39 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 0.0267 \text{ W/mK}$, $\alpha = 23.2 \times 10^{-6} \text{ m}^2/\text{s}$, $Pr = 0.706$.

**ANALYSIS:** The appropriate correlation for the average heat transfer coefficient for free convection on a vertical wall is Eq. 9.26.

\[
\overline{Nu}_{L} = \frac{\overline{h} L}{k} = \left\{0.825 + \frac{0.387 \overline{Ra}_L^{0.1667}}{1 + (0.492/Pr)^{0.563}0.296}\right\}^2
\]

where $\overline{Ra}_L = g \beta \Delta T L^3/\nu \alpha$, Eq. 9.25, with $\Delta T = T_s - T_\infty$ or $T_\infty - T_s$.

(a) Substituting numerical values typical of *winter* conditions gives

\[
\overline{Ra}_L = \frac{9.8 \text{ m/s}^2 \times 3.472 \times 10^{-3} \text{ K}^{-1} (20 - 10) \text{ K} (2.5 \text{ m})^3}{14.82 \times 10^{-6} \text{ m}^2/\text{s} \times 20.96 \times 10^{-6} \text{ m}^2/\text{s}} = 1.711 \times 10^{10}
\]

\[
\overline{Nu}_{L} = \left\{0.825 + \frac{0.387 \left(1.711 \times 10^{10}\right)^{0.1667}}{1 + (0.492/0.710)^{0.563}0.296}\right\}^2 = 299.6.
\]

Hence, $\overline{h} = \overline{Nu}_{L} k/L = 299.6 \left(0.0253 \text{ W/m} \cdot \text{K}\right)/2.5\text{m} = 3.03 \text{ W/m}^2 \cdot \text{K}.$

(b) Substituting numerical values typical of *summer* conditions gives

\[
\overline{Ra}_L = \frac{9.8 \text{ m/s}^2 \times 3.279 \times 10^{-3} \text{ K}^{-1} (37 - 27) \text{ K} (2.5 \text{ m})^3}{23.2 \times 10^{-6} \text{ m}^2/\text{s} \times 16.39 \times 10^{-6} \text{ m}^2/\text{s}} = 1.320 \times 10^{10}
\]

\[
\overline{Nu}_{L} = \left\{0.825 + \frac{0.387 \left(1.320 \times 10^{10}\right)^{0.1667}}{1 + (0.492/0.706)^{0.563}0.296}\right\}^2 = 275.8.
\]

Hence, $\overline{h} = \overline{Nu}_{L} k/L = 275.8 \left(0.0267 \text{ W/m} \cdot \text{K}\right)/2.5\text{m} = 2.94 \text{ W/m}^2 \cdot \text{K}.$

**COMMENTS:** There is a small influence due to $T_f$ on $\overline{h}$ for these conditions. We should expect radiation effects to be important with such low values of $\overline{h}$. 
PROBLEM 9.11

KNOWN: Vertical plate experiencing free convection with quiescent air at atmospheric pressure and film temperature 400 K.

FIND: Form of correlation for average heat transfer coefficient in terms of $\Delta T$ and characteristic length.

SCHEMATIC:

ASSUMPTIONS: (1) Air is extensive, quiescent medium, (2) Perfect gas behavior.

PROPERTIES: Table A-6, Air ($T_f = 400$ K, 1 atm): $\nu = 26.41 \times 10^{-6}$ m$^2$/s, $k = 0.0338$ W/mK, $\alpha = 38.3 \times 10^{-6}$ m$^2$/s.

ANALYSIS: Consider the correlation having the form of Eq. 9.24 with $Ra_L$ defined by Eq. 9.25.

$$\overline{Nu}_L = \frac{hL}{k} = CRa_L^n$$

where

$$Ra_L = \frac{g\beta(T_S - T_\infty)L^3}{\nu \alpha} = \frac{9.8 \text{ m/s}^2 (1/400 \text{ K}) \Delta T \cdot L^3}{26.41 \times 10^{-6} \text{ m}^2/\text{s} \times 38.3 \times 10^{-6} \text{ m}^2/\text{s}} = 2.422 \times 10^7 \Delta T \cdot L^3.$$  (2)

Combining Eqs. (1) and (2),

$$\overline{h}_L = \left(\frac{k}{L}\right) CRa_L^n = \frac{0.0338 \text{ W/m K}}{L} C \left(2.422 \times 10^7 \Delta T L^3\right)^n.$$  (3)

From Fig. 9.6, note that for laminar boundary layer conditions, $10^4 < Ra_L < 10^9$, $C = 0.59$ and $n = 1/4$. Using Eq. (3),

$$\overline{h} = 1.40 \left[ L^{-1} \left(\Delta T \cdot L^3\right)^{1/4} \right] = 1.40 \left(\frac{\Delta T}{L}\right)^{1/4}$$

For turbulent conditions in the range $10^9 < Ra_L < 10^{13}$, $C = 0.10$ and $n = 1/3$. Using Eq. (3),

$$\overline{h}_L = 0.98 \left[ L^{-1} \left(\Delta T \cdot L^3\right)^{1/3} \right] = 0.98 \Delta T^{1/3}.$$  

COMMENTS: Note the dependence of the average heat transfer coefficient on $\Delta T$ and $L$ for laminar and turbulent conditions. The characteristic length $L$ does not influence $\overline{h}_L$ for turbulent conditions.
PROBLEM 9.12

KNOWN: Temperature dependence of free convection coefficient, \( \bar{h} = C \Delta T^{1/4} \), for a solid suddenly submerged in a quiescent fluid.

FIND: (a) Expression for cooling time, \( t_f \), (b) Considering a plate of prescribed geometry and thermal conditions, the time required to reach 80°C using the appropriate correlation from Problem 9.10 and (c) Plot the temperature-time history obtained from part (b) and compare with results using a constant \( \bar{h}_o \) from an appropriate correlation based upon an average surface temperature \( \bar{T} = (T_i + T_f)/2 \).

SCHEMATIC:

ASSUMPTIONS: (1) Lumped capacitance approximation is valid, (2) Negligible radiation, (3) Constant properties.

PROPERTIES: Table A.1, Aluminum alloy 2024 (\( \bar{T} = (T_i + T_f)/2 \approx 400 \text{ K} \)): \( \rho = 2770 \text{ kg/m}^3 \), \( c_p = 925 \text{ J/kg} \cdot \text{K} \), \( k = 186 \text{ W/m} \cdot \text{K} \); Table A.4, Air (\( \bar{T}_{\text{film}} = 362 \text{ K} \)): \( \nu = 2.221 \times 10^{-5} \text{ m}^2/\text{s} \), \( k = 0.03069 \text{ W/m} \cdot \text{K} \), \( \alpha = 3.187 \times 10^{-5} \text{ m}^2/\text{s} \), \( \text{Pr} = 0.6976 \), \( \beta = 1/\bar{T}_{\text{film}} \).

ANALYSIS: (a) Apply an energy balance to a control surface about the object, \(-\dot{E}_{\text{out}} = \dot{E}_{\text{st}}\), and substitute the convection rate equation, with \( \bar{h} = C \Delta T^{1/4} \), to find
\[
-C A_S (T - T_\infty)^{5/4} = \frac{d}{dt} (\rho V c T).
\]
Separating variables and integrating, find
\[
dT/dt = -\left(\frac{C A_S}{\rho V c}\right)(T - T_\infty)^{5/4}
\]
\[
\int_{T_i}^{T_f} \frac{dT}{(T - T_\infty)^{5/4}} = \left[\frac{C A_S}{\rho V c}\right] \int_{T_i}^{T_f} dt
\]
\[
t_f = \frac{4 \rho V c}{C A_S} \left[\left(\frac{T_f - T_\infty}{T_i - T_\infty}\right)^{-1/4} - 1\right] = \frac{4 \rho V c}{C A_S (T_i - T_\infty)^{1/4}} \left[\left(\frac{T_i - T_\infty}{T_f - T_\infty}\right)^{1/4} - 1\right].
\]

(b) Considering the aluminum plate, initially at \( T(0) = 225^\circ \text{C} \), and suddenly exposed to ambient air at \( T_\infty = 25^\circ \text{C} \), from Problem 9.10 the convection coefficient has the form
\[
\bar{h}_i = 1.40 \left(\frac{\Delta T}{L}\right)^{1/4} = \bar{h}_i = C \Delta T^{1/4}
\]
where \( C = 1.40/L^{1/4} = 1.40/(0.150)^{1/4} = 2.2496 \text{ W/m}^2 \cdot \text{K}^{3/4} \). Using Eq. (2), find

Continued...
PROBLEM 9.12 (Cont.)

\[
t_f = \frac{4 \times 2770 \text{kg/m}^3 \left(0.150^2 \times 0.005\right) \text{m}^3 \times 9251/\text{kg} \cdot \text{K}}{2.2496 \text{W/m}^2 \cdot \text{K}^{3/4} \times 2 \times (0.150 \text{m})^2 \left(225 - 25\right)^{1/4} \text{K}^{1/4} \left[\frac{225 - 25}{80 - 25}\right]^{1/4} - 1} = 1154 \text{s}
\]

(c) For the vertical plate, Eq. 9.27 is an appropriate correlation. Evaluating properties at

\[
\overline{T}_\text{film} = \left(\overline{T}_S + T_\infty\right)/2 = \left((T_i + T_f)/2 + T_\infty\right)/2 = 362 \text{ K}
\]

where \(\overline{T}_S = 426\text{ K}\), the average plate temperature, find

\[
\text{Ra}_L = \frac{g \beta \left(T_S - T_\infty\right) L^3}{v \alpha} = \frac{9.8 \text{ m/s}^2 \left(1/362\text{K}\right) (426 - 298) \text{K} (0.150 \text{m})^3}{2.22 \times 10^{-5} \text{ m}^2/\text{s} \times 3.187 \times 10^{-5} \text{ m}^2/\text{s}} = 1.652 \times 10^7
\]

\[
\overline{\text{Nu}}_L = 0.68 + \frac{0.670 \text{Ra}^{1/4}_L}{\left[1 + \left(0.492/\text{Pr}\right)^{9/16}\right]^{4/9}} = 0.68 + \frac{0.670 \left(1.652 \times 10^7\right)^{1/4}}{\left[1 + \left(0.492/0.6976\right)^{9/16}\right]^{4/9}} = 33.4
\]

\[
\overline{h}_o = \frac{k}{\text{Nu}_L} = \frac{0.03069 \text{ W/m} \cdot \text{K}}{0.150 \text{m}} \times 33.4 = 6.83 \text{ W/m}^2 \cdot \text{K}
\]

From Eq. 5.6, the temperature-time history with a constant convection coefficient is

\[
T(t) = T_\infty + (T_i - T_\infty) \exp\left[-\left(\overline{h}_o A_S / \rho c V \right) t\right]
\]

where \(A_S / V = 2L^2 / (L \times L \times w) = 2/ w = 400 \text{ m}^{-1}\). The temperature-time histories for the \(h = C \Delta T^{1/4}\) and \(\overline{h}_o\) analyses are shown in plot below.

![Plot of temperature-time history](image)

**COMMENTS:**

1. The times to reach \(T(t_o) = 80^\circ\text{C}\) were 1154 and 1212s for the variable and constant coefficient analysis, respectively, a difference of 5%. For convenience, it is reasonable to evaluate the convection coefficient as described in part (b).

2. Note that \(\text{Ra}_L < 10^9\) so indeed the expression selected from Problem 9.10 was the appropriate one.

3. Recognize that if the emissivity of the plate were unity, the average linearized radiation coefficient using Eq. (1.9) is \(\overline{h}_\text{rad} = 11.0 \text{ W/m}^2 \cdot \text{K}\) and radiative exchange becomes an important process.
PROBLEM 9.13

KNOWN: Oven door with average surface temperature of 32°C in a room with ambient air at 22°C.

FIND: Heat loss to the room. Also, find effect on heat loss if emissivity of door is unity and the surroundings are at 22°C.

SCHEMATIC:

ASSUMPTIONS: (1) Ambient air is quiescent, (2) Surface radiation effects are negligible.

PROPERTIES: Table A-4, Air (T_f = 300K, 1 atm): \( \nu = 15.89 \times 10^{-6} \, \text{m}^2/\text{s}, \) \( k = 0.0263 \, \text{W/mK}, \) \( \alpha = 22.5 \times 10^{-6} \, \text{m}^2/\text{s}, \) \( \Pr = 0.707, \) \( \beta = 1/T_f = 3.33 \times 10^{-3} \, \text{K}^{-1}. \)

ANALYSIS: The heat rate from the oven door surface by convection to the ambient air is

\[
q = -\bar{h} A_s (T_s - T_\infty)
\]

where \( \bar{h} \) can be estimated from the free-convection correlation for a vertical plate, Eq. 9.26,

\[
\frac{\bar{Nu}_L}{k} = \frac{0.825 + \frac{0.387Ra_L^{1/6}}{[1+(0.492/Pr)^{9/16}]^{8/27}}}{k_{L}} = \left[ \frac{0.825 + \frac{0.387 \times 1.142 \times 10^8^{1/6}}{[1+(0.492/0.707)^{9/16}]^{8/27}}}{k_{L}} \right] = 63.5
\]

The heat rate using Eq. (1) is

\[
q = 3.34 \, \text{W/m}^2 \cdot \text{K} \times (0.5 \times 0.7) \, \text{m}^2 \times (32-22) \, \text{K} = 11.7 \, \text{W}.
\]

Heat loss by radiation, assuming \( \varepsilon = 1, \) is

\[
q_{\text{rad}} = \varepsilon A_s \sigma (T_s^4 - T_{\text{sur}}^4)
\]

\[
q_{\text{rad}} = 1(0.5 \times 0.7) \, \text{m}^2 \times 5.67 \times 10^{-8} \, \text{W/m}^2 \cdot \text{K}^4 \left[ (273+32)^4 - (273+22)^4 \right] K^4 = 21.4 \, \text{W}.
\]

Note that heat loss by radiation is nearly double that by free convection. Using Eq. (1.9), the radiation heat transfer coefficient is \( h_{\text{rad}} = 6.4 \, \text{W/m}^2 \cdot \text{K}, \) which is twice the coefficient for the free convection process.
PROBLEM 9.14

KNOWN: Aluminum plate (alloy 2024) at an initial uniform temperature of 227°C is suspended in a room where the ambient air and surroundings are at 27°C.

FIND: (a) Expression for time rate of change of the plate, (b) Initial rate of cooling (K/s) when plate temperature is 227°C, (c) Validity of assuming a uniform plate temperature, (d) Decay of plate temperature and the convection and radiation rates during cooldown.

SCHEMATIC:

ASSUMPTIONS: (1) Plate temperature is uniform, (2) Ambient air is quiescent and extensive, (3) Surroundings are large compared to plate.

PROPERTIES: Table A.1, Aluminum alloy 2024 (T = 500 K): \( \rho = 2770 \text{ kg/m}^3 \), \( k = 186 \text{ W/m} \cdot \text{K} \), \( c = 983 \text{ J/kg} \cdot \text{K} \); Table A.4, Air (\( T_f = 400 \text{ K}, 1 \text{ atm} \)): \( \nu = 26.41 \times 10^{-6} \text{ m}^2/\text{s} \), \( k = 0.0388 \text{ W/m} \cdot \text{K} \), \( \alpha = 38.3 \times 10^{-6} \text{ m}^2/\text{s} \), \( Pr = 0.690 \).

ANALYSIS: (a) From an energy balance on the plate with free convection and radiation exchange, \( -\dot{E}_{\text{out}} = \dot{E}_{\text{st}} \), we obtain

\[
-\bar{h}_L 2A_s (T_s - T_\infty) - \varepsilon 2A_s \sigma (T_s^4 - T_{\text{sur}}^4) = \rho A_s c \frac{dT}{dt} \quad \text{or} \quad \frac{dT}{dt} = -\frac{2}{\rho c} \left[ \bar{h}_L (T_s - T_\infty) + \varepsilon \sigma (T_s^4 - T_{\text{sur}}^4) \right]
\]

where \( T_s \), the plate temperature, is assumed to be uniform at any time.

(b) To evaluate \( (dT/dt) \), estimate \( \bar{h}_L \). First, find the Rayleigh number,

\[
Ra_L = g \beta (T_s - T_\infty) L^3 / \nu \alpha = \frac{9.8 \text{ m/s}^2 (1/400 \text{ K}) (227 - 27) \text{K} \times (0.3 \text{ m})^3}{26.41 \times 10^{-6} \text{ m}^2/\text{s} \times 38.3 \times 10^{-6} \text{ m}^2/\text{s}} = 1.308 \times 10^8
\]

Eq. 9.27 is appropriate; substituting numerical values, find

\[
\bar{Nu}_L = 0.68 + \frac{0.670 \operatorname{Ra}_L^{1/4}}{\left[ 1 + (0.492/Pr)^{9/16} \right]^{4/9}} = 0.68 + \frac{0.670 \left( 1.308 \times 10^8 \right)^{1/4}}{\left[ 1 + (0.492/0.690)^{9/16} \right]^{4/9}} = 55.5
\]

\[
\bar{h}_L = \bar{Nu}_L k/L = 55.5 \times 0.0338 \text{ W/m} \cdot \text{K} / 0.3 \text{ m} = 6.25 \text{ W/m}^2 \cdot \text{K}
\]

Continued...
PROBLEM 9.14 (Cont.)

\[
\frac{dT}{dt} = -\frac{2}{2770 \text{ kg/m}^3 \times 0.015 \text{ m} \times 983 \text{ J/kg.K}} \times 
\left[ 6.25 \text{ W/m}^2 \cdot \text{K} \times (227 - 27) \text{ K} + 0.25 \left( 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \right) \left( 500^4 - 300^4 \right) \text{ K}^4 \right] = -0.099 \text{ K/s}.
\]

(c) The uniform temperature assumption is justified if the Biot number criterion is satisfied. With \( L_c \equiv \frac{V}{2A_s} = (A_s \cdot t/2A_s) = (t/2) \) and \( \bar{h}_{\text{tot}} = \bar{h}_{\text{conv}} + \bar{h}_{\text{rad}} \), \( \text{Bi} = \frac{\bar{h}_{\text{tot}} (t/2)/k \leq 0.1} \). Using the linearized radiation coefficient relation, find

\[
\bar{h}_{\text{rad}} = \varepsilon \sigma (T_s + T_{\text{sur}}) \left( T_s^2 + T_{\text{sur}}^2 \right) = 0.25 \left( 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \right) (500 + 300) \left( 500^2 + 300^2 \right) \text{ K}^3 = 3.86 \text{ W/m}^2 \cdot \text{K}
\]

Hence, \( \text{Bi} = (6.25 + 3.86) \text{ W/m}^2 \cdot \text{K}(0.015 \text{ m}/2)/186 \text{ W/m.K} = 4.07 \times 10^{-4} \). Since \( \text{Bi} \ll 0.1 \), the assumption is appropriate.

(d) The temperature history of the plate was computed by combining the Lumped Capacitance Model of IHT with the appropriate Correlations and Properties Toolpads.

Due to the small values of \( \bar{h}_{\ell} \) and \( \bar{h}_{\text{rad}} \), the plate cools slowly and does not reach 30°C until \( t \approx 14000 \text{s} \) = 3.89h. The convection and radiation rates decrease rapidly with increasing \( t \) (decreasing \( T \)), thereby decelerating the cooling process.

**COMMENTS:** The reduction in the convection rate with increasing time is due to a reduction in the thermal conductivity of air, as well as the values of \( \bar{h}_{\ell} \) and \( T \).
PROBLEM 9.15

KNOWN: Instantaneous temperature and time rate of temperature change of a vertical plate cooling in a room.

FIND: Average free convection coefficient for the prescribed conditions; compare with standard empirical correlation.

SCHEMATIC:

ASSUMPTIONS: (1) Uniform plate temperature, (2) Quiescent room air, (3) Large surroundings.

PROPERTIES: Table A-1, Aluminum alloy 2024 ($T_s = 127^\circ C = 400K$); $\rho = 2770$ kg/m$^3$, $c_p = 925$ J/kg·K; Table A-4, Air ($T_f = (T_s + T_{\infty})/2 = 350K$, 1 atm): $v = 20.92 \times 10^{-6}$ m$^2$/s, $k = 0.020$ W/mK, $\alpha = 29.9 \times 10^{-6}$ m$^2$/s, $Pr = 0.700$.

ANALYSIS: From an energy balance on the plate considering free convection and radiation exchange,

$$\dot{E}_{in} - \dot{E}_{out} = \dot{E}_{st}$$

$$-\bar{h}_L (2A_s) (T_s - T_{\infty}) - \varepsilon (2A_s) \sigma (T^4_s - T^4_{sur}) = \rho A_s \ell c_p \frac{dT}{dt}$$

Noting that the plate area is $2A_s$, solving for $\bar{h}_L$, and substituting numerical values, find

$$\bar{h}_L = 6.5 \text{ W/m}^2 \cdot \text{K}.$$ 

To select an appropriate empirical correlation, first evaluate the Rayleigh number,

$$Ra_L = \frac{g \beta \Delta T L^3}{\nu \alpha}$$

$$Ra_L = 9.8 \text{ m/s}^2 \left(1/350K\right) \left(127 - 27\right) \text{K} (0.3 \text{m})^3 \left(20.92 \times 10^{-6} \text{ m}^2/\text{s}\right) \left(29.9 \times 10^{-6} \text{ m}^2/\text{s}\right) = 1.21 \times 10^8.$$ 

Since $Ra_L < 10^9$, the flow is laminar and Eq. 9.27 is applicable,

$$\bar{N}u_L = \bar{h}_L L \frac{L}{k} = 0.68 + \frac{0.670 Ra_L^{1/4}}{1 + (0.492/Pr)^{9/16}}$$

$$\bar{h}_L = \left(\frac{0.030 \text{ W/m} \cdot \text{K}}{0.3 \text{ m}}\right) \left(0.68 + 0.670 \left(1.21 \times 10^8\right)^{1/4} \left[1 + (0.492/0.700)^{9/16}\right]^{-4/9}\right) = 5.5 \text{ W/m}^2 \cdot \text{K}.$$ 

COMMENTS: (1) The correlation estimate is 15% lower than the experimental result. (2) This transient method, useful for obtaining an average free convection coefficient for spacewise isothermal objects, requires $Bi \leq 0.1$. 

PROBLEM 9.16

KNOWN: Person, approximated as a cylinder, experiencing heat loss in water or air at 10°C.

FIND: Whether heat loss from body in water is 30 times that in air.

ASSUMPTIONS: (1) Person can be approximated as a vertical cylinder of diameter $D = 0.3$ m and length $L = 1.8$ m, at 25°C, (2) Loss is only from the lateral surface.

PROPERTIES: Table A-4, Air \( \left( T = (25 + 10)^\circ C / 2 = 290K, 1 atm \right) \): \( k = 0.0293 \text{ W/mK}, \nu = 19.91 \times 10^{-6} \text{ m}^2/\text{s}, \alpha = 28.4 \times 10^{-6} \text{ m}^2/\text{s}; \) Table A-6, Water (290K): \( k = 0.598 \text{ W/mK}, \nu = \mu v_f = 1.081 \times 10^{-6} \text{ m}^2/\text{s}, \alpha = k v_f/c_p = 1.431 \times 10^{-7} \text{ m}^2/\text{s}, \beta_f = 174 \times 10^{-6} \text{ K}^{-1} \).

ANALYSIS: In both water (wa) and air (a), the heat loss from the lateral surface of the cylinder approximating the body is

\[
q = \bar{h} \pi DL (T_s - T_\infty)
\]

where $T_s$ and $T_\infty$ are the same for both situations. Hence,

\[
\frac{q_{wa}}{q_a} = \frac{\bar{h}_{wa}}{\bar{h}_a}
\]

**Vertical cylinder in air:**

\[
Ra_L = \frac{g \beta \Delta T L^3}{\nu \alpha} = \frac{9.8 \text{ m/s}^2 \times (1/290K)(25 - 10)K (1.8m)^3}{19.91 \times 10^{-6} \text{ m}^2/\text{s} \times 28.4 \times 10^{-6} \text{ m}^2/\text{s}} = 5.228 \times 10^9
\]

Using Eq. 9.24 with $C = 0.1$ and $n = 1/3$,

\[
\bar{Nu}_{L} = \frac{\bar{h}_L}{k} = CRa^n_L = 0.1 \left( 5.228 \times 10^9 \right)^{1/3} = 173.4 \quad \bar{h}_L = 2.82 \text{ W/m}^2 \cdot \text{K}.
\]

**Vertical cylinder in water:**

\[
Ra_L = \frac{9.8 \text{ m/s}^2 \times 174 \times 10^{-6} \text{ K}^{-1}(25 - 10)K (1.8m)^3}{1.081 \times 10^{-6} \text{ m}^2/\text{s} \times 1.431 \times 10^{-7} \text{ m}^2/\text{s}} = 9.643 \times 10^{11}
\]

Using Eq. 9.24 with $C = 0.1$ and $n = 1/3$,

\[
\bar{Nu}_{L} = \frac{\bar{h}_L}{k} = CRa^n_L = 0.1 \left( 9.643 \times 10^{11} \right)^{1/3} = 978.9 \quad \bar{h}_L = 328 \text{ W/m}^2 \cdot \text{K}.
\]

Hence, from this analysis we find

\[
\frac{q_{wa}}{q_a} = \frac{328 \text{ W/m}^2 \cdot \text{K}}{2.8 \text{ W/m}^2 \cdot \text{K}} = 117
\]

which compares poorly with the claim of 30.
PROBLEM 9.17

KNOWN: Dimensions of window pane with frost formation on inner surface. Temperature of room air and walls.

FIND: Heat loss through window.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Surface of frost is isothermal with $T_s \approx 0^\circ C$, (3) Radiation exchange is between a small surface (window) and a large enclosure (walls of room), (4) Room air is quiescent.

PROPERTIES: Table A-4, air ($T_f = 9^\circ C = 282 K$): $k = 0.0249 \text{ W/m}\cdot\text{K}$, $\nu = 14.3 \times 10^{-6} \text{ m}^2/\text{s}$, $\alpha = 20.1 \times 10^{-6} \text{ m}^2/\text{s}$, $\Pr = 0.712$, $\beta = 3.55 \times 10^{-3} \text{ K}^{-1}$.

ANALYSIS: Under steady-state conditions, the heat loss through the window corresponds to the rate of heat transfer to the frost by convection and radiation.

$$q = q_{\text{conv}} + q_{\text{rad}} = W \times L \left[ \bar{h} (T_\infty - T_s) + \varepsilon \sigma (T_{\text{sur}}^4 - T_s^4) \right]$$

With $Ra_L = g \beta (T_\infty - T_s) L^3 / \alpha \nu = 9.8 \text{ m/s}^2 \times 0.00355 \text{ K}^{-1} \times 18 \text{ K} \left(1 \text{ m} \right)^3 / \left(14.3 \times 20.1 \times 10^{-12} \text{ m}^4 / \text{s}^2 \right)$

$= 2.18 \times 10^9$, Eq. (9.26) yields

$$\overline{Nu}_L = \left\{ 0.825 + \frac{0.387 Ra_L^{1/6}}{1 + (0.492 / Pr)^{9/16}} \right\}^2 = 156.5$$

$$\bar{h} = \overline{Nu}_L \frac{k}{L} = 156.5 \left( \frac{0.0249 \text{ W/m}\cdot\text{K}}{1 \text{ m}} \right) = 3.9 \text{ W/m}^2\cdot\text{K}$$

$$q = 1 \text{ m}^2 \left[ 3.9 \text{ W/m}^2\cdot\text{K} (18 \text{ K}) + 0.90 \times 5.67 \times 10^{-8} \text{ W/m}^2\cdot\text{K}^4 (291^4 - 273^4) \right]$$

$$= 70.2 \text{ W} + 82.5 \text{ W} = 152.7 \text{ W} <$$

COMMENTS: (1) The thickness of the frost layer does not affect the heat loss, since the inner surface of the layer remains at $T_s = 0^\circ C$. However, the temperature of the glass/frost interface decreases with increasing thickness, from a value of $0^\circ C$ for negligible thickness. (2) Since the thermal boundary layer thickness is zero at the top of the window and has its maximum value at the bottom, the temperature of the glass will actually be largest and smallest at the top and bottom, respectively. Hence, frost will first begin to form at the bottom.
**PROBLEM 9.18**

**KNOWN:** During a winter day, the window of a patio door with a height of 1.8 m and width of 1.0 m shows a frost line near its base.

**FIND:** (a) Explain why the window would show a frost layer at the base of the window, rather than at the top, and (b) Estimate the heat loss through the window due to free convection and radiation. If the room has electric baseboard heating, estimate the daily cost of the window heat loss for this condition based upon the utility rate of 0.08 $/kW-h.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Window has a uniform temperature, (3) Ambient air is quiescent, and (4) Room walls are isothermal and large compared to the window.

**PROPERTIES:** *Table A-4*, Air \((T_f = (T_s + T_\infty)/2 = 280 \text{ K}, 1 \text{ atm}): v = 14.11 \times 10^{-6} \text{ m}^2/\text{s}, k = 0.0247 \text{ W/m-K}, \alpha = 1.986 \times 10^{-5} \text{ m}^2/\text{s}.

**ANALYSIS:**

(a) For these winter conditions, a frost line could appear and it would be at the bottom of the window. The boundary layer is thinnest at the top of the window, and hence the heat flux from the warmer room is greater than compared to that at the bottom portion of the window where the boundary layer is thicker. Also, the air in the room may be stratified and cooler near the floor compared to near the ceiling.

(b) The heat loss from the room to the window having a uniform temperature \(T_s = 0^\circ\text{C}\) by convection and radiation is

\[
q_{loss} = q_{cv} + q_{rad}
\]

\[
q_{loss} = A_s \left[ h_L (T_\infty - T_s) + \varepsilon \sigma (T_{sur}^4 - T_s^4) \right]
\]

The average convection coefficient is estimated from the Churchill-Chu correlation, Eq. 9.26, using properties evaluated at \(T_f = (T_s + T_\infty)/2\).

\[
\frac{\overline{Nu}_L}{k} = \left\{ 0.825 + \frac{0.387 \frac{Ra_L^{1/6}}{Pr^{9/16}}}{1 + (0.492/Pr)^{9/16}} \right\}^{2/3}
\]

\[
Ra_L = g \beta T (T_\infty - T_s) L^3 / v \alpha
\]

Substituting numerical values in the correlation expressions, find

\[
Ra_L = 1.084 \times 10^{10} \quad \overline{Nu}_L = 258.9 \quad \overline{h}_L = 3.6 \text{ W/m}^2 \cdot \text{K}
\]

Continued ....
PROBLEM 9.18 (Cont.)

Using Eq. (2), the heat loss with $\sigma = 5.67 \times 10^{-8}$ W/m$^2$K$^4$ is

$$q_{\text{loss}} = (1 \times 1.8) m^2 \left[ 3.6 \text{ W/m}^2 \cdot \text{K} \cdot (15 \text{ K}) + 0.940 \sigma \left( 288^4 - 273^4 \right) \text{K}^4 \right]$$

$$q_{\text{loss}} = (96.1 + 127.1) \text{ W} = 223 \text{ W}$$

The daily cost of the window heat loss for the given utility rate is

$$\text{cost} = q_{\text{loss}} \times \text{(utility rate)} \times 24 \text{ hours}$$

$$\text{cost} = 223 \text{ W} \times \left( 10^{-3} \text{ kW/W} \right) \times 0.08 \$/\text{kW} - \text{h} \times 24 \text{ h}$$

$$\text{cost} = 0.43 \$/\text{day}$$

COMMENTS: Note that the heat loss by radiation is 30% larger than by free convection.
PROBLEM 9.19

KNOWN: Room and ambient air conditions for window glass.
FIND: Temperature of the glass and rate of heat loss.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible temperature gradients in the glass, (3) Inner and outer surfaces exposed to large surroundings.

PROPERTIES: Table A.4, air (T_{i} and T_{o}): Obtained from the IHT Properties Tool Pad.

ANALYSIS: Performing an energy balance on the window pane, it follows that

\[ \frac{\text{in}}{\text{out}} = \frac{\text{out}}{\text{in}} \]

or

\[ \varepsilon \sigma \left( T_{\text{sur},i}^4 - T^4 \right) + \bar{h}_i \left( T_{\text{in},i} - T \right) = \varepsilon \sigma \left( T^4 - T_{\text{sur},i}^4 \right) + \bar{h}_o \left( T - T_{\text{in},o} \right) \]

where \( \bar{h}_i \) and \( \bar{h}_o \) may be evaluated from Eq. 9.26.

Using the First Law Model for an Isothermal Plane Wall and the Correlations and Properties Tool Pads of IHT, the energy balance equation was formulated and solved to obtain

\[ T = 273.8 \text{ K} \]

The heat rate is then \( q_i = q_o \), or

\[ q_i = L^2 \left[ \varepsilon \sigma \left( T_{\text{sur},i}^4 - T^4 \right) + \bar{h}_i \left( T_{\text{in},i} - T \right) \right] = 174.8 \text{ W} \]

COMMENTS: The radiative and convective contributions to heat transfer at the inner and outer surfaces are \( q_{\text{rad},i} = 99.04 \text{ W} \), \( q_{\text{conv},i} = 75.73 \text{ W} \), \( q_{\text{rad},o} = 86.54 \text{ W} \), and \( q_{\text{conv},o} = 88.23 \text{ W} \), with corresponding convection coefficients of \( \bar{h}_i = 3.95 \text{ W/m}^2\cdot\text{K} \) and \( \bar{h}_o = 4.23 \text{ W/m}^2\cdot\text{K} \). The heat loss could be reduced significantly by installing a double pane window.
**PROBLEM 9.20**

**KNOWN:** Room and ambient air conditions for window glass. Thickness and thermal conductivity of glass.

**FIND:** Inner and outer surface temperatures and heat loss.

**SCHEMATIC:**

![Schematic](image)

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional conduction in the glass, (3) Inner and outer surfaces exposed to large surroundings.

**PROPERTIES:** Table A.4, air ($T_{f,i}$ and $T_{f,o}$): Obtained from the IHT Properties Tool Pad.

**ANALYSIS:** Performing energy balances at the inner and outer surfaces, we obtain, respectively,

\[
\varepsilon \sigma \left( T_{\text{sur},i}^4 - T_{s,i}^4 \right) + \overline{h}_i \left( T_{\infty,i} - T_{s,i} \right) = \left( \text{kg}/\text{tg} \right) \left( T_{s,i} - T_{s,o} \right) \tag{1}
\]

\[
\left( \text{kg}/\text{tg} \right) \left( T_{s,i} - T_{s,o} \right) = \varepsilon \sigma \left( T_{s,o}^4 - T_{\text{sur},o}^4 \right) + \overline{h}_o \left( T_{s,o} - T_{\infty,o} \right) \tag{2}
\]

where Eq. 9.26 may be used to evaluate $\overline{h}_i$ and $\overline{h}_o$

\[
\overline{Nu}_L = \left\{ 0.825 + \frac{0.387 \text{Ra}_L^{1/6}}{1 + (0.492/\text{Pr})^{9/16}} \right\}^{8/27}
\]

Using the *First Law Model* for *One-dimensional Conduction in a Plane Wall* and the *Correlations* and *Properties* Tool Pads of IHT, the energy balance equations were formulated and solved to obtain

\[
T_{s,i} = 274.4 \; \text{K} \quad T_{s,o} = 273.2 \; \text{K}
\]

from which the heat loss is

\[
q = \frac{k_g L^2}{t_g} \left( T_{s,i} - T_{s,o} \right) = 168.8 \; \text{W}
\]

**COMMENTS:** By accounting for the thermal resistance of the glass, the heat loss is smaller (168.8 W) than that determined in the preceding problem (174.8 W) by assuming an isothermal pane.
PROBLEM 9.21

KNOWN: Plate dimensions, initial temperature, and final temperature. Air temperature.

FIND: (a) Initial cooling rate, (b) Time to reach prescribed final temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Plate is spacewise isothermal as it cools (lumped capacitance approximation), (2) Negligible heat transfer from minor sides of plate, (3) Thermal boundary layer development corresponds to that for an isolated plate (negligible interference between adjoining boundary layers). (4) Negligible radiation. (5) Constant properties.

PROPERTIES: Table A-1, AISI 1010 steel ($T = 473$ K): $\rho = 7854$ kg/m$^3$, $c = 513$ J/kg·K. Table A-4, air ($T_{f,i} = 433$ K): $\nu = 30.4 \times 10^{-6}$ m$^2$/s, $k = 0.0361$ W/m·K, $\alpha = 44.2 \times 10^{-6}$ m$^2$/s, $Pr = 0.687$, $\beta = 0.0023$ K$^{-1}$.

ANALYSIS: (a) The initial rate of heat transfer is $q_i = \bar{h}A_s(T_i - T_\infty)$, where $A_s = 2L^2 = 2$ m$^2$.

With $Ra_{L,i} = g\beta(T_i - T_\infty)L^3/\alpha\nu = 9.8$ m/s$^2 \times 0.0021 \times (280)^1 m^3/44.2 \times 10^{-6}$ m$^2$/s $\times 30.4 \times 10^{-6}$ m$^2$/s = $4.72 \times 10^9$, Eq. 9.26 yields

$$\bar{h} = \frac{0.0361 \text{ W/m·K}}{1 \text{ m}} \left\{0.825 + \frac{0.387 \left(4.72 \times 10^9\right)^{1/6}}{1 + \left(0.492/0.687\right)^{0.90/27}}\right\}^2 = 7.16 \text{ W/m}^2\cdot\text{K}$$

Hence, $q_i = 7.16 \text{ W/m}^2\cdot\text{K} \times 2 \text{ m}^2 \times 280\text{°C} = 4010 \text{ W}$

(b) From an energy balance at an instant of time for a control surface about the plate, $-q = \dot{E}_{st}$ $= \rho L^2 \delta c dT/dt$, the rate of change of the plate temperature is

$$\frac{dT}{dt} = -\frac{\bar{h}2L^2(T - T_\infty)}{\rho L^2 \delta c} = -\frac{2\bar{h}}{\rho \delta c}(T - T_\infty)$$

where the Rayleigh number, and hence $\bar{h}$, changes with time due to the change in the temperature of the plate. Integrating the foregoing equation with the DER function of IHT, the following results are obtained for the temperature history of the plate.

Continued …..
The time for the plate to cool to 100°C is

\[ t = 2365 \text{ s} \]

**COMMENTS:** (1) Although the plate temperature is comparatively large and radiation emission is significant relative to convection, much of the radiation leaving one plate is intercepted by the adjoining plate if the spacing between plates is small relative to their width. The net effect of radiation on the plate temperature would then be small. (2) Because of the increase in \( \beta \) and reductions in \( \nu \) and \( \alpha \) with increasing \( t \), the Rayleigh number decreases only slightly as the plate cools from 300°C to 100°C (from \( 4.72 \times 10^9 \) to \( 4.48 \times 10^9 \)), despite the significant reduction in \( (T - T_\infty) \).

The reduction in \( \overline{h} \) from 7.2 to 5.6 W/m\(^2\)·K is principally due to a reduction in the thermal conductivity.
PROBLEM 9.22

KNOWN: Thin-walled container with hot process fluid at 50°C placed in a quiescent, cold water bath at 10°C.

FIND: (a) Overall heat transfer coefficient, U, between the hot and cold fluids, and (b) Compute and plot U as a function of the hot process fluid temperature for the range 20 ≤ T_{w,h} ≤ 50°C.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Heat transfer at the surfaces approximated by free convection from a vertical plate, (3) Fluids are extensive and quiescent, (4) Hot process fluid thermophysical properties approximated as those of water, and (5) Negligible container wall thermal resistance.

PROPERTIES: Table A.6, Water (assume T_{f,h} = 310 K): ρ_h = 1/1.007 × 10^{-3} = 993 kg/m^3, c_{p,h} = 4178 J/kg·K, ν_h = μ_h/ρ_h = 695 × 10^{-6} m/s^2/993 kg/m^3 = 6.999 × 10^{-7} m^2/s, k_h = 0.628 W/m·K, Pr_h = 4.62, α_h = k_h/ρ_h c_{p,h} = 1.514 × 10^{-7} m^2/s, β_h = 361.9 × 10^{-6} K^{-1}; Table A.6, Water (assume T_{f,c} = 295 K): ρ_c = 1/1.002 × 10^{-3} = 998 kg/m^3, c_{p,c} = 4181 J/kg·K, ν_c = μ_c/ρ_c = 959 × 10^{-6} m/s^2/998 kg/m^3 = 9.609 × 10^{-7} m^2/s, k_c = 0.606 W/m·K, Pr_c = 6.62, α_c = k_c/ρ_c c_{p,c} = 1.452 × 10^{-7} m^2/s, β_c = 227.5 × 10^{-6} K^{-1}.

ANALYSIS: (a) The overall heat transfer coefficient between the hot process fluid, T_{w,h}, and the cold water bath fluid, T_{w,c}, is

\[ U = \left( \frac{1}{\overline{h}_h} + \frac{1}{\overline{h}_c} \right)^{-1} \]  

where the average free convection coefficients can be estimated from the vertical plate correlation Eq. 9.26, with the Rayleigh number, Eq. 9.25,

\[ \frac{\overline{Nu}_L}{R\alpha} = \left[ 0.825 + \frac{0.387 Ra_L^{1/6}}{1 + \left( \frac{492}{Pr} \right)^{9/16}} \right]^{2/3} \]  

To affect a solution, assume \( T_s = \left( T_{w,h} - T_{w,i} \right)/2 = 30^0 \text{C} = 303 \text{K} \), so that the hot and cold fluid film temperatures are \( T_{w,h} = 313 \text{K} = 310 \text{K} \) and \( T_{w,c} = 293 \text{K} = 295 \text{K} \). From an energy balance across the container walls,

\[ \overline{h}_h \left( T_{w,h} - T_s \right) = \overline{h}_c \left( T_s - T_{w,c} \right) \]  

the surface temperature \( T_s \) can be determined. Evaluating the correlation parameters, find:

Hot process fluid:

\[ Ra_{L,h} = \frac{9.8 \text{ m/s}^2 \times 361.9 \times 10^{-6} \text{ K}^{-1} \left( 50 - 30 \right) \text{K} \left( 0.200 \text{m} \right)^3}{6.999 \times 10^{-7} \text{ m}^2/\text{s} \times 1.514 \times 10^{-7} \text{ m}^2/\text{s}} = 5.357 \times 10^9 \]

Continued...
PROBLEM 9.22 (Cont.)

\[
\overline{\text{Nu}_{L,h}} = \left(0.825 + \frac{0.387 \times 10^9}{1 + (0.492/4.62)^{9/16}} \right)^{8/27} = 251.5
\]

\[
\overline{h}_h = \frac{\overline{\text{Nu}_{L,h}} h}{L} = 251.5 \times 0.628 \text{ W/m}^2\cdot\text{K}/0.200\text{m} = 790 \text{ W/m}^2\cdot\text{K}
\]

Cold water bath:

\[
\text{Ra}_{L,c} = \frac{9.8 \text{ m/s}^2 \times 227.5 \times 10^{-6} \text{ K}^{-1} (30 - 10) (0.200\text{m})^3}{9.609 \times 10^{-7} \text{ m}^2/\text{s} \times 1.452 \times 10^{-7} \text{ m}^2/\text{s}} = 2.557 \times 10^9
\]

\[
\overline{\text{Nu}_{L,c}} = \left(0.825 + \frac{0.387 \times 2.557 \times 10^9}{1 + (0.492/6.62)^{9/16}} \right)^{8/27} = 203.9
\]

\[
\overline{h}_c = 203.9 \times 0.606 \text{ W/m} \cdot \text{K}/0.200\text{m} = 618 \text{ W/m}^2\cdot\text{K}
\]

From Eq. (1) find

\[
U = \left(1/790 + 1/618\right)^{-1} \text{ W/m}^2\cdot\text{K} = 347 \text{ W/m}^2\cdot\text{K}
\]

Using Eq.(4), find the resulting surface temperature

\[
790 \text{ W/m}^2\cdot\text{K} (50 - T_s) \text{K} = 618 \text{ W/m}^2\cdot\text{K} (T_s - 30) \text{K}
\]

Which compares favorably with our assumed value of 30°C.

(b) Using the IHT Correlations Tool, Free Convection, Vertical Plate and following the foregoing approach, the overall coefficient was computed as a function of the hot fluid temperature and is plotted below. Note that U increases almost linearly with $T_{\infty,h}$.

![Graph of Overall coefficient vs Hot process fluid temperature](image)

COMMENTS: For the conditions of part (a), using the IHT model of part (b) with thermophysical properties evaluated at the proper film temperatures, find $U = 352 \text{ W/m-K}$ with $T_s = 32.4°C$. Our approximate solution was a good one.

(2) Because the set of equations for part (b) is quite stiff, when using the IHT model you should follow the suggestions in the IHT Example 9.2 including use of the intrinsic function $T_{\text{fluid_avg}}(T1,T2)$. 
**PROBLEM 9.23**

**KNOWN:** Height, width, emissivity and temperature of heating panel. Room air and wall temperature.

**FIND:** Net rate of heat transfer from panel to room.

**SCHEMATIC:**

![Schematic](image)

**ASSUMPTIONS:** (1) Quiescent air, (2) Walls of room form a large enclosure, (3) Negligible heat loss from back of panel.

**PROPERTIES:** *Table A-4, Air (T_f = 350K, 1 atm): v = 20.9 \times 10^{-6} \text{ m}^2/\text{s}, k = 0.03 \text{ W/m-K}, \alpha = 29.9 \times 10^{-6} \text{ m}^2/\text{s}, Pr = 0.700.*

**ANALYSIS:** The heat loss from the panel by convection and radiation exchange is

\[ q = \bar{h}A(T_S - T_\infty) + \varepsilon\sigma A(T_S^4 - T_{sur}^4) \]

With

\[ \text{Ra}_L = \frac{g\beta (T_S - T_\infty)L^3}{\alpha v^3} = \frac{9.8 \text{ m}^2/\text{s}^2 (1/350\text{K})(100\text{K})(1\text{m})^3}{(20.9)(29.9) \times 10^{-12} \text{ m}^4/\text{s}^2} = 4.48 \times 10^9 \]

and using the Churchill-Chu correlation for free convection from a vertical plate,

\[ \bar{Nu}_L = \frac{\bar{h}L}{k} = \left[ 0.825 + \frac{0.387 \text{Ra}_L^{1/6}}{1 + (0.492/Pr)^{9/16}} \right]^{8/27} = 196 \]

\[ \bar{h} = 196k/L = 196 \times 0.03 \text{ W/m-K} = 5.87 \text{ W/m}^2 \cdot \text{K} \]

Hence,

\[ q = 5.86 \text{ W/m}^2 \cdot \text{K} (0.5 \text{ m}^2) (100\text{K}) + 0.9 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (0.5 \text{ m}^2) \left[ 400^4 - 300^4 \right] \text{K} \]

\[ q = 293 \text{ W} + 447 \text{ W} = 740 \text{ W} \]

**COMMENTS:** As is typical of free convection in gases, heat transfer by surface radiation is comparable to, if not larger than, the convection rate. The *relative* contribution of free convection would increase with decreasing L and T_s.
PROBLEM 9.24

FIND: (a) Initial cooling rate, (b) Validity of assuming negligible temperature gradients in the plate during the cooling process.

SCHEMATIC:

ASSUMPTIONS: (1) Plate temperature is uniform, (2) Chamber air is quiescent, (3) Chamber surface is much larger than that of plate, (4) Negligible heat transfer from edges.

PROPERTIES: Table A-1, Aluminum (573K): $k = 232 \text{ W/m} \cdot \text{K}$, $c_p = 1022 \text{ J/kg} \cdot \text{K}$, $\rho = 2702 \text{ kg/m}^3$; Table A-4, Air ($T_f = 436\text{K}$, 1 atm): $\nu = 30.72 \times 10^{-6} \text{ m}^2/\text{s}$, $\alpha = 44.7 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 0.0363 \text{ W/m} \cdot \text{K}$, $Pr = 0.687$, $\beta = 0.00229 \text{ K}^{-1}$.

ANALYSIS: (a) Performing an energy balance on the plate,

$$-q = -2A_s \left[ \bar{h} (T - T_{\infty}) + \varepsilon \sigma \left( T^4 - T_{\text{sur}}^4 \right) \right] = E_{\text{st}} = \rho V c_p \frac{dT}{dt}$$

$$\frac{dT}{dt} = -2 \left[ \bar{h} (T - T_{\infty}) + \varepsilon \sigma \left( T^4 - T_{\text{sur}}^4 \right) \right] / \rho w c_p$$

Using the correlation of Eq. 9.27, with

$$Ra_L = \frac{g \beta (T_i - T_{\infty}) L^3}{\nu \alpha} = \frac{9.8 \text{ m/s}^2 \times 0.00229 \text{ K}^{-1} (300 - 27) \text{ K} (0.5 \text{ m})^3}{30.72 \times 10^{-6} \text{ m}^2/\text{s} \times 44.7 \times 10^{-6} \text{ m}^2/\text{s}} = 5.58 \times 10^8$$

$$\bar{h} = \frac{k}{L} \left[ 0.68 + \frac{0.670 \text{Ra}^{1/4}}{[1 + (0.492/Pr)^{9/16}]^{4/9}} \right] = \frac{0.0363}{0.5} \left[ 0.68 + \frac{0.670 (5.58 \times 10^8)^{1/4}}{[1 + (0.492/0.687)^{9/16}]^{4/9}} \right]$$

$$\bar{h} = 5.8 \text{ W/m}^2 \cdot \text{K}.$$ 

Hence the initial cooling rate is

$$\frac{dT}{dt} = -\left[ \frac{2 (5.8 \text{ W/m}^2 \cdot \text{K} (300 - 27)^\circ \text{C} + 0.25 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left[ (573\text{K})^4 - (300\text{K})^4 \right] )}{2702\text{kg/m}^3 (0.016\text{m}) 1022\text{J/kg} \cdot \text{K}} \right]$$

$$\frac{dT}{dt} = -0.136 \text{ K/s}.$$ 

(b) To check the validity of neglecting temperature gradients across the plate thickness, calculate $Bi = h_{\text{eff}} (w/2)/k$

where $h_{\text{eff}} = \frac{q_{\text{tot}}}{(T_i - T_{\infty})} = (1583 + 1413) \text{ W/m}^2/273 \text{ K} = 11.0 \text{ W/m}^2 \cdot \text{K}$. Hence

$$Bi = \left( 11 \text{ W/m}^2 \cdot \text{K} \right) (0.008\text{m}) / 232 \text{ W/m} \cdot \text{K} = 3.8 \times 10^{-4}$$

and the assumption is excellent.

COMMENTS: (1) Longitudinal (x) temperature gradients are likely to be more severe than those associated with the plate thickness due to the variation of $h$ with x. (2) Initially $q_{\text{conv}} = q_{\text{rad}}$. 
**PROBLEM 9.25**

**KNOWN:** Boundary conditions associated with a rear window experiencing uniform volumetric heating.

**FIND:** (a) Volumetric heating rate \( \dot{q} \) needed to maintain inner surface temperature at \( T_{s,i} = 15^\circ C \), (b) Effects of \( T_{w,o} \), \( u_\infty \), and \( T_{w,i} \) on \( \dot{q} \) and \( T_{s,o} \).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, one-dimensional conditions, (2) Constant properties, (3) Uniform volumetric heating in window, (4) Convection heat transfer from interior surface of window to interior air may be approximated as free convection from a vertical plate, (5) Heat transfer from outer surface is due to forced convection over a flat plate in parallel flow.

**PROPERTIES:** Table A.3, Glass (300 K): \( k = 1.4 \text{ W/m·K} \); Table A.4, Air (\( T_{f,i} = 12.5^\circ C \), 1 atm): \( \nu = 14.6 \times 10^{-6} \text{ m}^2/\text{s}, k = 0.0251 \text{ W/m·K}, \alpha = 20.59 \times 10^{-6} \text{ m}^2/\text{s}, \beta = (1/285.5) = 3.503 \times 10^{-3} \text{ K}^{-1} \), \( \text{Pr} = 0.711 \); \( T_{f,o} \approx 0^\circ C \): \( \nu = 13.49 \times 10^{-6} \text{ m}^2/\text{s}, k = 0.0241 \text{ W/m·K}, \text{Pr} = 0.714 \).

**ANALYSIS:** (a) The temperature distribution in the glass is governed by the appropriate form of the heat equation, Eq. 3.39, whose general solution is given by Eq. 3.40.

\[
T(x) = -\frac{\dot{q}}{2k}x^2 + C_1x + C_2.
\]

The constants of integration may be evaluated by applying appropriate boundary conditions at \( x = 0 \). In particular, with \( T(0) = T_{s,i}, C_2 = T_{s,i} \). Applying an energy balance to the inner surface, \( q_{\text{cond}} = q_{\text{conv},i} \)

\[
-k \frac{dT}{dx} \bigg|_{x=0} = \bar{h}_1 (T_{\infty,i} - T_{s,i}) - k \left( -\frac{\dot{q}}{k}x + C_1 \right) \bigg|_{x=0} = \bar{h}_1 (T_{\infty,i} - T_{s,i})
\]

\[
C_1 = -\left( \frac{\bar{h}_1}{k} \right) (T_{\infty,i} - T_{s,i})
\]

\[
T(x) = -\frac{\dot{q}}{2k}x^2 + \frac{\bar{h}_1 (T_{\infty,i} - T_{s,i})}{k} x + T_{s,i}
\]

The required generation may then be obtained by formulating an energy balance at the outer surface, where \( q_{\text{cond}} = q_{\text{conv},o} \). Using Eq. (1),

\[
-k \frac{dT}{dx} \bigg|_{x=L} = \bar{h}_o (T_{s,o} - T_{\infty,o})
\]

Continued...
Substituting Eq. (3) into Eq. (2), the energy balance becomes

\[ q_L = \overline{h}_o (T_{s,o} - T_{\infty,o}) + \overline{h}_i (T_{s,i} - T_{\infty,i}) \]

where \( T_{s,o} \) may be evaluated by applying Eq. (1) at \( x = L \).

The \textit{inside} convection coefficient may be obtained from Eq. 9.26. With

\[ \overline{Nu}_H = \frac{g \beta (T_{s,i} - T_{\infty,i}) H^3}{\nu \alpha} = \frac{9.8 \text{ m/s}^2 \left(3.503 \times 10^{-3} \text{ K}^{-1}\right)(15 - 10) \text{K} (0.5 \text{ m})^3}{14.60 \times 10^{-6} \text{ m}^2/\text{s} \times 20.59 \times 10^{-6} \text{ m}^2/\text{s}} = 7.137 \times 10^7, \]

\[ \overline{Nu}_H = \left[ 0.825 + \frac{0.387 \text{Ra}_H^{1/6}}{1 + (0.492/\text{Pr})^{9/16}} \right]^{8/27} = \left[ 0.825 + \frac{0.387 (7.137 \times 10^7)^{1/6}}{1 + (0.492/0.711)^{9/16}} \right]^{8/27} = 56 \]

\[ \overline{h}_i = \frac{k \overline{Nu}_H}{H} = \frac{56 \times 0.0251 \text{W/m} \cdot \text{K}}{0.5 \text{ m}} = 2.81 \text{ W/m}^2 \cdot \text{K} \]

The \textit{outside} convection coefficient may be obtained by first evaluating the Reynolds number. With

\[ \text{Re}_H = \frac{u_{\infty} H}{\nu} = \frac{20 \text{ m/s} \times 0.5 \text{ m}}{13.49 \times 10^{-6} \text{ m}^2/\text{s}} = 7.413 \times 10^5 \]

and with \( \text{Re}_{x,c} = 5 \times 10^5 \), mixed boundary layer conditions exist. Hence,

\[ \overline{Nu}_H = \left(0.037 \text{Re}_H^{4/5} - 871\right) \text{Pr}^{1/3} = \left[ 0.037 (7.413 \times 10^5)^{4/5} - 871\right](0.714)^{1/3} = 864 \]

\[ \overline{h}_o = \overline{Nu}_H \left(k/H\right) = (864 \times 0.0241 \text{W/m} \cdot \text{K})/0.5 \text{ m} = 41.6 \text{ W/m}^2 \cdot \text{K}. \]

Eq. (5) may now be expressed as

\[ T_{s,o} = -\frac{1}{2} \frac{\dot{q} (0.008 \text{ m})^2}{(1.4 \text{ W/m} \cdot \text{K})} = \frac{2.81 \text{ W/m}^2 \cdot \text{K}(10-15) \text{K}}{1.4 \text{ W/m} \cdot \text{K}} \times 0.008 \text{ m} + 288 \text{ K} = -2.286 \times 10^{-5} \dot{q} + 288.1 \text{ K} \]

or, solving for \( \dot{q} \),

\[ \dot{q} = -43,745 \left(T_{s,o} - 288.1\right) \]

and substituting into Eq. (4),

\[ -43,745 \left(T_{s,o} - 288.1\right)(0.008 \text{ m}) = 41.6 \text{ W/m}^2 \cdot \text{K}(T_{s,o} - 263 \text{ K}) + 2.81 \text{ W/m}^2 \cdot \text{K}(288 \text{ K} - 283 \text{ K}) \]

It follows that \( T_{s,o} = 285.4 \text{ K} \) in which case, from Eq. (6)

\[ \dot{q} = 118 \text{ kW/m}^3. \]

(b) The parametric calculations were performed using the \textit{One-Dimensional, Steady-state Conduction Model of IHT} with the appropriate \textit{Correlations and Properties Tool Pads}, and the results are as follows.

Continued...
For fixed $T_{s,i}$ and $T_{\infty,i}$, $T_{s,o}$ and $\dot{q}$ are strongly influenced by $T_{\infty,o}$ and $u_{\infty}$, increasing and decreasing, respectively, with increasing $T_{\infty,o}$ and decreasing and increasing, respectively, with increasing $u_{\infty}$. For fixed $T_{s,i}$ and $u_{\infty}$, $T_{s,o}$ and $\dot{q}$ are independent of $T_{\infty,i}$, but increase and decrease, respectively, with increasing $T_{\infty,o}$.

**COMMENTS:** In lieu of performing a surface energy balance at $x = L$, Eq. (4) may also be obtained by applying an energy balance to a control volume about the entire window.
PROBLEM 9.26

KNOWN: Vertical panel with uniform heat flux exposed to ambient air.

FIND: Allowable heat flux if maximum temperature is not to exceed a specified value, \( T_{\text{max}} \).

SCHEMATIC:

ASSUMPTIONS: (1) Constant properties, (2) Radiative exchange with surroundings negligible.

PROPERTIES: Table A-4, Air (\( T_f = (T_{L/2} + T_\infty)/2 = (35.4 + 25)\text{°C}/2 = 30.2\text{°C} = 303\text{K}, 1 \text{ atm}) \): \( \nu = 16.19 \times 10^{-6} \text{ m}^2/\text{s}, k = 26.5 \times 10^{-3} \text{ W/m} \cdot \text{K}, \alpha = 22.9 \times 10^{-6} \text{ m}^2/\text{s}, \text{Pr} = 0.707. \)

ANALYSIS: Following the treatment of Section 9.6.1 for a vertical plate with uniform heat flux (constant \( q_s'' \)), the heat flux can be evaluated as

\[
q_s'' = \overline{h} \Delta T_{L/2}
\]

where

\[
\Delta T_{L/2} = T_s(L/2) - T_\infty
\]

and \( \overline{h} \) is evaluated using an appropriate correlation for a constant temperature vertical plate. From Eq. 9.28,

\[
\Delta T_x = T_x - T_\infty = 1.15 \left( \frac{x}{L} \right)^{1/5} \Delta T_{L/2}
\]

and recognizing that the maximum temperature will occur at the top edge, \( x = L \), use Eq. (3) to find

\[
\Delta T_{L/2} = (37 - 25)\text{°C}/1.15(1/1)^{1/5} = 10.4\text{°C} \quad \text{or} \quad T_{L/2} = 35.4\text{°C}.
\]

Calculate now the Rayleigh number based upon \( \Delta T_{L/2} \), with \( T_f = (T_{L/2} + T_\infty)/2 = 303\text{K}, \)

\[
\text{Ra}_L = \frac{g \beta \Delta T L^3}{\nu \alpha}
\]

where

\[
\Delta T = \Delta T_{L/2}
\]

\[
\text{Ra}_L = 9.8 \text{m/s}^2 \left( \frac{1/303\text{K}}{10.4\text{K}} \right) \left( \frac{1/1}{16.19 \times 10^{-6} \text{m}^2/\text{s} \times 22.9 \times 10^{-6} \text{m}^2/\text{s} \times 9.07 \times 10^8}ight)
\]

Since \( \text{Ra}_L < 10^9 \), the boundary layer flow is laminar; hence the correlation of Eq. 9.27 is appropriate,

\[
\overline{\text{Nu}}_L = \frac{\overline{h} L}{k} = 0.68 + \frac{0.670 \text{Ra}_L^{1/4}}{\left[ 1 + (0.492/\text{Pr})^{9/16} \right]^{4/9}}
\]

\[
\overline{h} = \left[ \frac{0.0265 \text{W/m} \cdot \text{K}}{1 \text{m}} \right] \left[ 0.68 + 0.670 \left( 9.07 \times 10^8 \right)^{1/4} / \left[ 1 + (0.492/0.707)^{9/16} \right]^{4/9} \right] = 2.38 \text{W/m}^2 \cdot \text{K}.
\]

From Eqs. (1) and (2) with numerical values for \( \overline{h} \) and \( \Delta T_{L/2} \), find

\[
q_s'' = 2.38 \text{W/m}^2 \cdot \text{K} \times 10.4\text{°C} = 24.8 \text{W/m}^2.
\]

COMMENTS: Recognize that radiation exchange with the environment will be significant. Assuming \( \overline{T}_s = T_{L/2} \), \( T_{\text{sur}} = T_\infty \) and \( \varepsilon = 1 \), find \( q_{\text{rad}}'' = \sigma \left( \overline{T}_s^{-4} - T_{\text{sur}}^{-4} \right) = 6.6 \text{ W/m}^2. \)
PROBLEM 9.27

KNOWN: Vertical circuit board dissipating 5W to ambient air.

FIND: (a) Maximum temperature of the board assuming uniform surface heat flux and (b) Temperature of the board for an isothermal surface condition.

SCHEMATIC:

ASSUMPTIONS: (1) Either uniform $q_s''$ or $T_s$ on the board, (2) Quiescent room air.

PROPERTIES: Table A-4, Air ($T_f=(T_L/2 + T_\infty)/2$ or $(T_s + T_\infty)/2$, 1 atm), values used in iterations:

ANALYSIS: (a) For the uniform heat flux case (see Section 9.6.1), the heat flux is

$$q_s'' = h \Delta T_{L/2}$$

where $\Delta T_{L/2} = T_{L/2} - T_\infty$ (1,2)

and $q_s'' = q / A_s = 5\text{W} / (0.150\text{m})^2 = 222 \text{W/m}^2$.

The maximum temperature on the board will occur at $x = L$ and from Eq. 9.28 is

$$\Delta T_x = 1.15(x / L)^{1/5} \Delta T_{L/2}$$

$$T_L = T_{\text{max}} = T_\infty + 1.15 \Delta T_{L/2}$$

The average heat transfer coefficient $h$ is estimated from a vertical (uniform $T_s$) plate correlation based upon the temperature difference $\Delta T_{L/2}$. Recognize that an iterative procedure is required: (i) assume a value of $T_{L/2}$, use Eq. (2) to find $\Delta T_{L/2}$; (ii) evaluate the Rayleigh number

$$Ra_L = g \beta \Delta T_{L/2} L^3 / \nu \alpha$$

and select the appropriate correlation (either Eq. 9.26 or 9.27) to estimate $\overline{h}$; (iii) use Eq. (1) with values of $\overline{h}$ and $\Delta T_{L/2}$ to find the calculated value of $q_s''$; and (iv) repeat this procedure until the calculated value for $q_s''$ is close to $q_s'' = 222 \text{W/m}^2$, the required heat flux.

Continued .....
PROBLEM 9.27 (Cont.)

To evaluate properties for the correlation, use the film temperature,
\[ T_f = (T_{L/2} + T_\infty)/2. \]  

**Iteration #1:** Assume \( T_{L/2} = 50^\circ C \) and from Eqs. (2) and (5) find
\[ \Delta T_{L/2} = (50 - 27)^\circ C = 23^\circ C \quad T_f = (50 + 27)^\circ C / 2 = 312K. \]

From Eq. (4), with \( \beta = 1/T_f \), the Rayleigh number is
\[ Ra_L = 9.8 \text{m/s}^2 \left(1/312K\right) \times 23^\circ C \left(0.150m\right)^3 / \left(17.10 \times 10^{-6} \text{m}^2/\text{s}\right) \times \left(24.3 \times 10^{-6} \text{m}^2/\text{s}\right) = 5.868 \times 10^6. \]

Since \( Ra_L < 10^9 \), the flow is laminar and Eq. 9.27 is appropriate
\[
\overline{Nu}_L = \frac{\overline{h}_L}{k} = 0.68 + \left[ \frac{0.670Ra_L^{1/4}}{1 + (0.492/Pr)^{9/16}} \right]^{4/9}
\]
\[ \overline{h}_L = \frac{0.0272 \text{W/m} \cdot \text{K}}{0.150 \text{m}} \left\{ 0.68 + 0.670 \left(5.868 \times 10^6\right)^{1/4} / \left[1 + (0.492/0.705)^{9/16}\right]^{4/9} \right\} = 4.71 \text{W/m}^2 \cdot \text{K}. \]

Using Eq. (1), the calculated heat flux is
\[ q_s^* = 4.71 \text{W/m}^2 \cdot \text{K} \times 23^\circ C = 108 \text{W/m}^2. \]

Since \( q_s^* < 222 \text{ W/m}^2 \), the required value, another iteration with an increased estimate for \( T_{L/2} \) is warranted. Further iteration results are tabulated.

<table>
<thead>
<tr>
<th>Iteration</th>
<th>( T_{L/2}(^\circ \text{C}) )</th>
<th>( \Delta T_{L/2}(^\circ \text{C}) )</th>
<th>( T_f(\text{K}) )</th>

<td>5.39</td>
<td>221</td>
</tr>
</tbody>
</table>

After Iteration 4, close agreement between the calculated and required \( q_s^* \) is achieved with \( T_{L/2} = 68^\circ \text{C} \). From Eq. (3), the maximum board temperature is
\[ T_L = T_{\text{max}} = 27^\circ \text{C} + 1.15(41)^\circ \text{C} = 74^\circ \text{C}. \]

(b) For the uniform temperature case, the procedure for estimation of the average heat transfer coefficient is the same. Hence,
\[ T_s = T_{L/2} \left| q_s^* = 68^\circ \text{C} \right. \]

**COMMENTS:** In both cases, \( q = 5\text{W} \) and \( \overline{h} = 5.38 \text{W/m}^2 \). However, the temperature distributions for the two cases are quite different as shown on the sketch. For \( q_s^* = \) constant, \( \Delta T_x \sim x^{1/5} \) according to Eq. 9.28.
**PROBLEM 9.28**

**KNOWN:** Coolant flow rate and inlet and outlet temperatures. Dimensions and emissivity of channel side walls. Temperature of surroundings. Power dissipation.

**FIND:** (a) Temperature of sidewalls for $\varepsilon_s = 0.15$, (b) Temperature of sidewalls for $\varepsilon_s = 0.90$, (c) Sidewall temperatures with loss of coolant for $\varepsilon_s = 0.15$ and $\varepsilon_s = 0.90$.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Negligible heat transfer from top and bottom surfaces of duct, (3) Isothermal side walls, (4) Large surroundings, (5) Negligible changes in flow work and potential and kinetic energies of coolant, (6) Constant properties.

**PROPERTIES:** Table A-4, air ($\overline{T_m} = 298$ K): $c_p = 1007$ J/kg·K. Air properties required for the free convection calculations depend on $T_s$ and were evaluated as part of the iterative solution obtained using the IHT software.

**ANALYSIS:** (a) The heat dissipated by the components is transferred by forced convection to the coolant ($q_c$), as well as by natural convection ($q_{conv}$) and radiation ($q_{rad}$) to the ambient air and the surroundings. Hence,

$$q = q_c + q_{conv} + q_{rad} = 200 \text{ W}$$

$$q_c = \dot{m} c_p \left( T_{m,o} - T_{m,i} \right) = 0.015 \text{ kg/s} \times 1007 \text{ J/kg K} \times 10^\circ \text{C} = 151 \text{ W}$$

$$q_{conv} = 2\overline{h} A_s (T_s - T_{\infty})$$

where $A_s = H \times L = 0.32 \text{ m}^2$ and $\overline{h}$ is obtained from Eq. 9.26, with $Ra_H = g \beta (T_s - T_{\infty}) H^3 / \alpha v$.

$$\overline{h} = \frac{k}{H} \left[ 0.825 + \frac{0.387 Ra_H^{1/6}}{1 + (0.492/Pr)^{9/16}} \right]^{2/7}$$

$$q_{rad} = 2 A_s \varepsilon_s \sigma \left( T_s^4 - T_{sur}^4 \right)$$

Substituting Eqs. (2) – (4) into (1) and solving using the IHT software with $\varepsilon_s = 0.15$, we obtain

$$T_s = 308.8 \text{ K} = 35.8^\circ \text{C}$$

The corresponding heat rates are $q_{conv} = 39.6 \text{ W}$ and $q_{rad} = 9.4 \text{ W}$.

(b) For $\varepsilon_s = 0.90$ and $q_c = 151 \text{ W}$, the solution to Eqs. (1) – (4) yields

Continued ….
PROBLEM 9.28 (Cont.)

\[ T_s = 301.8 \text{ K} = 28.8^\circ \text{C} \]

with \( q_{\text{conv}} = 18.7 \text{ W} \) and \( q_{\text{rad}} = 30.3 \text{ W} \). Hence, enhanced emission from the surface yields a lower operating temperature and heat transfer by radiation now exceeds that due to conduction.

(c) With loss of coolant flow, we can expect all of the heat to be dissipated from the sidewalls \( (q_c = 0) \). Solving Eqs. (1), (3) and (4), we obtain

\[ \varepsilon_s = 0.15: \quad T_s = 341.8 \text{ K} = 68.8^\circ \text{C} \]
\[ q_{\text{conv}} = 165.9 \text{ W}, \quad q_{\text{rad}} = 34.1 \text{ W} \]

\[ \varepsilon_s = 0.90: \quad T_s = 322.5 \text{ K} = 49.5^\circ \text{C} \]
\[ q_{\text{conv}} = 87.6 \text{ W}, \quad q_{\text{rad}} = 112.4 \text{ W} \]

Since the temperature of the electronic components exceeds that of the sidewalls, the value of \( T_s = 68.8^\circ \text{C} \) corresponding to \( \varepsilon_s = 0.15 \) may be unacceptable, in which case the high emissivity coating should be applied to the walls.

COMMENTS: For the foregoing cases the convection coefficient is in the range \( 3.31 \leq \theta \leq 5.31 \text{ W/m}^2\cdot\text{K} \), with the smallest value corresponding to \( (q_c = 151 \text{ W}, \varepsilon_s = 0.90) \) and the largest value to \( (q_c = 0, \varepsilon_s = 0.15) \). The radiation coefficient is in the range \( 0.93 \leq \theta_{\text{rad}} \leq 5.96 \text{ W/m}^2\cdot\text{K} \), with the smallest value corresponding to \( (q_c = 151 \text{ W}, \varepsilon_s = 0.15) \) and the largest value to \( (q_c = 0, \varepsilon_s = 0.90) \).
PROBLEM 9.29

KNOWN: Dimensions, interior surface temperature, and exterior surface emissivity of a refrigerator door. Temperature of ambient air and surroundings.

FIND: (a) Heat gain with no insulation, (b) Heat gain as a function of thickness for polystyrene insulation.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible thermal resistance of steel and polypropylene sheets, (3) Negligible contact resistance between sheets and insulation, (4) One-dimensional conduction in insulation, (5) Quiescent air.

PROPERTIES: Table A.4, air (T_i = 288 K): \( \nu = 14.82 \times 10^{-6} \text{ m}^2/\text{s} \), \( \alpha = 20.92 \times 10^{-6} \text{ m}^2/\text{s} \), \( k = 0.0253 \text{ W/m-K} \), \( Pr = 0.71 \), \( \beta = 0.00347 \text{ K}^{-1} \).

ANALYSIS: (a) Without insulation, \( T_{s,o} = T_{s,i} = 278 \text{ K} \) and the heat gain is

\[
q_{wo} = \frac{hA_s}{\varepsilon \sigma} \left( T_{\infty} - T_{s,i} \right) + \varepsilon \sigma A_s \left( T_{\text{sur}}^4 - T_{s,i}^4 \right)
\]

where \( A_s = HW = 0.65 \text{ m}^2 \). With a Rayleigh number of \( Ra_H = \frac{g \beta \left( T_{\infty} - T_{s,i} \right) H^3}{\alpha \nu} = 9.8 \text{ m/s}^2(0.00347 \text{ K}^{-1})(20 \text{ K})(1)^3/(20.92 \times 10^{-6} \text{ m}^2/\text{s})(14.82 \times 10^{-6} \text{ m}^2/\text{s}) = 2.19 \times 10^9 \), Eq. 9.26 yields

\[
\frac{Nu_H}{0.825} = \left[ \frac{0.387 (2.19 \times 10^9)^{1/6}}{1 + (0.492/0.71)^{9/16}} \right]^{8/27} = 156.6
\]

\[
h = \frac{Nu_H}{H} (k/H) = 156.6(0.0253 \text{ W/m-K}/1 \text{ m}) = 4.0 \text{ W/m}^2 \cdot \text{K}
\]

\[
q_{wo} = 4.0 \text{ W/m}^2 \cdot \text{K}(0.65 \text{ m}^2)(20 \text{ K}) + 0.6 \left( 5.67 \times 10^{-8} \text{ W/ m}^2 \cdot \text{K}^4 \right)(0.65 \text{ m}^2)(298^4 - 278^4) \text{ K}^4
\]

\[
q_{wo} = (52.00 + 42.3) \text{ W} = 94.3 \text{ W}
\]

(b) With the insulation, \( T_{s,o} \) may be determined by performing an energy balance at the outer surface, where \( q_{\text{conv}} + q_{\text{rad}} = q_{\text{cond}} \), or

\[
h \left( T_{\infty} - T_{s,o} \right) + \varepsilon \sigma \left( T_{\text{sur}}^4 - T_{s,o}^4 \right) = \frac{k_i}{L} \left( T_{s,o} - T_{s,i} \right)
\]

Using the IHT First Law Model for a Nonisothermal Plane Wall with the appropriate Correlations and Properties Tool Pads and evaluating the heat gain from Continued...
The outer surface temperature increases with increasing L, causing a reduction in the rate of heat transfer to the refrigerator compartment. For $L = 0.025$ m, $h = 2.29$ W/m$^2$K, $h_{\text{rad}} = 3.54$ W/m$^2$K, $q_{\text{conv}} = 5.16$ W, $q_{\text{rad}} = 7.99$ W, $q_w = 13.15$ W, and $T_{s,o} = 21.5^\circ$C.

**COMMENTS:** The insulation is extremely effective in reducing the heat load, and there would be little value to increasing L beyond 25 mm.
**PROBLEM 9.30**

**KNOWN:** Air receiving tank of height 2.5 m and diameter 0.75 m; inside air is at 3 atm and 100°C while outside ambient air is 25°C.

**FIND:** (a) Receiver wall temperature and heat transfer to the ambient air; assume receiver wall is $T_s = 60^\circ C$ to facilitate use of the free convection correlations; (b) Whether film temperatures $T_{f,i}$ and $T_{f,o}$ were reasonable; if not, use an iteration procedure to find consistent values; and (c) Receiver wall temperatures, $T_{s,i}$ and $T_{s,o}$, considering radiation exchange from the exterior surface ($\varepsilon_{s,o} = 0.85$) and thermal resistance of the wall (20 mm thick, $k = 0.25 W/m\cdot K$); represent the system by a thermal circuit.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Surface radiation effects are negligible, parts (a,b), (2) Losses from top and bottom of receiver are negligible, (3) Thermal resistance of receiver wall is negligible compared to free convection resistance, parts (a,b), (4) Interior and exterior air is quiescent and extensive.

**PROPERTIES:** *Table A-4*, Air (assume $T_{f,o} = 315 K$, 1 atm): $\nu = 1.74 \times 10^{-5} m^2/s$, $k = 0.02741 W/m\cdot K$, $\alpha = 2.472 \times 10^{-5} m^2/s$, $Pr = 0.7049$; *Table A-4*, Air (assume $T_{f,i} = 350 K$, 3 atm): $\nu = 2.092 \times 10^{-5} m^2/s$, $k = 0.030 W/m\cdot K$, $\alpha = 2.990 \times 10^{-5} m^2/s$, $Pr = 0.700$. Note that the pressure effect is present for $\nu$ and $\alpha$ since $\rho(1 \text{ atm}) = 1/3 \rho(3 \text{ atm})$; other properties ($c_p$, $k$, $\mu$) are assumed independent of pressure.

**ANALYSIS:** The heat transfer rate from the receiver follows from the thermal circuit,

$$q = \frac{\Delta T}{R_t} = \frac{T_{\infty,i} - T_{\infty,o}}{1/h_o A_s + 1/h_i A_s} = \frac{A_s (T_{\infty,i} - T_{\infty,o})}{h_o + h_i}$$

where $h_o$ and $h_i$ must be estimated from free convection correlations. We must assume a value of $T_s$ in order to obtain first estimates for $\Delta T_o = T_s - T_{\infty,o}$ and $\Delta T_i = T_{\infty,o} - T_s$ as well as $T_{f,o}$ and $T_{f,i}$. Assume that $T_s = 60^\circ C$, then $\Delta T_o = 60 - 25 = 35^\circ C$, $T_{f,o} = 315 K$ and $\Delta T_i = 100 - 60 = 40^\circ C$, and $T_{f,i} = 350 K$.

$$Ra_{L,o} = \frac{g \beta A T L^3}{\nu \alpha} = \frac{9.8 m/s^2 (1/315 K) \times 35 K (2.5 m)^3}{1.74 \times 10^{-5} m^2/s \times 2.472 \times 10^{-5} m^2/s} = 3.952 \times 10^{10}$$

$$Ra_{L,i} = \frac{9.8 m/s^2 (1/350 K) \times 40 K (2.5 m)^3}{6.973 \times 10^{-6} m^2/s \times 9.967 \times 10^{-6} m^2/s} = 2.518 \times 10^{11}$$

Approximating the receiver wall as a vertical plate, Eq. 9.26 yields

Continued...
PROBLEM 9.30 (Cont.)

\[ \overline{Nu}_{L,o} = \left[ 0.825 + \frac{0.387 \text{Ra}_{L,o}^{1/6}}{1 + (0.492/\text{Pr})^{9/16}} \right]^{2/27} = 390.0 \]

\[ \overline{Nu}_{L,i} = \left[ 0.825 + \frac{0.387 \left(2.518 \times 10^{11}\right)^{1/6}}{1 + (0.492/0.700)^{9/16}} \right]^{2/27} = 706.4 \]

\[ \overline{h}_{L,o} = \frac{0.02741 \text{W/m-K}}{2.5m} \times 390.0 = 4.27 \text{W/m}^2\text{K} \quad \overline{h}_{L,i} = \frac{0.030 \text{W/m-K}}{2.5m} \times 706.4 = 8.48 \text{W/m}^2\text{K} \]

From Eq. (1),

\[ q = \pi \times 0.75 \text{m} \times 2.5 \text{m} (100 - 25) \text{K} \times \frac{1}{4.27} + \frac{1}{8.48} \text{m}^2/\text{K} \cdot \text{W} = 1225 \text{W} \]

Also,

\[ T_s = T_{\infty,i} - q/\overline{h}_i A_s = 100 \text{°C} - 1255 \text{W} \times \left(8.48 \text{W/m}^2\text{K} \times \pi \times 0.75 \text{m} \times 2.5 \text{m}\right) = 74.9 \text{°C} \]

(b) From the above result for \( T_s \), the computed film temperatures are

\[ T_{f,o} = 323 \text{K} \quad T_{f,i} = 360 \text{K} \]

as compared to assumed values of 315 and 350 K, respectively. Using IHT Correlation Tools for the Free Convection, Vertical Plate, and the thermal circuit representing Eq. (1) to find \( T_s \), rather than using as assumed value,

\[ \frac{T_{\infty,o} - T_s}{1/\overline{h}_o} = \frac{T_s - T_{\infty,o}}{1/\overline{h}_o} \]

we found

\[ q = 1262 \text{ W} \quad T_s = 71.4 \text{°C} \]

with \( T_{f,o} = 321 \text{K} \) and 359 K. The iteration only influenced the heat rate slightly.

(c) Considering effects due to thermal resistance of the tank wall and radiation exchange, the thermal resistance network representing the system is shown below.

Continued .....

\[ \begin{aligned}

PROBLEM 9.30 (Cont.)

Using the IHT Model, Thermal Network, with the Correlation Tool for Free Convection, Vertical Plate, and Properties Tool for Air, a model was developed which incorporates all the foregoing equations of parts (a,b), but includes the thermal resistance of the wall, Table 3.3,

\[ R_{\text{wall}} = \frac{f_n(D_i/D_o)}{2\pi Lk} \quad \text{and} \quad D_o = D_i + 2 \times t \]

Continued...

The results of the analyses are tabulated below showing for comparison those from parts (a) and (b):

*Recall we assumed \( T_s = 60{}^{\circ}\text{C} \) in order to simplify the correlation calculation with fixed values of \( \Delta T_i \), \( \Delta T_o \) as well as \( T_{f,o}, T_{f,i} \).

COMMENTS: (1) In the table note the slight difference between results using assumed values for \( T_f \) and \( \Delta T \) in the correlations (part (a)) and the exact solution (part (b)).

(2) In the part (c) results, considering thermal resistance of the wall and the radiation exchange process, the net effect was to reduce the overall thermal resistance of the system and, hence, the heat rate increased.

(3) In the part (c) analysis, the IHT Thermal Resistance Network model was used to create the thermal circuit and generate the required energy balances. The convection resistances were determined from appropriate Convection Correlation Tools. The code was developed in two steps: (1) Solve the energy balance relations from the Network with assigned values for \( h_i \) and \( h_o \) to demonstrate that the energy relations were correct and then (2) Call in the Convection Correlations and solve with variable coefficients. Because this equation set is very stiff, we used the intrinsic heat transfer function \( T\text{fluid\_avg} \) and followed these steps in the solution: Step (1): Assign constant values to the film temperatures, \( T_{fi} \) and \( T_{fo} \), and to the temperature differences in the convection correlations, \( \Delta T_i \) and \( \Delta T_o \); and in the Initial Guesses table, restrain all thermal resistances to be positive (minimum value = 1e-20); Solve; Step (2): Allow the film temperatures to be unknowns but keep assigned variables for the temperature differences; use the Load option and Solve. Step (3): Repeat the previous step but allowing the temperature differences to be unknowns. Even though you get a "successful solve" message, repeat the Load-Solve sequence until you see no changes in key variables so that you are assured that the Solver has fully converged on the solution.
PROBLEM 9.31

KNOWN: Dimensions and emissivity of cylindrical solar receiver. Incident solar flux. Temperature of ambient air.

FIND: (a) Heat loss and collection efficiency for a prescribed receiver temperature, (b) Effect of receiver temperature on heat losses and collector efficiency.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Ambient air is quiescent, (3) Incident solar flux is uniformly distributed over receiver surface, (4) All of the incident solar flux is absorbed by the receiver, (5) Negligible irradiation from the surroundings, (6) Uniform receiver surface temperature, (7) Curvature of cylinder has a negligible effect on boundary layer development, (8) Constant properties.

PROPERTIES: Table A-4, air \((T_f = 550\, \text{K})\):  
\[ k = 0.0439\, \text{W/m} \cdot \text{K}, \quad \nu = 45.6 \times 10^{-6}\, \text{m}^2/\text{s}, \quad \alpha = 66.7 \times 10^{-6}\, \text{m}^2/\text{s}, \quad \text{Pr} = 0.683, \quad \beta = 1.82 \times 10^{-3}\, \text{K}^{-1}. \]

ANALYSIS: (a) The total heat loss is

\[ Q = q_{rad} + q_{conv} = A_s \varepsilon \sigma T_s^4 + \bar{n} A_s (T_s - T_\infty) \]

With \(\text{Ra}_{L} = g \beta (T_s - T_\infty)L^3/\nu \alpha = 9.8\, \text{m/s}^2 \times (1.82 \times 10^{-3}\, \text{K}^{-1}) \times 500\, \text{K} \times (12\, \text{m})^3/(45.6 \times 66.7 \times 10^{-12}\, \text{m}^4/\text{s}^2)\) = \(5.07 \times 10^{12}\), Eq. 9.26 yields

\[ \bar{n} = \frac{k}{L} \left( \frac{0.825 + \frac{0.387 \text{Ra}_{L}^{1/6}}{1 + (0.492/\text{Pr})^{9/16}}}{8/27} \right)^2 = \frac{0.0439\, \text{W/m} \cdot \text{K}}{12\, \text{m}} \left( \frac{0.825 + 42.4}{2} \right)^2 = 6.83\, \text{W/m}^2 \cdot \text{K} \]

Hence, with \(A_s = \pi DL = 264\, \text{m}^2\)

\[ Q = 264\, \text{m}^2 \times 0.2 \times 5.67 \times 10^{-8}\, \text{W/m}^2 \cdot \text{K}^4 \times (800\, \text{K})^4 + 264\, \text{m}^2 \times 6.83\, \text{W/m}^2 \cdot \text{K} \times (500\, \text{K}) \]

\[ q_{rad} = q_{conv} = 1.23 \times 10^6\, \text{W} + 9.01 \times 10^5\, \text{W} = 2.13 \times 10^6\, \text{W} \]

With \(A_s q_s^* = 2.64 \times 10^7\, \text{W}\), the collector efficiency is

\[ \eta = \left( \frac{A_s q_s^* - q}{A_s q_s^*} \right) \times 100 = \left( \frac{2.64 \times 10^7 - 2.13 \times 10^6}{2.64 \times 10^7} \right) \times 100 = 91.9\% \]

Continued .....
(b) As shown below, because of its dependence on temperature to the fourth power, $q_{\text{rad}}$ increases more significantly with increasing $T_s$ than does $q_{\text{conv}}$, and the effect on the efficiency is pronounced.

**COMMENTS:** The collector efficiency is also reduced by the inability to have a perfectly absorbing receiver. Partial reflection of the incident solar flux will reduce the efficiency by at least several percent.
**PROBLEM 9.32**

**KNOWN:** An experimental apparatus for measuring the local convection coefficient and the boundary layer temperature distribution for a heated vertical plate immersed in an extensive, quiescent fluid.

**FIND:** (a) An expression for estimating the radiation heat flux from the sensor as a function of the surface emissivity, surroundings temperature, and the quantity \((T_s - T_\infty)\); (b) Using this expression, apply the correction to the measured total heat flux, \(q_{\text{tot}}^{*}\), (see Table 1 below for data) to obtain the convection heat flux, \(q_{\text{cv}}^{*}\), and calculate the convection coefficient; (c) Calculate and plot the local convection coefficient, \(h_x(x)\), as a function the x-coordinate using the similarity solution, Eqs. 9.19 and 9.20; on the same graph, plot the experimental points; comment on the comparison between the experimental and analytical results; and (d) Compare the experimental boundary-layer air temperature measurements (see Table 2 below for data) with results from the similarity solution, Fig. 9.4(b).

Summarize the results of your analysis using the similarity parameter, \(\eta\), and the dimensionless temperature, \(T^*\). Comment on the comparison between the experimental and analytical results.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Test plate at a uniform temperature, (3) Ambient air is quiescent, (4) Room walls are isothermal and at the same temperature as the plate.

**PROPERTIES:** Table A-4, Air \((T_f = (T_s + T_\infty)/2 = 303 \text{ K}, 1 \text{ atm})\): \(\nu = 16.19 \times 10^{-6} \text{ m}^2/\text{s}, \text{Pr} = 0.707, \beta = 1/T_f\).

**ANALYSIS:** (a) The radiation heat flux from the sensor as a function of the surface emissivity, surroundings temperature, and the quantity \((T_s - T_\infty)\) follows from Eqs. (1.8) and (1.9)

\[
q_{\text{rad}}^{*} = \bar{h}_{\text{rad}} \left( T_s - T_\infty \right)
\]

where \(T_\text{sur} = T_\infty\). Since \(T_s \approx T_\infty\), \(\bar{h}_{\text{rad}} = 4\varepsilon\sigma \bar{T}^3\) where \(\bar{T} = (T_s + T_\infty)/2\).

(b) Using the above expression, the radiation heat flux, \(q_{\text{rad}}^{*}\), is calculated. This correction is applied to the measured total heat flux, \(q_{\text{tot}}^{*}\), to obtain the convection heat flux, \(q_{\text{cv}}^{*}\), from which the local convection coefficient, \(h_{x,\text{exp}}^{*}\), is calculated.

\[
q_{\text{cv}}^{*} = q_{\text{tot}}^{*} - q_{\text{rad}}^{*}
\]

\[
h_{x,\text{exp}}^{*} = q_{\text{cv}}^{*} / \left( T_s - T_\infty \right)
\]

Continued …..
The heat flux sensor data are given in the first row of the table below, and the subsequent rows labeled (b) are calculated using Eqs. (1, 3, 4).

**Table 1**

(c) The similarity solution for the vertical surface, Section 9.4, provides the expression for the local Nusselt number in terms of the dimensionless parameters $T^*$ and $\eta$. Using Eqs. (9.19) and (9.20),

$$\frac{h_{x,ss}x}{k} = \left(\frac{Gr_x}{4}\right)^{1/4} g(Pr) \quad (5)$$

$$g(Pr) = \frac{0.75 Pr^{1/2}}{\left(0.609 + 1.221 Pr^{1/2} + 1.238 Pr\right)^{1/4}} \quad (6)$$

where the local Grashof number is

$$Gr_x = g\beta (T_s - T_\infty) x^3 / \nu^2 \quad (7)$$

and the thermophysical properties are evaluated at the film temperature, $T_f = (T_s + T_\infty)/2$. Using the above relations in the *IHT* workspace along with the properties library for air, the convection coefficient $h_{x,ss}$ is calculated for selected values of $x$. The results are shown in Table 1 above and the graph below compared to the experimental results.

![Graph](attachment:image.png)
PROBLEM 9.32 (Cont.)

The experimental results and the calculated similarity solution coefficients are in good agreement. Except near the leading edge, the experimental results are systematically lower than those from the similarity solution.

(d) The experimental boundary-layer air temperature measurements for three discrete y-locations at two x-locations are shown in the first two rows of the table below. From Eq. 9.13, the similarity parameter is

$$\eta = \frac{y}{x} \left( \frac{Gr_x}{4} \right)^{1/4}$$

and the dimensionless temperature for the experimental data are

$$T_{exp}^* = \frac{T - T_\infty}{T_s - T_\infty}$$

Figure 9.4(b) is used to obtain the dimensionless temperature from the similarity solution, $T_{ss}^*$, for the required values of $\eta$ and are tabulated below.

</tbody>
</table>

The experimentally determined dimensionless temperatures, $T_{exp}^*$, are systematically lower than those from the similarity solution $T_{ss}^*$. The agreement is excellent at the x = 400 mm location, ranging from less than 1% near the wall to 2% far from the wall. For the x = 200 mm location, nearer to the leading edge, where the boundary layer is thinner and the boundary layer temperature gradient is higher, the agreement is good, but near the wall the differences are larger. Note that for both x-locations far from the wall, $T_{exp}^*$ and $T_{ss}^*$ are in excellent agreement. Would you have expected that behavior?
PROBLEM 9.33

KNOWN: Transformer which dissipates 1000 W whose surface is to be maintained at 47°C in quiescent air and surroundings at 27°C.

FIND: Power removal (a) by free convection and radiation from lateral and upper horizontal surfaces and (b) with 30 vertical fins attached to lateral surface.

SCHEMATIC:

ASSUMPTIONS: (1) Fins are isothermal at lateral surface temperature, T_s, (2) Vertical fins and lateral surface behave as vertical plate, (3) Transformer has isothermal surfaces and loses heat only on top and side.

PROPERTIES: Table A-4, Air (T_f = (27+47)/2=310K, 1 atm): ν = 16.90 × 10⁻⁶ m²/s, k = 27.0 × 10⁻³ W/m·K, α = 23.98 × 10⁻⁶ m²/s, Pr = 0.706, β = 1/T_f.

ANALYSIS: (a) For the vertical lateral (lat) and top horizontal (top) surfaces, the heat loss by radiation and convection is

\[ q = q_{lat} + q_{top} = \left( \bar{h}_{lat} + h_f \right) \pi D (T_s - T_\infty) + \left( \bar{h}_{top} + h_f \right) \left( \pi^2 D^2 / 4 \right) (T_s - T_\infty) \]

where, from Eq. 1.9, the linearized radiation coefficient is

\[ h_f = \varepsilon \sigma \left( T_s + T_\infty \right) \left( T_s + T_\infty^2 \right) \]

\[ h_f = 0.8 \times 5.67 \times 10^{-8} \text{W/m}^2 \cdot \text{K}^4 \left( 320 + 300 \right) \text{K} \left( 320^2 + 300^2 \right) \text{K}^2 = 5.41 \text{W/m}^2 \cdot \text{K}. \]

The free convection coefficient for the lateral and top surfaces is:

Lateral-vertical plate: Using Eq. 9.26 with

\[ \text{Ra}_L = \frac{g \beta (T_s - T_\infty) H^3}{\nu \alpha} = \frac{9.8 \text{m/s}^2 (1/1310 \text{K})(47 - 27) \text{K}(0.5 \text{m})^3}{16.90 \times 10^{-6} \text{m}^2 / \text{s} \times 23.98 \times 10^{-6} \text{m}^2 / \text{s}} = 1.95 \times 10^8 \]

\[ \bar{N}_u_L = \left\{ 0.825 + \frac{0.387 \text{Ra}_L^{1/6}}{\left( 1 + (0.492/\text{Pr})^{9/16} \right)^{8/27}} \right\}^2 \]

\[ \bar{N}_u_L = \left\{ 0.825 + \frac{0.387 \left( 1.950 \times 10^8 \right)^{1/6}}{\left( 1 + (0.492/0.706)^{9/16} \right)^{8/27}} \right\}^2 = 74.5 \]

\[ \bar{h}_{lat} = \bar{N}_u_L \cdot k / H = 74.5 \times 0.027 \text{W/m} \cdot \text{K} / 0.5 \text{m} = 4.02 \text{W/m}^2 \cdot \text{K}. \]

Continued …..
**PROBLEM 9.33 (Cont.)**

*Top-horizontal plate:* Using Eq. 9.30 with

\[
L_c = A_s / P = \frac{\pi D^2 / 4}{\pi D} = D / 4 = 0.075 \text{m}
\]

\[
Ra_L = \frac{g \beta (T_s - T_\infty) L_c^3}{\nu \alpha} = \frac{9.8 \text{m/s}^2 (1/310 \text{K}) (47 - 27) \text{K} (0.075 \text{m})^3}{16.90 \times 10^{-6} \text{m}^2 / \text{s} \times 23.98 \times 10^{-6} \text{m}^2 / \text{s}} = 6.598 \times 10^5
\]

\[
\overline{Nu}_L = 0.54 Ra_L^{1/4} = 0.54 \left(6.598 \times 10^5\right)^{1/4} = 15.39
\]

\[
\overline{h}_{\text{top}} = \overline{Nu}_L \cdot k / L_c = 15.39 \times 0.027 \text{W/m} \cdot \text{K} / 0.075 \text{m} = 5.54 \text{W/m}^2 \cdot \text{K}
\]

Hence, the heat loss by convection and radiation is

\[
q = (4.02 + 5.41) \text{W/m}^2 \cdot \text{K} (\pi \times 0.30 \text{m} \times 0.50 \text{m}) (47 - 20) \text{K}
\]

\[
+ (5.54 + 5.41) \text{W/m}^2 \cdot \text{K} \left(\pi \times 0.30^2 \text{m}^2 / 4\right) (47 - 20) \text{K}
\]

\[
q = (88.9 + 15.5) \text{W} = 104 \text{W}. \quad <
\]

(b) The effect of adding the vertical fins is to increase the area of the lateral surface to

\[
A_{wf} = [\pi DH - 30 (t \cdot H)] + 30 \times 2 (w \cdot H)
\]

\[
A_{wf} = [\pi 0.30 \text{m} \times 0.50 \text{m} - 30 (0.005 \times 0.500) \text{m}^2] + 30 \times 2 (0.075 \times 0.500) \text{m}^2
\]

\[
A_{wf} = [0.471 - 0.075] \text{m}^2 + 2.25 \text{m}^2 = 2.646 \text{m}^2.
\]

where \( t \) and \( w \) are the thickness and width of the fins, respectively. Hence, the heat loss is now

\[
q = q_{\text{lat}} + q_{\text{top}} = (\overline{h}_{\text{lat}} + h_f) A_{wf} (T_s - T_\infty) + q_{\text{top}}
\]

\[
q = (4.02 + 5.41) \text{W/m}^2 \times 2.646 \text{m}^2 \times 20 \text{K} + 15.5 \text{W} = 515 \text{W}. \quad <
\]

Adding the fins to the lateral surface increases the heat loss by a factor of five.

**COMMENTS:** Since the fins are not likely to have 100% efficiency, our estimate is optimistic. Further, since the fins see one another, as well as the lateral surface, the radiative heat loss is over predicted.
**PROBLEM 9.34**

**KNOWN:** Surface temperature of a long duct and ambient air temperature.

**FIND:** Heat gain to the duct per unit length of the duct.

**SCHEMATIC:**

![Schematic of a long duct with air flow](image)

**ASSUMPTIONS:** (1) Surface radiation effects are negligible, (2) Ambient air is quiescent.

**PROPERTIES:** *Table A-4*, Air ($T_f = (T_{\infty} + T_s)/2 \approx 300 K$, 1 atm): $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 0.0263 \text{ W/m-K}$, $\alpha = 22.5 \times 10^{-6} \text{ m}^2/\text{s}$, $Pr = 0.707$, $\beta = 1/T_f$.

**ANALYSIS:** The heat gain to the duct can be expressed as

$$q' = 2q_H + q_T + q_B = \left(2\overline{h_s} \cdot H + \overline{h_t} \cdot W + \overline{h_b} \cdot W \right) (T_{\infty} - T_s). \quad (1)$$

Consider now correlations to estimate $\overline{h_s}$, $\overline{h_t}$, and $\overline{h_b}$. From Eq. 9.25, for the sides with $L \equiv H$,

$$Ra_L = \frac{g \beta (T_{\infty} - T_s) L^3}{v \alpha} = \frac{9.8 \text{ m/s}^2 (1/300 K)(35 - 10) K \times (0.2 \text{ m})^3}{15.89 \times 10^{-6} \text{ m}^2/\text{s} \times 22.5 \times 10^{-6} \text{ m}^2/\text{s}} = 1.827 \times 10^7. \quad (2)$$

Eq. 9.27 is appropriate to estimate $\overline{h_s}$,

$$\overline{Nu}_L = 0.68 + \frac{0.670Ra_L^{1/4}}{1 + (0.492/Pr)^{9/16}} \approx 0.68 + \frac{0.670(1.827 \times 10^7)^{1/4}}{1 + (0.492/0.707)^{9/16}} = 34.29 \quad (3)$$

For the top and bottom portions of the duct, $L \equiv A_s/P \approx W/2$, (see Eq. 9.29), find the Rayleigh number from Eq. (2) with $L = 0.1 \text{ m}$, $Ra_L = 2.284 \times 10^6$. From the correlations, Eqs. 9.31 and 9.32 for the top and bottom surfaces, respectively, find

$$\overline{h_t} = \frac{k}{(W/2)} \times 0.15Ra_L^{1/3} = \frac{0.0263 \text{ W/m-K}}{0.1 \text{ m}} \times 0.15 \left(2.284 \times 10^6\right)^{1/3} = 5.17 \text{ W/m}^2 \cdot \text{K} \quad (4)$$

$$\overline{h_b} = \frac{k}{(W/2)} \times 0.0263 \text{ W/m-K} \times 0.27 \left(2.284 \times 10^6\right)^{1/4} = 2.76 \text{ W/m}^2 \cdot \text{K}. \quad (5)$$

The heat rate, Eq. (1), can now be evaluated using the heat transfer coefficients estimated from Eqs. (3), (4), and (5).

$$q' = \left(2 \times 4.51 \text{ W/m}^2 \cdot \text{K} \times 0.2 \text{ m} + 5.17 \text{ W/m}^2 \cdot \text{K} \times 0.2 \text{ m} + 2.76 \text{ W/m}^2 \cdot \text{K} \times 0.2 \text{ m} \right)(35 - 10) K$$

$$q' = 84.8 \text{ W/m}. \quad <$$

**COMMENTS:** Radiation surface effects will be significant in this situation. With knowledge of the duct emissivity and surroundings temperature, the radiation heat exchange could be estimated.
**PROBLEM 9.35**

**KNOWN:** Inner surface temperature and dimensions of rectangular duct. Thermal conductivity, thickness and emissivity of insulation.

**FIND:** (a) Outer surface temperatures and heat losses from the walls, (b) Effect of insulation thickness on outer surface temperatures and heat losses.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Ambient air is quiescent, (2) One-dimensional conduction, (3) Steady-state.

**PROPERTIES:** *Table A.4*, air (obtained from *Properties* Tool Pad of IHT).

**ANALYSIS:** (a) The analysis follows that of Example 9.3, except the surface energy balance must now include the effect of radiation. Hence, \( q''_{\text{cond}} = q''_{\text{conv}} + q''_{\text{rad}} \), in which case

\[
(k_i/t)(T_{s,1} - T_{s,2}) = \bar{h}(T_{s,2} - T_{\infty}) + h_r(T_{s,2} - T_{\text{sur}})
\]

where \( h_r = \varepsilon \sigma (T_{s,2} + T_{\text{sur}})(T_{s,2}^2 + T_{\text{sur}}^2) \). Applying this expression to each of the top, bottom and side walls, with the appropriate correlation obtained from the *Correlations* Tool Pad of IHT, the following results are determined for \( t = 25 \text{ mm} \).

*Sides:* \( T_{s,2} = 19.3^\circ \text{C}, \bar{h} = 2.82 \text{ W/m}^2\cdot\text{K}, h_{\text{rad}} = 5.54 \text{ W/m}^2\cdot\text{K} \)

*Top:* \( T_{s,2} = 19.3^\circ \text{C}, \bar{h} = 2.94 \text{ W/m}^2\cdot\text{K}, h_{\text{rad}} = 5.54 \text{ W/m}^2\cdot\text{K} \)

*Bottom:* \( T_{s,2} = 20.1^\circ \text{C}, \bar{h} = 1.34 \text{ W/m}^2\cdot\text{K}, h_{\text{rad}} = 5.56 \text{ W/m}^2\cdot\text{K} \)

With \( q'' = q''_{\text{cond}} \), the surface heat losses may also be evaluated, and we obtain

*Sides:* \( q' = 2Hq'' = 21.6 \text{ W/m}; \quad \text{Top: } q' = wq''' = 27.0 \text{ W/m}; \quad \text{Bottom: } q' = wq''' = 26.2 \text{ W/m} \)

(b) For the top surface, the following results are obtained from the parametric calculations

Continued...
COMMENTS: Contrasting the heat rates of part (a) with those predicted in Comment 1 of Example 9.3, it is evident that radiation is significant and increases the total heat loss from 57.6 W/m to 74.8 W/m. As shown in part (b), reductions in $T_{s,o}$ and $q'$ may be effected by increasing the insulation thickness above 0.025 W/m-K, although attendant benefits diminish with increasing $t$. 
PROBLEM 9.36

KNOWN: Electric heater at bottom of tank of 400mm diameter maintains surface at 70°C with engine oil at 5°C.

FIND: Power required to maintain 70°C surface temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Oil is quiescent, (2) Quasi-steady state conditions exist.

PROPERTIES: Table A-5, Engine Oil \( T_f = (T_\infty + T_s)/2 = 310 \text{K} \): \( \nu = 288 \times 10^{-6} \text{m}^2/\text{s} \), \( k = 0.145 \text{W/m}\cdot\text{K} \), \( \alpha = 0.847 \times 10^{-7} \text{m}^2/\text{s} \), \( \beta = 0.70 \times 10^{-3} \text{K}^{-1} \).

ANALYSIS: The heat rate from the bottom heater surface to the oil is

\[ q = h A_s \left( T_s - T_\infty \right) \]

where \( h \) is estimated from the appropriate correlation depending upon the Rayleigh number \( \text{Ra}_L \), from Eq. 9.25, using the characteristic length, \( L \), from Eq. 9.29,

\[ L = \frac{A_s}{P} = \frac{\pi D^2/4}{\pi D} = \frac{D}{4} = \frac{0.4 \text{m}}{4} = 0.1 \text{m}. \]

The Rayleigh number is

\[ \text{Ra}_L = \frac{g \beta (T_s - T_\infty) L^3}{\nu \alpha} \]

\[ \text{Ra}_L = \frac{9.8 \text{m/s}^2 \times 0.70 \times 10^{-3} \text{K}^{-1} (70 - 5) \text{K} \times 0.1^3 \text{m}^3}{288 \times 10^{-6} \text{m}^2/\text{s} \times 0.847 \times 10^{-7} \text{m}^2/\text{s}} = 1.828 \times 10^7. \]

The appropriate correlation is Eq. 9.31 giving

\[ \bar{\text{Nu}}_L = \frac{h L}{k} = 0.15 \text{Ra}_L^{1/3} = 0.15 \left(1.828 \times 10^7\right)^{1/3} = 39.5 \]

\[ h = \frac{k}{L \bar{\text{Nu}}_L} = \frac{0.145 \text{W/m} \cdot \text{K}}{0.1 \text{m}} \times 39.5 = 57.3 \text{W/m}^2 \cdot \text{K}. \]

The heat rate is then

\[ q = 57.3 \text{W/m}^2 \cdot \text{K} (\pi/4) (0.4 \text{m})^2 (70 - 5) \text{K} = 468 \text{W}. \]

COMMENTS: Note that the characteristic length is \( D/4 \) and not \( D \); however, \( A_s \) is based upon \( D \). Recognize that if the oil is being continuously heated by the plate, \( T_\infty \) could change. Hence, here we have analyzed a quasi-steady state condition.
PROBLEM 9.37

KNOWN: Horizontal, straight fin fabricated from plain carbon steel with thickness 6 mm and length 100 mm; base temperature is 150°C and air temperature is 26°C.

FIND: (a) Fin heat rate per unit width, \( q'_f \), assuming an average fin surface temperature \( T_s = 125°C \) for estimating free convection and linearized radiation coefficient; how sensitive is \( q'_f \) to the assumed value for \( T_s \)?; (b) Compute and plot the heat rate, \( q'_f \) as a function of emissivity \( 0.05 \leq \varepsilon \leq 0.95 \); show also the fraction of the total heat ratio due to radiation exchange.

SCHEMATIC:

ASSUMPTIONS: (1) Air is quiescent medium, (2) Surface radiation effects are negligible, (3) One dimensional conduction in fin, (4) Characteristic length, \( L_C = A_s / P = \ell L (2\ell + 2L) = L/2 \).

PROPERTIES: Plain carbon steel, Given \( \text{finT} = 125°C \approx 400 K \); \( k = 57 \text{ W/m} \cdot \text{K} \), \( \varepsilon = 0.5 \); Table A-4.

Air \( \left( T_f = \left( T_{\text{fin}} + T_{\infty} \right) / 2 = \left( 125 + 25 \right)^° \right)/2 = 350 \text{ K} \), 1 atm): \( v = 20.92 \times 10^6 \text{ m}^2/\text{s} \), \( \alpha = 29.9 \times 10^6 \text{ m}^2/\text{s} \), \( k = 0.030 \text{ W/m} \cdot \text{K} \), \( Pr = 0.70 \), \( \beta = 1/T_f \).

ANALYSIS: (a) We estimate \( \overline{h} \) as the average of the values for a heated plate facing upward and a heated plate facing downward. See Table 9.2, Case 3(a) and (b). Begin by evaluating the Rayleigh number, using Eq. 9.29 for \( L_C \).

\[
Ra_L = \frac{g \beta (T_{\text{fin}} - T_{\infty}) L_C^3}{v \alpha} = \frac{9.8 \text{ m/s}^2 \left( 1/350 \text{K} \right)(125-25) \text{K} \times (0.1 \text{m}/2)^3}{20.92 \times 10^{-6} \text{ m}^2/\text{s} \times 29.9 \times 10^{-6} \text{ m}^2/\text{s}} = 5.595 \times 10^5
\]

An average fin temperature of \( T_{\text{fin}} = 125°C \) has been assumed in evaluating properties and \( Ra_L \).

According to Table 9.2, Eqs. 9.30 and 9.32 are appropriate. For the upper fin surface, Eq. 9.30,

\[
\overline{Nu}_L = \overline{h} L_C / k = 0.54 Ra_L^{1/4} = 0.54 \left( 5.595 \times 10^5 \right)^{1/4} = 14.77
\]

\[
\overline{h}_{\text{upper}} = \overline{Nu}_L k / L_C = 14.77 \times 0.030 \text{ W/m} \cdot \text{K}/0.05 \text{ m} = 8.86 \text{ W/m} \cdot \text{K}.
\]

For the lower fin surface, Eq. 9.32,

\[
\overline{Nu}_L = \overline{h} / k = 0.27 Ra_L^{1/4} = 0.27 \left( 5.595 \times 10^5 \right)^{1/4} = 7.384
\]

\[
\overline{h}_{\text{lower}} = \overline{Nu}_L k / L = 7.384 \times 0.030 \text{ W/m} \cdot \text{K}/0.05 \text{ m} = 4.43 \text{ W/m}^2 \cdot \text{K}.
\]

The linearized radiation coefficient follows from Eq. 1.9

\[
\overline{h}_r = \varepsilon \sigma (T_{\text{fin}} + T_{\text{sur}}) (T_{\text{fin}}^4 + T_{\text{sur}}^4)
\]

\[
\overline{h}_r = 0.5 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (398 + 298) \left( 398^2 + 298^2 \right) \text{K}^3 = 4.88 \text{ W/m}^2 \cdot \text{K}
\]

Continued ….
PROBLEM 9.37 (Cont.)

Hence, the average heat transfer coefficient for the fin is

\[
\bar{h} = \left( \bar{h}_{\text{upper}} + \bar{h}_{\text{lower}} \right) / 2 + \bar{h}_r = \left[ \left( 8.86 + 4.43 \right) / 2 + 4.88 \right] W/m^2 \cdot K = 11.53 W/m^2 \cdot K
\]

Assuming the fin experiences convection at the tip, from Eq. 3.72,

\[ q_f = M \tanh \left( mL \right) \]

\[
M = \left( \bar{h} P k A_c \right)^{1/2} \theta_b = \left( 11.53 W/m^2 \cdot K \times 2 \ell \times 57 W/m \cdot K \left( 6 \times 10^{-3} m \times \ell \right) \right)^{1/2} (150 - 25) K = 352.1 W/m \cdot K
\]

\[
m = \left( \bar{h} P - k A_c \right)^{1/2} = \left( 11.53 W/m^2 \cdot K \times 2 \ell / 57 W/m \cdot K \left( 6 \times 10^{-3} m \times \ell \right) \right)^{1/2} = 8.236 m^{-1}
\]

\[
mL = 8.236 m^{-1} \times 0.1 m = 0.824
\]

\[
q_f' = q_f / \ell = 352.1 W/m \times \tanh \left( 0.824 \right) = 238 W/m.
\]

To determine how sensitive the estimate for \( \bar{h} \) is to the choice of the average fin surface temperature, the foregoing calculations were repeated using the IHT Correlations Tool and Extended Surface Model and the results are tabulated below; coefficients have units W/m²·K,

<table>
<thead>
<tr>
<th>( T_{\text{fin}} ) (°C)</th>
<th>125</th>
<th>135</th>
<th>145</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \bar{h}_{\text{upper}} )</td>
<td>4.43</td>
<td>4.54</td>
<td>4.64</td>
</tr>
<tr>
<td>( \bar{h}_{\text{lower}} )</td>
<td>8.86</td>
<td>9.08</td>
<td>9.28</td>
</tr>
<tr>
<td>( \bar{h}_r )</td>
<td>4.88</td>
<td>5.11</td>
<td>5.35</td>
</tr>
<tr>
<td>( \bar{h} )</td>
<td>11.5</td>
<td>11.9</td>
<td>12.3</td>
</tr>
<tr>
<td>( q_f' ) (W/m)</td>
<td>238</td>
<td>245</td>
<td>252</td>
</tr>
</tbody>
</table>

The temperature distribution for the \( T_{\text{fin}} = 125^\circ C \) case is shown above. With \( T_{\text{fin}} = 145^\circ C \), the tip temperature is about 2°C higher. It appears that \( T_{\text{fin}} = 125^\circ C \) was a reasonable choice. Note \( T_{\text{fin}} \) is the value at the mid length.

(b) Using the IHT code developed for part (a), the fin heat rate, \( q_f \), was plotted as a function of the emissivity. In this analysis, the convection and radiation coefficients were evaluated for an average fin temperature \( T_{\text{fin}} \) evaluated at L/2. On the same plot we have also shown rad (%) = (\( \bar{h}_r / \bar{h} \))×100, which is the portion of the total heat rate due to radiation exchange.
PROBLEM 9.38

KNOWN: Width and thickness of sample material. Rate of heat dissipation at bottom surface of sample and temperatures of top and bottom surfaces. Temperature of quiescent air and surroundings.

FIND: Thermal conductivity and emissivity of the sample.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) One-dimensional conduction in sample, (3) Quiescent air, (4) Sample is small relative to surroundings, (5) All of the heater power dissipation is transferred through the sample, (6) Constant properties.

PROPERTIES: Table A-4, air (T_f = 335.5K): \( \nu = 19.5 \times 10^{-6} \text{ m}^2/\text{s} \), \( k = 0.0289 \text{ W/m} \cdot \text{K} \), \( \alpha = 27.8 \times 10^{-6} \text{ m}^2/\text{s} \), \( Pr = 0.703 \), \( \beta = 0.00298 \text{ K}^{-1} \).

ANALYSIS: The thermal conductivity is readily obtained by applying Fourier’s law to the sample. Hence, with \( q = P_{\text{elec}} \),

\[
k = \frac{P_{\text{elec}} / W^2}{(T_1 - T_2)/L} = \frac{70 \text{ W} / (0.250 \text{ m})^2}{50^\circ \text{C} / 0.025 \text{ m}} = 0.560 \text{ W} / \text{m} \cdot \text{K}
\]

The surface emissivity may be obtained by applying an energy balance to a control surface about the sample, in which case

\[
\varepsilon = \left( \frac{P_{\text{elec}} / W^2}{\sigma (T_4^4 - T_{\text{sur}}^4)} \right)^{1/4} h (T_2 - T_{\infty})
\]

With \( L = A_s/P = W^2/4W = W/4 = 0.0625 \text{ m} \), \( Ra_L = g\beta(T_2 - T_{\infty}) L^3 / \nu \alpha = 9.86 \times 10^5 \) and Eq. 9.30 yields

\[
\bar{h} = \frac{\overline{Nu}}{L} = \frac{k}{L} \frac{0.54 \text{ Ra}^{1/4}}{0.0625} = \frac{0.0289 \text{ W/m} \cdot \text{K}}{0.54(9.86 \times 10^5)^{1/4}} = 7.87 \text{ W/m}^2 \cdot \text{K}
\]

Hence,

\[
\varepsilon = \frac{70 \text{ W} / (0.250 \text{ m})^2 - 7.87 \text{ W/m}^2 \cdot \text{K}(75^\circ \text{C})}{5.67 \times 10^{-8} \text{ W/m} \cdot \text{K}^4 \left(373^4 - 298^4\right) \text{K}^4} = 0.815
\]

COMMENTS: The uncertainty in the determination of \( \varepsilon \) is strongly influenced by uncertainties associated with using Eq. 9.30. If, for example, \( \bar{h} \) is overestimated by 10%, the actual value of \( \varepsilon \) would be 0.905.
PROBLEM 9.39

KNOWN: Diameter, power dissipation, emissivity and temperature of gage(s). Air temperature (Cases A and B) and temperature of surroundings (Case A).

FIND: (a) Convection heat transfer coefficient (Case A), (b) Convection coefficient and temperature of surroundings (Case B).

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Quiescent air, (3) Net radiation exchange from surface of gage approximates that of a small surface in large surroundings, (4) All of the electrical power is dissipated by convection and radiation heat transfer from the surface(s) of the gage, (5) Negligible thickness of strip separating semi-circular disks of Part B, (6) Constant properties.

PROPERTIES: Table A-4, air (T_f = 320K): ν = 17.9 × 10^{-6} m^2/s, α = 25.5 × 10^{-6} m^2/s, k = 0.0278 W/m·K, Pr = 0.704, β = 0.00313 K^{-1}.

ANALYSIS: (a) With \( q = q_{\text{conv}} + q_{\text{rad}} = P_{\text{elec}} \) and \( A_s = \pi D^2/4 = 0.0201 \text{ m}^2 \),

\[
\overline{h}_{\text{meas}} = \frac{P_{\text{elec}} - \varepsilon A_s \left( T^4 - T_{\text{sur}}^4 \right)}{0.0201 \text{ m}^2 \left( 40 \text{ K} \right)} = 7.46 \text{ W} / \text{m}^2 \cdot \text{K} <
\]

With \( L = A_s/P = D/4 = 0.04 \text{ m} \) and \( Ra_L = g \beta (T - T_{\infty}) L^3 / \nu \alpha = 1.72 \times 10^5 \), Eq. 9.30 yields

\[
\overline{h} = \frac{k}{0.04 \text{ m}} \left( \frac{0.0278 \text{ W} / \text{m} \cdot \text{K}}{0.54} \right) \left( \frac{1.72 \times 10^5}{40 \text{ K}} \right)^{1/4} = 7.64 \text{ W} / \text{m}^2 \cdot \text{K} <
\]

Agreement between the two values of \( \overline{h} \) is well within the uncertainty of the measurements.

(b) Since the semi-circular disks have the same temperature, each is characterized by the same convection coefficient and \( q_{\text{conv,1}} = q_{\text{conv,2}} \). Hence, with

\[
P_{\text{elec,1}} = q_{\text{conv,1}} + \varepsilon_1 \sigma \left( A_s / 2 \right) \left( T^4 - T_{\text{sur}}^4 \right) \tag{1}
\]

\[
P_{\text{elec,2}} = q_{\text{conv,2}} + \varepsilon_2 \sigma \left( A_s / 2 \right) \left( T^4 - T_{\text{sur}}^4 \right) \tag{2}
\]

\[
T_{\text{sur}} = \left[ \frac{P_{\text{elec,1}} - P_{\text{elec,2}}}{\left( \varepsilon_1 - \varepsilon_2 \right) \sigma \left( A_s / 2 \right)} \right]^{1/4} = \left[ \frac{350^4 - 4.03 \text{ W}}{0.7 \times 5.67 \times 10^{-8} \text{ W} / \text{m}^2 \cdot \text{K}^4 \times 0.01 \text{ m}^2} \right]^{1/4} = 264 \text{ K} <
\]

From Eq. (1), the convection coefficient is then

\[
\overline{h}_{\text{meas}} = \frac{P_{\text{elec,1}} - \varepsilon_1 \sigma \left( A_s / 2 \right) \left( T^4 - T_{\text{sur}}^4 \right)}{A_s / 2 \left( T - T_{\infty} \right)} = \frac{9.70 \text{ W} - 4.60 \text{ W}}{(0.01 \times 60) \text{ m}^2 \cdot \text{K}} = 8.49 \text{ W} / \text{m}^2 \cdot \text{K} <
\]

With \( Ra_L = 2.58 \times 10^5 \), Eq. 9.30 yields

\[
\overline{h} = \frac{k}{0.04 \text{ m}} \left( \frac{0.0278 \text{ W} / \text{m} \cdot \text{K}}{0.54} \right) \left( \frac{2.58 \times 10^5}{40 \text{ K}} \right)^{1/4} = 8.46 \text{ W} / \text{m}^2 \cdot \text{K} <
\]

Again, agreement between the two values of \( \overline{h} \) is well within the experimental uncertainty of the measurements.

COMMENTS: Because the semi-circular disks are at the same temperature, the characteristic length corresponds to that of the circular disk, \( L = D/4 \).
**PROBLEM 9.40**

**KNOWN:** Horizontal, circular grill of 0.2m diameter with emissivity 0.9 is maintained at a uniform surface temperature of 130°C when ambient air and surroundings are at 24°C.

**FIND:** Electrical power required to maintain grill at prescribed surface temperature.

**SCHEMATIC:**

![Schematic diagram of a horizontal, circular grill with dimensions and ambient conditions](image)

**ASSUMPTIONS:** (1) Room air is quiescent, (2) Surroundings are large compared to grill surface.

**PROPERTIES:** Table A-4, Air \((T_f = (T_\infty + T_s)/2 = (24 + 130)/2 = 350K, 1\ atm)\): \(\nu = 20.92 \times 10^{-6} \text{ m}^2/\text{s}, k = 0.030 \text{ W/m\cdot K}, \alpha = 29.9 \times 10^{-6} \text{ m}^2/\text{s}, \beta = 1/T_f\).

**ANALYSIS:** The heat loss from the grill is due to free convection with the ambient air and to radiation exchange with the surroundings.

\[
q = A_s \left[ \overline{h}(T_s - T_\infty) + \varepsilon \sigma \left( T_s^4 - T_{\text{sur}}^4 \right) \right]. \tag{1}
\]

Calculate \( Ra_L \) from Eq. 9.25,

\[
Ra_L = g \beta (T_s - T_\infty) L_c^3 / \nu \alpha
\]

where for a horizontal disc from Eq. 9.29, \( L_c = A_s / P = (\pi D^2 / 4) / \pi D = D / 4 \). Substituting numerical values, find

\[
Ra_L = \frac{9.8 \text{ m/s}^2 (1/350K)(130 - 24) \text{ K}(0.25 \text{ m}/4)^3}{20.92 \times 10^{-6} \text{ m}^2/\text{s} \times 29.9 \times 10^{-6} \text{ m}^2/\text{s}} = 1.158 \times 10^6.
\]

Since the grill is an upper surface heated, Eq. 9.30 is the appropriate correlation,

\[
\bar{N}u_L = \bar{h}_L L_c / k = 0.54 Ra_L^{1/4} = 0.54 \left( 1.158 \times 10^6 \right)^{1/4} = 17.72
\]

\[
\bar{h}_L = \bar{N}u_L L_c k / L_c = 17.72 \times 0.030 \text{ W/m\cdot K} / (0.25 \text{ m}/4) = 8.50 \text{ W/m}^2\cdot \text{ K}.
\]  

Substituting from Eq. (2) for \( \bar{h} \) into Eq. (1), the heat loss or required electrical power, \( q_{\text{elec}} \), is

\[
q = \frac{\pi}{4} (0.25 \text{ m})^2 \left[ 8.50 \text{ W/m}^2 \cdot \text{ K} (130 - 24) \text{ K} + 0.9 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{ K} (130 + 273)^4 - (24 + 273)^4) K^4 \right]
\]

\[
q = 44.2 \text{ W} + 46.0 \text{ W} = 90.2 \text{ W}.
\]

**COMMENTS:** Note that for this situation, free convection and radiation modes are of equal importance. If the grill were highly polished such that \( \varepsilon \approx 0.1 \), the required power would be reduced by nearly 50%.
PROBLEM 9.41

KNOWN: Plate dimensions and maximum allowable temperature. Freestream temperature.

FIND: Maximum allowable power dissipation.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Negligible heat loss from sides and bottom, (4) Isothermal plate.

PROPERTIES: Table A-4, Air ($T_f = 325K$, 1 atm): $\nu = 18.4 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 0.028 \text{ W/m-K}$, $\alpha = 26.2 \times 10^{-6} \text{ m}^2/\text{s}$.

ANALYSIS: The power dissipated by convection is

$$ P_{\text{elec}} = q = \overline{h}A_s (T_s - T_\infty). $$

With

$$ L = \frac{A_s}{P} = \frac{(1.2\text{m})^2}{4(1.2\text{m})} = 0.3 \text{ m} $$

$$ Ra_L = \frac{g\beta (T_s - T_\infty) L^3}{\nu \alpha} = \frac{9.8 \text{ m/s}^2 (325\text{K})^{-1} (50\text{K})(0.3\text{m})^3}{(18.4 \times 10^{-6} \text{ m}^2/\text{s}) (26.2 \times 10^{-6} \text{ m}^2/\text{s})} $$

$$ Ra_L = 8.44 \times 10^7. $$

With the upper surface heated, Eq. 9.31 yields

$$ \overline{Nu}_L = \frac{\overline{h}L}{k} = 0.15 Ra_L^{1/3} = 65.8 $$

$$ \overline{h} = 65.8 \frac{0.028 \text{ W/m-K}}{0.3 \text{m}} = 6.14 \text{ W/m}^2 \cdot \text{K} $$

and the power dissipated is

$$ q = 6.14 \text{ W/m}^2 \cdot \text{K} (1.2\text{m})^2 (50\text{K}) $$

$$ P_{\text{elec}} = q = 442\text{W}. $$

COMMENTS: This result corresponds to an average surface heat flux of 442 W/1.44 m$^2 = 307$ W/m$^2 = 0.03$ W/cm$^2$, which is extremely small. Heat dissipation by free convection in this manner is a poor option compared to the heat flux with forced convection ($u_\infty = 15 \text{ m/s}$) of 0.15 W/cm$^2$. 
**PROBLEM 9.42**

**KNOWN:** Material properties, inner surface temperature and dimensions of roof of refrigerated truck compartment. Solar irradiation and ambient temperature.

**FIND:** Outer surface temperature of roof and rate of heat transfer to compartment.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible irradiation from the sky, (2) \( T_{s,o} > T_{\infty} \) (hot surface facing upward) and \( Ra_L > 10^7 \), (3) Constant properties.

**PROPERTIES:** Table A-4, air (\( p = 1 \) atm, \( T_f \approx 310K \)): \( \nu = 16.9 \times 10^{-6} \) m/s, \( k = 0.0270 \) W/m·K, \( Pr = 0.706 \), \( \alpha = \nu/Pr = 23.9 \times 10^{-6} \) m²/s, \( \beta = 0.00323 \) K⁻¹.

**ANALYSIS:** From an energy balance for the outer surface,

\[
\begin{align*}
\alpha_S G_S - q_{\text{conv}}^* - E &= q_{\text{cond}}^* = \frac{T_{s,o} - T_{s,i}}{R_{\text{tot}}} \\
\alpha_S G_S - \overline{h} (T_{s,o} - T_{\infty}) &= -\varepsilon \sigma T_{s,o}^4 = \frac{T_{s,o} - T_{s,i}}{2R_p^* + R_i^*}
\end{align*}
\]

where \( R_p^* = (t_1 / k_p) = 2.78 \times 10^{-5} \) m²·K/W and \( R_i^* = (t_2 / k_i) = 1.923 \) m²·K/W. For a hot surface facing upward and \( Ra_L = g\beta (T_{s,o} - T_{\infty}) L^3 / \alpha \nu > 10^7 \), \( \overline{h} \) is obtained from Eq. 9.31. Hence, with cancellation of \( L \),

\[
\overline{h} = \frac{k}{L} = -0.15Ra_L^{1/3} = 0.15 \times 0.0270 W/m \cdot K \left( \frac{9.8 m/s^2 \times 0.00323 K^{-1}}{16.9 \times 23.9 \times 10^{-12} m^4/s^2} \right)^{1/3} (T_{s,o} - T_{\infty})^{1/3}
\]

\[
= 1.73 W/m^2 \cdot K^{4/3} (T_{s,o} - 305 K)^{4/3}
\]

Hence,

\[
0.5 \left( 750 W/m^2 \cdot K \right) + 1.73 W/m^2 \cdot K^{4/3} (T_{s,o} - 305 K)^{4/3} - 0.5 \times 5.67 \times 10^{-8} W/m^2 \cdot K^4 T_{s,o}^4 = \frac{T_{s,o} - 263K}{(5.56 \times 10^{-5} + 1.923) m^2 \cdot K/W}
\]

Solving, we obtain \( T_{s,o} = 318.3K = 45.3^\circ C \).<br>

Hence, the heat load is \( q = (W \cdot L_t) q_{\text{cond}}^* = (3.5m \times 10m) \frac{(45.3+10)^{\circ}C}{1.923 m^2 \cdot K/W} = 1007 W \).<br>

**COMMENTS:** (1) The thermal resistance of the aluminum panels is negligible compared to that of the insulation. (2) The value of the convection coefficient is \( \overline{h} = 1.73 (T_{s,o} - T_{\infty})^{1/3} = 4.10 W/m^2 \cdot K. \)
**PROBLEM 9.43**

**KNOWN:** Inner surface temperature and composition of a furnace roof. Emissivity of outer surface and temperature of surroundings.

**FIND:** (a) Heat loss through roof with no insulation, (b) Heat loss with insulation and inner surface temperature of insulation, and (c) Thickness of fire clay brick which would reduce the insulation temperature, $T_{ins,i}$, to 1350 K.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional conduction through the composite wall, (3) Negligible contact resistance, (4) Constant properties.

**PROPERTIES:** Table A-4, Air ($T_f \approx 400$ K, 1 atm): $k = 0.0338$ W/m·K, $\nu = 26.4 \times 10^{-6}$ m$^2$/s, $\alpha = 38.3 \times 10^{-6}$ m$^2$/s, $Pr = 0.69$, $\beta = (400 \text{ K})^{-1} = 0.0025$ K$^{-1}$; Table A-1, Steel 1010 (600 K): $k = 48.8$ W/m·K; Table A-3, Alumina-Silica blanket (64 kg/m$^3$, 750 K): $k = 0.125$ W/m·K; Table A-3, Fire clay brick (1478 K): $k = 1.8$ W/m·K.

**ANALYSIS:** (a) *Without the insulation*, the thermal circuit is

Performing an energy balance at the outer surface, it follows that

$$q_{\text{cond}} = q_{\text{conv}} + q_{\text{rad}}$$

where the radiation term is evaluated from Eq. 1.7. The characteristic length associated with free convection from the roof is, from Eq. 9.29 $L = A_s / P = 16 \text{ m}^2 / 16 \text{ m} = 1 \text{ m}$. From Eq. 9.25, with an assumed value for the film temperature, $T_f = 400$ K,

$$Ra_L = \frac{g \beta (T_{s,o} - T_\infty) L^3}{\nu \alpha} = \frac{9.8 \text{ m/s}^2 (0.0025 \text{ K}^{-1}) (T_{s,o} - T_\infty) (1 \text{ m})^3}{26.4 \times 10^{-6} \text{ m}^2/\text{s} \times 38.3 \times 10^{-6} \text{ m}^2/\text{s}} = 2.42 \times 10^7 (T_{s,o} - T_\infty)$$

Hence, from Eq. 9.31

$$h = \frac{k}{L} 0.15Ra_L^{1/3} = \frac{0.0338 \text{ W/m·K}}{1 \text{ m}} 0.15 \left(2.42 \times 10^7\right)^{1/3} (T_{s,o} - T_\infty)^{1/3} = 1.47(T_{s,o} - T_\infty)^{1/3} \text{ W/m}^2 \cdot \text{K}.$$  

Continued...
PROBLEM 9.43 (Cont.)

The energy balance can now be written
\[
\frac{(1700 - T_{s,o}) K}{(0.08m/1.8 W/m \cdot K + 0.005m/48.8 W/m \cdot K)} = 1.47 \left( T_{s,o} - 298 K \right)^{4/3} + 0.3 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K} \left[ T_{s,o}^4 - (298 K)^4 \right]
\]
and from iteration, find \( T_{s,o} \approx 895 K \). Hence,
\[
q = 16m^2 \left\{ 1.47 \left( 895 - 298 \right)^{4/3} \text{ W/m}^2 + 0.3 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left[ (895 K)^4 - (298 K)^4 \right] \right\}
\]
\[
q = 16m^2 \{7,389 + 10,780\} \text{ W/m}^2 = 2.91 \times 10^5 \text{ W}.
\]

(b) *With the insulation*, an additional conduction resistance is provided and the energy balance at the outer surface becomes
\[
\frac{T_{s,i} - T_{s,o}}{L_i/k_i A + L_2/k_2 A + L_3/k_3 A} = hA \left( T_{s,o} - T_{\infty} \right) + \varepsilon \sigma A \left( T_{s,o}^4 - T_{\text{sur}}^4 \right)
\]
\[
\frac{(1700 - T_{s,o}) K}{(0.08m/1.8 + 0.02/0.125 + 0.005/48.8) \text{ m}^2 \cdot \text{K/W}} = 1.47 \left( T_{s,o} - 298 K \right)^{4/3} + 0.3 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left[ T_{s,o}^4 - (298 K)^4 \right].
\]
From an iterative solution, it follows that \( T_{s,o} \approx 610 K \). Hence,
\[
q = 16m^2 \left\{ 1.47 \left( 610 - 298 \right)^{4/3} \text{ W/m}^2 + 0.3 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left[ (610 K)^4 - (298 K)^4 \right] \right\}
\]
\[
q = 16m^2 \{3111 + 2221\} \text{ W/m}^2 = 8.53 \times 10^4 \text{ W}.
\]
The insulation inner surface temperature is given by
\[
q = \frac{T_{s,i} - T_{\text{ins,i}}}{L_i/k_i A}.
\]
Hence
\[
T_{\text{ins,i}} = -q \frac{L_i}{k_i A} + T_{s,i} = -8.53 \times 10^4 \text{ W} \frac{0.08 \text{ m}}{1.8 \text{ W/m} \cdot \text{K} \times 16 \text{ m}^2} + 1700 K = 1463 K.
\]
(c) To determine the required thickness \( L_1 \) of the fire clay brick to reduce \( T_{\text{ins,i}} = 1350 K \), we keyboarded Eq. (4) into the IHT Workspace and found
\[
L_1 = 0.13 \text{ m}.
\]

**COMMENTS:**
1. The accuracy of the calculations could be improved by re-evaluating thermophysical properties at more appropriate temperatures.
2. Convection and radiation heat losses from the roof are comparable. The relative contribution of radiation increases with increasing \( T_{s,o} \), and hence decreases with the addition of insulation.
3. Note that with the insulation, \( T_{\text{ins,i}} = 1463 K \) exceeds the melting point of aluminum (933 K). Hence, molten aluminum, which can seep through the refractory, would penetrate, and thereby degrade the insulation, under the specified conditions.
PROBLEM 9.44

KNOWN: Dimensions and emissivity of top surface of amplifier. Temperature of ambient air and large surroundings.

FIND: Effect of surface temperature on convection, radiation and total heat transfer from the surface.

SCHEMATIC:

\[ T_{\text{sur}} = 298 \text{ K} \]

\[ T_{\infty} = 298 \text{ K} \]

\[ L = 0.5 \text{ m} \]

\[ 50 \leq T_s \leq 75 \text{ } ^\circ\text{C} \]

\[ \varepsilon = 0.8 \]

ASSUMPTIONS: (1) Steady-state, (2) Quiescent air.

PROPERTIES: Table A.4, air (Obtained from Properties Tool Pad of IHT).

ANALYSIS: The total heat rate from the surface is \( q = q_{\text{conv}} + q_{\text{rad}} \). Hence,

\[ q = \bar{h}A_s (T_s - T_{\infty}) + \varepsilon\sigma A_s \left( T_s^4 - T_{\text{sur}}^4 \right) \]

where \( A_s = L^2 = 0.25 \text{ m}^2 \). Using the Correlations and Properties Tool Pads of IHT to evaluate the average convection coefficient for the upper surface of a heated, horizontal plate, the following results are obtained.

Over the prescribed temperature range, the radiation and convection heat rates are virtually identical and the heat rate increases from approximately 66 to 153 W.

COMMENTS: A surface temperature above 50°C would be excessive and would accelerate electronic failure mechanisms. If operation involves large power dissipation (> 100 W), the receiver should be vented.
PROBLEM 9.45

KNOWN: Diameter, thickness, emissivity and initial temperature of silicon wafer. Temperature of air and surrounding.

FIND: (a) Initial cooling rate, (b) Time required to achieve prescribed final temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible heat transfer from side of wafer, (2) Large surroundings, (3) Wafer may be treated as a lumped capacitance, (4) Constant properties, (5) Quiescent air.

PROPERTIES: Table A-1, Silicon (\( \overline{T} = 187^\circ C = 460K \)): \( \rho = 2330 \text{ kg/m}^3 \), \( c_p = 813 \text{ J/kg⋅K} \), \( k = 87.8 \text{ W/m⋅K} \).

Table A-4, Air (\( T_i = 175^\circ C = 448K \)): \( \nu = 32.15 \times 10^{-6} \text{ m}^2/\text{s} \), \( k = 0.0372 \text{ W/m⋅K} \), \( \alpha = 46.8 \times 10^{-6} \text{ m}^2/\text{s} \), \( Pr = 0.686 \), \( \beta = 0.00223 \text{ K}^{-1} \).

SOLUTION: (a) Heat transfer is by natural convection and net radiation exchange from top and bottom surfaces. Hence, with \( A_s = \pi D^2/4 = 0.0177 \text{ m}^2 \),

\[
q = A_s \left( (\overline{h}_t + \overline{h}_b)(T_i - T_\infty) + 2\varepsilon\sigma(T_i^4 - T_{sur}^4) \right)
\]

where the radiation flux is obtained from Eq. 1.7, and with \( L = A_s/P = 0.0375\text{m} \) and \( Ra_L = g\beta(T_i - T_\infty)L^3/\nu = 2.30 \times 10^5 \), the convection coefficients are obtained from Eqs. 9.30 and 9.32. Hence,

\[
\overline{h}_t = \frac{k}{L} \left( 0.54Ra_L^{1/4} \right) = \frac{0.0372 \text{ W/m⋅K} \times 11.8}{0.0375\text{m}} = 11.7 \text{ W/m}^2 \cdot \text{K}
\]

\[
\overline{h}_b = \frac{k}{L} \left( 0.27Ra_L^{1/4} \right) = \frac{0.0372 \text{ W/m⋅K} \times 5.9}{0.0375\text{m}} = 5.9 \text{ W/m}^2 \cdot \text{K}
\]

\[
q = 0.0177 \text{ m}^2 \left( (11.7 + 5.9) \text{ W/m}^2 \cdot \text{K} (300\text{K}) + 2 \times 0.65 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (598^4 - 298^4) \right)
\]

\[
q = 0.0177 \text{ m}^2 \left( 5280 + 8845 \right) \text{ W/m}^2 = 250 \text{ W}
\]

(b) From the generalized lumped capacitance model, Eq. 5.15,

\[
\rho c A_s \delta \frac{dT}{dt} = -\left( (\overline{h}_t + \overline{h}_b)(T - T_\infty) + 2\varepsilon\sigma(T_i^4 - T_{sur}^4) \right) A_s
\]

\[
\int_{T_i}^{T} dT = -\int_{0}^{t} \left( \frac{(\overline{h}_t + \overline{h}_b)(T - T_\infty) + 2\varepsilon\sigma(T_i^4 - T_{sur}^4)}{\rho c \delta} \right) dt
\]

Continued …
PROBLEM 9.45 (Cont.)

Using the DER function of IHT to perform the integration, thereby accounting for variations in $\overline{h}_t$ and $\overline{h}_b$ with $T$, the time $t_f$ to reach a wafer temperature of 50°C is found to be

$$t_f (T = 320K) = 181s$$

As shown above, the rate at which the wafer temperature decays with increasing time decreases due to reductions in the convection and radiation heat fluxes. Initially, the surface radiative flux (top or bottom) exceeds the heat flux due to natural convection from the top surface, which is twice the flux due to natural convection from the bottom surface. However, because $q_{\text{rad}}^r$ and $q_{\text{conv}}^r$ decay approximately as $T^4$ and $T^{5/4}$, respectively, the reduction in $q_{\text{rad}}^r$ with decreasing $T$ is more pronounced, and at $t = 181s$, $q_{\text{rad}}^r$ is well below $q_{\text{conv},t}^r$ and only slightly larger than $q_{\text{conv},b}^r$.

COMMENTS: With $\overline{h}_{r,i} = \varepsilon\sigma (T_i + T_{\text{sur}}) \left(T_i^2 + T_{\text{sur}}^2\right) = 14.7 \text{ W} / \text{m}^2 \cdot \text{K}$, the largest cumulative coefficient of $\overline{h}_{\text{tot}} = \overline{h}_{r,i} + \overline{h}_{t,i} = 26.4 \text{ W} / \text{m}^2 \cdot \text{K}$ corresponds to the top surface. If this coefficient is used to estimate a Biot number, it follows that $Bi = \overline{h}_{\text{tot}} (\delta / 2) / k = 1.5 \times 10^{-4} \leq 1$ and the lumped capacitance approximation is excellent.
PROBLEM 9.46

KNOWN: Pyrex tile, initially at a uniform temperature $T_i = 140^\circ C$, experiences cooling by convection with ambient air and radiation exchange with surroundings.

FIND: (a) Time required for tile to reach the safe-to-touch temperature of $T_f = 40^\circ C$ with free convection and radiation exchange; use $\bar{T} = (T_i + T_f) / 2$ to estimate the average free convection and linearized radiation coefficients; comment on how sensitive result is to this estimate, and (b) Time-to-cool if ambient air is blown in parallel flow over the tile with a velocity of 10 m/s.

SCHEMATIC:

ASSUMPTIONS: (1) Tile behaves as spacewise isothermal object, (2) Backside of tile is perfectly insulated, (3) Surroundings are large compared to the tile, (4) For forced convection situation, part (b), assume flow is fully turbulent.

PROPERTIES: Table A.3, Pyrex (300 K): $\rho = 2225$ kg/m$^3$, $c_p = 835$ J/kg·K, $k = 1.4$ W/m·K, $\varepsilon = 0.80$ (given); Table A.4, Air ($T_f = (T_s + T_\infty)/2 = 330.5$ K, 1 atm): $\nu = 18.96 \times 10^{-6}$ m$^2$/s, $k = 0.0286$ W/m·K, $\alpha = 27.01 \times 10^{-6}$ m$^2$/s, $Pr = 0.7027$, $\beta = 1/T_f$.

ANALYSIS: (a) For the lumped capacitance system with a constant coefficient, from Eq. 5.6,

$$\frac{T_s(t) - T_\infty}{T_i - T_\infty} = \exp \left[ -\left( \frac{hA_s}{\rho Vc} \right) t \right]$$

(1)

where $h$ is the combined coefficient for the convection and radiation processes,

$$h = h_{cv} + h_{rad}$$

(2)

and

$$A_s = L^2 \quad V = L^2 d$$

(3,4)

The linearized radiation coefficient based upon the average temperature, $T_s$, is

$$\bar{T}_s = \left( T_i + T_f \right)/2 = \left( 140 + 40 \right)^\circ C/2 = 90^\circ C = 363$ K

(5)

$$\bar{h}_{rad} = \varepsilon \sigma \left( T_s + T_\infty \right) \left( T_s^2 + T_\infty^2 \right)$$

(6)

$$\bar{h}_{rad} = 0.8 \times 5.67 \times 10^{-8} W/m^2 \cdot K \left( 363^2 + 298^2 \right) \left( 363^2 + 298^2 \right) K^3 = 6.61 W/m^2 \cdot K$$

The free convection coefficient can be estimated from the correlation for the flat plate, Eq. 9.30, with

$$Ra_L = \frac{g \beta \Delta TL^3}{\nu \alpha} \quad L = A_s/P = L^2/4L = 0.25L$$

(7,8)

Continued...
PROBLEM 9.46 (Cont.)

\[
Ra_{L} = \frac{9.8 \text{ m/s}^2 (1/330 \text{ K}) (363 - 298) \text{ K} (0.25 \times 0.200 \text{ m})^3}{18.96 \times 10^{-6} \text{ m}^2/\text{s} \times 27.01 \times 10^{-6} \text{ m}^2/\text{s}} = 4.712 \times 10^5
\]

\[
Nu_{L} = 0.54 Ra_{L}^{1/4} = 0.54 \left(4.712 \times 10^5\right)^{1/4} = 14.18
\]

\[
\bar{h}_{cv} = Nu_{L} k/L = 14.18 \times 0.0286 \text{ W/m K} / 0.25 \times 0.200 \text{ m} = 8.09 \text{ W/m}^2 \text{ K}
\]

From Eq. (2), it follows

\[
\bar{h} = (6.61 + 8.09) \text{ W/m}^2 \text{ K} = 14.7 \text{ W/m}^2 \text{ K}
\]

From Eq. (1), with \(A_s/V = 1/d\), where \(d\) is the tile thickness, the time-to-cool is found as

\[
t_f = \frac{40 - 25}{140 - 25} \exp \left[ -\frac{14.7 \text{ W/m}^2 \text{ K} \times t_f}{2225 \text{ kg/m}^3 \times 0.010 \text{ m} \times 835 \text{ J/kg K}} \right]
\]

\[
t_f = 2574 \text{s} = 42.9 \text{ min}
\]

Using the IHT Lumped Capacitance Model with the Correlations Tool, Free Convection, Flat Plate, we can perform the analysis where both \(h_{cv}\) and \(h_{rad}\) are evaluated as a function of the tile temperature. The time-to-cool is

\[
t_f = 2860 \text{s} = 47.7 \text{ min}
\]

which is 10% higher than the approximate value.

(b) Considering parallel flow with a velocity, \(u_{\infty} = 10 \text{ m/s}\) over the tile, the Reynolds number is

\[
Re_{L} = \frac{u_{\infty} L}{\nu} = \frac{10 \text{ m/s} \times 0.200 \text{ m}}{18.96 \times 10^{-6} \text{ m}^2/\text{s}} = 1.055 \times 10^5
\]

but, assuming the flow is turbulent at the upstream edge, use Eq. 7.41 to estimate \(\bar{h}_{cv}\),

\[
Nu_{L} = 0.037 Re_{L}^{4/5} Pr^{1/3} = 0.037 \left(1.055 \times 10^5\right)^{4/5} (0.7027)^{1/3} = 343.3
\]

\[
\bar{h}_{cv} = Nu_{L} k/L = 343.3 \times 0.0286 \text{ W/m K} / 0.200 \text{ m} = 49.1 \text{ W/m}^2 \text{ K}
\]

Hence, using Eqs. (2) and (1), find

\[
\bar{h} = 57.2 \text{ W/m}^2 \text{ K} \quad t_f = 661 \text{s} = 11.0 \text{ min}
\]

COMMENTS: (1) For the conditions of part (a), \(Bi = h d/k = 14.7 \text{ W/m}^2 \text{ K} \times 0.01 \text{ m} / 1.4 \text{ W/m K} = 0.105\). We conclude that the lumped capacitance analysis is marginally applicable. For the condition of part (b), \(Bi = 0.4\) and, hence, we need to consider spatial effects as explained in Section 5.4. If we considered spatial effects, would our estimates for the time-to-cool be greater or less than those from the foregoing analysis?

(2) For the conditions of part (a), the convection and radiation coefficients are shown in the plot below as a function of cooling time. Can you use this information to explain the relative magnitudes of the \(t_f\) estimates?
**PROBLEM 9.47**

**KNOWN:** Stacked IC boards within a duct dissipating 500 W with prescribed air flow inlet temperature, flow rate, and internal convection coefficient. Outer surface has emissivity of 0.5 and is exposed to ambient air and large surroundings at 25°C.

**FIND:** Develop a model to estimate outlet temperature of the air, \( T_{m,o} \), and the average surface temperature of the duct, \( \bar{T}_s \), following these steps: (a) Estimate the average free convection for the outer surface, \( \bar{h}_f \), assuming an average surface temperature of 37°C; (b) Estimate the average (linearized) radiation coefficient for the outer surface, \( \bar{h}_{rad} \), assuming an average surface temperature of 37°C; (c) Perform an overall energy balance on the duct considering (i) advection of the air flow, (ii) dissipation of electrical power in the ICs, and (iii) heat transfer from the fluid to the ambient air and surroundings. Express the last process in terms of thermal resistances between the fluid and the mean fluid temperature, \( \bar{T}_m \), and the outer temperatures \( T_\infty \) and \( T_{sur} \); (d) Substituting numerical values into the expression of part (c), calculate \( T_{m,o} \) and \( \bar{T}_s \); comment on your results and the assumptions required to develop your model.

**SCHEMATIC:**

![Air flow schematic](image)

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible potential energy, kinetic energy and flow work changes for the internal flow, (3) Constant properties, (4) Power dissipated in IC boards nearly uniform in longitudinal direction, (5) Ambient air is quiescent, and (5) Surroundings are isothermal and large relative to the duct.

**PROPERTIES:** Table A-4, Air (\( T_f = (\bar{T}_s + T_\infty)/2 = 304 \) K): \( \nu = 1.629 \times 10^{-5} \) m\(^2\)/s, \( \alpha = 2.309 \times 10^{-5} \) m\(^2\)/s, \( k = 0.0266 \) W/m-K, \( \beta = 0.003289 \) K\(^{-1}\), \( Pr = 0.706 \).

**ANALYSIS:** (a) *Average, free-convection coefficient over the duct.* Heat loss by free convection occurs on the vertical sides and horizontal top and bottom. The methodology for estimating the average coefficient assuming the average duct surface temperature \( \bar{T}_s = 37°C \) follows that of Example 9.3. For the *vertical sides*, from Eq. 9.25 with \( L = H \), find

\[
Ra_L = \frac{g \beta (\bar{T}_s - T_\infty) H^3}{\nu \alpha}
\]

\[
Ra_L = \frac{9.8 \, m/s^2 \times 0.003289 \, K^{-1} (37 - 25) \, K \times (0.150 \, m)^3}{1.629 \times 10^{-5} \, m^2/s \times 2.309 \times 10^{-5} \, m^2/s} = 3.47 \times 10^6
\]

The free convection is laminar, and from Eq. 9.27,

\[
\overline{Nu}_L = 0.68 + \frac{0.670 \, Ra_L^{1/4}}{1 + (0.492/Pr)^{9/16}}^{4/9}
\]

Continued …..
PROBLEM 9.47 (Cont.)

\[
\overline{\text{Nu}}_L = \frac{\overline{h}_v H}{k} = 0.68 + \frac{0.670 \times \left(3.47 \times 10^6\right)^{1/4}}{\left[1 + \left(0.492/0.706\right)^{9/16}\right]^{4/9}} = 23.2
\]

\[
\overline{h}_v = 4.11 \text{ W/m}^2 \cdot \text{K}
\]

For the top and bottom surfaces, \( L_c = (A_s/P) = (w \times L)/(2w + 2L) = 0.0577 \text{ m}, \) hence, \( \text{Ra}_L = 1.974 \times 10^5 \) and with Eqs. 9.30 and 9.32, respectively,

**Top surface:**

\[
\overline{\text{Nu}}_L = \frac{\overline{h}_t L_c}{k} = 0.54 \text{ Ra}_L^{1/4}; \quad \overline{h}_t = 5.25 \text{ W/m}^2 \cdot \text{K}
\]

**Bottom surface:**

\[
\overline{\text{Nu}}_L = \frac{\overline{h}_b L_c}{k} = 0.27 \text{ Ra}_L^{1/4}; \quad \overline{h}_b = 2.62 \text{ W/m}^2 \cdot \text{K}
\]

The average coefficient for the entire duct is

\[
\overline{\text{h}}_{cv,o} = \left(2\overline{h}_v + \overline{h}_t + \overline{h}_b\right)/2 = (2 \times 4.11 + 5.25 + 2.62) \text{ W/m}^2 \cdot \text{K} = 4.02 \text{ W/m}^2 \cdot \text{K}
\]

(b) Average (linearized) radiation coefficient over the duct. Heat loss by radiation exchange between the duct outer surface and the surroundings on the vertical sides and horizontal top and bottom. With \( T_s = 37{\circ} \text{C}, \) from Eq. 1.9,

\[
\overline{h}_{rad} = \varepsilon\sigma \left(T_s + T_{sur}\right)\left(T_s^2 + T_{sur}^2\right)
\]

\[
\overline{h}_{rad} = 0.5 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left(310 + 298\right)\left(310^2 + 298^2\right) K^3 = 3.2 \text{ W/m}^2 \cdot \text{K}
\]

(c) Overall energy balance on the fluid in the duct. The control volume is shown in the schematic below and the energy balance is

\[
\dot{E}_\text{in} - \dot{E}_\text{out} + \dot{E}_\text{gen} = 0
\]

\[
-q_{\text{adv}} + P_{\text{elec}} - q_{\text{out}} = 0
\]

The advection term has the form, with \( \dot{m} = \dot{\gamma} \rho, \)

\[
q_{\text{adv}} = \dot{m} c_p \left(T_{m,o} - T_{m,i}\right)
\]

and the heat rate \( q_{\text{out}} \) is represented by the thermal circuit shown below and has the form, with \( T_{\text{sur}} = T_{\infty}, \)

\[
q_{\text{out}} = \frac{T_{\text{m}} - T_{\infty}}{R_{cv,i} + \left(1/R_{cv,o} + 1/R_{\text{rad}}\right)^{-1}}
\]

where \( T_{\text{m}} \) is the average mean temperature of the fluid, \((T_{m,i} + T_{m,o})/2.\) The thermal resistances are evaluated with \( A_s = 2(w + H) L \) as

\[
R_{cv,i} = 1/\overline{h}_i A_s
\]

\[
R_{cv,o} = 1/\overline{h}_{cv,o} A_s
\]

\[
R_{\text{rad}} = 1/\overline{h}_{\text{rad}} A_s
\]

Continued .....
Using this energy balance, the outlet temperature of the air can be calculated. From the thermal circuit, the average surface temperature can be calculated from the relation

\[ q_{\text{out}} = \left( T_m - T_s \right) / R_{cv,i} \]  \hspace{1cm} (7)

(d) Calculating \( T_{m,o} \) and \( T_s \). Substituting numerical values into the expressions of Part (c), find

\[ T_{m,o} = 45.7^\circ \text{C} \quad T_s = 34.0^\circ \text{C} \]

The heat rates and thermal resistance results are

\[ q_{\text{adv}} = 480.5 \text{ W} \quad q_{\text{out}} = 19.5 \text{ W} \]
\[ R_{cv,i} = 0.020 \text{ K/W} \quad R_{cv,o} = 0.250 \text{ K/W} \quad R_{\text{rad}} = 0.313 \text{ K/W} \]

**COMMENTS:**

1. We assumed \( T_s = 37^\circ \text{C} \) for estimating \( h_{cv,o} \) and \( h_{\text{rad}} \), whereas from the energy balance we found the value was 34.0^\circ \text{C}. Performing an interactive solution, with different assumed \( T_s \) we would find that the results are not sensitive to the \( T_s \) value, and that the foregoing results are satisfactory.

2. From the results of Part (d) for the heat rates, note that about 4% of the electrical power is transferred from the duct outer surface. The present arrangement does not provide a practical means to cool the IC boards.

3. Note that \( T_{m,i} < T_s < T_{m,o} \). As such, we can’t utilize the usual log-mean temperature (LMTD) expression, Eq. 8.45, in the rate equation for the internal flow analysis. It is for this reason we used the overall coefficient approach representing the heat transfer by the thermal circuit. The average surface temperature of the duct, \( T_s \), is only used for the purposes of estimating \( h_{cv,o} \) and \( h_{\text{rad}} \). We represented the effective temperature difference between the fluid and the ambient/surroundings as \( T_m - T_\infty \). Because the fluid temperature rise is not very large, this assumption is a reasonable one.
PROBLEM 9.48

KNOWN: Parallel flow of air over a highly polished aluminum plate flat plate maintained at a uniform temperature $T_s = 47^\circ C$ by a series of segmented heaters.

FIND: (a) Electrical power required to maintain the heater segment covering the section between $x_1 = 0.2$ m and $x_2 = 0.3$ m and (b) Temperature that the surface would reach if the air blower malfunctions and heat transfer occurs by free, rather than forced, convection.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Backside of plate is perfectly insulated, (3) Flow is turbulent over the entire length of plate, part (a), (4) Ambient air is extensive, quiescent at $23^\circ C$ for part (b).

PROPERTIES: Table A.4, Air ($T_f = (T_s + T_\infty)/2 = 308 K$): $\nu = 16.69 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 0.02689 \text{ W/m} \cdot \text{K}$, $\alpha = 23.68 \times 10^{-6} \text{ m}^2/\text{s}$, $Pr = 0.7059$, $\beta = 1/T_f$; Table A.12, Aluminum, highly polished: $\varepsilon = 0.03$.

ANALYSIS: (a) The power required to maintain the segmented heater $(x_1 - x_2)$ is

$$P_e = \bar{h}_{x_1-x_2}(x_2-x_1)w(T_s-T_\infty) \quad (1)$$

where $\bar{h}_{x_1-x_2}$ the average coefficient for the section between $x_1$ and $x_2$ can be evaluated as the average of the local values at $x_1$ and $x_2$,

$$\bar{h}_{x_1-x_2} = \frac{(h(x_1)+h(x_2))}{2} \quad (2)$$

Using Eq. 7.37 appropriate for fully turbulent flow, with $Re_x = u_x x /k$,

$$Nu_{x_1} = 0.0296 Re_x^{4/5} Pr^{1/3}$$

$$Nu_{x_1} = 0.0296 \left( \frac{10 \text{m/s} \times 0.2 \text{m}}{16.69 \times 10^{-6} \text{ m}^2/\text{s}} \right)^{4/5} (0.7059)^{1/3} = 304.6$$

$$h_{x_1} = Nu_{x_1} k / x_1 = 304.6 \times 0.02689 \text{ W/m} \cdot \text{K} / 0.2 \text{m} = 40.9 \text{ W}/\text{m}^2 \cdot \text{K}$$

$$h_{x_2} = 421.3$$

Hence, from Eq (2) to obtain $\bar{h}_{x_1-x_2}$ and Eq. (1) to obtain $P_e$,

$$\bar{h}_{x_1-x_2} = \frac{(40.9 + 37.8)}{2} \text{ W}/\text{m}^2 \cdot \text{K} = 39.4 \text{ W}/\text{m}^2 \cdot \text{K}$$

$$P_e = 39.4 \text{ W}/\text{m}^2 \cdot \text{K} \times 0.3 \text{ m} \times 0.2 \text{ m} (47 - 23)^\circ \text{C} = 18.9 \text{ W}$$

Continued...
PROBLEM 9.48 (Cont.)

(b) Without the airstream flow, the heater segment experiences free convection and radiation exchange with the surroundings,

\[
\dot{P}_c = \left[ \bar{h}_{cv} (T_s - T_{\infty}) + \varepsilon \sigma \left( T_s^4 - T_{sur}^4 \right) \right] (x_2 - x_1) w
\]  

We will assume that the free convection coefficient, \( \bar{h}_{cv} \), for the segment is the same as that for the entire plate. Using the correlation for a flat plate, Eq. 9.30, with

\[
Ra_L = \frac{g \beta \Delta T L^3}{\nu \alpha} \quad L_c = \frac{A_s}{P} = \frac{0.2 \times 0.5 m^2}{2(0.2 + 0.5) m} = 0.0714 m
\]

and evaluating properties at \( T_f = 308 \text{ K} \),

\[
Ra_L = \frac{9.8 \text{ m/s}^2 (1/308 \text{K})(47 - 23)(0.0714 \text{m})^3}{16.69 \times 10^{-6} \text{ m/s}^2 \times 23.68 \times 10^{-6} \text{ m}^2/\text{s}} = 7.033 \times 10^5
\]

\[
\bar{Nu}_L = 0.54 Ra_L^{1/4} = 0.54 \left( 7.033 \times 10^5 \right)^{1/4} = 15.64
\]

\[
\bar{h}_{cv} = \frac{\bar{Nu}_L k}{L_c} = 15.64 \times 0.02689 \text{ W/m} \cdot \text{K}/0.0714 \text{m} = 5.89 \text{ W/m}^2 \cdot \text{K}
\]

Substituting numerical values into Eq. (3),

\[
18.9W = \left[ 5.89 \text{ W/m}^2 \cdot \text{K} \left( T_s - 296 \right) + 0.03 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left( T_s^4 - 296^4 \right) \right] (0.3 - 0.2) \text{ m} \times 0.2 \text{m}
\]

\[
T_s = 447 \text{ K} = 174^\circ \text{C}
\]

COMMENTS: Recognize that in part (b), the assumed value for \( T_f = 308 \text{ K} \) is a poor approximation. Using the above relations in the IHT work space with the Properties Tool, find that \( T_s = 406 \text{ K} = 133^\circ \text{C} \) using the properly evaluated film temperature \( (T_f) \) and temperature difference \( (\Delta T) \) in the correlation. From this analysis, \( \bar{h}_{cv} = 8.29 \text{ W/m}^2 \cdot \text{K} \) and \( h_{\text{rad}} = 0.3 \text{ W/m}^2 \cdot \text{K} \). Because of the low emissivity of the plate, the radiation exchange process is not significant.
PROBLEM 9.49

KNOWN: Correlation for estimating the average free convection coefficient for the exterior surface of a long horizontal rectangular cylinder (duct) exposed to a quiescent fluid. Consider a horizontal 0.15 m-square duct with a surface temperature of 35°C passing through ambient air at 15°C.

FIND: (a) Calculate the average convection coefficient and the heat rate per unit length using the H-D correlation, (b) Calculate the average convection coefficient and the heat rate per unit length considering the duct as formed by vertical plates (sides) and horizontal plates (top and bottom), and (c) Using an appropriate correlation, calculate the average convection coefficient and the heat rate per unit length for a duct of circular cross-section having a diameter equal to the wetted perimeter of the rectangular duct of part (a). Do you expect the estimates for parts (b) and (c) to be lower or higher than those obtained with the H-D correlation? Explain the differences, if any.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Ambient air is quiescent, (3) Duct surface has uniform temperature.

PROPERTIES: Table A-4, air ($T_f = (T_s + T_\infty)/2 = 298$ K, 1 atm): $\nu = 1.571 \times 10^{-5}$ m$^2$/s, $k = 0.0261$ W/m·K, $\alpha = 2.22 \times 10^{-5}$ m$^2$/s, Pr = 0.708.

ANALYSIS: (a) The Hahn-Didion (H-D) correlation [ASHRAE Proceedings, Part 1, pp 262-67, 1972] has the form

$$\overline{Nu}_p = 0.55 \frac{Ra_p^{1/4} (H/p)^{1/8}}{Ra_p \leq 10^7}$$

where the characteristic length is the half-perimeter, $p = (w + H)$, and $w$ and $H$ are the horizontal width and vertical height, respectively, of the duct. The thermophysical properties are evaluated at the film temperature. Using IHT, with the correlation and thermophysical properties, the following results were obtained.

<table>
<thead>
<tr>
<th>$Ra_p$</th>
<th>$\overline{Nu}_D$</th>
<th>$\overline{h}_p$ (W/m$^2$·K)</th>
<th>$q'_p$ (W/m)</th>
</tr>
</thead>
<tbody>
<tr>
<td>$5.08 \times 10^7$</td>
<td>42.6</td>
<td>3.71</td>
<td>44.5</td>
</tr>
</tbody>
</table>

where the heat rate per unit length of the duct is

$$q'_p = \overline{h}_p 2(H+w)(T_s - T_\infty).$$

(b) Treating the duct as a combination of horizontal (top: hot-side up and bottom: hot-side down) and two vertical plates (v) as considered in Example 9.3, the following results were obtained.

<table>
<thead>
<tr>
<th>$\overline{h}_t$ (W/m$^2$·K)</th>
<th>$\overline{h}_b$ (W/m$^2$·K)</th>
<th>$\overline{h}_v$ (W/m$^2$·K)</th>
<th>$\overline{h}_{hv}$ (W/m$^2$·K)</th>
<th>$q'_{hv}$ (W/m)</th>
</tr>
</thead>
<tbody>
<tr>
<td>5.62</td>
<td>2.81</td>
<td>4.78</td>
<td>4.50</td>
<td>54.0</td>
</tr>
</tbody>
</table>

Continued
where the average coefficient and heat rate per unit length for the horizontal-vertical plate duct are

\[ \bar{h}_{hv} = \left( \bar{h}_t + \bar{h}_b + 2\bar{h}_v \right) / 4 \]

\[ q'_{hv} = \bar{h}_{hv} 2 \left( H + w \right) \left( T_s - T_\infty \right). \]

(c) Consider a circular duct having a wetted perimeter equal to that of the rectangular duct, for which the diameter is

\[ \pi D = 2 \left( H + w \right) \quad D = 0.191 \text{ m} \]

Using the Churchill-Chu correlation, Eq. 9.34, the following results are obtained.

\[
\begin{array}{cccc}
\text{Ra}_D & \text{Nu}_D & \bar{h}_{D} \left( \text{W} / \text{m}^2 \cdot \text{K} \right) & q'_{D} \left( \text{W} / \text{m} \right) \\
1.31 \times 10^7 & 30.6 & 4.19 & 50.3 \\
\end{array}
\]

where the heat rate per unit length for the circular duct is

\[ q'_{D} = \pi D \bar{h}_{D} \left( T_s - T_\infty \right). \]

**COMMENTS:**

(1) The H-D correlation, based upon experimental measurements, provided the lowest estimate for \( \bar{h} \) and \( q' \). The circular duct analysis results are in closer agreement than are those for the horizontal-vertical plate duct.

(2) An explanation for the relative difference in \( \bar{h} \) and \( q' \) values can be drawn from consideration of the boundary layers and induced flows around the surfaces. Viewing the cross-section of the square duct, recognize that flow induced by the bottom surface flows around the vertical sides, joining the vertical plume formed on the top surface. The flow over the vertical sides is quite different than would occur if the vertical surface were modeled as an *isolated* vertical surface. Also, flow from the top surface is likewise modified by flow rising from the sides, and doesn’t behave as an *isolated* horizontal surface. It follows that treating the duct as a combination of horizontal-vertical plates (hv results), each considered as *isolated*, would over estimate the average coefficient and heat rate.

(3) It follows that flow over the horizontal cylinder more closely approximates the situation of the square duct. However, the flow is more streamlined; thinnest along the bottom, and of increasing thickness as the flow rises and eventually breaks away from the upper surface. The edges of the duct disrupt the rising flow, lowering the convection coefficient. As such, we expect the horizontal cylinder results to be systematically higher than for the H-D correlation that accounts for the edges.
PROBLEM 9.50

KNOWN: Straight, rectangular cross-sectioned fin with prescribed geometry, base temperature, and environmental conditions.

FIND: (a) Effectiveness considering only free convection with average coefficient, (b) Effectiveness considering also radiative exchange, (c) Finite-difference equations suitable for considering local, rather than average, values.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) One-dimensional conduction in fin, (4) Width of fin much larger than length, \( w \gg L \), (5) Uniform heat transfer coefficient over length for Parts (a) and (b).

PROPERTIES: Table A-1, Aluminum alloy 2024-T6 \((T_b = (45 + 25) / 2 = 35 \degree C = 300 K)\), \( k = 177 \) W/m-K; Table A-11, Aluminum alloy 2024-T6 (Given), \( \varepsilon = 0.82 \); Table A-4. Air \((T_f = 300 K)\), \( \nu = 15.89 \times 10^{-6} \) m/s, \( k = 26.3 \times 10^{-3} \) W/m-K, \( \alpha = 22.5 \times 10^{-6} \) m/s, \( \beta = 1/T_f = 33.3 \times 10^{-3} K^{-1} \).

ANALYSIS: (a) The effectiveness of a fin is determined from Eq. 3.81

\[
\varepsilon = \frac{q_f}{h A_{c,b} \theta_b} \quad (1)
\]

where \( h \) is the average heat transfer coefficient. The fin heat transfer follows from Eq. 3.72

\[
q_f = M \frac{\sinh mL + (h / mk) \cosh mL}{\cosh mL + (h / mk) \sinh mL} \quad (2)
\]

where

\[
M = (h P \kappa A_c)^{1/2} \theta_b \quad \text{and} \quad m = (h P / k A_c)^{1/2}. \quad (3,4)
\]

Horizontal, flat plate correlations assuming \( T_f = (T_b + T_\infty) / 2 \approx 300 K \) may be used to estimate \( h \), Eqs. 9.30 to 9.32. Calculate first the Rayleigh number

\[
Ra_{L_c} = \frac{g \beta (\bar{T}_s - T_\infty) L_c^3}{\nu \alpha} \quad (5)
\]

where \( \bar{T}_s \) is the average temperature of the fin surface and \( L_c \) is the characteristic length from Eq. 9.29,

\[
L_c \equiv \frac{A_s}{P} = \frac{L \times w}{2L + 2w} \approx \frac{L}{2}. \quad (6)
\]

Substituting numerical values,

\[
Ra_{L_c} = \frac{9.8 m/s^2 \times 1/300 K \times (310 - 298) K \left(100 \times 10^{-3} / 2\right)^3 m^3}{22.5 \times 10^{-6} m^2/s \times 15.89 \times 10^{-6} m^2/s} = 1.37 \times 10^5 \quad (7)
\]

Continued...
where $T_s = (T_b + T_f)/2 = 310K$. Recognize the importance of this assumption which must be justified for a precise result. Using Eq. 9.30 and 9.32 for the upper and lower surfaces, respectively,

\[
\text{Nu}_{L_c} = 0.54 \left(1.37 \times 10^5\right)^{1/4} = 10.4, \quad \text{Nu}_L = \frac{k}{L_c} \times \frac{0.0263 \text{ W/m} \cdot \text{K}}{\left(100 \times 10^{-8}/2\right) \text{m}} = 5.47 \text{ W/m}^2 \cdot \text{K}
\]

\[
\text{Nu}_{L_c} = 0.27 \left(1.37 \times 10^5\right)^{1/4} = 5.20, \quad \text{Nu}_L = 2.73 \text{ W/m}^2 \cdot \text{K}
\]

The average value is estimated as $\text{Nu}_c = (\text{Nu}_u + \text{Nu}_\ell)/2 = 4.10 \text{ W/m}^2 \cdot \text{K}$. Using this value in Eqs. (3) and (4), find

\[
\begin{align*}
M &= \left[4.10 \text{ W/m}^2 \cdot \text{K (2w)} m \times 177 \text{ W/m} \cdot \text{K (} w \times 2 \times 10^{-3} \text{ m}^2 \right]^{1/2} (45 - 25)° C = 34.1 \text{ W/m} \\
m &= (\text{Nu}_c P / kA_c)^{1/2} = \left[4.10 \text{ W/m}^2 \cdot \text{K (2w)} m \times 177 \text{ W/m} \cdot \text{K (} w \times 2 \times 10^{-3} \text{ m}^2 \right]^{1/2} = 4.81 \text{ m}^{-1}.
\end{align*}
\]

Substituting these values into Eq. (2), with $mL = 0.481$ and $q_f/w = q_{f}^\prime$,

\[
q_f^\prime = 34.1 \text{ W/m} \times \frac{\sinh 0.481 + \left(4.1 \text{ W/m}^2 \cdot \text{K} / 4.81 \text{ m}^{-1} \times 177 \text{ W/m} \cdot \text{K}\right) \cosh 0.481}{\cosh 0.481 + \left(4.86 \times 10^{-3}\right) \sinh 0.481} = 15.2 \text{ W/m}
\]

and then from Eq. (1), the effectiveness is

\[
\varepsilon = 15.2 \text{ W/m} \times w / 4.1 \text{ W/m}^2 \cdot \text{K} (w \times 2 \times 10^{-3} \text{ m}) (45 - 25)° C = 92.7.
\]

(b) If radiation exchange with the surroundings is considered, use Eq. 1.9 to determine

\[
\overline{\text{h}}_r = \varepsilon \sigma (T_s + T_{\text{sur}}) \left(T_s^2 + T_{\text{sur}}^2\right) = 0.82 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (310 + 298) (310^2 + 298^2) K^3 = 5.23 \text{ W/m}^2 \cdot \text{K}.
\]

This assumes the fin surface is gray-diffuse and small compared to the surroundings. Using $\overline{\text{h}} = \overline{\text{h}}_c + \overline{\text{h}}_r$

where $\overline{\text{h}}_c$ is the convection parameter from part (a), find $\overline{\text{h}} = (4.10 + 5.23) \text{ W/m}^2 \cdot \text{K} = 9.33 \text{ W/m}^2 \cdot \text{K}$, $M = 51.4 \text{ W/m}$, $m = 7.26 \text{ m}^{-1}$, $q_f^\prime = 31.8 \text{ W/m}$ giving

\[
\varepsilon = 85.2
\]

(c) To perform the numerical method, we used the IHT Finite Difference Equation Tool for I-D, SS, extended surfaces. The convection coefficient for each node was expressed as

\[
\overline{\text{h}}_{\text{tot,m}} = \overline{\text{h}}_u (T_m) + \overline{\text{h}}_\ell (T_m) / 2 + \overline{\text{h}}_r (T_m)
\]

The effectiveness was calculated from Eq. (1) where the fin heat rate is determined from an energy balance on the base node.

\[
\begin{align*}
q_f &= q_{\text{cond}} + q_{\text{cv}} + q_{\text{rad}} \\
q_b &= q_{\text{cond}} = kA_c (T_b - T_1) / \Delta x \\
q_a &= q_{\text{cv}} + q_{\text{rad}} = \overline{\text{h}}_{\text{tot,b}} (P \cdot \Delta w / 2) (T_b - T_{\text{inf}}) \\
\overline{\text{h}}_{\text{tot,b}} &= (\overline{\text{h}}_u (T_b) + \overline{\text{h}}_\ell (T_b)) / 2 + \overline{\text{h}}_r (T_b)
\end{align*}
\]

Continued...
The results of the analysis (15 nodes, $\Delta x = L/15$)

$$q_f = 33.6 \text{ W/m} \quad \epsilon = 83.2$$

COMMENTS: (1) From the analytical treatments, parts (a) and (b), considering radiation exchange nearly doubles the fin heat rate (31.8 vs. 15.2 W/m) and reduces the effectiveness from 92.7 to 85.2. The numerical method, part (c) considering local variations for $h_c$ and $h_{ad}$, provides results for $q_f'$ and $\epsilon$ which are in close agreement with the analytical method, part (b).

(2) The IHT Finite Difference Equation Tool provides a powerful approach to solving a problem as tedious as this one. Portions of the work space are copied below to illustrate the general logic of the analysis.

```c
// Method of Solution: The Finite-Difference Equation tool for One-Dimensional, Steady-State Conditions for an extended surface was used to write 15 nodal equations. The convection and linearized radiation coefficient for each node was separately calculated by a User-Defined Function.

// User-Defined Function - Upper surface convection coefficients:
/* FUNCTION h_up ( Ts )
  h_up = 0.0263 / 0.05 * NuLcu
  NuLcu = 0.54 * (11,421 * (Ts - 298))^{0.25}
  RETURN h_up
END */

// User-Defined Function - Linearized radiation coefficients:
/* FUNCTION h_rad ( Ts )
  h_rad = 0.82 * sigma * (Ts + 298) * (Ts^2 + 298^2)
  sigma = 5.67e-8
  RETURN h_rad
END */

/* Node 1: extended surface interior node; e and w labeled 2 and b. */

```
PROBLEM 9.51

KNOWN: Dimensions, emissivity and operating temperatures of a wood burning stove. Temperature of ambient air and surroundings.

FIND: Rate of heat transfer.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Quiescent air, (3) Negligible heat transfer from pipe elbow, (4) Free convection from pipe corresponds to that from a vertical plate.

PROPERTIES: Table A.4, air (T_f = 400 K): ν = 26.41 × 10^{-6} m^2/s, k = 0.0338 W/m·K, α = 38.3 × 10^{-6} m^2/s, β = 0.0025 K^{-1}, Pr = 0.69. Table A.4, air (T_f = 350 K): ν = 20.92 × 10^{-6} m^2/s, k = 0.030 W/m·K, α = 29.9 × 10^{-6} m^2/s, Pr = 0.70, β = 0.00286 K^{-1}.

ANALYSIS: Three distinct contributions to the heat rate are made by the 4 side walls, the top surface, and the pipe surface. Hence \( q_t = 4q_s + q_t + q_p \), where each contribution includes transport due to convection and radiation.

The radiation coefficients are
\[
\begin{align*}
q_s &= \bar{h}_s L^2_s \left( T_{s,s} - T_\infty \right) + h_{rad,s} L^2_s \left( T_{s,s} - T_{sur} \right) \\
q_t &= \bar{h}_t L^2_s \left( T_{s,s} - T_\infty \right) + h_{rad,s} L^2_s \left( T_{s,s} - T_{sur} \right) \\
q_p &= \bar{h}_p \left( \pi D_p L_p \right) \left( T_{s,p} - T_\infty \right) + h_{rad,p} \left( \pi D_p L_p \right) \left( T_{s,p} - T_{sur} \right)
\end{align*}
\]

For the stove side walls, \( Ra_{s,s} = g \beta \left( T_{s,s} - T_\infty \right) L^3_s / \alpha \nu = 4.84 \times 10^9 \). Similarly, with \( (A_s/P) = L^2_s / 4L_s \), \( Ra_{s,t} = 7.57 \times 10^7 \) for the top surface, and with \( L_p = 2 \) m, \( Ra_{s,p} = 3.59 \times 10^{10} \) for the stove pipe.

For the side walls and the pipe, the average convection coefficient may be determined from Eq. 9.26,

\[
\text{Nu}_L = \left\{ 0.825 + \frac{0.387 \text{Ra}_L^{1/6}}{\left[ 1 + (0.492/\text{Pr})^{9/16} \right]^{8/27}} \right\}^2
\]

Continued...
which yields \( \overline{Nu}_{L,s} = 199.9 \) and \( \overline{Nu}_{L,p} = 377.6 \). For the top surface, the average coefficient may be obtained from Eq. 9.31,

\[
\overline{Nu}_L = 0.15Ra_L^{1/3}
\]

which yields \( \overline{Nu}_{L,t} = 63.5 \). With \( \overline{h} = \overline{Nu}(k/L) \), the convection coefficients are

\[
\overline{h}_s = 6.8 \text{ W/m}^2\cdot\text{K}, \quad \overline{h}_t = 8.6 \text{ W/m}^2\cdot\text{K}, \quad \overline{h}_p = 5.7 \text{ W/m}^2\cdot\text{K}
\]

Hence,

\[
q_s = \left( \overline{h}_s + h_{rad,s} \right) L_s^2 \left( T_{s,s} - 300 \text{ K} \right) = 19.1 \text{ W/m}^2\cdot\text{K} \left( 1 \text{ m}^2 \right) \left( 200 \text{ K} \right) = 3820 \text{ W}
\]

\[
q_t = \left( \overline{h}_t + h_{rad,s} \right) L_s^2 \left( T_{s,s} - 300 \text{ K} \right) = 20.9 \text{ W/m}^2\cdot\text{K} \left( 1 \text{ m}^2 \right) \left( 200 \text{ K} \right) = 4180 \text{ W}
\]

\[
q_p = \left( \overline{h}_p + h_{rad,p} \right) \left( \pi D_p L_p \right) \left( T_{s,p} - 300 \text{ K} \right) = 13.6 \text{ W/m}^2\cdot\text{K} \left( \pi \times 0.25 \text{ m} \times 2 \text{ m} \right) \left( 100 \text{ K} \right) = 2140 \text{ W}
\]

and the total heat rate is

\[
q_{tot} = 4q_s + q_t + q_p = 21,600 \text{ W}
\]

**COMMENTS:** The amount of heat transfer is significant, and the stove would be capable of maintaining comfortable conditions in a large, living space under harsh (cold) environmental conditions.
PROBLEM 9.52

KNOWN: Plate, 1m × 1m, inclined at 45° from the vertical is exposed to a net radiation heat flux of 300 W/m²; backside of plate is insulated and ambient air is at 0°C.

FIND: Temperature plate reaches for the prescribed conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Net radiation heat flux (300 W/m²) includes exchange with surroundings, (2) Ambient air is quiescent, (3) No heat losses from backside of plate, (4) Steady-state conditions.

PROPERTIES: Table A-4, Air (assuming Tₛ = 84°C, Tᵢ ≈ (Tₛ + Tᵢ)/2 = (84 + 0)/2 = 315K, 1 atm): ν = 17.40 × 10⁻⁶ m²/s, k = 0.0274 W/m·K, α = 24.7 × 10⁻⁶ m²/s, Pr = 0.705, β = 1/Tᵢ.

ANALYSIS: From an energy balance on the plate, it follows that

That is, the net radiation heat flux into the plate is equal to the free convection heat flux to the ambient air. The temperature of the surface can be expressed as

where \( \overline{h}_L \) must be evaluated from an appropriate correlation. Since this is the bottom surface of a heated inclined plate, “g” may be replaced by “g cos θ”; hence using Eq. 9.25, find

Since Ra_L > 10⁹, conditions are turbulent and Eq. 9.26 is appropriate for estimating \( \overline{Nu}_L \)

Substituting \( \overline{h}_L \) from Eq. (3) into Eq. (1), the plate temperature is

COMMENTS: Note that the resulting value of \( Tₛ = 57°C \) is substantially lower than the assumed value of 84°C. The calculation should be repeated with a new estimate of \( Tₛ \), say, 60°C. An alternate approach is to write Eq. (2) in terms of \( Tₛ \), the unknown surface temperature and then combine with Eq. (1) to obtain an expression which can be solved, by trial-and-error, for \( Tₛ \).
PROBLEM 9.53

KNOWN: Horizontal rod immersed in water maintained at a prescribed temperature.

FIND: Free convection heat transfer rate per unit length of the rod, \( q'_{\text{conv}} \)

SCHEMATIC:

\[
\begin{array}{c}
\text{Quiescent water,} \\
T_s = 56^\circ\text{C} \\
T_\infty = 18^\circ\text{C} \\
D = 5\text{mm}
\end{array}
\]

ASSUMPTIONS: (1) Water is extensive, quiescent medium.

PROPERTIES: Table A-6, Water (\( T_f = (T_s + T_\infty)/2 = 310\text{K} \)): \( \rho = 1/\nu_f = 993.0 \text{ kg/m}^3 \), \( \nu = \mu/\rho = 695 \times 10^{-6} \text{ N} \cdot \text{s/m}^2/993.0 \text{ kg/m}^3 = 6.999 \times 10^{-7} \text{ m}^2/\text{s} \), \( \alpha = k/\rho c = 0.628 \text{ W/m} \cdot \text{K}/993.0 \text{ kg/m}^3 \times 4178 \text{ J/kg} \cdot \text{K} = 1.514 \times 10^{-7} \text{ m}^2/\text{s} \cdot \text{K} \), \( \Pr = 4.62 \), \( \beta = 361.9 \times 10^{-6} \text{ K}^{-1} \).

ANALYSIS: The heat rate per unit length by free convection is given as

\[
q'_{\text{conv}} = \bar{h}_D \cdot \pi D (T_s - T_\infty). \tag{1}
\]

To estimate \( \bar{h}_D \), first find the Rayleigh number, Eq. 9.25,

\[
\text{Ra}_D = \frac{g \beta (T_s - T_\infty) D^3}{\nu \alpha} = \frac{9.8 \text{ m/s}^2 \left(361.9 \times 10^{-6} \text{ K}^{-1}\right) (56 - 18) \text{ K}(0.005 \text{ m})^3}{6.999 \times 10^{-7} \text{ m}^2/\text{s} \times 1.514 \times 10^{-7} \text{ m}^2/\text{s}} = 1.587 \times 10^5
\]

and use Eq. 9.34 for a horizontal cylinder,

\[
\overline{Nu}_D = \left\{0.60 + \frac{0.387 \text{Ra}_D^{1/6}}{\left[1 + (0.599/\Pr)^{9/16}\right]^{8/27}}\right\}^2 = 10.40
\]

\[
\overline{Nu}_D = \left\{0.60 + \frac{0.387 (1.587 \times 10^5)^{1/6}}{\left[1 + (0.599/4.62)^{9/16}\right]^{8/27}}\right\}^2 = 10.40
\]

\[
\bar{h}_D = \overline{Nu}_D k / D = 10.40 \times 0.628 \text{ W/m} \cdot \text{K}/0.005 \text{ m} = 1306 \text{ W/m}^2 \cdot \text{K}. \tag{2}
\]

Substituting for \( \bar{h}_D \) from Eq. (2) into Eq. (1),

\[
q'_{\text{conv}} = 1306 \text{ W/m}^2 \cdot \text{K} \times \pi (0.005 \text{ m})(56 - 18) \text{ K} = 780 \text{ W/m}.
\]

COMMENTS: (1) Note the relatively large value of \( \bar{h}_D \); if the rod were immersed in air, the heat transfer coefficient would be close to 5 \text{ W/m}^2 \cdot \text{K}.

(2) Eq. 9.33 with appropriate values of \( C \) and \( n \) from Table 9.1 could also be used to estimate \( \bar{h}_D \). Find

\[
\overline{Nu}_D = CRa_D^n = 0.48 \left(1.587 \times 10^5\right)^{0.25} = 9.58
\]

\[
\bar{h}_D = \overline{Nu}_D k / D = 9.58 \times 0.628 \text{ W/m} \cdot \text{K}/0.005 \text{ m} = 1203 \text{ W/m}^2 \cdot \text{K}.
\]

By comparison with the result of Eq. (2), the disparity of the estimates is \( \sim 8\% \).
PROBLEM 9.54

KNOWN: Horizontal, uninsulated steam pipe passing through a room.

FIND: Heat loss per unit length from the pipe.

SCHEMATIC:

ASSUMPTIONS: (1) Pipe surface is at uniform temperature, (2) Air is quiescent medium, (3) Surroundings are large compared to pipe.

PROPERTIES: Table A-4, Air ($T_f = (T_s + T_\infty)/2 = 350K$, 1 atm): $v = 20.92 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 0.030 \text{ W/mK}$, $\alpha = 29.9 \times 10^{-6} \text{ m}^2/\text{s}$, $Pr = 0.700$, $\beta = 1/T_f = 2.857 \times 10^{-3} \text{ K}^{-1}$.

ANALYSIS: Recognizing that the heat loss from the pipe will be by free convection to the air and by radiation exchange with the surroundings, we can write

$$ q' = q'_{\text{conv}} + q'_{\text{rad}} = \pi D \left( h_D (T_s - T_\infty) + \varepsilon \sigma \left( T_s^4 - T_{\text{sur}}^4 \right) \right). \tag{1} $$

To estimate $h_D$, first find $Ra_L$, Eq. 9.25, and then use the correlation for a horizontal cylinder, Eq. 9.34,

$$ Ra_L = \frac{g \beta (T_s - T_\infty) D^3}{\nu \alpha} = \frac{9.8 \times 10^3 (1/350K)(400 - 300) K (0.150m)^3}{20.92 \times 10^{-6} \text{ m}^2/\text{s} \times 29.9 \times 10^{-6} \text{ m}^2/\text{s}} \approx 1.51 \times 10^7 $$

$$ \overline{Nu}_D = \left[ 0.60 + \frac{0.387 \overline{Ra}_L^{1/6}}{1 + (0.559/Pr)^{9/16}} \right]^{8/27} \approx 31.88 $$

$$ h_D = \frac{\overline{Nu}_D \cdot k}{D} = 31.88 \times 0.030 \text{ W/m} \cdot \text{K}/0.15m = 6.38 \text{ W/m}^2 \cdot \text{K}. \tag{2} $$

Substituting for $h_D$ from Eq. (2) into Eq. (1), find

$$ q' = \pi (0.150m) \left[ 6.38 \text{ W/m}^2 \cdot \text{K} (400 - 300) K + 0.85 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (400^4 - 300^4) \right]^4 $$

$$ q' = 301 \text{ W/m} + 397 \text{ W/m} = 698 \text{ W/m}. $$

COMMENTS: (1) Note that for this situation, heat transfer by radiation and free convection are of equal importance.

(2) Using Eq. 9.33 with constants $C,n$ from Table 9.1, the estimate for $h_D$ is

$$ \overline{Nu}_D = CRa_L^n = 0.125 \left( 1.51 \times 10^7 \right)^{0.333} = 30.73 $$

$$ h_D = \frac{\overline{Nu}_D \cdot k}{D} = 30.73 \times 0.030 \text{ W/m} \cdot \text{K}/0.150m = 6.15 \text{ W/m}^2 \cdot \text{K}. $$

The agreement is within 4% of the Eq. 9.34 result.
PROBLEM 9.55

KNOWN: Diameter and outer surface temperature of steam pipe. Diameter, thermal conductivity, and emissivity of insulation. Temperature of ambient air and surroundings.

FIND: Effect of insulation thickness and emissivity on outer surface temperature of insulation and heat loss.

SCHEMATIC: See Example 9.4, Comment 2.

ASSUMPTIONS: (1) Pipe surface is small compared to surroundings, (2) Room air is quiescent.

PROPERTIES: *Table A.4*, air (evaluated using *Properties* Tool Pad of IHT).

ANALYSIS: The appropriate model is provided in Comment 2 of Example 9.4 and includes use of the following energy balance to evaluate $T_{s,2}$,

\[ q'_{\text{cond}} = q'_{\text{conv}} + q'_{\text{rad}} \equiv q' \]

\[
\frac{2\pi k_l \left( T_{s,1} - T_{s,2} \right)}{\ln \left( r_2/r_1 \right)} = h_2 \pi r_2 \left( T_{s,2} - T_{\infty} \right) + \varepsilon 2\pi r_2 \sigma \left( T_{s,2}^4 - T_{\text{sur}}^4 \right)
\]

from which the total heat rate $q'$ can then be determined. Using the IHT *Correlations* and *Properties* Tool Pads, the following results are obtained for the effect of the insulation thickness, with $\varepsilon = 0.85$.

The insulation significantly reduces $T_{s,2}$ and $q'$, and little additional benefits are derived by increasing $t$ above 25 mm. For $t = 25$ mm, the effect of the emissivity is as follows.

Continued...
Although the surface temperature decreases with increasing emissivity, the heat loss increases due to an increase in net radiation to the surroundings.
PROBLEM 9.56

KNOWN: Dimensions and temperature of beer can in refrigerator compartment.

FIND: Orientation which maximizes cooling rate.

SCHEMATIC:

ASSUMPTIONS: (1) End effects are negligible, (2) Compartment air is quiescent, (3) Constant properties.

PROPERTIES: Table A-4, Air (T_f = 288.5K, 1 atm): ν = 14.87 × 10^{-6} m^2/s, k = 0.0254 W/m·K, α = 21.0 × 10^{-6} m^2/s, Pr = 0.71, β = 1/T_f = 3.47 × 10^{-3} K^{-1}.

ANALYSIS: The ratio of cooling rates may be expressed as
\[
\frac{q_v}{q_h} = \frac{\overline{h_v} \cdot \pi DL (T_s - T_\infty)}{\overline{h_h} \cdot \pi DL (T_s - T_\infty)} = \frac{\overline{h_v}}{\overline{h_h}}.
\]

For the **vertical** surface, find
\[
Ra_L = \frac{g \beta (T_s - T_\infty) L^3}{\nu \alpha} = \frac{9.8 \text{ m/s}^2 \times 3.47 \times 10^{-3} \text{ K}^{-1}}{(14.87 \times 10^{-6} \text{ m}^2/\text{s}) (21 \times 10^{-6} \text{ m}^2/\text{s})} L^3 = 2.5 \times 10^9 L^3
\]
\[
Ra_L = 2.5 \times 10^9 (0.15)^3 = 8.44 \times 10^6,
\]
and using the correlation of Eq. 9.26,
\[
\overline{Nu}_L = \left[ 0.825 + \frac{0.387 (8.44 \times 10^6)^{1/6}}{1 + (0.492/0.71)^{9/16}} \right]^{8/27}
\]
\[
= 29.7.
\]
Hence
\[
\overline{h}_L = \overline{h}_v = \frac{\overline{Nu}_L \cdot k}{L} = 29.7 \frac{0.0254 \text{ W/m·K}}{0.15 \text{ m}} = 5.03 \text{ W/m}^2 \cdot \text{K}.
\]

For the **horizontal** surface, find
\[
Ra_D = \frac{g \beta (T_s - T_\infty) D^3}{\nu \alpha} = 2.5 \times 10^9 (0.06)^3 = 5.4 \times 10^5
\]
and using the correlation of Eq. 9.34,
\[
\overline{Nu}_D = \left[ 0.60 + \frac{0.387 (5.4 \times 10^5)^{1/6}}{1 + (0.559/0.71)^{9/16}} \right]^{8/27}
\]
\[
= 12.24.
\]
Hence
\[
\overline{h}_D = \overline{h}_v = \frac{\overline{Nu}_D \cdot k}{D} = 12.24 \frac{0.0254 \text{ W/m·K}}{0.06 \text{ m}} = 5.18 \text{ W/m}^2 \cdot \text{K}.
\]

COMMENTS: In view of the uncertainties associated with Eqs. 9.26 and 9.34 and the neglect of end effects, the above result is inconclusive. The cooling rates are approximately the same.
PROBLEM 9.57

KNOWN: Length and diameter of tube submerged in paraffin of prescribed dimensions. Properties of paraffin. Inlet temperature, flow rate and properties of water in the tube.

FIND: (a) Water outlet temperature, (b) Heat rate, (c) Time for complete melting.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible k.e. and p.e. changes for water, (2) Constant properties for water and paraffin, (3) Negligible tube wall conduction resistance, (4) Free convection at outer surface associated with horizontal cylinder in an infinite quiescent medium, (5) Negligible heat loss to surroundings, (6) Fully developed flow in tube.

PROPERTIES: Water (given): \(c_p = 4185 \, \text{J/kg} \cdot \text{K}, k = 0.653 \, \text{W/m} \cdot \text{K}, \mu = 467 \times 10^{-6} \, \text{kg/s} \cdot \text{m}, \text{Pr} = 2.99\); Paraffin (given): \(T_{mp} = 27.4 \, ^\circ\text{C}, h_{sf} = 244 \, \text{kJ/kg}, k = 0.15 \, \text{W/m} \cdot \text{K}, \beta = 8 \times 10^{-4} \, \text{K}^{-1}, \rho = 770 \, \text{kg/m}^3, v = 5 \times 10^{-6} \, \text{m}^2 / \text{s}, \alpha = 8.85 \times 10^{-8} \, \text{m}^2 / \text{s}.

ANALYSIS: (a) The overall heat transfer coefficient is

\[
\frac{1}{U} = \frac{1}{h_1} + \frac{1}{h_o}.
\]

To estimate \(h_1\), find

\[
\text{Re}_D = \frac{4 \cdot m}{\pi D \mu} = \frac{4 \times 0.1 \, \text{kg/s}}{\pi \times 0.025 \, \text{m} \times 467 \times 10^{-6} \, \text{kg/s} \cdot \text{m}} = 10,906
\]

and noting the flow is turbulent, use the Dittus-Boelter correlation

\[
\text{Nu}_D = 0.023 \text{Re}_D^{4/5} \text{Pr}^{0.3} = 0.023 (10,906)^{4/5} (2.99)^{0.3} = 54.3
\]

\[
h_1 = \frac{\text{Nu}_D \, k}{D} = \frac{54.3 \times 0.653 \, \text{W/m} \cdot \text{K}}{0.025 \, \text{m}} = 1418 \, \text{W/m}^2 \cdot \text{K}.
\]

To estimate \(h_o\), find

\[
\text{Ra}_D = \frac{g \beta (T_s - T_{\infty}) D^3}{\nu \alpha} = \frac{9.8 \, \text{m/s}^2 \times 8 \times 10^{-4} \, \text{K}^{-1} (55 - 27.4) \, \text{K} (0.025 \, \text{m})^3}{5 \times 10^{-6} \, \text{m}^2 / \text{s} \times 8.85 \times 10^{-8} \, \text{m}^2 / \text{s}} = 7.64 \times 10^6
\]

and using the correlation of Eq. 9.34,

\[
\text{Nu}_D = \left[ 0.60 + \frac{0.387 \text{Ra}_D^{1/6}}{1 + (0.559 / \text{Pr})^{9/16}} \right]^{2/7} = 35.0
\]

\[
h_o = \frac{\text{Nu}_D \, k}{D} = 35.0 \frac{0.15 \, \text{W/m} \cdot \text{K}}{0.025 \, \text{m}} = 210 \, \text{W/m}^2 \cdot \text{K}.
\]

Alternatively, using the correlation of Eq. 9.33,
PROBLEM 9.57 (Cont.)

\[ \text{Nu}_D = C \text{Ra}_D^n \text{ with } C = 0.48, \ n = 0.25 \quad \text{Nu}_D = 25.2 \]

\[ h_o = 25.2 \frac{0.15 \text{W/m} \cdot \text{K}}{0.025 \text{m}} = 151 \text{W/m}^2 \cdot \text{K}. \]

The significant difference in \( h_o \) values for the two correlations may be due to difficulties associated with high Pr applications of one or both correlations. Continuing with the result from Eq. 9.34,

\[ \frac{1}{U} = \frac{1}{h_i} + \frac{1}{h_o} = \frac{1}{1418} + \frac{1}{210} = 5.467 \times 10^{-3} \text{m}^2 \cdot \text{K} / \text{W} \]

\[ \bar{U} = 183 \text{W/m}^2 \cdot \text{K}. \]

Using Eq. 8.46, find

\[ \frac{T_\infty - T_{m,o}}{T_\infty - T_{m,i}} = \exp \left( -\frac{\pi D L}{m c_p U} \right) = \exp \left( -\frac{\pi \times 0.025 \text{m} \times 3 \text{m}}{0.1 \text{kg/s} \times 4185 \text{J/kg} \cdot \text{K}} \times \frac{183 \text{ W}}{\text{m}^2 \cdot \text{K}} \right) \]

\[ T_{m,o} = T_\infty - (T_\infty - T_{m,i}) 0.902 = [27.4 - (27.4 - 60) 0.902] \degree \text{C} \]

\[ T_{m,o} = 56.8 \degree \text{C}. \]

(b) From an energy balance, the heat rate is

\[ q = m c_p (T_{m,i} - T_{m,o}) = 0.1 \text{kg/s} \times 4185 \text{J/kg} \cdot \text{K} (60 - 56.8) \text{K} = 1335 \text{W} \]

or using the rate equation,

\[ q = \bar{U} A \Delta T \ell m = 183 \text{W/m}^2 \cdot \text{K} \pi (0.025 \text{m}) 3 \text{m} \left( \frac{(60 - 27.4) \text{K} - (56.8 - 27.4) \text{K}}{56.8 - 27.4} \right) \]

\[ q = 1335 \text{W}. \]

(c) Applying an energy balance to a control volume about the paraffin,

\[ E_{in} = \Delta E_{sf} \]

\[ q \cdot t = \rho V h_{sf} = \rho L \left[ WH - \pi D^2 / 4 \right] h_{sf} \]

\[ t = \frac{770 \text{kg/m}^3 \times 3 \text{m}}{1335 \text{W}} \left[ \frac{(0.25 \text{m})^2 - \frac{\pi}{4} (0.025 \text{m})^2}{2.44 \times 10^5 \text{J/kg}} \right] 2.44 \times 10^5 \text{J/kg} \]

\[ t = 2.618 \times 10^4 \text{s} = 7.27 \text{h}. \]

COMMENTS: (1) The value of \( h_o \) is overestimated by assuming an infinite quiescent medium. The fact that the paraffin is enclosed will increase the resistance due to free convection and hence decrease \( q \) and increase \( t \).

(2) Using \( h_o = 151 \text{W/m}^2 \cdot \text{K} \) results in \( \bar{U} = 136 \text{W/m}^2 \cdot \text{K}, T_{m,o} = 57.6 \degree \text{C}, q = 1009 \text{W} \) and \( t = 9.62 \text{h}. \)
**PROBLEM 9.58**

**KNOWN:** A long uninsulated steam line with a diameter of 89 mm and surface emissivity of 0.8 transports steam at 200°C and is exposed to atmospheric air and large surroundings at an equivalent temperature of 20°C.

**FIND:** (a) The heat loss per unit length for a calm day when the ambient air temperature is 20°C; (b) The heat loss on a breezy day when the wind speed is 8 m/s; and (c) For the conditions of part (a), calculate the heat loss with 20-mm thickness of insulation (k = 0.08 W/m·K). Would the heat loss change significantly with an appreciable wind speed?

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Calm day corresponds to quiescent ambient conditions, (3) Breeze is in crossflow over the steam line, (4) Atmospheric air and large surroundings are at the same temperature; and (5) Emissivity of the insulation surface is 0.8.

**PROPERTIES:** Table A-4, Air (T_f = (T_s + T_∞)/2 = 383 K, 1 atm): \( \nu = 2.454 \times 10^{-5} \) m²/s, \( k = 0.03251 \) W/m·K, \( \alpha = 3.544 \times 10^{-5} \) m²/s, Pr = 0.693.

**ANALYSIS:** (a) The heat loss per unit length from the pipe by convection and radiation exchange with the surroundings is

\[
q_b' = q_c' + q_r'
\]

\[
q_b' = \overline{h}_D P_b (T_{s,b} - T_\infty) + \varepsilon P_b \sigma (T_{s,b}^4 - T_\infty^4)
\]

\[
P_b = \pi D_b
\]

where \( D_b \) is the diameter of the bare pipe. Using the Churchill-Chu correlation, Eq. 9.34, for free convection from a horizontal cylinder, estimate \( \overline{h}_D \)

\[
\overline{Nu}_D = \frac{\overline{h}_D}{k} = \left\{ \frac{0.60 + \frac{0.387 \overline{Ra}_D^{1/6}}{1 + (0.559/Pr)^{9/16}}^{8/27}}{0.387 \overline{Ra}_D^{1/6}} \right\}^{2}
\]

where properties are evaluated at the film temperature, \( T_f = (T_s + T_\infty)/2 \) and

\[
\overline{Ra}_D = \frac{g \beta (T_s - T_\infty) D_b^3}{\nu \alpha}
\]

Substituting numerical values, find for the bare steam line

PROBLEM 9.58 (Cont.)

(b) For forced convection conditions with $V = 8 \text{ m/s}$, use the Churchill-Bernstein correlation, Eq. 7.56,

$$
\overline{N_u}_D = \frac{\overline{h}_D D_b}{k} = 0.3 + \frac{0.62 \text{Re}_{D}^{1/2} \text{Pr}^{1/3}}{1 + (0.4/\text{Pr})^{2/3}} \left[1 + \left(\text{Re}_{D}^{5/8} \text{Pr}^{1/2} \right)^{4/5}\right]
$$

where $\text{Re}_{D} = V D / \nu$. Substituting numerical values, find

<table>
<thead>
<tr>
<th>$\text{Re}_{D}$</th>
<th>$\overline{N_u}_D$</th>
<th>$\overline{h}_D, b$ (W/m$^2$ K)</th>
<th>$q'_c$ (W/m)</th>
<th>$q'_r$ (W/m)</th>
<th>$q'_b$ (W/m)</th>
</tr>
</thead>
<tbody>
<tr>

<td>82.5</td>
<td>30.1</td>
<td>1517</td>
<td>541</td>
<td>2058</td>
</tr>
</tbody>
</table>

(c) With 20-mm thickness insulation, and for the calm-day condition, the heat loss per unit length is

$$
q'_\text{ins} = \left( T_{s,o} - T_\infty \right) / R'_\text{tot}
$$

$$
R'_t = R'_\text{ins} + \left[1/R'_c + 1/R'_\text{rad}\right]^{-1}
$$

where the thermal resistance of the insulation from Eq. 3.28 is

$$
R'_\text{ins} = \ln \left( D_o / D_b \right) / \left[2\pi k \right]
$$

and the convection and radiation thermal resistances are

$$
R'_c = 1 / \left( \overline{h}_{D,o} \pi D_o \right)
$$

$$
R'_\text{rad} = 1 / \left( \overline{h}_{\text{rad}} \pi D_o \right)
$$

The outer surface temperature on the insulation, $T_{s,o}$, can be determined by an energy balance on the surface node of the thermal circuit.

$$
T_{s,b} - T_{s,o} = \frac{T_{s,o} - T_\infty}{\left[1/R'_c + 1/R'_\text{rad}\right]^{-1}}
$$

Substituting numerical values with $D_{b,o} = 129 \text{ mm}$, find the following results.

<table>
<thead>
<tr>
<th>$R'_\text{ins}$</th>
<th>$\overline{h}_{D,o}$</th>
<th>$\overline{h}_{\text{rad}}$</th>
<th>$q'_\text{ins}$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$0.7384 \text{ m} \cdot \text{K} / \text{W}$</td>
<td>$5.30 \text{ W/m}^2 \cdot \text{K}$</td>
<td>$5.65 \text{ W/m}^2 \cdot \text{K}$</td>
<td>$187 \text{ W/m}$</td>
</tr>
</tbody>
</table>
COMMENTS: (1) For the calm-day conditions, the heat loss by radiation exchange is 58% of the total loss. Using a reflective shield (say, $\varepsilon = 0.1$) on the outer surface could reduce the heat loss by 50%.

(2) The effect of a 8-m/s breeze over the steam line is to increase the heat loss by more than a factor of two above that for a calm day. The heat loss by radiation exchange is approximately 25% of the total loss.

(3) The effect of the 20-mm thickness insulation is to reduce the heat loss to 20% the rate by free convection or to 9% the rate on the breezy day. From the results of part (c), note that the insulation resistance is nearly 3 times that due to the combination of the convection and radiation process thermal resistances. The effect of increased wind speed is to reduce $R_{cv}'$, but since $R_{ins}'$ is the dominant resistance, the effect will not be very significant.

(4) Comparing the free convection coefficients for part (a), $D_b = 89 \text{ mm}$ with $T_{s,b} = 200^\circ \text{C}$, and part (b), $D_{b,o} = 129 \text{ mm}$ with $T_{s,o} = 62.1^\circ \text{C}$, it follows that $\overline{h}_{D,o}$ is less than $\overline{h}_{D,b}$ since, for the former, the steam line diameter is larger and the diameter smaller.

(5) The convection correlation models in *IHT* are especially useful for applications such as the present one to eliminate the tediousness of evaluating properties and performing the calculations. However, it is essential that you have experiences in hand calculations with the correlations before using the software.
PROBLEM 9.59

KNOWN: Horizontal tube, 12.5mm diameter, with surface temperature 240°C located in room with an air temperature 20°C.

FIND: Heat transfer rate per unit length of tube due to convection.

SCHEMATIC:

ASSUMPTIONS: (1) Ambient air is quiescent, (2) Surface radiation effects are not considered.

PROPERTIES: Table A-4, Air ($T_f = 400$K, 1 atm): $ν = 26.41 \times 10^{-6}$ m$^2$/s, $k = 0.0338$ W/m·K, $α = 38.3 \times 10^{-6}$ m$^2$/s, Pr = 0.690, $β = 1/T_f = 2.5 \times 10^{-3}$ K$^{-1}$.

ANALYSIS: The heat rate from the tube, per unit length of the tube, is

$$ q' = -\bar{h} \pi D (T_s - T_\infty) $$

where $\bar{h}$ can be estimated from the correlation, Eq. 9.34,

$$ \frac{1}{\bar{Nu}_D} = \left\{ 0.60 + \frac{0.387 Ra_D^{1/6}}{1 + (0.559/Pr)^{9/16}} \right\}^2 $$

From Eq. 9.25,

$$ Ra_D = \frac{g β (T_s - T_\infty) D^3}{να} = \frac{9.8 \text{m/s}^2 \times 2.5 \times 10^{-3} \text{K}^{-1} (240 - 20) \text{K} \times (12.5 \times 10^{-3} \text{m})^3}{26.41 \times 10^{-6} \text{m}^2/\text{s} \times 38.3 \times 10^{-6} \text{m}^2/\text{s}} = 10,410. $$

Hence,

$$ \frac{1}{\bar{Nu}_D} = \left\{ 0.60 + \frac{0.387 (10,410)^{1/6}}{1 + (0.559/0.690)^{9/16}} \right\}^2 = 4.40 $$

Then,

$$ \bar{h} = \frac{k}{D \bar{Nu}_D} = \frac{0.0338 \text{W/m·K}}{12.5 \times 10^{-3} \text{m}} \times 4.40 = 11.9 \text{W/m}^2 \cdot \text{K}. $$

The heat rate is

$$ q' = 11.9 \text{W/m}^2 \cdot \text{K} \times \pi (12.5 \times 10^{-3} \text{m}) (240 - 20) \text{K} = 103 \text{W/m}. $$

COMMENTS: Heat loss rate by radiation, assuming an emissivity of 1.0 for the surface, is

$$ q'_{rad} = ε \sigma (T_s^4 - T_\infty^4) = 1 \times \pi (12.5 \times 10^{-3} \text{m}) \times 5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} \left[ (240 + 273)^4 - (20 + 273)^4 \right] \text{K}^4 $$

$$ q'_{rad} = 138 \text{W/m}. $$

Note that $P = π D$. Note also this estimate assumes the surroundings are at ambient air temperature. In this instance, $q'_{rad} > q'_{conv}$. <
PROBLEM 9.60

KNOWN: Insulated steam tube exposed to atmospheric air and surroundings at 25°C.

FIND: (a) Heat transfer rate by free convection to the room, per unit length of the tube; effect on quality, x, at outlet of 30 m length of tube; (b) Effect of radiation on heat transfer and quality of outlet flow; (c) Effect of emissivity and insulation thickness on heat rate.

SCHEMATIC:

ASSUMPTIONS: (1) Ambient air is quiescent, (2) Negligible surface radiation (part a), (3) Tube wall resistance negligible.

PROPERTIES: Steam tables, steam (sat., 4 bar): $h_f = 566 \text{ kJ/kg}$, $T_{sat} = 416 \text{ K}$, $h_g = 2727 \text{ kJ/kg}$, $h_{fg} = 2160 \text{ kJ/kg}$, $v_g = 4.76 \times 10^3 \text{ m}^3/\text{kg}$; Table A.3, magnesia, 85% (310 K): $k_m = 0.051 \text{ W/m·K}$; Table A.4, air (assume $T_s = 60^\circ\text{C}$, $T_f = (60 + 25)/2 = 315 \text{ K}$, 1 atm): $v = 17.4 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 0.0274 \text{ W/m·K}$, $\alpha = 24.7 \times 10^{-6} \text{ m}^2/\text{s}$, $Pr = 0.705$, $T_f = 1/315 \text{ K} = 3.17 \times 10^{-3} \text{ K}^{-1}$.

ANALYSIS: (a) The heat rate per unit length of the tube (see sketch) is given as,

$$q' = \frac{T_i - T_{\infty}}{R'_1}$$

where

$$\frac{1}{R'_1} = \left[ \frac{1}{h_o \pi D_3} + \frac{1}{2\pi k_m} \ln \frac{D_3}{D_2} + \frac{1}{h_i \pi D_1} \right]^{-1}$$

To estimate $h_o$, we have assumed $T_s = 60^\circ\text{C}$ in order to calculate $Ra_D$ from Eq. 9.25,

$$Ra_D = \frac{\varepsilon (T_s - T_{\infty}) D_3^3}{\nu \alpha} = \frac{9.8 \text{ m}^2/\text{s} \times 3.17 \times 10^{-3} \text{ K}^{-1} \times (60 - 25) \text{ K}}{17.4 \times 10^{-6} \text{ m}^2/\text{s} \times 24.7 \times 10^{-6} \text{ m}^2/\text{s}} = 3.85 \times 10^6.$$  

The appropriate correlation is Eq. 9.34; find

$$\overline{Nu}_D = \left\{0.60 + \frac{0.387 \left( Ra_D \right)^{1/6}}{1 + \left( 0.559/Pr \right)^{9/16}} \right\}^2 = \left\{0.60 + \frac{0.387 \left( 3.85 \times 10^6 \right)^{1/6}}{1 + \left( 0.559/0.705 \right)^{9/16}} \right\}^2 = 21.4.$$  

$$h_o = \frac{k}{D_3} \overline{Nu}_D = \frac{0.0274 \text{ W/m·K}}{0.115 \text{ m}} \times 21.4 = 5.09 \text{ W/m}^2 \cdot \text{K}.$$  

Substituting numerical values into Eq. (2), find

$$\frac{1}{R'_1} = \left[ \frac{1}{5.09 \text{ W/m}^2 \cdot \text{K} \times \pi \times 0.115 \text{ m}} + \frac{1}{2\pi \times 0.051 \text{ W/m·K}} \ln \frac{115}{65} + \frac{1}{11.000 \text{ W/m}^2 \cdot \pi \times 0.055 \text{ m}} \right]^{-1} = 0.430 \text{ W/m·K}.$$  

and from Eq. (1), $q' = 0.430 \text{ W/m·K} (416 - 298) \text{ K} = 50.8 \text{ W/m}$

Continued...
PROBLEM 9.60 (Cont.)

We need to verify that the assumption of \( T_s = 60^\circ\text{C} \) is reasonable. From the thermal circuit,

\[
T_s = T_\infty + \frac{q'}{\overline{h_0} \pi D_3} = 25^\circ\text{C} + 50.8 \text{W/m}/\left(5.09 \text{W/m}^2 \cdot \text{K} \times \pi \times 0.115 \text{m}\right) = 53^\circ\text{C}.
\]

Another calculation using \( T_s = 53^\circ\text{C} \) would be appropriate for a more precise result.

Assuming \( q' \) is constant, the enthalpy of the steam at the outlet (\( L = 30 \text{m} \)), \( h_2 \), is

\[
h_2 = h_1 - q' \cdot L/m = 2727 \text{kJ/kg} - 50.8 \text{W/m} \times 30 \text{m}/14.97 \text{kg/s} = 2625 \text{kJ/kg}
\]

where \( m = \rho_g A_c u_m \) with \( \rho_g = 1/v_g \) and \( A_c = \pi D_1^2/4 \). For negligible pressure drop,

\[
x = (h_2 - h_f)/h_{fg} = (2625 - 566) \text{kJ/kg}/(2160 \text{kJ/kg}) = 0.953.
\]

(b) With radiation, we first determine \( T_s \) by performing an energy balance at the outer surface, where

\[
q'_i = q'_{\text{conv,o}} + q'_{\text{rad}}
\]

\[
\frac{T_i - T_s}{R_i^*} = \overline{h_0} \pi D_3 (T_s - T_\infty) + \pi D_3 \varepsilon \sigma \left(T_s^4 - T_{\text{sur}}^4\right)
\]

and

\[
R_i^* = \frac{1}{\overline{h_i} \pi D_1} + \frac{1}{2\pi k_m} \ln \frac{D_3}{D_2}
\]

From knowledge of \( T_s \), \( q'_i = (T_i - T_s)/R_i^* \) may then be determined. Using the Correlations and Properties Tool Pads of IHT to determine \( \overline{h}_o \) and the properties of air evaluated at \( T_f = (T_s + T_\infty)/2 \), the following results are obtained.

<table>
<thead>
<tr>
<th>Condition</th>
<th>( T_s ) (°C)</th>
<th>( q'_i ) (W/m²)</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \varepsilon = 0.8, D_3 = 115 \text{mm} )</td>
<td>41.8</td>
<td>56.9</td>
</tr>
<tr>
<td>( \varepsilon = 0.8, D_3 = 165 \text{mm} )</td>
<td>33.7</td>
<td>37.6</td>
</tr>
<tr>
<td>( \varepsilon = 0.2, D_3 = 115 \text{mm} )</td>
<td>49.4</td>
<td>52.6</td>
</tr>
<tr>
<td>( \varepsilon = 0.2, D_3 = 165 \text{mm} )</td>
<td>38.7</td>
<td>35.9</td>
</tr>
</tbody>
</table>

COMMENTS: Clearly, a significant reduction in heat loss may be realized by increasing the insulation thickness. Although \( T_s \) and hence \( q'_{\text{conv,o}} \), increases with decreasing \( \varepsilon \), the reduction in \( q'_{\text{rad}} \) is more than sufficient to reduce the heat loss.
PROBLEM 9.61

KNOWN: Dissipation rate of an electrical cable suspended in air.

FIND: Surface temperature of the cable, \( T_s \).

SCHEMATIC:

![Schematic diagram](ambient_air_T_infinity=27°C, T_s, 9'=30 W/m, D=25 mm)

ASSUMPTIONS: (1) Quiescent air, (2) Cable in horizontal position, (3) Negligible radiation exchange.

PROPERTIES: Table A-4, Air \( (T_f = (T_s + T_\infty)/2 = 325 \text{ K}) \), based upon initial estimate for \( T_s \), 1 atm):
\[ \nu = 18.41 \times 10^{-6} \text{ m}^2/\text{s}, \ k = 0.0282 \text{ W/m K}, \ \alpha = 26.2 \times 10^{-6} \text{ m}^2/\text{s}, \ \text{Pr} = 0.704. \]

ANALYSIS: From the rate equation on a unit length basis, the surface temperature is
\[ T_s = T_\infty + \frac{q}{\pi Dh} \]
where \( \bar{h} \) is estimated by an appropriate correlation. Since such a calculation requires knowledge of \( T_s \), an iteration procedure is required. Begin by assuming \( T_s = 77^\circ \text{C} \) and calculated \( \text{Ra}_D \),
\[ \text{Ra}_D = g \beta \Delta T D^3 / \nu \alpha \] where \( \Delta T = T_s - T_\infty \) and \( T_f = (T_s + T_\infty)/2 \) (1,2,3)
For air, \( \beta = 1/T_f \), and substituting numerical values,
\[ \text{Ra}_D = 9.8 \frac{m}{s^2} \left( \frac{1}{1/325 \text{K}} \right) (77-27) \text{K} (0.025 \text{m})^3 \times 18.41 \times 10^{-6} \text{ m}^2/\text{s} \times 26.2 \times 10^{-6} \text{ m}^2/\text{s} = 4.884 \times 10^4. \]
Using the Churchill-Chu relation, find \( \bar{h} \).
\[ \frac{\bar{h}}{k} = \frac{\nu D}{\bar{h} D} = \left[ 0.60 + \frac{0.387 \text{Ra}_D^{1/6}}{1 + (0.559/\text{Pr})^{9/16}} \right]^{8/27} \] (4)
\[ \bar{h} = \frac{0.0282 \text{ W/m K}}{0.025 \text{m}} \left[ 0.60 + \frac{0.387 \left(4.884 \times 10^4 \right)^{1/6}}{1 + (0.559/0.704)^{9/16}} \right]^{8/27} = 7.28 \text{ W/m}^2 \cdot \text{K}. \]
Substituting numerical values into Eq. (1), the calculated value for \( T_s \) is
\[ T_s = 27^\circ \text{C} + \left( \frac{30 \text{ W/m}}{\pi \times 0.025 \text{m} \times 7.28 \text{ W/m}^2 \cdot \text{K}} \right) = 79.5^\circ \text{C}. \]
This value is very close to the assumed value (77°C), but an iteration with a new value of 79°C is warranted. Using the same property values, find for this iteration:
\[ \text{Ra}_D = 5.08 \times 10^4 \quad \bar{h} = 7.35 \text{ W/m}^2 \cdot \text{K} \quad T_s = 79^\circ \text{C}. \]
We conclude that \( T_s = 79^\circ \text{C} \) is a good estimate for the surface temperature.

COMMENTS: Recognize that radiative exchange is likely to be significant and would have the effect of reducing the estimate for \( T_s \).
PROBLEM 9.62

KNOWN: Dissipation rate of an immersion heater in a large tank of water.

FIND: Surface temperature in water and, if accidentally operated, in air.

SCHEMATIC:

ASSUMPTIONS: (1) Quiescent ambient fluid, (2) Negligible radiative exchange.

PROPERTIES: Table A-6, Water and Table A-4, Air:

<table>
<thead>
<tr>
<th></th>
<th>T(K)</th>
<th>k \times 10^3 (W/mK)</th>
<th>ν \times 10^7 (\mu/\rho \cdot m^2/s)</th>

<td>1500</td>
<td>100</td>
<td>2400</td>
<td>3500</td>
<td>0685</td>
<td>666.7</td>
</tr>
</tbody>
</table>

ANALYSIS: From the rate equation, the surface temperature, \( T_s \), is

\[
T_s = T_\infty + \frac{q}{\pi D L \overline{h}}
\]  

where \( \overline{h} \) is estimated by an appropriate correlation. Since such a calculation requires knowledge of \( T_s \), an iteration procedure is required. Begin by assuming for water that \( T_s = 64^\circ C \) such that \( T_f = 315K \). Calculate the Rayleigh number,

\[
Ra_D = \frac{g \beta \Delta T D^3}{\nu \alpha} = \frac{9.8 \times 6.25 \times 10^{-7} m^2/s \times 1.531 \times 10^{-7} m^2/s}{400.4 \times (64 - 20) K (0.010m)^3} = 1.804 \times 10^6.
\]  

Using the Churchill-Chu relation, find

\[
\overline{Nu}_D = \frac{\overline{h} D}{k} = \frac{0.60 + \frac{0.387 Ra_D^{1/6}}{1 + (0.559/Pr)^{9/16}}^{8/27}}{0.60 + \frac{0.387 (1.804 \times 10^6)^{1/6}}{1 + (0.559/4.16)^{9/16}}^{8/27}} = 1301 \text{W/m}^2 \cdot \text{K}.
\]  

Substituting numerical values into Eq. (1), the calculated value for \( T_s \) in water is

\[
T_s = 20^\circ C + 550 \text{W/} \pi \times 0.010m \times 0.30m \times 1301 \text{W/m}^2 \cdot \text{K} = 64.8^\circ C.
\]  

Continued .....
PROBLEM 9.62 (Cont.)

Our initial assumption of $T_s = 64^\circ C$ is in excellent agreement with the calculated value.

With accidental operation in air, the heat transfer coefficient will be nearly a factor of 100 less.

Suppose $h \approx 25 \text{ W/m}^2 \cdot \text{K}$, then from Eq. (1), $T_s \approx 2360^\circ C$. Very likely the heater will burn out.

Using air properties at $T_f \approx 1500 \text{K}$ and Eq. (2), find $Ra_D = 1.815 \times 10^2$. Using Eq. 9.33,

$$Nu_D = C Ra_D^n$$

with $C = 0.85$ and $n = 0.188$ from Table 9.1, find $h = 22.6 \text{ W/m}^2 \cdot \text{K}$. Hence, our first estimate for the surface temperature in air was reasonable,

$$T_s = 2300^\circ C.$$  

However, radiation exchange will be the dominant mode, and would reduce the estimate for $T_s$.

Generally such heaters could not withstand operating temperatures above $1000^\circ C$ and safe operation in air is not possible.
**PROBLEM 9.63**

**KNOWN:** Motor shaft of 20-mm diameter operating in ambient air at $T_\infty = 27^\circ\text{C}$ with surface temperature $T_s \leq 87^\circ\text{C}$.

**FIND:** Convection coefficients and/or heat removal rates for different heat transfer processes: (a) For a rotating horizontal cylinder as a function of rotational speed 5000 to 15,000 rpm using the recommended correlation, (b) For free convection from a horizontal stationary shaft; investigate whether mixed free and forced convection effects for the range of rotational speeds in part (a) are significant using the recommended criterion; (c) For radiation exchange between the shaft having an emissivity of 0.8 and the surroundings also at ambient temperature, $T_{\text{surf}} = T_\infty$; and (d) For cross flow of ambient air over the stationary shaft, required air velocities to remove the heat rates determined in part (a).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Shaft is horizontal with isothermal surface.

**PROPERTIES:** *Table A.4*, Air ($T_f = (T_s + T_\infty)/2 = 330$ K, 1 atm): $\nu = 18.91 \times 10^{-6}$ m$^2$/s, $k = 0.02852$ W/m$^\circ$K, $\alpha = 26.94 \times 10^{-6}$ m$^2$/s, $Pr = 0.7028$, $\beta = 1/T_f$.

**ANALYSIS:** (a) The recommended correlation for the a horizontal rotating shaft is

$$\overline{Nu}_D = 0.133 \frac{Re_D^{2/3} Pr^{1/3}}{Re_D < 4.3 \times 10^5 \text{ for } 0.7 < Pr < 670}$$

where the Reynolds number is

$$Re_D = \frac{\Omega D^2}{\nu}$$

and $\Omega \text{ (rad/s)}$ is the rotational velocity. Evaluating properties at $T_f = (T_s + T_\infty)/2$, find for $\omega = 5000$ rpm,

$$Re_D = (5000 \text{rpm} \times 2\pi \text{ rad/rev} \times 60 \text{s/min}) (0.020 \text{m})^2 / 18.91 \times 10^{-6} \text{ m}^2/\text{s} = 11,076$$

$$\overline{Nu}_D = 0.133 (11,076)^{2/3} (0.7028)^{1/3} = 58.75$$

$$\overline{h}_{D,\text{rot}} = \frac{\overline{Nu}_D k}{D} = 58.75 \times 0.02852 \text{ W/m} \cdot \text{K}/0.020 \text{m} = 83.8 \text{ W/m}^2 \cdot \text{K} <$$

The heat rate per unit shaft length is

$$q'_{\text{rot}} = \overline{h}_{D,\text{rot}} (\pi D) (T_s - T_\infty) = 83.8 \text{ W/m}^2 \cdot \text{K} (\pi \times 0.020 \text{m})(87 - 27) \circ \text{C} = 316 \text{ W/m} <$$

The convection coefficient and heat rate as a function of rotational speed are shown in a plot below.

(b) For the stationary shaft condition, the free convection coefficient can be estimated from the Churchill-Chu correlation, Eq. (9.34) with

Continued...
PROBLEM 9.63 (Cont.)

\[ Ra_D = \frac{g \beta \Delta T D^3}{\nu \alpha} \]

\[ Ra_D = \frac{9.8 \text{ m/s}^2 \left( \frac{1}{330 \text{ K}} \right) (87 - 27) \text{ K} \left( 0.020 \text{ m} \right)^3}{18.91 \times 10^{-6} \text{ m}^2 / \text{s} \times 26.94 \times 10^{-6} \text{ m}^2 / \text{s}} = 27,981 \]

\[ \bar{Nu}_D = \left\{ 0.60 + \frac{0.387 Ra_D^{1/6}}{\left[ 1 + (0.559/Pr)^{9/16} \right]^{8/27}} \right\}^2 \]

\[ \bar{Nu}_D = \left\{ 0.60 + \frac{0.387 (27,981)^{1/6}}{\left[ 1 + (0.559/0.7028)^{9/16} \right]^{8/27}} \right\}^2 = 5.61 \]

\[ \bar{h}_{D, fc} = \bar{Nu}_D \frac{k}{D} = 5.61 \times 0.02852 \text{ W/m} \cdot \text{K} / 0.020 \text{ m} = 8.00 \text{ W/m}^2 \cdot \text{K} \]

\[ q_{fc} = 8.00 \text{ W/m}^2 \cdot \text{K} (\pi \times 0.020 \text{ m}) (87 - 27)^{9} \text{ C} = 30.2 \text{ W/m} \]

Mixed free and forced convection effects may be significant if

\[ \text{Re}_D < 4.7 \left( \text{Gr}_D^3 / \text{Pr} \right)^{0.137} \]

where \( \text{Gr}_D = Ra_D / \text{Pr} \), find using results from above and in part (a) for \( \omega = 5000 \text{ rpm} \),

\[ 11,076 \times ? < 4.7 \left[ (27,981/0.7028)^{3} / 0.7018 \right]^{0.137} = 383 \]

We conclude that free convection effects are not significant for rotational speeds above 5000 rpm.

(c) Considering radiation exchange between the shaft and the surroundings,

\[ h_{rad} = \varepsilon \sigma (T_s + T_{sur})(T_s^2 + T_{sur}^4) \]

\[ h_{rad} = 0.8 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K} (360 + 300) \left( 360^2 + 300^2 \right) \text{K}^3 = 6.57 \text{ W/m}^2 \cdot \text{K} \]

and the heat rate by radiation exchange is

\[ q'_{rad} = h_{rad} (\pi D)(T_s - T_{sur}) \]

\[ q'_{rad} = 6.57 \text{ W/m}^2 \cdot \text{K} (\pi \times 0.020 \text{ m}) (87 - 27) \text{ K} = 24.8 \text{ W/m} \]

(d) For cross flow of ambient air at a velocity \( V \) over the shaft, the convection coefficient can be estimated using the Churchill-Bernstein correlation, Eq. 7.57, with

\[ \text{Re}_{D, cf} = \frac{VD}{\nu} \]

\[ \bar{Nu}_{D, cf} = \bar{h}_{D, cf} D/k = 0.3 + \frac{0.62 \left( \text{Re}_{D, cf}^{1/2} \text{Pr}^{1/3} \right)^{5/8}}{\left[ 1 + (0.4/\text{Pr})^{2/3} \right]^{1/4}} \left[ 1 + \left( \frac{\text{Re}_{D, cf}}{282,000} \right)^{5/8} \right]^{4/5} \]

Continued...
PROBLEM 9.63 (Cont.)

From the plot below (left) for the rotating shaft condition of part (a), $h_{D,rot}$ vs. rpm, note that the convection coefficient varies from approximately 75 to 175 W/m$^2 \cdot$ K. Using the IHT Correlations Tool, Forced Convection, Cylinder, which is based upon the above relations, the range of air velocities $V$ required to achieve $h_{D,cf}$ in the range 75 to 175 W/m$^2 \cdot$ K was computed and is plotted below (right).

Note that the air cross-flow velocities are quite substantial in order to remove similar heat rates for the rotating shaft condition.

**COMMENTS:** We conclude for the rotational speed and surface temperature conditions, free convection effects are not significant. Further, radiation exchange, part (c) result, is less than 10% of the convection heat loss for the lowest rotational speed condition.
PROBLEM 9.64

KNOWN: Horizontal pin fin of 6-mm diameter and 60-mm length fabricated from plain carbon steel \((k = 57 \text{ W/m-K}, \varepsilon = 0.5)\). Fin base maintained at \(T_b = 150^\circ \text{C}\). Ambient air and surroundings at 25°C.

FIND: Fin heat rate, \(q_f\), by two methods: (a) Analytical solution using average fin surface temperature of \(\overline{T}_s = 125^\circ \text{C}\) to estimate the free convection and linearized radiation coefficients; comment on sensitivity of fin heat rate to choice of \(\overline{T}_s\); and, (b) Finite-difference method when coefficients are based upon local temperatures, rather than an average fin surface temperature; compare result of the two solution methods.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in the pin fin, (3) Ambient air is quiescent and extensive, (4) Surroundings are large compared to the pin fin, and (5) Fin tip is adiabatic.

PROPERTIES: Table A.4, Air \((T_f = \left(\overline{T}_b + T_\infty\right)/2 = 348^\circ \text{K}\): \(\nu = 20.72 \times 10^{-6} \text{ m}^2/\text{s}\), \(k = 0.02985 \text{ W/m-K}\), \(\alpha = 29.60 \times 10^{-6} \text{ m}^2/\text{s}\), \(Pr = 0.7003\), \(\beta = 1/T_f\).

ANALYSIS: (a) The heat rate for the pin fin with an adiabatic tip condition is, Eq. 3.76,

\[
q_f = M \tanh \left( mL \right) \tag{1}
\]

\[
M = \left(\overline{h}_{\text{tot}} \frac{kA_c}{\varepsilon} \right)^{1/2} \theta_b \quad m = \left(\frac{hP}{kA_c} \right)^{1/2} \tag{2,3}
\]

\[
P = \pi D \quad A_c = \pi D^2/4 \quad \theta_b = T_b - T_\infty \tag{4-6}
\]

and the average coefficient is the sum of the convection and linearized radiation processes, respectively,

\[
\overline{h}_{\text{tot}} = \overline{h}_{\text{fc}} + \overline{h}_{\text{rad}} \tag{7}
\]

evaluated at \(\overline{T}_s = 125^\circ \text{C}\) with \(\overline{T}_f = \left(\overline{T}_s + T_\infty\right)/2 = 75^\circ \text{C} = 348^\circ \text{K}\).

Estimating \(\overline{h}_{\text{fc}}\): For the horizontal cylinder, Eq. 9.34, with

\[
\frac{Ra_D}{\nu \alpha} = \frac{\varepsilon \beta A T D^3}{\nu \alpha}
\]

Continued …..
PROBLEM 9.64 (Cont.)

\[ \text{Ra}_D = \frac{9.8 \text{ m} / \text{s}^2 (1/348 \text{K})(125 - 25)(0.006 \text{m})^3}{20.72 \times 10^{-6} \text{ m}^2 / \text{s} \times 29.60 \times 10^{-6} \text{ m}^2 / \text{s}} = 991.79 \]

\[ \overline{\text{Nu}}_D = \left( 0.60 + \frac{0.387 \left( \frac{\text{Ra}^{1/6}}{D} \right)}{1 + (0.559/\text{Pr})^{9/16}} \right)^2 \]

\[ \overline{\text{Nu}}_D = \left( 0.60 + \frac{0.387 \left( 991.79 \right)^{1/6}}{1 + (0.559/0.7003)^{9/16}} \right)^2 = 2.603 \]

\[ \overline{h}_{\text{fc}} = \overline{\text{Nu}}_D k / D = 2.603 \times 0.02985 \text{ W/m} \cdot \text{K} / 0.006 \text{m} = 12.95 \text{ W/m}^2 \cdot \text{K} \]

Calculating \( \overline{h}_{\text{rad}} \): The linearized radiation coefficient is

\[ \overline{h}_{\text{rad}} = \epsilon \sigma \left( \overline{T}_s + T_{\text{sur}} \right) \left( \overline{T}_s^2 + T_{\text{sur}}^2 \right) \]

\[ \overline{h}_{\text{rad}} = 0.5 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (398 + 298) \left( 398^2 + 298^2 \right) \text{K}^3 = 4.88 \text{ W/m}^2 \cdot \text{K} \]

Substituting numerical values into Eqs. (1-7), find

\[ q_{\text{fin}} = 2.04 \text{W} \]

with \( \theta_b = 125 \text{K}, A_c = 2.827 \times 10^{-5} \text{ m}^2, P = 0.01885 \text{m}, m = 2.603 \text{m}^{-1}, M = 2.909 \text{W}, \) and \( \overline{h}_{\text{tot}} = 17.83 \text{ W/m}^2 \cdot \text{K} \).

Using the IHT Model, Extended Surfaces, Rectangular Pin Fin, with the Correlations Tool for Free Convection and the Properties Tool for Air, the above analysis was repeated to obtain the following results.

<table>
<thead>
<tr>
<th>( \overline{T}_s ) (°C)</th>

</tbody>
</table>

The fin heat rate is not very sensitive to the choice of \( \overline{T}_s \) for the range \( T_s = 125 \pm 10 \text{ °C} \). For the base case condition, the fin tip temperature is \( T(L) = 114 \text{ °C} \) so that \( \overline{T}_s = (T(L) + T_b) / 2 = 132 \text{ °C} \) would be a consistent assumed value.

Continued …..
PROBLEM 9.64 (Cont.)

(b) Using the IHT Tool, Finite-Difference Equation, Steady State, Extended Surfaces, the temperature distribution was determined for a 15-node system from which the fin heat rate was determined. The local free convection and linearized radiation coefficients \( h_{\text{tot}} = h_{\text{fc}} + h_{\text{rad}} \) were evaluated at local temperatures, \( T_m \), using IHT with the Correlations Tool, Free Convection, Horizontal Cylinder, and the Properties Tool for Air, and Eq. (8). The local coefficient \( h_{\text{tot}} \) vs. \( T_s \) is nearly a linear function for the range \( 114 \leq T_s \leq 150^\circ \text{C} \) so that it was reasonable to represent \( h_{\text{tot}}(T_s) \) as a Lookup Table Function. The fin heat rate follows from an energy balance on the base node, (see schematic next page)

\[
q_f = q_a + q_b = (0.08949 + 1.879) \text{ W} = 1.97 \text{ W}
\]

\[
q_a = h_b (P \Delta x/2)(T_b - T_{\infty})
\]

\[
q_b = k A_c (T_b - T_1)/\Delta x
\]

where \( T_b = 150^\circ \text{C} \), \( T_1 = 418.3 \text{ K} = 145.3^\circ \text{C} \), and \( h_b = h_{\text{tot}}(T_b) = 18.99 \text{ W/m}^2 \cdot \text{K} \).

Considering variable coefficients, the fin heat rate is -3.3% lower than for the analytical solution with the assumed \( T_s = 125^\circ \text{C} \).

**COMMENTS:**

(1) To validate the FDE model for part (b), we compared the temperature distribution and fin heat rate using a constant \( h_{\text{tot}} \) with the analytical solution (\( T_s = 125^\circ \text{C} \)). The results were identical indicating that the 15-node mesh is sufficiently fine.

(2) The fin temperature distribution (K) for the IHT finite-difference model of part (b) is

PROBLEM 9.65

FIND: Cost of daily heat loss from an uninsulated pipe.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Negligible convection resistance for water flow, (3) Negligible radiation from pipe surroundings, (4) Quiescent air, (5) Constant properties.

PROPERTIES: Table A-4, air (p = 1 atm, T_f ≈ 295K): k_a = 0.0259 W/mK, ν = 15.45 × 10^{-6} m^2/s, α = 21.8 × 10^{-6} m^2/s, Pr = 0.708, β = 3.39 × 10^{-3} K^{-1}.

ANALYSIS: Performing an energy balance for a control surface about the outer surface, \( q'_{\text{cond}} = q'_{\text{conv}} + q'_{\text{rad}} \), it follows that

\[
\frac{T - T_{s,0}}{R'_{\text{cond}}} = \frac{\pi D_o}{\alpha} \left( T_{s,0} - T_\infty \right) + \varepsilon \pi D_o \sigma T_{s,0}^4
\]

where \( R'_{\text{cond}} = \frac{\epsilon n (D_o / D_t)}{2 \pi k_p} = \frac{\epsilon n (100 / 84)}{2 \pi (60 \text{ W}/\text{m} \cdot \text{K})} = 4.62 \times 10^{-4} \text{ m} \cdot \text{K} / \text{W} \). The convection coefficient may be obtained from the Churchill and Chu correlation. Hence, with \( \text{Ra}_D = \frac{g \beta (T_{s,0} - T_\infty)}{\alpha \nu \cdot \frac{D_o^3}{9.8 \text{ m} / \text{s}^3} \cdot 3.39 \times 10^{-3} \text{ K}^{-1} \cdot (0.1 \text{ m})^3 (T_{s,0} - 268 \text{ K}) / \left( 21.8 \times 15.45 \times 10^{-12} \text{ m}^4 / \text{s}^2 \right) = 98.637 (T_{s,0} - 268) \),

\[
\overline{Nu}_D = \left\{ 0.60 + \frac{0.387 \text{Ra}_D^{1/6}}{1 + (0.559 / \text{Pr})^{9/8} / 27} \right\}^2 = \left\{ 0.60 + 2.182 (T_{s,0} - 268)^{1/6} \right\}^2
\]

\[
\overline{h} = \frac{k_a}{D_o \overline{Nu}_D} = 0.259 \text{ W} / \text{m}^2 \cdot \text{K} \left\{ 0.60 + 2.182 (T_{s,0} - 268)^{1/6} \right\}^2
\]

Substituting the foregoing expression for \( \overline{h} \), as well as values of \( R'_{\text{cond}}, D_o, \varepsilon, \sigma \) and \( \sigma \) into Eq. (1), an iterative solution yields \( T_{s,0} = 322.9 \text{ K} = 49.9^\circ \text{C} \).

It follows that \( \overline{h} = 6.10 \text{ W} / \text{m}^2 \cdot \text{K} \), and the heat loss per unit length of pipe is

\[
q' = q'_{\text{conv}} + q'_{\text{rad}} = 6.10 \text{ W} / \text{m}^2 \cdot \text{K} \left( \pi \times 0.1 \text{ m} \right) 54.9 \text{ K} + 0.6 \left( \pi \times 0.1 \text{ m} \right) 5.67 \times 10^{-8} \text{ W} / \text{m}^2 \cdot \text{K}^4 (322.9 \text{ K})^4 = (105.2 + 116.2) \text{ W} / \text{m} = 221.4 \text{ W} / \text{m}
\]

The corresponding daily energy loss is \( Q' = 0.221 \text{ kW} / \text{m} \times 24 \text{ h} / \text{d} = 5.3 \text{ kW} \cdot \text{h} / \text{m} \cdot \text{d} \) and the associated cost is \( C' = (5.3 \text{ kW} \cdot \text{h} / \text{m} \cdot \text{d}) (\$0.05 / \text{kw} \cdot \text{h}) = \$0.265 / \text{m} \cdot \text{d} \)<

COMMENTS: (1) The heat loss is significant, and the pipe should be insulated. (2) The conduction resistance of the pipe wall is negligible relative to the combined convection and radiation resistance at the outer surface. Hence, the temperature of the outer surface is only slightly less than that of the water.
**PROBLEM 9.66**

**KNOWN:** Insulated, horizontal pipe with aluminum foil having emissivity which varies from 0.12 to 0.36 during service. Pipe diameter is 300 mm and its surface temperature is 90°C.

**FIND:** Effect of emissivity degradation on heat loss with ambient air at 25°C and (a) quiescent conditions and (b) cross-wind velocity of 5 m/s.

**SCHEMATIC:**

![Schematic diagram showing a horizontal pipe with a temperature of 90°C and emissivity varying from 0.12 to 0.36, a quiescent air condition at 25°C, and a cross-wind velocity of 10 m/s.

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Surroundings are large compared to pipe, (3) Pipe has uniform temperature.

**PROPERTIES:** *Table A-4*, Air \( (T_f = (90 + 25)°C/2 = 330K, 1\ atm): \) \( v = 18.9 \times 10^{-6} \text{ m}^2/\text{s}, k = 28.5 \times 10^{-3} \text{ W/m-K}, \alpha = 26.9 \times 10^{-6} \text{ m}^2/\text{s}, \text{Pr} = 0.703.\)

**ANALYSIS:** The heat loss per unit length from the pipe is

\[
q' = \bar{h} P (T_s - T_\infty) + \varepsilon \sigma P \left( T_s^4 - T_{\text{sur}}^4 \right)
\]

where \( P = \pi D \) and \( \bar{h} \) needs to be evaluated for the two ambient air conditions.

(a) *Quiescent air.* Treating the pipe as a horizontal cylinder, find

\[
\text{Ra}_D = \frac{g \beta (T_s - T_\infty) D^3}{\nu \alpha} = \frac{9.8 \text{ m/s}^2 \left(1/330K\right)(90 - 25) K (0.30m)^3}{18.9 \times 10^{-6} \text{ m}^2/\text{s} \times 26.9 \times 10^{-6} \text{ m}^2/\text{s}} = 1.025 \times 10^8
\]

and using the Churchill-Chu correlation for \(10^{-5} < \text{Re}_D < 10^{12}.\)

\[
\bar{\text{Nu}}_D = \begin{cases} 
0.60 + \frac{0.387 \text{Ra}_D^{1/6}}{1 + (0.559/\text{Pr})^{9/16}}^{8/27} \\
\end{cases}
\]

\[
\bar{\text{Nu}}_D = \begin{cases} 
0.60 + \frac{0.387 \left(1.025 \times 10^8\right)^{1/6}}{1 + (0.559/0.703)^{9/16}}^{8/27} = 56.93
\end{cases}
\]

\[
\bar{h}_D = \bar{\text{Nu}}_D k / D = 56.93 \times 0.0285 \text{ W/m-K}/0.300m = 5.4 \text{ W/m}^2\cdot\text{K.}
\]

Continued …..
Hence, the heat loss is

\[ q' = 5.4 \text{W/m}^2 \cdot K (\pi 0.300 \text{m}) (90 - 25) K + \varepsilon \times 5.67 \times 10^{-8} \text{W/m}^2 \cdot K (\pi 0.300 \text{m}) (363^4 - 298^4) K^4 \]

\[ q' = 331 + 506 \varepsilon \]

\[ \begin{align*}
\varepsilon &= 0.12 \rightarrow q' &= (331 + 61) = 392 \text{W/m} \\
\varepsilon &= 0.36 \rightarrow q' &= (331 + 182) = 513 \text{W/m}
\end{align*} \]

The radiation effect accounts for 16 and 35%, respectively, of the heat rate.

(b) Cross-wind condition. With a cross-wind, find

\[ \text{Re}_D = \frac{V_D D}{\nu} = \frac{10 \text{m/s} \times 0.30 \text{m}}{18.9 \times 10^{-6} \text{m}^2 / \text{s}} = 1.587 \times 10^5 \]

and using the Hilpert correlation where \( C = 0.027 \) and \( m = 0.805 \) from Table 7.2,

\[ \overline{\text{Nu}}_D = C \text{Re}_D^m \Pr^{1/3} = 0.027 \left(1.587 \times 10^5\right)^{0.805} (0.703)^{1/3} = 368.9 \]

\[ \overline{h}_D = \text{Nu}_D \cdot k / D = 368.9 \times 0.0285 \text{W/m} \cdot \text{K} / 0.300 \text{m} = 35 \text{W/m}^2 \cdot \text{K}. \]

Recognizing that combined free and forced convection conditions may exist, from Eq. 9.64 with \( n = 3 \),

\[ \text{Nu}^3_m = \text{Nu}^3_F + \text{Nu}^3_N \]

\[ \overline{h}_m = \left(5.4^3 + 35^3\right)^{1/3} = 3.5 \text{ W/m}^2 \cdot \text{K} \]

we find forced convection dominates. Hence, the heat loss is

\[ q' = 3.5 \text{ W/m}^2 \cdot K (\pi 0.300 \text{m}) (90 - 25) K + \varepsilon \times 5.67 \times 10^{-8} \text{W/m}^2 \cdot K (\pi 0.300 \text{m}) (393^4 - 298^4) K^4 \]

\[ q' = 2144 + 853 \varepsilon \]

\[ \begin{align*}
\varepsilon &= 0.12 \rightarrow q' &= 2144 + 102 = 2246 \text{W/m} \\
\varepsilon &= 0.36 \rightarrow q' &= 2144 + 307 = 2451 \text{W/m}
\end{align*} \]

The radiation effect accounts for 5 and 13%, respectively, of the heat rate.

COMMENTS: (1) For high velocity wind conditions, radiation losses are quite low and the degradation of the foil is not important. However, for low velocity and quiescent air conditions, radiation effects are significant and the degradation of the foil can account for a nearly 25% change in heat loss.

(2) The radiation coefficient is in the range 0.83 to 2.48 W/m²·K for \( \varepsilon = 0.12 \) and 0.36, respectively. Compare these values with those for convection.
PROBLEM 9.67

KNOWN: Diameter, emissivity, and power dissipation of cylindrical heater. Temperature of ambient air and surroundings.

FIND: Steady-state temperature of heater and time required to come within 10°C of this temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Air is quiescent, (2) Duct wall forms large surroundings about heater, (3) Heater may be approximated as a lumped capacitance.

PROPERTIES: Table A.4, air (Obtained from Properties Tool Pad of IHT).

ANALYSIS: Performing an energy balance on the heater, the final (steady-state) temperature may be obtained from the requirement that \( q' = q_{\text{conv}} + q_{\text{rad}} \), or

\[
q' = \bar{h} \left( \pi D \right) \left( T - T_\infty \right) + h_r \left( \pi D \right) \left( T - T_{\text{sur}} \right)
\]

where \( \bar{h} \) is obtained from Eq. 9.34 and \( h_r = \varepsilon \sigma \left( T + T_{\text{sur}} \right) \left( T^2 + T_{\text{sur}}^2 \right) \). Using the Correlations Tool Pad of IHT to evaluate \( \bar{h} \), this expression may be solved to obtain

\[ T = 854 \, \text{K} = 581°C \]

Under transient conditions, the energy balance is of the form, \( \dot{E}'_{\text{st}} = q' - q_{\text{conv}} - q_{\text{rad}} \), or

\[
\rho c_p \left( \pi D^2 / 4 \right) \frac{dT}{dt} = q' - \bar{h} \left( \pi D \right) \left( T - T_\infty \right) - h_r \left( \pi D \right) \left( T - T_{\text{sur}} \right)
\]

Using the IHT Lumped Capacitance model with the Correlations Tool Pad, the above expression is integrated from \( t = 0 \), for which \( T_i = 562.4 \, \text{K} \), to the time for which \( T = 844 \, \text{K} \). The integration yields

\[ t = 183 \, \text{s} \]

The value of \( T_i = 562.4 \, \text{K} \) corresponds to the steady-state temperature for which the power dissipation is balanced by convection and radiation (see solution to Problem 7.44).

COMMENTS: The forced convection coefficient (Problems 7.43 and 7.44) of 105 W/m²·K is much larger than that associated with free convection for the steady-state conditions of this problem (14.6 W/m²·K). However, because of the correspondingly larger heater temperature, the radiation coefficient with free convection (42.9 W/m²·K) is much larger than that associated with forced convection (15.9 W/m²·K).
PROBLEM 9.68

KNOWN: Cylindrical sensor of 12.5 mm diameter positioned horizontally in quiescent air at 27°C.

FIND: An expression for the free convection coefficient as a function of only ΔT = T_s - T_∞ where T_s is the sensor temperature.

ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform temperature over cylindrically shaped sensor, (3) Ambient air extensive and quiescent.

PROPERTIES: Table A-4, Air (T_f, 1 atm): β = 1/T_f and

<table>
<thead>
<tr>
<th>T_s (°C)</th>

ANALYSIS: For the cylindrical sensor, using Eqs. 9.25 and 9.34,

\[
Ra_D = \frac{g \beta \Delta T D^3}{v \alpha} \quad \text{Nu}_D = \frac{\overline{h}_D D}{k} = \left\{ 0.60 + \frac{0.387 (Ra_D)^{1/6}}{\left[ 1 + (0.559/Pr)^{9/16} \right]^{8/17}} \right\}^{2} \quad (1.2)
\]

where properties are evaluated at \( (T_f = T_s + T_\infty)/2 \). With 30 ≤ T_s ≤ 80°C and T_∞ = 27°C, 302 ≤ T_f ≤ 326 K. Using properties evaluated at the mid-range of T_f, \( \overline{T}_f = 314 \) K, find

\[
Ra_D = \frac{9.8 \times 10^{-3} (1/314K) \Delta T (0.0125m)^3}{17.30 \times 10^{-6} m^2/s \times 24.6 \times 10^{-6} m^2/s} = 143.2 \Delta T
\]

\[
\overline{h}_D = \frac{0.0273 W/m \cdot K}{0.0125m} \left\{ 0.60 + \frac{0.387 \left( 143 \Delta T \right)^{1/6}}{\left[ 1 + (0.559/0.705)^{9/16} \right]^{8/27}} \right\}^{2} \]

\[
\overline{h}_D = 2.184 \left\{ 0.60 + 0.734 \Delta T^{1/6} \right\}^{2} \quad \text{(3)}
\]

COMMENTS: (1) The effect of using a fixed film temperature, \( T_f = 314K = 41°C \), for the full range 30 ≤ T_s ≤ 80°C can be seen by comparing results from the approximate Eq. (3) and the correlation, Eq. (2), with the proper film temperature. The results are summarized in the table.

<table>
<thead>
<tr>
<th>T_s (°C)</th>
<th>ΔT = T_s - T_∞ (°C)</th>

<td>4011</td>
<td>3.534</td>
<td>7.72</td>
<td>7.71</td>
</tr>
</tbody>
</table>

The approximate expression for \( \overline{h}_D \) is in excellent agreement with the correlation.

(2) In calculating heat rates it may be important to consider radiation exchange with the surroundings.
PROBLEM 9.69

KNOWN: Thin-walled tube mounted horizontally in quiescent air and wrapped with an electrical tape passing hot fluid in an experimental loop.

FIND: (a) Heat flux \( q_e^* \) from the heating tape required to prevent heat loss from the hot fluid when (a) neglecting and (b) including radiation exchange with the surroundings, (c) Effect of insulation on \( q_e^* \) and convection/radiation rates.

SCHEMATIC:

\[ T_{\text{sur}} = T_\infty \]
\[ T_\infty = 15 \, ^\circ C \]
\[ D_i = 20 \, \text{mm} \]
\[ D_o = (2t + D_i) \]

Thin heater, \( q_e^* \), \( \varepsilon_h = 0.95 \)

Insulation, \( 0 \leq l \leq 20 \, \text{mm} \)
\( \varepsilon_i = 0.60 \), \( k_i = 0.050 \, \text{W/m-K} \)

Hot fluid \( T_m = 45 \, ^\circ C \)

ASSUMPTIONS: (1) Steady-state conditions, (2) Ambient air is quiescent and extensive, (3) Surroundings are large compared to the tube.

PROPERTIES: Table A.4, Air \( (T_\gamma = (T_s + T_\infty)/2 = (45 + 15)\,^\circ C/2 = 303 \, \text{K}, 1 \, \text{atm}) \): \( \nu = 16.19 \times 10^{-6} \, \text{m}^2/\text{s} \), \( \alpha = 22.9 \times 10^{-6} \, \text{m}^2/\text{s} \), \( k = 26.5 \times 10^{-3} \, \text{W/m-K} \), \( \text{Pr} = 0.707 \), \( \beta = 1/T_\gamma \).

ANALYSIS: (a,b) To prevent heat losses from the hot fluid, the heating tape temperature must be maintained at \( T_m \); hence \( T_{s,i} = T_m \). From a surface energy balance,

\[ q_e^* = q_{\text{conv}} + q_{\text{rad}} = (\bar{h}D_i + h_r)\left(T_{s,i} - T_\infty\right) \]

where the linearized radiation coefficient, Eq. 1.9, is

\[ h_r = \varepsilon \sigma \left(T_{s,i} + T_\infty\right) \left(T_{s,i}^2 + T_\infty^2\right), \]

or

\[ h_r = 0.95 \times 5.67 \times 10^{-8} \, \text{W/m}^2\cdot\text{K}^4 \left(318+288\right) \left(318^2+288^2\right) \left(318^2+288^2\right)^{3/2} = 6.01 \, \text{W/m}^2\cdot\text{K}. \]

Neglecting radiation: For the horizontal cylinder, Eq. 9.34 yields

\[ \text{Ra}_D = \frac{g \beta (T_{s,i} - T_\infty) D_i^3}{\nu \alpha} = \frac{9.8 \, \text{m/s}^2 \left(1/303 \, \text{K}\right) \left(45-15\right) \, \text{K} \, \left(0.020 \, \text{m}\right)^3}{16.19 \times 10^{-6} \, \text{m}^2/\text{s} \times 22.9 \times 10^{-6} \, \text{m}^2/\text{s}} = 20,900 \]

\[ \text{Nu}_D = \frac{\bar{h}D_i}{k} = \left\{0.60 + \frac{0.386 \text{Ra}_D^{1/6}}{1 + (0.559/\text{Pr})^{9/16}}\right\}^{2/7} \]

Continued ....
PROBLEM 9.69 (Cont.)

\[
\overline{h}_{D_1} = \frac{0.0265 \text{ W/m} \cdot \text{K}}{0.020 \text{ m}} \left\{ 0.60 + \frac{0.386 (20,900)^{1/6}}{1 + (0.559/0.707)^{9/16}} \right\}^{8/27} = 6.90 \text{ W/m}^2 \cdot \text{K}
\]

Hence, neglecting radiation, the required heat flux is

\[
q_e^* = 6.90 \text{ W/m}^2 \cdot \text{K} (45 - 15) \text{K} = 207 \text{ W/m}^2 \cdot \text{K}
\]

**Considering radiation:** The required heat flux considering radiation is

\[
q_e^* = (6.90 + 6.01) \text{ W/m}^2 \cdot \text{K} (45 - 15) \text{K} = 387 \text{ W/m}^2 \cdot \text{K}
\]

(c) With insulation, the surface energy balance must be modified to account for an increase in the outer diameter from \(D_i\) to \(D_o = D_i + 2t\) and for the attendant thermal resistance associated with conduction across the insulation. From an energy balance at the inner surface of the insulation,

\[
q_e^* (\pi D_i) = q_{\text{cond}} = \frac{2\pi k_i (T_m - T_{s,o})}{\ln (D_o/D_i)}
\]

and from an energy balance at the outer surface,

\[
q_{\text{cond}} = q_{\text{conv}} + q_{\text{rad}} = \pi D_o \left( \overline{h}_{D_o} + h_r \right) (T_{s,o} - T_{\infty})
\]

The foregoing expressions may be used to determine \(T_{s,o}\) and \(q_e^*\) as a function of \(t\), with the IHT Correlations and Properties Tool Pads used to evaluate \(\overline{h}_{D_o}\). The desired results are plotted as follows.

By adding 20 mm of insulation, the required power dissipation is reduced by a factor of approximately 3. Convection and radiation heat rates at the outer surface are comparable.

**COMMENTS:** Over the range of insulation thickness, \(T_{s,o}\) decreases from 45°C to 20°C, while \(\overline{h}_{D_o}\) and \(h_r\) decrease from 6.9 to 3.5 W/m²·K and from 3.8 to 3.3 W/m²·K, respectively.
PROBLEM 9.70

KNOWN: A billet of stainless steel AISI 316 with a diameter of 150 mm and length 500 mm emerges from a heat treatment process at 200°C and is placed into an unstirred oil bath maintained at 20°C.

FIND: (a) Determine whether it is advisable to position the billet in the bath with its centerline horizontal or vertical in order to decrease the cooling time, and (b) Estimate the time for the billet to cool to 30°C for the better positioning arrangement.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions for part (a), (2) Oil bath approximates a quiescent fluid, (3) Consider only convection from the lateral surface of the cylindrical billet; and (4) For part (b), the billet has a uniform initial temperature.

PROPERTIES: Table A-5, Engine oil \((T_f = (T_s + T_\infty)/2)\): see Comment 1. Table A-1, AISI 316 (400 K): \(\rho = 8238 \text{ kg/m}^3\), \(c_p = 468 \text{ J/kg} \cdot \text{K}\), \(k = 15 \text{ W/m} \cdot \text{K}\).

ANALYSIS: (a) For the purpose of determining whether the horizontal or vertical position is preferred for faster cooling, consider only free convection from the lateral surface. The heat loss from the lateral surface follows from the rate equation

\[
q = \overline{h} A_s (T_s - T_\infty)
\]

Vertical position. The lateral surface of the cylindrical billet can be considered as a vertical surface of height \(L\), width \(P = \pi D\), and area \(A_s = PL\). The Churchill-Chu correlation, Eq. 9.26, is appropriate to estimate \(\overline{h}_L\),

\[
\overline{Nu}_L = \frac{\overline{h}_L L}{k} = 0.825 + \frac{0.387 \overline{Ra}_L^{1/6}}{1 + (0.492/Pr)^{9/16}}^{8/27}
\]

Horizontal position. In this position, the billet is considered as a long horizontal cylinder of diameter \(D\) for which the Churchill-Chu correlation of Eq. 9.34 is appropriate to estimate \(\overline{h}_D\),

\[
\overline{Nu}_L = \frac{\overline{h}_D D}{k} = 0.60 + \frac{0.387 \overline{Ra}_D^{1/6}}{1 + (0.55/Pr)^{9/16}}^{8/27}
\]

Continued …..
PROBLEM 9.70 (Cont.)

\[ \text{Ra}_D = \frac{g\beta(T_S - T_{\infty})D^3}{\nu\alpha} \]

with properties evaluated at \( T_f \). The heat transfer area is also \( A_s = PL \).

Using the foregoing relations in IHT with the thermophysical properties library as shown in Comment 1, the analysis results are tabulated below.

\[
\begin{align*}
\text{Ra}_L &= 1.36 \times 10^{11} & \text{Nu}_L &= 801 & \bar{h}_L &= 218 \text{ W/m}^2\cdot\text{K} \\
\text{Ra}_D &= 3.67 \times 10^9 & \text{Nu}_D &= 245 & \bar{h}_D &= 221 \text{ W/m}^2\cdot\text{K}
\end{align*}
\]

(vertial)

(horizontal)

Recognize that the orientation has a small effect on the convection coefficient for these conditions, but we’ll select the horizontal orientation as the preferred one.

(b) Evaluate first the Biot number to determine if the lumped capacitance method is valid.

\[
\text{Bi} = \frac{\bar{h}_D (D_o / 2)}{k} = \frac{221 \text{ W/m}^2\cdot\text{K} \left(0.150 \text{ m/2}\right)}{15 \text{ W/m} \cdot \text{K}} = 1.1
\]

Since \( \text{Bi} \gg 0.1 \), the spatial effects are important and we should use the one-term series approximation for the infinite cylinder, Eq. 5.49. Since \( \bar{h}_D \) will decrease as the billet cools, we need to estimate an average value for the cooling process from 200°C to 30°C. Based upon the analysis summarized in Comment 1, use \( \bar{h}_D = 119 \text{ W/m}^2\cdot\text{K} \). Using the transient model for the infinite cylinder in IHT, (see Comment 2) find for \( T(r_o, t_o) = 30°C \),

\[
t_o = 3845 \text{ s} = 1.1 \text{ h}
\]

COMMENTS: (1) The IHT code using the convection correlation functions to estimate the coefficients is shown below. This same code was used to calculate \( \bar{h}_D \) for the range 30 \( \leq T_s \leq 200°C \) and determine that an average value of the cooling period of part (b) is 119 W/m²-K.

alpha = k / (rho * cp)
PROBLEM 9.71

KNOWN: Diameter, initial temperature and emissivity of long steel rod. Temperature of air and surroundings.

FIND: (a) Average surface convection coefficient, (b) Effective radiation coefficient, (c,d) Maximum allowable conveyor time.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible effect of forced convection, (2) Constant properties, (3) Large surroundings, (4) Quiescent air.

PROPERTIES: Stainless steel (given): $k = 25 \text{ W/m} \cdot \text{K}$, $\alpha = 5.2 \times 10^{-6} \text{ m}^2/\text{s}$; Table A.4, Air ($T_f = 650 \text{ K}$, 1 atm): $\nu = 6.02 \times 10^{-5} \text{ m}^2/\text{s}$, $\alpha = 8.73 \times 10^{-5} \text{ m}^2/\text{s}$, $k = 0.0497 \text{ W/m} \cdot \text{K}$, $\text{Pr} = 0.69$.

ANALYSIS: (a) For free convection from a horizontal cylinder,

$$\text{Ra}_D = \frac{g \beta (T_s - T_\infty)D^3}{\alpha \nu} = \frac{9.8 \text{ m/s}^2 (1/650 \text{ K})(0.05 \text{ m})^3}{6.02 \times 8.73 \times 10^{-10} \text{ m}^4/\text{s}^2} = 2.51 \times 10^5$$

The Churchill and Chu correlation yields

$$\text{Nu}_D = \left\{ 0.60 + \frac{0.387 \text{Ra}_D^{1/6}}{1 + (0.559/\text{Pr})^{9/16}} \right\}^2$$

$$= \left\{ 0.60 + \frac{0.387 (2.51 \times 10^5)^{1/6}}{1 + (0.559/0.69)^{9/16}} \right\}^2 = 9.9$$

$$h = \text{Nu}_D k/D = 9.9 (0.0497 \text{ W/m} \cdot \text{K})/0.05 \text{ m} = 9.84 \text{ W/ m}^2 \cdot \text{K}$$

(b) The radiation heat transfer coefficient is

$$h_r = \varepsilon \sigma (T_s + T_{\text{sur}}) \left( T_s^2 + T_{\text{sur}}^2 \right) = 0.4 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (1000$$

$$+ 300) K \left( (1000)^2 + (300)^2 \right) K^2 = 32.1 \text{ W/ m}^2 \cdot \text{K}$$

(c) For the long stainless steel rod and the initial values of $h$ and $h_r$,

$$\text{Bi} = \left( h + h_r \right)(r_o/2)/k = 42.0 \text{ W/ m}^2 \cdot \text{K} \times 0.0125 \text{ m}/25 \text{ W/ m} \cdot \text{K} = 0.021. $$

Hence, the lumped capacitance method can be used.

$$\frac{T - T_\infty}{T_i - T_\infty} = \frac{600 \text{ K}}{700 \text{ K}} = \exp(-\text{Bi} \cdot \text{Fo}) = \exp(-0.021\text{Fo})$$

Continued...
PROBLEM 9.71 (Cont.)

\[ \text{Fo} = 7.34 = \alpha \frac{t}{(r_0/2)^2} = 0.0333t \]
\[ t = 221 \text{ s.} \]

(d) Using the IHT Lumped Capacitance Model with the Correlations and Properties Tool Pads, a more accurate estimate of the maximum allowable transit time may be obtained by evaluating the numerical integration,

\[
\int_0^t dt = -\frac{\rho c_p D}{4} \int_{1000K}^{900K} \frac{dT}{(\bar{h} + h_r)(T - T_\infty)}
\]

where \( \rho c_p = k/\alpha = 4.81 \times 10^6 \text{ J/K·m}^3 \). The integration yields

\[ t = 245 \text{ s} \]

At this time, the convection and radiation coefficients are \( \bar{h} = 9.75 \) and \( h_r = 24.5 \text{ W/m}^2\cdot\text{K} \), respectively.

COMMENTS: Since \( \bar{h} \) and \( h_r \) decrease with increasing time, the maximum allowable conveyor time is underestimated by the result of part (c).
PROBLEM 9.72

KNOWN: Velocity and temperature of air flowing through a duct of prescribed diameter. Temperature of duct surroundings. Thickness, thermal conductivity and emissivity of applied insulation.

FIND: (a) Duct surface temperature and heat loss per unit length with no insulation, (b) Surface temperatures and heat loss with insulation.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Fully-developed internal flow, (3) Negligible duct wall resistance, (4) Duct outer surface is diffuse-gray, (5) Outside air is quiescent, (6) Pressure of inside and outside air is atmospheric.

PROPERTIES: Table A.4, Air (T_m = 70°C): \( \nu = 20.22 \times 10^{-6} \text{ m}^2/\text{s}, \) \( Pr = 0.70, \) \( k = 0.0295 \text{ W/m·K}; \) Table A.4, Air (T_f \approx 27°C): \( \nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}, \) \( Pr = 0.707, \) \( k = 0.0263 \text{ W/m·K}, \) \( \alpha = 22.5 \times 10^{-6} \text{ m}^2/\text{s}, \) \( \beta = 0.00333 \text{ K}^{-1}. \)

ANALYSIS: (a) Performing an energy balance on the duct wall with no insulation (\( T_{s,i} = T_{s,o} \)),

\[
q'_{\text{conv,i}} = q'_{\text{conv,o}} + q'_{\text{rad,o}} \quad h_i \left( \pi D_i \right) \left( T_m - T_{s,i} \right) = h_o \left( \pi D_i \right) \left( T_{s,i} - T_{\infty} \right) + \epsilon_i \sigma \left( \pi D_i \right) \left( T_{s,i}^4 - T_{\text{sur}}^4 \right)
\]

with \( Re_{D,i} = \frac{D_o u_m}{\nu} = 3 \text{ m/s} \times 0.15 \text{ m}/(20.22 \times 10^{-6} \text{ m}^2/\text{s}) = 2.23 \times 10^4 \), the internal flow is turbulent, and from the Dittus-Boelter correlation,

\[
h_i = \frac{k}{D_i} 0.023 \text{Re}^{4/5} \text{Pr}^{0.3} = \frac{0.0295 \text{ W/m·K}}{0.15} 0.023 \left( 2.23 \times 10^4 \right)^{4/5} (0.7)^{0.3} = 12.2 \text{ W/m}^2 \cdot \text{K}.
\]

For free convection, the Rayleigh number is

\[
Ra_{D,i} = \frac{g \beta \left( T_{s,i} - T_{\infty} \right) D_i^3}{\nu \alpha} = 9.8 \text{ m/s}^2 \left( 0.0033 \right) \left( T_{s,i} - 273 \right) (0.15)^3 \text{ m}^3 = 15.89 \times 10^{-6} \text{ m}^2/\text{s} \times 22.5 \times 10^{-6} \text{ m}^2/\text{s}
\]

and from Eq. 9.34,

\[
\bar{h}_o = \frac{k}{D_i} \left[ \frac{0.387 Ra_{D,i}^{1/6}}{1 + \left( 0.559/Pr \right)^{9/16}} \right]^{8/27} = \frac{0.0263}{0.15} \left[ \frac{0.387 \left( 3.08 \times 10^5 \right)^{1/6}}{1 + \left( 0.559/0.707 \right)^{9/16}} \right]^{8/27}
\]

Continued...
PROBLEM 9.72 (Cont.)

\[ \bar{h}_0 = 0.175 \left[ 0.60 + 2.64 \left( T_{s,i} - T_\infty \right) \right]^{1/6} \]

Hence

\[ 12.2 \left( 343 - T_{s,i} \right) = 0.175 \left[ 0.60 + 2.64 \left( T_{s,i} - 273 \right) \right]^{1/6} \left( T_{s,i} - 273 \right) + 0.5 \times 5.67 \times 10^{-8} \left[ T_{s,i}^4 - (273)^4 \right] \]

A trial-and-error solution gives \( T_{s,i} \approx 314.7 \text{ K} = 41.7^\circ \text{C} \)

The heat loss per unit length is then

\[ q' = q'_{\text{conv},i} = 12.2 \left( \pi \times 0.15 \right)(70 - 42) = 163 \text{ W/m}. \]

(b) Performing energy balances at the inner and outer surfaces, we obtain, respectively,

\[ q'_{\text{conv},i} = q'_{\text{cond}} \]

or,

\[ \frac{2\pi k_s \left( T_{s,i} - T_{s,o} \right)}{\ln \left( D_o/D_i \right)} \]

and,

\[ q'_{\text{cond}} = q'_{\text{conv},o} + q'_{\text{rad},o} \]

or,

\[ \frac{2\pi k_s \left( T_{s,i} - T_{s,o} \right)}{\ln \left( D_o/D_i \right)} = \bar{h}_0 \left( \pi D_o \right) (T_s - T_\infty) + \varepsilon_o \sigma \left( \pi D_o \right) \left( T_{s,o}^4 - T_{\text{sur}}^4 \right) \]

Using the IHT workspace with the Correlations and Properties Tool Pads to solve the energy balances for the unknown surface temperatures, we obtain

\( T_{s,i} = 60.8^\circ \text{C} \quad T_{s,o} = 12.5^\circ \text{C} \)

With the heat loss per unit length again evaluated from the inside convection process, we obtain

\[ q' = q'_{\text{conv},i} = 52.8 \text{ W/m} \]

COMMENTS: For part (a), the outside convection coefficient is \( \bar{h}_o = 5.4 \text{ W/m}^2 \text{K} < h_i \). The outside heat transfer rates are \( q'_{\text{conv},o} \approx 106 \text{ W/m} \) and \( q'_{\text{rad},o} \approx 57 \text{ W/m} \). For part (b), \( \bar{h}_o = 3.74 \text{ W/m}^2 \text{K} \), \( q'_{\text{conv},o} = 29.4 \text{ W/m} \), and \( q'_{\text{rad},o} = 23.3 \text{ W/m} \). Although \( T_{s,i} \) increases with addition of the insulation, there is a substantial reduction in \( T_{s,o} \) and hence the heat loss.
PROBLEM 9.73

KNOWN: Biological fluid with prescribed flow rate and inlet temperature flowing through a coiled, thin-walled, 5-mm diameter tube submerged in a large water bath maintained at 50°C.

FIND: (a) Length of tube and number of coils required to provide an exit temperature of $T_{m,o} = 38°C$, and (b) Variations expected in $T_{m,o}$ for a $\pm 10\%$ change in the mass flow rate for the tube length determined in part (a).

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Coiled tube approximates a horizontal tube experiencing free convection in a quiescent, extensive medium (water bath), (3) Biological fluid has thermophysical properties of water, and (4) Negligible tube wall thermal resistance.

PROPERTIES: Table A.4 Water - cold side ($T_{m,c} = (T_{m,i} + T_{m,o}) / 2 = 304.5 K$): $c_{p,c} = 4178 \text{ J/kg} \cdot \text{K}, \mu_c = 777.6 \times 10^{-6} \text{ N} \cdot \text{s/m}^2, k_c = 0.6193 \text{ W/m} \cdot \text{K}, Pr_c = 5.263$; Table A.4, Water - hot side ($T_{m,h} = (T_{m,i} + T_{m,o}) / 2 = 320.1 K$, see comment 1): $\rho_h = 989.1 \text{ kg/m}^3, c_{p,h} = 4180 \text{ J/kg} \cdot \text{K}, \mu_h = 575.6 \times 10^{-6} \text{ N} \cdot \text{s/m}^2, k_h = 0.6401 \text{ W/m} \cdot \text{K}, \nu_h = \mu_h / \rho_h = 5.827 \times 10^{-7} \text{ m}^2/\text{s}, \alpha_h = k_h / \rho_h c_{p,h} = 15.48 \times 10^{-8} \text{ m}^2/\text{s}.$

ANALYSIS: (a) Following the treatment of Section 8.3.3, the coil experiences internal flow of the cold biological fluid (c) and free convection with the external hot fluid (h). From Eq. 8.46a,

$$\frac{T_{\infty} - T_{m,o}}{T_{\infty} - T_{m,i}} = \exp \left(-\frac{\overline{U}PL}{mc_{p,c}}\right) \overline{U} = \left(1/\overline{h}_c + 1/\overline{h}_h\right)^{-1} \tag{1}$$

with $P = \pi D$ and for the overall coefficient $\overline{U}$, $\overline{h}_c$ and $\overline{h}_h$ are the average convection coefficients for internal flow and external free convection, respectively. These coefficients are estimated as follows.

Internal flow, $\overline{h}_c$: To characterize the flow, calculate the Reynolds number,

$$Re_{D,c} = \frac{4 \dot{m}}{\pi D \mu_c} = \frac{4 \times 0.02 \text{ kg/s}}{\pi \times 0.005 \text{ m} \times 777.6 \times 10^{-6} \text{ N} \cdot \text{s/m}^2} = 6550 \tag{3}$$

evaluating properties at $\overline{T}_m = (T_{m,i} + T_{m,o}) / 2 = (25 + 38)\degree C / 2 = 31.5\degree C = 304.5 K$. Note that $Re_{D,c}$ is between the laminar upper limit (2300) and the turbulent lower limit (10,000). To provide a conservative estimate, we choose to consider the flow as laminar and anticipate that the flow will be fully developed. From Eq. 8.55, $Nu_{D,c} = 3.66,$

$$\overline{h}_c = Nu_{D,c} k_c / D = 3.66 \times 0.6193 \text{ W/m} \cdot \text{K} / 0.005 \text{ m} = 453 \text{ W/m}^2 \cdot \text{K} \tag{4}$$

External free convection, $\overline{h}_h$: For the horizontal tube, Eq. 9.34, with

$$Ra_{D,h} = \frac{g \beta_h cTD^3}{\nu_h \alpha_h} \Delta T = \overline{T}_s - T_{\infty} \tag{5,6}$$

Continued...
where $T_s$ is the average tube wall temperature determined from the thermal circuit for which

$$\overline{h}_c (\overline{T}_m - \overline{T}_s) = \overline{h}_h (\overline{T}_s - \overline{T}_\infty) \quad (7)$$

and the average film temperature at which to evaluate properties is

$$T_{f,c} = \left( T_s + T_\infty \right) / 2 \quad (8)$$

We need to guess a value for $T_s$ and iterate the solution of the system of equations until all the equations are satisfied. See Comments 1 and 2.

**Results of the analysis:** Using the foregoing relations in IHT (see Comment 2) the following results were obtained

$$\bar{U} = 313.4 \text{ W/m}^2 \text{ K}, \quad \bar{h}_c = 453 \text{ W/m}^2 \text{ K}, \quad \bar{h}_h = 1015 \text{ W/m}^2 \text{ K}$$

$$T_{m,c} = 304.5 \text{ K}, \quad T_{f,h} = 320.1 \text{ K}, \quad T_s = 317.0 \text{ K} \quad L = 12.46 \text{ m}$$

From knowledge of the tube length with the diameter of the coil $D_c = 200 \text{ mm}$, the number of coils required is

$$N = \frac{L}{\pi D_c} = \frac{12.46 \text{ m}}{\pi \times 0.200 \text{ m}} = 19.8 \approx 20$$

(b) With the length fixed at $L = 12.46 \text{ m}$, we can backsolve the foregoing IHT workspace model to find what effect a ±10% change in the mass flow rate has on the outlet temperature, $T_{m,o}$. The results of the analysis are tabulated below.

<table>
<thead>
<tr>
<th>$\dot{m}$ (kg/s)</th>
<th>0.018</th>
<th>0.02</th>
<th>0.022</th>
</tr>
</thead>
<tbody>
<tr>
<td>$T_{m,o}$ ($^\circ$C)</td>
<td>38.95</td>
<td>38.00</td>
<td>37.17</td>
</tr>
</tbody>
</table>

That is, a ±10% change in the flow rate causes a ±1°C change in the outlet temperature. While this change seems quite small, the effect on biological processes can be significant.

**COMMENTS:**

1. For the hot fluid, the Properties section shows the relevant thermophysical properties evaluated at the proper average (rather than a guess value for the film temperature).

2. For the tube $L/D = 12.46 \text{ m}/0.005 \text{ m} = 2492$ which is substantially greater than the entrance length criterion, $0.05Re_D = 0.05 \times 6550 = 328$. Hence, the assumption of fully developed internal flow is justified.

3. The IHT model for the system can be constructed beginning with the Rate Equation Tools, Tube Flow, Constant Surface Temperature along with the Correlation Tools for Free Convection, Horizontal Cylinder and Internal Flow, Laminar, Fully Developed Flow and the Properties Tool for the hot and cold fluids (water). The full set of equations is extensive and very stiff. Review of the IHT Example 8.5 would be helpful in understanding how to organize the complete model.
PROBLEM 9.74

KNOWN: Volume, thermophysical properties, and initial and final temperatures of a pharmaceutical. Diameter and length of submerged tubing. Pressure of saturated steam flowing through the tubing.

FIND: (a) Initial rate of heat transfer to the pharmaceutical, (b) Time required to heat the pharmaceutical to 70°C and the amount of steam condensed during the process.

SCHEMATIC:

ASSUMPTIONS: (1) Pharmaceutical may be approximated as an infinite, quiescent fluid of uniform, but time-varying temperature, (2) Free convection heat transfer from the coil may be approximated as that from a heated, horizontal cylinder, (3) Negligible thermal resistance of condensing steam and tube wall, (4) Negligible heat transfer from tank to surroundings, (5) Constant properties.

PROPERTIES: Table A-4, Saturated water (2.455 bars): T_{sat} = 400K = 127°C, h_{fg} = 2.183 \times 10^6 J/kg. Pharmaceutical: See schematic.

ANALYSIS: (a) The initial rate of heat transfer is \( q = \hbar A_s (T_s - T_i) \), where \( A_s = \pi DL = 0.707 \text{ m}^2 \) and \( \hbar \) is obtained from Eq. 9.34. With \( \alpha = \nu/Pr = 4.0 \times 10^{-7} \text{ m}^2/\text{s} \) and \( \text{Ra}_D = g\beta (T_s - T_i) D^3/\alpha \nu = 9.8 \text{ m/s}^2 (0.002 \text{ K}^{-1}) (102\text{K}) (0.015\text{m})^3/16 \times 10^{-13} \text{ m}^4/\text{s}^2 = 4.22 \times 10^6 \),

\[
\text{Nu}_D = \left\{ 0.60 + \frac{0.387 \text{Ra}_D^{1/6}}{1 + (0.559/\text{Pr})^{9/16}} \right\}^{8/27} \\
= \left\{ 0.60 + \frac{0.387 (4.22 \times 10^6)^{1/6}}{1 + (0.559/10)^{9/16}} \right\}^{8/27} = 27.7
\]

Hence, \( \hbar = \text{Nu}_D k / D = 27.7 \times 0.250 \text{ W/m.K} / 0.015 \text{m} = 462 \text{ W/m}^2 \cdot \text{K} \) and \( q = \hbar A_s (T_s - T_i) = 462 \text{ W/m}^2 \cdot \text{K} \times 0.707 \text{ m}^2 (102\text{°C}) = 33,300 \text{ W} \)

(b) Performing an energy balance at an instant of time for a control surface about the liquid,

\[
\frac{d \left( \rho \gamma c T \right)}{dt} = q(t) = \hbar(t) A_s (T_s - T(t))
\]

where the Rayleigh number, and hence \( \hbar \), changes with time due to the change in the temperature of the liquid. Integrating the foregoing equation using the DER function of IHT, the following results are obtained for the variation of \( T \) and \( \hbar \) with \( t \).
The time at which the liquid reaches 70°C is

\[ t_f \approx 855 \text{s} \]

The rate at which T increases decreases with increasing time due to the corresponding reduction in \((T_s - T)\), and hence reductions in \(Ra_p\), \(\overline{h}\) and \(q\). The Rayleigh number decreases from \(4.22 \times 10^6\) to \(2.16 \times 10^6\), while the heat rate decreases from 33,300 to 14,000 W. The convection coefficient decreases approximately as \((T_s - T)^{1/3}\), while \(q \sim (T_s - T)^{4/3}\). The latent energy released by the condensed steam corresponds to the increase in thermal energy of the pharmaceutical. Hence,

\[ m_c h_{fg} = \rho \overline{c} (T_f - T_i) \]

and

\[ m_c = \frac{\rho \overline{c} (T_f - T_i)}{h_{fg}} = \frac{1100 \text{ kg/m}^3 \times 0.2 \text{ m}^3 \times 2000 \text{ J/kg} \cdot \text{K} \times 45^\circ\text{C}}{2.183 \times 10^6 \text{ J/kg}} = 9.07 \text{ kg} \]

**COMMENTS:** (1) Over such a large temperature range, the fluid properties are likely to vary significantly, particularly \(\nu\) and \(Pr\). A more accurate solution could therefore be performed if the temperature dependence of the properties were known. (2) Condensation of the steam is a significant process expense, which is linked to the equipment (capital) and energy (operating) costs associated with steam production.
PROBLEM 9.75

KNOWN: Fin of uniform cross section subjected to prescribed conditions.

FIND: Tip temperature and fin effectiveness based upon (a) average values for free convection and radiation coefficients and (b) local values using a numerical method of solution.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Surroundings are isothermal and large compared to the fin, (3) One-dimensional conduction in fin, (4) Constant fin properties, (5) Tip of fin is insulated, (6) Fin surface is diffuse-gray.

PROPERTIES: Table A-4, Air (Tf = 325 K, 1 atm): ν = 18.41 × 10^-6 m^2/s, k = 0.0282 W/m·K, α = 26.2 × 10^-6 m^2/s, Pr = 0.704, β = 1/Tf = 3.077 × 10^-3 K^-1; Table A-1, Steel AISI 316 (Ts = 350 K): k = 14.3 W/m·K.

ANALYSIS: (a) Average value h_c and h_r: From Table 3.4 for a fin of constant cross section with an insulated tip and constant heat transfer coefficient h, the tip temperature (x = L) is given by Eq. 3.75,

\[ \theta_L = \theta_b \frac{\cosh m(L-x)}{\cosh mL} = \theta_b \frac{m}{\sinh mL} \]

where \( \theta_L = T_L - T_\infty \) and \( \theta_b = T_b - T_\infty \). For this situation, the average heat transfer coefficient is

\[ \bar{h} = \frac{h_c + h_r}{2} \]

and is evaluated at the average temperature of the fin. The fin effectiveness \( \eta_f \) follows from Eqs. 3.81 and 3.76

\[ \eta_f = \frac{q_f}{\bar{h}A_c b \theta_b}, \quad q_f = M \cdot \tanh (mL), \quad M = \left( \frac{\bar{h}P A_c}{2} \right)^{1/2} \theta_b. \]

To estimate the coefficients, assume a value of \( \bar{T}_s \); the lowest \( \bar{T}_s \) occurs when the tip reaches \( T_\infty \). That is,

\[ \bar{T}_s = \left( \bar{T}_\infty + T_b \right)/2 = (27 + 125) \text{°C} / 2 = 76 \text{°C} = 350 \text{K} \]

\[ T_f = \left( \bar{T}_s + T_\infty \right)/2 = 325 \text{ K}. \]

The free convection coefficient can be estimated from Eq. 9.33,

\[ \frac{\bar{h}D}{k} = C R a_D^n \]

\[ R a_D = \frac{g \beta \Delta T D^3}{\nu \alpha} = \frac{9.8 \text{ m/s}^2 \times 3.077 \times 10^{-3} \text{ K}^{-1} (350 - 300) \text{K} \times (0.006 \text{ m})^3}{18.41 \times 10^{-6} \text{ m}^2/\text{s} \times 26.2 \times 10^{-6} \text{ m}^2/\text{s}} = 675 \]

and from Table 9.1 with \( 10^3 < R a_L < 10^4 \), \( C = 0.850 \) and \( n = 0.188 \). Hence

Continued...
PROBLEM 9.75 (Cont.)

\[ \bar{h}_c = \frac{0.0282 \text{ W/m} \cdot \text{K}}{0.006 \text{ m}} \times 0.850(675)^{0.188} = 13.6 \text{ W/m}^2 \cdot \text{K}. \]  \hfill (8)

The radiation coefficient is estimated from Eq. 1.9,

\[ \bar{h}_r = \varepsilon \sigma \left( T_s + T_{\text{sur}} \right) \left( T_s^2 + T_{\text{sur}}^2 \right) \]

\[ \bar{h}_r = 0.6 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (350 + 300)(350^2 + 300^2)K^3 = 4.7 \text{ W/m}^2 \cdot \text{K} \]  \hfill (9)

Hence, the average coefficient, Eq. (3), is

\[ \bar{h} = (13.6 + 4.7) \text{ W/m}^2 \cdot \text{K} = 18.3 \text{ W/m}^2 \cdot \text{K}. \]

Evaluate the fin parameters, Eq. (2) and (6) with

\[ P = \pi D = \pi \times 0.006 \text{ m} = 1.885 \times 10^{-2} \text{ m} \]

\[ A_c = \pi D^2 / 4 = \pi (0.006 \text{ m})^2 / 4 = 2.827 \times 10^{-5} \text{ m}^2 \]

\[ m = \left( 18.3 \text{ W/m}^2 \cdot \text{K} \times 1.885 \times 10^{-2} \text{ m} / 14.3 \text{ W/m} \cdot \text{K} \times 2.827 \times 10^{-5} \text{ m} \right)^{1/2} = 29.21 \text{ m}^{-1} \]

\[ M = \left( 18.3 \text{ W/m}^2 \cdot \text{K} \times 1.885 \times 10^{-2} \text{ m} \times 14.3 \text{ W/m} \cdot \text{K} \times 2.827 \times 10^{-5} \text{ m}^2 \right)^{1/2} (125 - 27) \text{ K} = 1.157 \text{ W}. \]

From Eq. (1), the tip temperature is

\[ \theta_L = T_L - T_b = (125 - 27) \text{ K}/\cosh (29.21 \text{ m}^{-1} \times 0.050 \text{ m}) = 43.2 \text{ K} \quad T_L = 70.2^\circ \text{C} = 343 \text{ K}. \]

Note this value of \( T_L \) provides for \( \bar{T}_s = 370 \text{ K} \); so we underestimated \( \bar{T}_s \). For best results, an iteration is warranted. The fin effectiveness, Eqs. (4) and (5), is

\[ q_f = 1.157 \text{ W} \tanh (29.21 \text{ m}^{-1} \times 0.050 \text{ m}) = 1.039 \text{ W} \]

\[ \varepsilon_f = 1.039 \text{ W}/18.3 \text{ W} / \text{m}^2 \cdot \text{K} \times 2.827 \times 10^{-5} \text{ m}^2 (125 - 27) \text{ K} = 20.5. \]

(b) Local values \( h_c \) and \( h_r \): Consider the nodal arrangement for using a numerical method to find the tip temperature \( T_L \), the heat rate \( q_f \), and the fin effectiveness \( \varepsilon \).

From an energy balance on a control volume about node \( m \), the finite-difference equation is of the form

\[ T_m = \left[ T_{m+1} + T_{m-1} + (h_c + h_r)(4 \Delta x^2 / kD)T_\infty \right] / \left[ 2 + (h_r + h_c)(4 \Delta x^2 / kD) \right]. \]  \hfill (10)

The local coefficient \( h_c \) follows from Eq. (3), with Eq. 9.33, yielding

\[ h_c = \frac{k}{D} \frac{C}{R} \frac{a}{D} \]

\[ h_c = \frac{0.0282 \text{ W/m} \cdot \text{K}}{0.006 \text{ m}} \times 0.850(675[\Delta T/(350 - 300)])^{0.188} = 6.517 (T_m - 300)^{0.188}. \]  \hfill (11)

The local coefficient \( h_r \) follows from Eq. (9),

\[ h_r = 0.6 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (T_m + 300)(T_m^2 + 300^2) \]

Continued...
PROBLEM 9.75 (Cont.)

\[ h_r = 3.402 \times 10^{-8} (T_m + 300) \left( T_m^2 + 300^2 \right). \]  

(12)

The 20-node system of finite-difference equations based upon Eq. (10) with the variable coefficients \( h_c \) and \( h_r \), prescribed Eqs. (11) and (12), respectively, can be solved simultaneously using IHT or another approach. The temperature distribution is

</tbody>
</table>

From these results the tip temperature is

\[ T_{L_e} = T_{fd} = 343.7 \, K = 70.7^\circ C. \]

The fin heat rate follows from an energy balance for the control surface about node b.

\[
q_f = q_{\text{conv}} + q_{\text{cond}}
\]

\[
q_f = h_b P \frac{\Delta x}{2} (T_b - T_{\infty}) + k A_c \frac{T_b - T_{1}}{\Delta x}
\]

where \( h_b \) follows from Eqs. (11) and (12), with \( T_b = 125^\circ C = 398 \, K \),

\[
h_b = 6.517 (398 - 300)^{0.188} + 3.402 \times 10^{-8} (398 + 300) \left( 398^2 + 300^2 \right) = 21.33 \, \text{W/m}^2 \cdot \text{K}
\]

\[
q_f = 21.33 \, \text{W/m}^2 \cdot \text{K} \times 1.855 \times 10^{-2} \, \text{m} \times 0.0025 \, \text{m} = 0.049 \, \text{W}
\]

\[
+ 14.3 \, \text{W/m} \times 2.827 \times 10^{-5} \, \text{m}^2 \times 398 - 391.70 \, \text{K} = 0.049 + 1.018 = 1.067 \, \text{W}.
\]

The effectiveness follows from Eq. (4)

\[
\varepsilon_f = 1.067 \, \text{W/21.33 W/m}^2 \cdot \text{K} \times 2.827 \times 10^{-5} \, \text{m}^2 \times (125 - 27) \, \text{K} = 18.1
\]

COMMENTS: (1) The results by the two methods of solution compare as follows:

<table>
<thead>
<tr>
<th>Coefficients</th>
<th>( T(L), K )</th>
<th>( q_f(W) )</th>
<th>( \varepsilon_f )</th>
</tr>
</thead>
<tbody>
<tr>
<td>average</td>
<td>343.1</td>
<td>1.039</td>
<td>20.5</td>
</tr>
<tr>
<td>local</td>

<td>1.067</td>
<td>18.1</td>
</tr>
</tbody>
</table>

The temperature predictions are in excellent agreement and the heat rates very close, within 4%.

(2) To obtain the finite-different equation for node \( n = 20 \), use Eq. (10) but consider the adiabatic surface as a symmetry plane.
**PROBLEM 9.76**

**KNOWN:** Horizontal tubes of different shapes each of the same cross-sectional area transporting a hot fluid in quiescent air. Lienhard correlation for immersed bodies.

**FIND:** Tube shape which has the minimum heat loss to the ambient air by free convection.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Ambient air is quiescent, (2) Negligible heat loss by radiation, (3) All shapes have the same cross-sectional area and uniform surface temperature.

**PROPERTIES:** *Table A-4*, Air ($T_f \approx 300K$, 1 atm): $\nu = 15.89 \times 10^{-6} m^2/s$, $\alpha = 22.5 \times 10^{-6} m^2/s$, $k = 0.0263 \text{ W/m} \cdot \text{K}$, $Pr = 0.707$, $\beta = 1/T_f$.

**ANALYSIS:** The Lienhard correlation approximates the laminar convection coefficient for an immersed body on which the boundary layer does not separate from the surface by

$$Nu_{\ell} = \left( \frac{h_{\ell}}{\ell} \right)/k = 0.52Ra_{\ell}^{1/4},$$

where the characteristic length, $\ell$, is the length of travel of the fluid in the boundary layer across the shape surface. The heat loss per unit length from any shape is $q' = \overline{hP} (T_s - T_\infty)$. For the shapes,

$$Ra_{\ell} = \frac{gB\Delta T\ell^3}{\nu \alpha} = \frac{9.8 \text{ m/s}^2 (1/300K)(35 - 25) \text{ K} \ell^3 \text{ m}^3}{15.89 \times 10^{-6} \text{ m}^2 / \text{s} \times 22.5 \times 10^{-6} \text{ m}^2 / \text{s}} = 9.137 \times 10^8 \ell^3$$

$$\overline{h_{\ell}} = (0.0263 \text{ W/m} \cdot \text{K} / \ell) 0.52 \left(9.137 \times 10^8 \ell^3 \right)^{1/4} = 2.378\ell^{-1/4}.$$

For the shapes, $\ell$ is half the total wetted perimeter $P$. Evaluating $\overline{h_{\ell}}$ and $q'$, find

<table>
<thead>
<tr>
<th>Shape</th>
<th>P (mm)</th>
<th>$\ell$ (mm)</th>
<th>$\overline{h_{\ell}}$ (W/m$^2$·K)</th>
<th>$q'$ (W/m)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>$2 \times 40 + 2 \times 10 = 100$</td>
<td>50</td>
<td>5.03</td>
<td>5.03</td>
</tr>
<tr>
<td>2</td>
<td>$4 \times 20 = 80$</td>
<td>40</td>
<td>5.32</td>
<td>4.26</td>
</tr>
<tr>
<td>3</td>
<td>$4 \times 20 = 80$</td>
<td>40</td>
<td>5.32</td>
<td>4.26</td>
</tr>
<tr>
<td>4</td>
<td>$\pi \times 22.56 = 70.9$</td>
<td>35.4</td>
<td>5.48</td>
<td>3.89</td>
</tr>
</tbody>
</table>

Hence, it follows that shape 4 has the minimum heat loss.

**COMMENTS:** Using the Lienhard correlation for a sphere of $D = 22.56$ mm, find $\ell = 35.4$ mm, the same as for a cylinder, namely, $h_s = 5.48 \text{ W/m}^2 \cdot \text{K}$. Using the Churchill correlation, Eq. 9.35, find $\overline{h} = 7.69 \text{ W/m}^2 \cdot \text{K}$. Hence, the approximation for the sphere is 29% low. For a cylinder, using Eq. 9.34, find $\overline{h} = 5.15 \text{ W/m}^2 \cdot \text{K}$. The approximation for the cylinder is 6% high.
PROBLEM 9.77

KNOWN: Sphere of 2-mm diameter immersed in a fluid at 300 K.

FIND: (a) The conduction limit of heat transfer from the sphere to the quiescent, extensive fluid, \( \text{Nu}_{D,\text{cond}} = 2 \); (b) Considering free convection, surface temperature at which the Nusselt number is twice that of the conduction limit for the fluids air and water; and (c) Considering forced convection, fluid velocity at which the Nusselt number is twice that of the conduction limit for the fluids air and water.

SCHEMATIC:

ASSUMPTIONS: (1) Sphere is isothermal, (2) For part (a), fluid is stationary, and (3) For part (b), fluid is quiescent, extensive.

ANALYSIS: (a) Following the hint provided in the problem statement, the thermal resistance of a hollow sphere, Eq. 3.36 of inner and outer radii, \( r_1 \) and \( r_2 \), respectively, and thermal conductivity \( k \), is

\[
R_{t,\text{cond}} = \frac{1}{4\pi k} \left( \frac{1}{r_1} - \frac{1}{r_2} \right)
\]

and as \( r_2 \rightarrow \infty \), that is the medium is extensive

\[
R_{t,\text{cond}} = \frac{1}{4\pi kr_1} = \frac{1}{2\pi kD}
\]

The Nusselt number can be expressed as

\[
\text{Nu} = \frac{hD}{k}
\]

and the conduction resistance in terms of a convection coefficient is

\[
R_{t,\text{cond}} = \frac{1}{hA_s} = \frac{1}{h\pi D^2}
\]

Combining Eqs. (3) and (4)

\[
\text{Nu}_{D,\text{cond}} = \left( \frac{1}{R_{t,\text{cond}} \pi D^2} \right) D = \left[ \frac{1}{(1/2\pi kD)(\pi D^2)} \right] D = 2
\]

(b) For free convection, the recommended correlation, Eq. 9.35, is

\[
\text{Nu}_D = 2 + \frac{0.589\text{Ra}_D^{1/4}}{\left[ 1 + (0.469/\text{Pr})^{9/16} \right]^{4/9}}
\]

Continued...
PROBLEM 9.77 (Cont.)

\[ \text{Ra}_D = \frac{g \beta \Delta T D^3}{\nu \alpha} \quad \Delta T = T_s - T_\infty \]

where properties are evaluated at \( T_i = (T_s + T_\infty) / 2 \). What value of \( T_s \) is required for \( \overline{\text{Nu}}_D = 4 \) for the fluids air and water? Using the IHT Correlations Tool, Free Convection, Sphere and the Properties Tool for Air and Water, find

Air: \( \overline{\text{Nu}} \leq 3.1 \) for all \( T_s \)

Water: \( T_s = 301.1 \text{K} \)

(c) For forced convection, the recommended correlation, Eq. 7.59, is

\[ \overline{\text{Nu}}_D = 2 + \left( 0.4 \text{Re}_D^{1/2} + 0.06 \text{Re}_D^{2/3} \right) \text{Pr}^{0.4} \left( \mu / \mu_s \right)^{1/4} \]

\[ \text{Re}_D = V D / \nu \]

where properties are evaluated at \( T_\infty \), except for \( \mu_s \) evaluated at \( T_s \). What value of \( V \) is required for \( \overline{\text{Nu}}_D = 4 \) if the fluids are air and water? Using the IHT Correlations Tool, Forced Convection, Sphere and the Properties Tool for Air and Water, find

Air: \( V = 0.17 \text{ m/s} \)  
Water: \( V = 0.00185 \text{ m/s} \)

**COMMENTS:**
(1) For water, \( \overline{\text{Nu}}_D = 2 \times \overline{\text{Nu}}_{D,\text{cond}} \) can be achieved by \( \Delta T \approx 1 \) for free convection and with very low velocity, \( V < 0.002 \text{ m/s} \), for forced convection.

(2) For air, \( \overline{\text{Nu}}_D = 2 \times \overline{\text{Nu}}_{D,\text{cond}} \) can be achieved in forced convection with low velocities, \( V < 0.2 \text{ m/s} \).

In free convection, \( \overline{\text{Nu}}_D \) increases with increasing \( T_s \) and reaches a maximum, \( \overline{\text{Nu}}_{D,\text{max}} = 3.1 \), around 450 K. Why is this so? Hint: Plot \( \text{Ra}_D \) as a function of \( T_s \) and examine the role of \( \beta \) and \( \Delta T \) as a function of \( T_s \).
PROBLEM 9.78

KNOWN: Sphere with embedded electrical heater is maintained at a uniform surface temperature when suspended in various media.

FIND: Required electrical power for these media: (a) atmospheric air, (b) water, (c) ethylene glycol.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible surface radiation effects, (2) Extensive and quiescent media.

PROPERTIES: Evaluated at $T_f = (T_s + T_\infty)/2 = 330K$:

<table>
<thead>
<tr>
<th></th>
<th>$\nu \cdot 10^6$, m$^2$/s</th>
<th>$k \cdot 10^3$, W/mK</th>
<th>$\alpha \cdot 10^6$, m$^2$/s</th>
<th>Pr</th>
<th>$\beta \cdot 10^3$, K$^{-1}$</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table A-4, Air (1 atm)</td>
<td>18.91</td>
<td>28.5</td>
<td>26.9</td>
<td>0.711</td>
<td>3.03</td>
</tr>
<tr>
<td>Table A-6, Water</td>
<td>0.497</td>
<td>650</td>
<td>0.158</td>
<td>3.15</td>
<td>0.504</td>
</tr>
<tr>
<td>Table A-5, Ethylene glycol</td>
<td>5.15</td>
<td>260</td>
<td>0.0936</td>
<td>55.0</td>
<td>0.65</td>
</tr>
</tbody>
</table>

ANALYSIS: The electrical power ($P_e$) required to offset convection heat transfer is

$$q_{\text{conv}} = h A_s (T_s - T_\infty) = \pi h D^2 (T_s - T_\infty).$$  \hspace{1cm} (1)

The free convection heat transfer coefficient for the sphere can be estimated from Eq. 9.35 using Eq. 9.25 to evaluate $Ra_D$.

$$\overline{Nu}_D = 2 + \frac{0.589 Ra_D^{1/4}}{\left[ 1 + (0.469/Pr)^{9/16} \right]^{4/9}} \begin{cases} \text{Pr} \geq 0.7 & Ra_D = \frac{g \beta \Delta T D^3}{\nu \alpha} \quad (2,3) \\ \text{Ra}_D \leq 10^{11} & \end{cases}$$

(a) For air

$$Ra_D = \frac{9.8 \text{m}^2/\text{s} (3.03 \times 10^{-3} \text{K}^{-1}) (94 - 20) \text{K} (0.025 \text{m})^3}{18.91 \times 10^{-6} \text{m}^2/\text{s} \times 26.9 \times 10^{-6} \text{m}^2/\text{s}} = 6.750 \times 10^4$$

$$h_D = \frac{k}{D \overline{Nu}_D} = \frac{0.02285 \text{W/m} \cdot \text{K}}{0.025 \text{m}} \left\{ 2 + \frac{0.589 \left( 6.750 \times 10^4 \right)^{1/4}}{\left[ 1 + (0.469/0.711)^{9/16} \right]^{4/9}} \right\} = 10.6 \text{W/m}^2 \cdot \text{K}$$

$$q_{\text{conv}} = \pi \times 10.6 \text{W/m}^2 \cdot \text{K} (0.025 \text{m})^2 (94 - 20) \text{K} = 1.55 \text{W}.$$
(b,c) Summary of the calculations above and for water and ethylene glycol:

<table>
<thead>

</tbody>
</table>

**COMMENTS:** Note large differences in the coefficients and heat rates for the fluids.
PROBLEM 9.79

KNOWN: Surface temperature and emissivity of a 20W light bulb (spherical) operating in room air

FIND: Heat loss from bulb surface.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Quiescent room air, (3) Surroundings much larger than bulb.

PROPERTIES: Table A-4, Air \( (T_f = \frac{T_s + T_\infty}{2} = 348K, 1 \text{ atm}) \): \( \nu = 20.72 \times 10^{-6} \text{ m}^2/\text{s} \), \( k = 0.0298 \text{ W/mK} \), \( \alpha = 29.6 \times 10^{-6} \text{ m}^2/\text{s} \), \( Pr = 0.700 \), \( \beta = 1/T_f \).

ANALYSIS: Heat loss from the surface of the bulb is by free convection and radiation. The rate equations are

\[
q = q_{\text{conv}} + q_{\text{rad}} = \overline{h} A_s (T_s - T_\infty) + \varepsilon A_s \sigma (T_s^4 - T_{\text{sur}}^4)
\]

where \( A_s = \pi D^2 \). To estimate \( \overline{h} \) for free convection, first evaluate the Rayleigh number.

\[
Ra_D = \frac{g \beta \Delta T D^3}{\nu \alpha} = \frac{9.8 \text{ m/s}^2 \left( \frac{1}{348K} \right) (125 - 25) \text{ K} (0.040m)^3}{20.72 \times 10^{-6} \text{ m}^2/\text{s} \times 29.6 \times 10^{-6} \text{ m}^2/\text{s}} = 2.93 \times 10^5.
\]

Since \( Pr \geq 0.7 \) and \( Ra_D < 10^{11} \), the Churchill relation, Eq. 9.35, is appropriate.

\[
\overline{Nu}_D = 2 + \frac{0.589 \left( 2.93 \times 10^5 \right)^{1/4}}{1 + (0.469/Pr)^{9/16}} = 12.55
\]

\[
\overline{h} = \overline{Nu}_D k/D = 12.55 \left( 0.0298 \text{ W/m} \cdot \text{K} \right) /0.040m = 9.36 \text{ W/m}^2 \cdot \text{K}.
\]

Substituting numerical values, the heat loss from the bulb is,

\[
q = \pi (0.040m)^2 \left[ 9.36 - \frac{W}{\text{m}^2 \cdot \text{K}} (125 - 25) \text{ K} + 0.80 \times 5.67 \times 10^{-8} \frac{W}{\text{m}^2 \cdot \text{K}} \left( (125 + 273)^4 - (25 + 273)^4 \right) \text{ K}^4 \right]
\]

\[
q = (4.70 + 3.92) \text{ W} = 8.62 \text{ W}.
\]

COMMENTS: (1) The contributions of convection and radiation to the surface heat loss are comparable.

(2) The remaining heat loss \( (20 - 8.62 = 11.4 \text{ W}) \) is due to the transmission of radiant energy (light) through the bulb and heat conduction through the base.
**PROBLEM 9.80**

**KNOWN:** A copper sphere with a diameter of 25 mm is removed from an oven at a uniform temperature of 85°C and allowed to cool in a quiescent fluid maintained at 25°C.

**FIND:** (a) Convection coefficients for the initial condition for the cases when the fluid is air and water, and (b) Time for the sphere to reach 30°C when the cooling fluid is air and water using two different approaches, average coefficient and numerically integrated energy balance.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions for part (a); (2) Low emissivity coating makes radiation exchange negligible for the in-air condition; (3) Fluids are quiescent, and (4) Constant properties.

**PROPERTIES:** Table A-4, Air \((T_f = (25 + 85)°C/2 = 328 K, 1 \text{ atm})\): \(\nu = 1.871 \times 10^{-5} \text{ m}^2/\text{s}, k = 0.0284 \text{ W/m} \cdot \text{K}, \alpha = 2.66 \times 10^{-5} \text{ m}^2/\text{s}, \text{Pr} = 0.703, \beta = 1/T_f\); Table A-6, Water \((T_f = 328 K)\): \(\nu = 5.121 \times 10^{-7} \text{ m}^2/\text{s}, k = 0.648 \text{ W/m} \cdot \text{K}, \alpha = 1.57 \times 10^{-7} \text{ m}^2/\text{s}, \text{Pr} = 3.26, \beta = 4.909 \times 10^{-4} \text{ K}^{-1}\); Table A-1, Copper, pure \((\overline{T} = (25 + 85)°C/2 = 328 K)\): \(\rho = 8933 \text{ kg/m}^3, c = 382 \text{ J/kg} \cdot \text{K}, k = 399 \text{ W/m} \cdot \text{K}\).

**ANALYSIS:** (a) For the initial condition, the average convection coefficient can be estimated from the Churchill-Chu correlation, Eq. 9.35, 

\[
\frac{\overline{\text{Nu}_D}}{D} = \frac{\overline{\text{Nu}}_D}{k} = 2 + \frac{0.589 \text{ Ra}^{1/4}_D}{\left[1 + (0.469/\text{Pr})^{9/16}\right]^{4/9}}
\]

with properties evaluated at \(T_f = (T_s + T_\infty)/2 = 328 K\). Substituting numerical values find these results:

<table>
<thead>
<tr>
<th>Fluid</th>
<th>(T_s(°C))</th>
<th>(T_f(\text{K}))</th>
<th>(\text{Ra}_D)</th>
<th>(\overline{\text{Nu}}_D)</th>
<th>(\overline{\text{Nu}}_D(\text{W/m}^2 \cdot \text{K}))</th>
</tr>
</thead>
<tbody>
<tr>
<td>Air</td>
<td>85</td>
<td>328</td>
<td>(5.62 \times 10^4)</td>
<td>8.99</td>
<td>10.2</td>
</tr>
<tr>
<td>Water</td>
<td>85</td>
<td>328</td>
<td>(5.61 \times 10^7)</td>
<td>46.8</td>
<td>1213</td>
</tr>
</tbody>
</table>

(b) To establish the validity of the lumped capacitance (LC) method, calculate the Biot number for the worst condition (air).

\[
\text{Bi} = \frac{\overline{\text{Nu}}_D (D/3)^3}{k} = 10.2 \text{ W/m}^2 \cdot \text{K}(0.025 \text{ m/3})/399 \text{ W/m} \cdot \text{K} = 2.1 \times 10^{-4}
\]

Since \(\text{Bi} << 0.1\), the sphere can be represented by this energy balance for the cooling process

\[
\dot{E}_\text{in} - \dot{E}_\text{out} = \dot{E}_\text{st} - q_{cv} = \rho c V \frac{dT_s}{dt}
\]

\[
-\overline{\text{Nu}}_D A_s (T_s - T_\infty) = \rho V c \frac{dT_s}{dt}
\]

with \(A_s = \pi D^2\) and \(V = \pi D^3/6\). Two approaches are considered for evaluating appropriate values for \(\overline{\text{Nu}}_D\).

**Average coefficient.** Evaluate the convection coefficient corresponding to the average temperature of the sphere, \(\overline{T}_s = (30 + 85)°C/2 = 57.5°C\), for which the film temperature is \(T_f = (\overline{T}_s + T_\infty)/2\). Using the foregoing analyses of part (a), find these results.

Continued …..
PROBLEM 9.80 (Cont.)

<table>
<thead>
<tr>
<th>Fluid</th>

<td>37.1</td>
<td>940</td>
</tr>
</tbody>
</table>

Numerical integration of the energy balance equation. The more accurate approach is to numerically integrate the energy balance equation, Eq. (3), with $\bar{h}_D$ evaluated as a function of $T_s$ using Eqs. (1) and (2). The properties in the correlation parameters would likewise be evaluated at $T_f$, which varies with $T_s$. The integration is performed in the IHT workspace; see Comment 3.

Results of the lumped-capacitance analysis. The results of the LC analyses using the two approaches are tabulated below, where $t_o$ is the time to cool from 85°C to 30°C:

<table>
<thead>
<tr>
<th>Approach</th>
<th>Air</th>
<th>Water</th>
</tr>
</thead>
<tbody>
<tr>
<td>Average coefficient</td>
<td>3940</td>
<td>39</td>
</tr>
<tr>
<td>Numerical coefficient</td>
<td>4600</td>
<td>49</td>
</tr>
</tbody>
</table>

COMMENTS: (1) For these condition, the convection coefficient for the water is nearly two orders of magnitude higher than for air.

(2) Using the average-coefficient approach, the time-to-cool, $t_o$, values for both fluids is 15-20% faster than the more accurate numerical integration approach. Evaluating the average coefficient at $\bar{T}_s$ results in systematically over estimating the coefficient.

(3) The IHT code used for numerical integration of the energy balance equation and the correlations is shown below for the fluid water.

```plaintext
// LCM energy balance
- hDbar * As * (Ts - Tinf) = M * cps * der(Ts,t)
As = pi * D^2
M = rho * Vs
Vs = pi * D^3 / 6

PROBLEM 9.81

KNOWN: Temperatures and spacing of vertical, isothermal plates.

FIND: (a) Shape of velocity distribution, (b) Forms of mass, momentum and energy equations for laminar flow, (c) Expression for the temperature distribution, (d) Vertical pressure gradient, (e) Expression for the velocity distribution.

SCHEMATIC:

ASSUMPTIONS: (1) Laminar, incompressible, fully-developed flow, (2) Constant properties, (3) Negligible viscous dissipation, (4) Boussinesq approximation.

ANALYSIS: (a) For the prescribed conditions, there must be buoyancy driven ascending and descending flows along the surfaces corresponding to \( T_{s,1} \) and \( T_{s,2} \), respectively (see schematic). However, conservation of mass dictates equivalent rates of upflow and downflow and, assuming constant properties, inverse symmetry of the velocity distribution about the midplane.

(b) For fully-developed flow, which is achieved for long plates, \( v_x = 0 \) and the continuity equation yields

\[
\frac{\partial v_z}{\partial z} = 0
\]

Hence, there is no net transfer of momentum or energy by advection, and the corresponding equations are, respectively,

\[
0 = -\left(\frac{dp}{dz}\right) + \mu \left(\frac{d^2 v_z}{dx^2}\right) - \rho \left(\frac{g}{g_c}\right)
\]

\[
0 = \left(\frac{dT^2}{dx^2}\right)
\]

(c) Integrating the energy equation twice, we obtain

\[
T = C_1 x + C_2
\]

and applying the boundary conditions, \( T(-L) = T_{s,1} \) and \( T(L) = T_{s,2} \), it follows that \( C_1 = -(T_{s,1} - T_{s,2})/2L \) and \( C_2 = (T_{s,1} + T_{s,2})/2 = T_m \), in which case,

\[
\frac{T - T_m}{T_{s,1} - T_{s,2}} = -\frac{x}{2L}
\]

Continued...
PROBLEM 9.81 (Cont.)

(d) From hydrostatic considerations and the assumption of a constant density $\rho_m$, the balance between the gravitational and net pressure forces may be expressed as $\frac{dp}{dz} = -\rho_m \left( \frac{g}{\gamma_c} \right)$. The momentum equation is then of the form

$$0 = \mu \left( \frac{d^2v_z}{dx^2} \right) - \left( \rho - \rho_m \right) \left( \frac{g}{\gamma_c} \right)$$

or, invoking the Boussinesq approximation, $\rho - \rho_m \approx -\beta \rho_m (T - T_m)$,

$$\frac{d^2v_z}{dx^2} = -\left( \beta \rho_m / \mu \right) \left( \frac{g}{\gamma_c} \right) (T - T_m)$$

or, from the known temperature distribution,

$$\frac{d^2v_z}{dx^2} = \left( \beta \rho_m / 2\mu \right) \left( \frac{g}{\gamma_c} \right) (T_{s,1} - T_{s,2})(x/L)$$

(e) Integrating the foregoing expression, we obtain

$$\frac{dv_z}{dx} = \left( \beta \rho_m / 4\mu \right) \left( \frac{g}{\gamma_c} \right) (T_{s,1} - T_{s,2}) \left( \frac{x^2}{L} \right) + C_1$$

$$v_z = \left( \beta \rho_m / 12\mu \right) \left( \frac{g}{\gamma_c} \right) (T_{s,1} - T_{s,2}) \left( \frac{x^3}{L} \right) + C_1 x + C_2$$

Applying the boundary conditions $v_z(-L) = v_z(L) = 0$, it follows that $C_1 = -\left( \beta \rho_m / 12\mu \right) \left( \frac{g}{\gamma_c} \right) (T_{s,1} - T_{s,2}) L$ and $C_2 = 0$. Hence,

$$v_z = \left( \beta \rho_m L^2 / 12\mu \right) \left( \frac{g}{\gamma_c} \right) (T_{s,1} - T_{s,2}) \left[ \left( \frac{x^3}{L^2} \right) - \left( \frac{x}{L} \right) \right]$$

COMMENTS: The validity of assuming fully-developed conditions improves with increasing plate length and would be satisfied precisely for infinite plates.
PROBLEM 9.82

KNOWN: Dimensions of vertical rectangular fins. Temperature of fins and quiescent air.

FIND: Optimum fin spacing and corresponding fin heat transfer rate.

SCHEMATIC:

ASSUMPTIONS: (1) Isothermal fins, (2) Negligible radiation, (3) Quiescent air, (4) Negligible heat transfer from fin tips, (5) Negligible radiation.

PROPERTIES: Table A-4, Air (T_f = 325K, 1 atm): v = 18.41 × 10^{-6} m²/s, k = 0.0282 W/mK, α = 26.1 × 10^{-6} m²/s, Pr = 0.703.

ANALYSIS: From Table 9.3

\[
S_{\text{opt}} = 2.71 \left( \frac{Ra_S}{S^3 H} \right)^{-1/4} = 2.71 \left[ \frac{g \beta (T_s - T_\infty)}{\alpha v H} \right]^{-1/4}
\]

\[
S_{\text{opt}} = 2.71 \left[ \frac{9.8 \text{m/s}^2 (325 \text{K})^{-1} (50 \text{K})}{26.1 \times 10^{-6} \text{m}^2/\text{s} \times 18.4 \times 10^{-6} \text{m}^2/\text{s} \times 0.15 \text{m}} \right]^{-1/4} = 7.12 \text{mm}
\]

From Eq. 9.45 and Table 9.3

\[
\overline{Nu}_s = \left[ \frac{576}{(Ra_S S/L)^2} + \frac{2.87}{(Ra_S S/L)^{1/2}} \right]^{-1/2}
\]

\[
Ra_S (S/L) = \frac{g \beta (T_s - T_\infty) S^4}{\alpha v H} = \frac{9.8 \text{m/s}^2 (325 \text{K})^{-1} (50 \text{K}) (7.12 \times 10^{-3} \text{m})^4}{25.4 \times 10^{-6} \text{m}^2/\text{s} \times 18.4 \times 10^{-6} \text{m}^2/\text{s} \times 0.15 \text{m}} = 53.2
\]

\[
\overline{Nu}_s = \left[ \frac{576}{(53.2)^2} + \frac{2.87}{(53.2)^{1/2}} \right]^{-1/2} = [0.204 + 0.393]^{-1/2} = 1.29
\]

\[
\overline{h} = \overline{Nu}_s k / S = 1.29 (0.0282 \text{W/m} \cdot \text{K}/0.00712 \text{m}) = 5.13 \text{W/m}^2 \cdot \text{K}
\]

With N = W/(t + S) = (355 mm)/(8.62 × 10^{-3} m) = 41.2 ≈ 41,

\[
q = 2N \overline{h} (L \times H) (T_s - T_\infty) = 82 \left( 5.13 \text{W/m}^2 \cdot \text{K} \right) \left( 0.02 \text{m} \times 0.15 \text{m} \right) 50 \text{K} = 63.1 \text{W}
\]

COMMENTS: \( S_{\text{opt}} = 7.12 \text{ mm} \) is considerably less than the value of 34 mm predicted from previous considerations. Hence, the corresponding value of \( q = 63.1 \text{ W} \) is considerably larger than that of the previous predication.
PROBLEM 9.83

KNOWN: Length, width and spacing of vertical circuit boards. Maximum allowable board temperature.

FIND: Maximum allowable power dissipation per board.

SCHEMATIC:

ASSUMPTIONS: (1) Circuit boards are flat with uniform heat flux at each surface, (2) Negligible radiation.

PROPERTIES: Table A-4, Air \( \overline{T} = 320 \text{K}, 1 \text{atm} \): \( \nu = 17.9 \times 10^{-6} \text{ m}^2 / \text{s}, k = 0.0278 \text{ W/mK}, \alpha = 25.5 \times 10^{-6} \text{ m}^2 / \text{s} \).

ANALYSIS: From Eqs. 9.41 and 9.46 and Table 9.3,

\[
\frac{q_s^*}{T_{s,L} - T_\infty} = \frac{48}{\frac{2.51}{(Ra_S S/L)^{2/5}}} - \left( \frac{9.8 \text{ m/s}^2 (320 \text{K})^{-1} (0.025 \text{m})^5 q_s^*}{0.0278 \text{W/m} \cdot \text{K} \left(25.5 \times 10^{-6} \text{ m}^2 / \text{s}\right) \left(17.9 \times 10^{-6} \text{ m}^2 / \text{s}\right) 0.4 \text{m}} \right)
\]

where \( Ra_S \frac{S}{L} = \frac{g \beta q_s S^5}{k \alpha v L} \).

\[
Ra_S \frac{S}{L} = 58.9 q_s^*
\]

and \( \frac{q_s^*}{T_{s,L} - T_\infty} = \frac{0.025 \text{m} \cdot q_s^*}{(60 \text{ K})0.0278 \text{W/m} \cdot \text{K}} = 0.015 q_s^* \).

Hence, \( 0.015 q_s^* = \left[ \frac{0.815}{q_s^*} + \frac{0.492}{(q_s^*)^{0.4}} \right]^{-1/2} \).

A trial-and-error solution yields \( q_s^* = 287 \text{ W / m}^2 \).

Hence, \( q = 2A_s q_s^* = 2(0.4 \text{m})^2 \left(287 \text{ W/m}^2\right) = 91.8 \text{ W} \).<

COMMENTS: Larger heat rates may be achieved by using a fan to superimpose a forced flow on the buoyancy driven flow.
PROBLEM 9.84

KNOWN: Array of isothermal vertical fins attached to heat sink at 42°C with ambient air temperature at 27°C.

FIND: (a) Heat removal rate for 24 pairs of fins and (b) Optimum fin spacing for maximizing heat removal rate if overall size of sink is to remain unchanged.

SCHEMATIC:

ASSUMPTIONS: (1) Fins form vertical, symmetrically heated, isothermal plates, (2) Negligible radiation effects, (3) Ambient air is quiescent.

PROPERTIES: Table A-4, Air \( T_f = (T_s + T_\infty) / 2 = (42 + 27) / 2 \degree C = 308 \text{ K}, 1 \text{ atm} \):
\[
v = 16.69 \times 10^{-6} \text{ m}^2 / \text{s}, \quad \alpha = 23.5 \times 10^{-6} \text{ m}^2 / \text{s}, \quad k = 26.9 \times 10^{-3} \text{ W/m} \cdot \text{K}.
\]

ANALYSIS: Considering the fins as vertical isothermal plates, the heat rate can be determined from Eq. 9.37 with the Elenbaas correlation, Eq. 9.36,
\[
Ra_s = \frac{g \beta (T_s - T_\infty) S^3}{\nu \alpha} = \frac{9.8 \text{ m/s}^2 (1/308 \text{ K}) (42 - 27) \text{ K} (0.006 \text{ m})^3}{16.69 \times 10^{-6} \text{ m}^2 / \text{s} \times 23.5 \times 10^{-6} \text{ m}^2 / \text{s}} = 262.9
\]
\[
\overline{Nu}_s = \left( \frac{q / A_s}{T_s - T_\infty} \right) S k = \frac{1}{24} \frac{Ra_s (S / L)}{k} \left\{ 1 - \exp \left[ -\frac{35}{Ra_s (S / L)} \right] \right\}^{3/4}
\]
\[
\overline{Nu}_s = \frac{1}{24} (262.9) \left( \frac{0.006 \text{ m}}{0.150 \text{ m}} \right) \left\{ 1 - \exp \left[ -\frac{35}{262.9 (0.006 \text{ m}/0.150 \text{ m})} \right] \right\}^{3/4} = 0.4263
\]
find the heat rate as
\[
q_s = A_s \left( T_s - T_\infty \right) \frac{k}{S} \overline{Nu}_s
\]
\[
q_s = 2 \times 2 \times 24 (0.025 \times 0.150) \text{ m}^2 (42 - 27) \text{ K} \frac{0.0269 \text{ W/m} \cdot \text{K}}{0.006 \text{ m}} \times 0.4263 = 10.4 \text{ W}.
\]

(b) For symmetric isothermal plates, from Table 9.3, the optimum spacing to maximize the heat rate with \( L = 0.150 \text{ m} \) is
\[
S_{\text{opt}} = 2.71 \left( \frac{Ra_s / S^3 L}{1} \right)^{-1/4} = 2.71 \left[ \frac{g \beta (T_s - T_\infty) 1}{\nu \alpha L} \right]^{-1/4} = 9.03 \text{ mm}
\]

Continued ….
and using Eq. 9.45 with values of $C_1$ and $C_2$ from Table 9.3,

$$\text{Ra}_S = \frac{g \beta (T_s - T_\infty) S_{\text{opt}}^3}{\nu \alpha} = 896$$

$$\overline{N_u}_S = \left[ \frac{q / A_s}{T_s - T_\infty} \right] S = \left[ \frac{C_1}{(\text{Ra}_S S/L)^2} + \frac{C_2}{(\text{Ra}_S S/L)^{1/2}} \right]^{-1/2}$$

and solving for the heat rate,

$$q = 0.240 m^2 (42 - 27) K \frac{0.0269 \text{ W/mK}}{0.00903 m} \left[ \frac{576}{(896 \times 9/150)^2} + \frac{2.87}{(896 \times 9/150)^{1/2}} \right]^{-1/2}$$

$$q = 14.0 \text{ W}$$

where with spacing $S_{\text{opt}} = 9.03$ mm, rather than 6 mm, the available space for the fins has decreased by $(9.03 - 6)/6 = 50\%$; hence only 16 pairs are possible and $A_s = 4 \times 16(0.025 \times 0.150)m^2 = 0.240 m^2$.

**COMMENTS:** Note that with $S_{\text{opt}} = 9$ mm, the convection coefficient is increased by $(3.88 - 1.91)1.91 = 103\%$. However, the increased spacing reduces the number of surfaces possible within the given space constraint.
PROBLEM 9.85

KNOWN: Vertical air vent in front door of dishwasher with prescribed width and height. Spacing between isothermal and insulated surface of 20 mm.

FIND: (a) Heat loss from the tub surface and (b) Effect on heat rate of changing spacing by ± 10 mm.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Vent forms vertical parallel isothermal/adiabatic plates, (3) Ambient air is quiescent.

PROPERTIES: Table A-4, \( T_f = \frac{T_s + T_\infty}{2} = 312.5 \text{K}, \) 1 atm): \( \nu = 17.15 \times 10^{-6} \text{m}^2/\text{s}, \) \( \alpha = 24.4 \times 10^{-6} \text{m}^2/\text{s}, \) \( k = 27.2 \times 10^{-3} \text{W/m-K}, \) \( \beta = \frac{1}{T_f}. \)

ANALYSIS: The vent arrangement forms two vertical plates, one is isothermal, \( T_s, \) and the other is adiabatic \( (q'' = 0). \) The heat loss can be estimated from Eq. 9.37 with the correlation of Eq. 9.45 using \( C_1 = 144 \) and \( C_2 = 2.87 \) from Table 9.3:

\[
Ra_S = \frac{g \beta (T_s - T_\infty) S^3}{\nu \alpha} = \frac{9.8 \text{m/s}^2 \left[ \frac{(1/312.5 \text{ K})}{(52 - 27) \text{K}} \right] (0.020 \text{m})^3}{17.15 \times 10^{-6} \text{m}^2/\text{s} \times 24.4 \times 10^{-6} \text{m}^2/\text{s}} = 14,988
\]

\[
q = A_S \left( T_s - T_\infty \right) \frac{k}{S} \left[ \frac{C_1}{(Ra_S S/L)^2} + \frac{C_2}{(Ra_S S/L)^{1/2}} \right]^{-1/2} = (0.500 \times 0.580) \text{m}^2 \times (52 - 27) \text{K} \times \frac{0.0272 \text{W/m-K}}{0.020 \text{m}} \underbrace{\left[ \frac{C_1}{(Ra_S S/L)^2} + \frac{C_2}{(Ra_S S/L)^{1/2}} \right]}_{Q}^{-1/2} = 28.8 \text{W}. <
\]

(b) To determine the effect of the spacing at \( S = 30 \) and 10 mm, we need only repeat the above calculations with these results:

\[
\begin{array}{c|cc|c|}
S (mm) & Ra_S & q (W) \\
10 & 1874 & 26.1 & < \\
30 & 50,585 & 28.8 & <
\end{array}
\]

Since it would be desirable to minimize heat losses from the tub, based upon these calculations, you would recommend a decrease in the spacing.

COMMENTS: For this situation, according to Table 9.3, the spacing corresponding to the maximum heat transfer rate is \( S_{max} = (S_{max}/S_{opt}) \times 2.15 (Ra_S S/L)^{-1/4} = 14.5 \text{ mm}. \) Find \( q_{max} = 28.5 \text{ W}. \) Note that the heat rate is not very sensitive to spacing for these conditions.
PROBLEM 9.86

KNOWN: Dimensions, spacing and temperature of plates in a vertical array. Ambient air temperature. Total width of the array.

FIND: Optimal plate spacing for maximum heat transfer from the array and corresponding number of plates and heat transfer.

SCHEMATIC:

Assumptions:
(1) Steady-state, (2) Negligible plate thickness, (3) Constant properties.

Properties: Table A-4, air \( p = 1 \text{ atm}, \overline{T} = 320K \): \( \nu = 17.9 \times 10^{-6} \text{ m}^2/\text{s}, k = 0.0278 \text{ W/m-K}, \alpha = 25.5 \times 10^{-6} \text{ m}^2/\text{s}, \text{Pr} = 0.704, \beta = 0.00313 \text{ K}^{-1}. \)

Analysis: With \( \text{Ra}_S^3/L = g \beta (T_s - T_\infty)/\alpha \nu L = (9.8 \text{ m/s}^2 \times 0.00313 \text{ K}^{-1} \times 55 \degree \text{C})/(25.5 \times 17.9 \times 10^{-12} \text{ m}^4/\text{s}^2 \times 0.3 \text{m}) = 1.232 \times 10^{10} \text{ m}^4 \), from Table 9.3, the spacing which maximizes heat transfer for the array is

\[
S_{opt} = \frac{2.71}{\left(\text{Ra}_S^3/L\right)^{1/4}} = \frac{2.71}{\left(1.232\times10^{10} \text{ m}^{-4}\right)^{1/4}} = 8.13 \times 10^{-3} \text{ m} = 8.13 \text{ mm} <
\]

With the requirement that \( (N - 1) S_{opt} \leq W_{ar} \), it follows that \( N \leq 1 + 150 \text{ mm}/8.13 \text{ mm} = 19.4 \), in which case

\[
N = 19 <
\]

The corresponding heat rate is \( q = N (2WL) \bar{h} (T_s - T_\infty) \), where, from Eq. 9.45 and Table 9.3,

\[
\bar{h} = \frac{k}{S} \frac{Nu_S}{S} = \frac{k}{S} \left[ \frac{576}{\left(\text{Ra}_S^3/L\right)^2} + \frac{2.87}{\left(\text{Ra}_S^3/L\right)^{1/2}} \right]^{1/2}
\]

With \( \text{Ra}_S^3/L = (\text{Ra}_S^3/L)^4 = 1.232 \times 10^{10} \text{ m}^4 \times (0.00813 \text{m})^4 = 53.7 \),

\[
\bar{h} = \frac{0.0278 \text{ W/m-K}}{0.00457 \text{m}} \left[ \frac{576}{(53.7)^2} + \frac{2.87}{(53.7)^{1/2}} \right] = 6.08(0.200 + 0.392) = 3.60 \text{ W/m}^2 \cdot \text{K}
\]

\[
q = 19(2\times0.3\text{m}\times0.3\text{m})3.60 \text{ W/m}^2 \cdot \text{K} \times 55 \degree \text{C} = 677 \text{ W} <
\]

Comments: It would be difficult to fabricate heater plates of thickness \( \delta < S_{opt} \). Hence, subject to the constraint imposed on \( W_{ar} \), \( N \) would be reduced, where \( N \leq 1 + W_{ar}/(S_{opt} + \delta) \).
PROBLEM 9.87

KNOWN: A bank of drying ovens is mounted on a rack in a room with an ambient temperature of 27°C; the cubical ovens are 500 mm to a side and the spacing between the ovens is 15 mm.

FIND: (a) Estimate the heat loss from the facing side of an oven when its surface temperature is 47°C, and (b) Explore the effect of the spacing dimension on the heat loss. At what spacing is the heat loss a maximum? Describe the boundary layer behavior for this condition. Can this condition be analyzed by treating the oven side-surface as an isolated vertical plate?

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Adjacent oven sides form a vertical channel with symmetrically heated plates, (3) Room air is quiescent, and channel sides are open to the room air, and (4) Constant properties.

PROPERTIES: Table A-4, Air (T_f = (T_s + T_∞)/2 = 310 K, 1 atm): ν = 1.69 × 10^{-5} m^2/s, k = 0.0270 W/m·K, α = 2.40 × 10^{-5} m^2/s, Pr = 0.706, β = 1/T_f.

ANALYSIS: (a) For the isothermal plate channel, Eq. 9.45 with Eqs. 9.37 and 9.38, allow for calculation of the heat transfer from a plate to the ambient air.

\[
\overline{Nu}_S = \left[ \frac{C_1}{Ra_S S/L} + \frac{C_2}{(Ra_S S/L)^{1/2}} \right]^{-1/2}
\]

\[
\overline{Nu}_S = \frac{q/A}{T_s - T_\infty} \frac{S}{k}
\]

\[
Ra_S = \frac{g \beta (T_s - T_\infty) S^3}{\alpha \nu}
\]

where, from Table 9.3, for the symmetrical isothermal plates, C_1 = 576 and C_2 = 2.87. Properties are evaluated at the film temperature T_f. Substituting numerical values, evaluate the correlation parameters and the heat rate.

\[
Ra_S = \frac{9.8 \text{ m/s}^2 (1/310 \text{ K})(47 - 27) \text{K}(0.015 \text{ m})^3}{2.40 \times 10^{-5} \text{ m}^2/\text{s} \times 1.69 \times 10^{-5} \text{ m}^2/\text{s}} = 5267
\]

\[
\overline{Nu}_S = \left[ \frac{576}{5267 \times 0.015 \text{ m}/0.50 \text{ m}} + \frac{2.87}{(5267 \times 0.015 \text{ m}/0.050 \text{ m})^{1/2}} \right]^{-1/2} = 1.994
\]

\[
1.994 = \frac{q/(0.50 \times 0.50) \text{m}^2}{(47 - 27) \text{K}} \frac{0.015 \text{ m}}{0.0274 \text{ W/m·K}} \quad q = 18.0 \text{ W}
\]

Continued …..
PROBLEM 9.87 (Cont.)

(b) Using the foregoing relations in *IHT*, the heat rate is calculated for a range of spacing $S$.

![Graph showing heat loss vs. separation distance](image)

Note that the heat rate increases with increasing spacing up to about $S = 20$ mm. This implies that for $S > 20$ mm, the side wall of the oven behaves as an *isolated vertical plate*. From the treatment of the vertical channel, Section 9.7.1, the spacing to provide maximum heat rate from a plate occurs at $S_{\text{max}}$ which, from Table 9.3, is evaluated by

$$S_{\text{max}} = 1.71 \ v_{\text{opt}} = 0.01964 \ m = 19.6 \ mm$$

$$v_{\text{opt}} = 2.71 \left( \frac{R_{\text{eff}}}{S^3 \ L} \right)^{-1/4} = 0.01147 \ m$$

For the condition $S = S_{\text{max}}$, the spacing is sufficient that the boundary layers on the plates do not overlap.

**COMMENTS:** Using the Churchill-Chu correlation, Eq. 9.26, for the isolated vertical plate, where the characteristic dimension is the height $L$, find $q = 20.2 \ W$ ($R_{\text{eff}} = 1.951 \times 10^8$ and $h_\text{L} = 4.03 \ W/m^2 \cdot K$). This value is slightly larger than that from the channel correlation when $S > S_{\text{max}}$, but a good approximation.
PROBLEM 9.88

FIND: Rate of heat transfer to collector fluid.

SCHEMATIC:

ASSUMPTIONS: (1) Flow in collector corresponds to buoyancy driven flow between parallel plates with quiescent fluids at the inlet and outlet, (2) Constant properties.

PROPERTIES: Table A-6, Water (T = 320K): \( \rho = 989 \text{ kg/m}^3 \), \( c_p = 4180 \text{ J/kg K} \), \( \mu = 577 \times 10^{-6} \text{ kg/s m} \), \( k = 0.640 \text{ W/m K} \), \( \beta = 436.7 \times 10^{-6} \text{ K}^{-1} \).

ANALYSIS: With

\[
\alpha = \frac{k}{\rho c_p} = \frac{0.640 \text{ W/m K}}{989 \text{ kg/m}^3 (4180 \text{ J/kg K})} = 1.55 \times 10^{-7} \text{ m}^2 / \text{s}
\]

\[
\nu = \left(\frac{\mu}{\rho}\right) = \left(577 \times 10^{-6} \text{ kg/s m}\right)/989 \text{ kg/m}^3 = 5.83 \times 10^{-7} \text{ m}^2 / \text{s}
\]

find

\[
\frac{Ra S}{L} = \frac{g \beta (T_s - T_\infty) S^4}{\alpha \nu L} = \frac{9.8 \text{ m/s}^2 \left(436.7 \times 10^{-6} \text{ K}^{-1}\right) \left(40 \text{ K}\right) \left(0.015 \text{ m}\right)^4}{\left(1.55 \times 10^{-7} \text{ m}^2 / \text{s}\right) \left(5.83 \times 10^{-7} \text{ m}^2 / \text{s}\right) 1.5 \text{ m}}
\]

\[
\frac{Ra S}{L} = 6.39 \times 10^4.
\]

Since \( Ra S (S/L) > 200 \), Eq. 9.47 may be used,

\[
\overline{Nu}_S = 0.645 \left[ Ra S (S/L) \right]^{1/4} = 0.645 \left(6.39 \times 10^4\right)^{1/4} = 10.3
\]

\[
\overline{h} = \frac{\overline{Nu}_S k}{S} = 10.3 \left(0.64 \text{ W/m K}/0.015 \text{ m}\right) = 438 \text{ W/m}^2 \cdot \text{K}
\]

Hence the heat rate is

\[
q = \overline{h} A (T_s - T_\infty) = 438 \text{ W/m}^2 \cdot \text{K} (1.5 \text{ m})(67 - 27) \text{ K} = 26,300 \text{ W/m}.
\]

COMMENTS: Such a large heat rate would necessitate use of a concentrating solar collector for which the normal solar flux would be significantly amplified.
**PROBLEM 9.89**

**KNOWN:** Critical Rayleigh number for onset of convection in vertical cavity filled with atmospheric air. Temperatures of opposing surfaces.

**FIND:** Maximum allowable spacing for heat transfer by conduction across the air. Effect of surface temperature and air pressure.

**SCHEMATIC:**

![Schematic Diagram](image)

**ASSUMPTIONS:** (1) Critical Rayleigh number is \( Ra_{L,c} = 2000 \), (2) Constant properties.

**PROPERTIES:** Table A-4, air \([T = (T_1 + T_2)/2 = 1°C = 274K]\): \( \nu = 13.6 \times 10^{-6} \text{ m}^2/\text{s} \), \( k = 0.0242 \text{ W/m}\cdot \text{K} \), \( \alpha = 19.1 \times 10^{-6} \text{ m}^2/\text{s} \), \( \beta = 0.00365 \text{ K}^{-1} \).

**ANALYSIS:** With \( Ra_{L,c} = g \beta (T_1 - T_2) L_c^3 / \alpha \nu \),

\[
L_c = \left[ \frac{\alpha \nu Ra_{L,c}}{g \beta (T_1 - T_2)} \right]^{1/3} = \left[ \frac{19.1 \times 13.6 \times 10^{-12} \text{ m}^4/\text{s}^2 \times 2000}{9.8 \text{ m/s}^2 \times 0.00365 \text{ K}^{-1} \times 42°C} \right]^{1/3} = 0.007 \text{m} = 7 \text{ mm} <
\]

The critical value of the spacing, and hence the corresponding thermal resistance of the air space, increases with a decreasing temperature difference, \( T_1 - T_2 \), and decreasing air pressure. With \( \nu = \mu/\rho \) and \( \alpha = k/\rho c_p \), both quantities increase with decreasing \( p \), since \( \rho \) decreases while \( \mu \), \( k \) and \( c_p \) are approximately unchanged.

**COMMENTS:** (1) For the prescribed conditions and \( L_c = 7 \text{ mm} \), the conduction heat flux across the air space is \( q' = k (T_1 - T_2) / L_c = 0.0242 \text{ W/m} \cdot \text{K} \times 42°C / 0.007 \text{m} = 145 \text{ W/m}^2 \). (2) With triple pane construction, the conduction heat loss could be reduced by a factor of approximately two, (3) Heat loss is also associated with radiation exchange between the panes.
**PROBLEM 9.90**

**KNOWN:** Temperatures and dimensions of a window-storm window combination.

**FIND:** Rate of heat loss by free convection.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Both glass plates are of uniform temperature with insulated interconnecting walls and (2) Negligible radiation exchange.

**PROPERTIES:** *Table A-4, Air (278K, 1 atm):*  
\( \nu = 13.93 \times 10^{-6} \, \text{m}^2/\text{s}, \ k = 0.0245 \, \text{W/mK}, \ \alpha = 19.6 \times 10^{-6} \, \text{m}^2/\text{s}, \ \beta = 0.00360 \, \text{K}^{-1}. \)

**ANALYSIS:** For the vertical cavity,

\[
\text{Ra}_L = \frac{g \beta (T_1 - T_2) L^3}{\alpha \nu} = \frac{9.8 \times 10^3 \, \text{m/s}^2 \left(0.00360 \, \text{K}^{-1}\right)(30^\circ \text{C})(0.06 \, \text{m})^3}{19.6 \times 10^{-6} \, \text{m}^2/\text{s} 	imes 13.93 \times 10^{-6} \, \text{m}^2/\text{s}}
\]

\[
\text{Ra}_L = 8.37 \times 10^5.
\]

With \((H/L) = 20\), Eq. 9.52 may be used as a first approximation for \(Pr = 0.71\),

\[
\overline{\text{Nu}}_L = 0.42 \text{Ra}_L^{1/4} \, Pr^{0.012} \, (H/L)^{-0.3} = 0.42 \left(8.37 \times 10^5 \right)^{1/4} \, (0.71)^{0.012} \, (20)^{-0.3}
\]

\[
\overline{\text{Nu}}_L = 5.2
\]

\[
\overline{h} = \frac{\overline{\text{Nu}}_L \, k}{L} = 5.2 \frac{0.0245 \, \text{W/mK}}{0.06 \, \text{m}} = 2.1 \, \text{W/m}^2 \cdot \text{K}.
\]

The heat loss by free convection is then

\[
q = \overline{h} \, A \, (T_1 - T_2)
\]

\[
q = 2.1 \, \text{W/m}^2 \cdot \text{K} \, (1.2 \text{m} \times 0.8 \text{m})(30^\circ \text{C}) = 61 \text{W}.
\]

**COMMENTS:** In such an application, radiation losses should also be considered, and infiltration effects could render heat loss by free convection significant.
**PROBLEM 9.91**

**KNOWN:** Absorber plate and cover plate temperatures and geometry for a flat plate solar collector.

**FIND:** Heat flux due to free convection.

**SCHEMATIC:**

- **Cover plate**, \( T_2 = 35^\circ C \)
- **Absorber plate**, \( T_1 = 70^\circ C \)
- \( L = 0.05 \text{ m} \)
- \( \tau = 60^\circ \)

**ASSUMPTIONS:** (1) Aspect ratio, \( H/L \), is greater than 12.

**PROPERTIES:** Table A-4, Air (325K, 1 atm): \( \nu = 18.4 \times 10^{-6} \text{ m}^2/\text{s}, k = 0.028 \text{ W/m\( \cdot \)K}, \alpha = 26.2 \times 10^{-6} \text{ m}^2/\text{s}, \text{Pr} = 0.703, \beta = 3.08 \times 10^{-3} \text{ K}^{-1} \).

**ANALYSIS:** For the inclined enclosure,

\[
Ra_L = \frac{g \beta (T_1 - T_2) L^3}{\alpha \nu} = \frac{9.8 \text{ m/s}^2 \left(3.08 \times 10^{-3} \text{K}^{-1}\right) (70 - 35) \degree\text{C} (0.05 \text{m})^3}{(26.2 \times 10^{-6} \text{m}^2/\text{s})(18.4 \times 10^{-6} \text{m}^2/\text{s})}
\]

\[
Ra_L = 2.74 \times 10^5.
\]

With \( \tau < \tau^* = 70^\circ \), Table 9.4,

\[
\overline{Nu}_L = 1 + 1.44 \left[ 1 - \frac{1708}{Ra_L \cos \tau} \right]^{0.99} \left[ 1 - \frac{1708 \left(\sin 1.8 \tau\right)^{1.6}}{Ra_L \cos \tau} \right]^{0.99} \left[ 1 - \frac{1708 \left(\sin 1.8 \tau\right)^{1.6}}{Ra_L \cos \tau} \right]^{0.99}
\]

\[
\overline{Nu}_L = 1 + 1.44 (0.99) (0.99) + 1.86 = 4.28
\]

\[
\bar{h} = \frac{\overline{Nu}_L k}{L} = 4.28 \frac{0.028 \text{ W/m\( \cdot \)K}}{0.05 \text{m}} = 2.4 \text{ W/m}^2 \cdot \text{K}
\]

Hence, the heat flux is

\[
q^* = \bar{h} (T_1 - T_2) = 2.4 \text{ W/m}^2 \cdot \text{K}(70 - 35) \degree\text{C}
\]

\[
q^* = 8.4 \text{ W/m}^2.
\]

**COMMENTS:** Radiation exchange between the absorber and cover plates will also contribute to heat loss from the collector.
PROBLEM 9.92

KNOWN: Horizontal solar collector cover and absorber plates.

FIND: Heat loss from absorber to cover plate for spacings (a) 60mm and (b) 10mm.

SCHEMATIC:

ASSUMPTIONS: (1) Both plates are of uniform temperature with insulated interconnecting walls, (2) Surface radiation effects are negligible.

PROPERTIES: Table A-4, Air \((T_f=(T_1+T_2)/2=312\text{K}, 1\text{ atm})\): \(v = 17.15 \times 10^{-6}\text{ m}^2/\text{s}, k = 0.0272\text{ W/m-K}, \alpha = 24.35 \times 10^{-6}\text{ m}^2/\text{s}, Pr = 0.705, \beta = 1/T_f = 3.21 \times 10^{-3}\text{ K}^{-1}\).

ANALYSIS: The heat rate between the plates is

\[ q = q'' \cdot A_s = h A_s (T_1 - T_2) \] (1)

where \(h\) can be estimated by an appropriate correlation depending upon the magnitude of the Rayleigh number, Eq. 9.25,

\[ Ra_L = \frac{g \beta (T_1 - T_2) L^3}{\nu \alpha}. \] (2)

(a) For separation distance \(L = 60\text{mm}\),

\[ Ra_L = \frac{9.8 \text{m/s}^2 \times 3.21 \times 10^{-3} (50 - 29) \text{K} (0.060\text{m})^3}{17.15 \times 10^{-6} \text{m}^2/\text{s} \times 24.35 \times 10^{-6} \text{m}^2/\text{s}} = 3.417 \times 10^5. \] (3)

As a first approximation, Eq. 9.49 is appropriate (note \(Ra_L > 3 \times 10^5\)),

\[ \bar{h} = \frac{\bar{h}}{Nu_L} \cdot \frac{k}{L} = \frac{k}{L} \left[ 0.069 Ra_L^{1/3} Pr^{0.074} \right] \] (4)

\[ \bar{h} = 0.0272 \text{W/m-K} \left[ 0.069 \left(3.417 \times 10^5\right)^{1/3} \left(0.705\right)^{0.074} \right] = 2.13 \text{W/m}^2 \cdot \text{K} \]

\[ q = 2.13 \text{W/m}^2 \cdot \text{K} \times 3 \text{m}^2 (50 - 29) \text{K} = 134 \text{W}. \]

(b) For separation distance \(L = 10\text{mm}\), from Eq. (3) it follows that \(Ra_L = (10/60)^3 \times 3.417 \times 10^5 = 1582\). Since \(Ra_L < 1700\), heat transfer occurs by conduction only, such that

\[ \frac{\bar{h}}{k} \frac{L}{Nu_L} = 1 \quad \text{or} \quad \bar{h} = 1 \times \frac{0.0272 \text{W/m-K}}{0.010\text{m}} = 2.72 \text{W/m}^2 \cdot \text{K} \]

\[ q = 2.72 \text{W/m}^2 \cdot \text{K} \times 3 \text{m}^2 (50 - 29) \text{K} = 171 \text{W}. \]

COMMENTS: Note that as \(L\) increases, from 10mm to 60mm, the heat rate decreases. However, For \(L \geq 60\text{mm}\), the heat rate will not change. This follows from Eq. 4 which, for \(Ra > 3 \times 10^5\), \(\bar{h}\) is independent of separation distance \(L\).
PROBLEM 9.93

KNOWN: Rectangular cavity of two parallel, 0.5m square plates with insulated inter-connecting sides and with prescribed separation distance and surface temperatures.

FIND: Heat flux between surfaces for three orientations of the cavity: (a) Vertical \( \tau = 90^\circ \), (b) Horizontal with \( \tau = 0^\circ \), and (c) Horizontal with \( \tau = 180^\circ \).

SCHEMATIC:

![Schematic Image]

ASSUMPTIONS: (1) Radiation exchange is negligible, (2) Air is at atmospheric pressure.

PROPERTIES: Table A-4, Air \( (T_f = (T_1 + T_2)/2 = 300K, 1 \text{ atm}) \): \( \nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}, k = 0.0263 \text{ W/m} \cdot \text{K}, \alpha = 22.5 \times 10^{-6} \text{ m}^2/\text{s}, Pr = 0.707, \beta = 1/T_f = 3.333 \times 10^{-3} \text{ K}^{-1} \).

ANALYSIS: The convective heat flux between the two cavity plates is

\[
q_{\text{conv}} = \bar{h}(T_1 - T_2)
\]

where \( \bar{h} \) is estimated from the appropriate enclosure correlation which will depend upon the Rayleigh number. From Eq. 9.25, find

\[
Ra_L = \frac{g \beta (T_1 - T_2) L^3}{\nu \alpha} = \frac{9.8 \times 10^{-3} \times 3.333 \times 10^{-3} K^{-1} (325 - 275) K (0.05\text{ m})^3}{15.89 \times 10^{-6} \text{ m}^2/\text{s} \times 22.5 \times 10^{-6} \text{ m}^2/\text{s}} = 5.71 \times 10^5.
\]

Note that \( H/L = 0.5/0.05 = 10 \), a factor which is important in selecting correlations.

(a) With \( \tau = 90^\circ \), for a vertical cavity, Eq. 9.50, is appropriate,

\[
\bar{h}_L = \frac{k \cdot \bar{h}}{\nu \alpha} = \frac{k \cdot \bar{h}}{(0.069 \cdot 0.707) \cdot (0.05\text{ m})} = 2.47 \text{ W/m}^2 \cdot \text{K} \]

\[
q_{\text{conv}} = 2.47 \text{ W/m}^2 \cdot \text{K} (325 - 275) K = 123 \text{ W/m}^2.
\]

(b) With \( \tau = 0^\circ \) for a horizontal cavity heated from below, Eq. 9.49 is appropriate.

\[
\bar{h}_L = \frac{k \cdot \bar{h}}{\nu \alpha} = \frac{k \cdot \bar{h}}{(0.069 \cdot 0.707) \cdot (0.05\text{ m})} = 2.92 \text{ W/m}^2 \cdot \text{K} \]

\[
q_{\text{conv}} = 2.92 \text{ W/m}^2 \cdot \text{K} (325 - 275) K = 146 \text{ W/m}^2.
\]

(c) For \( \tau = 180^\circ \) corresponding to the horizontal orientation with the heated plate on the top, heat transfer will be by conduction. That is,

\[
\bar{h}_L = \frac{k \cdot \bar{h}}{\nu \alpha} = \frac{k \cdot \bar{h}}{(0.069 \cdot 0.707) \cdot (0.05\text{ m})} = 0.526 \text{ W/m}^2 \cdot \text{K} \]

\[
q_{\text{conv}} = 0.526 \text{ W/m}^2 \cdot \text{K} (325 - 275) K = 26.3 \text{ W/m}^2.
\]

COMMENTS: Compare the heat fluxes for the various orientations and explain physically their relative magnitudes.
PROBLEM 9.94

KNOWN: Horizontal flat roof and vertical wall sections of same dimensions exposed to identical temperature differences.

FIND: (a) Ratio of convection heat rate for horizontal section to that of the vertical section and (b) Effect of inserting a baffle at the mid-height of the vertical wall section on the convection heat rate.

SCHEMATIC:

ASSUMPTIONS: (1) Ends of sections and baffle adiabatic, (2) Steady-state conditions.

PROPERTIES: Table A-4, Air: \( T = (T_1 + T_2)/2 = 277 K \), 1 atm: \( \nu = 13.84 \times 10^{-6} \text{ m}^2/\text{s} \), \( k = 0.0245 \text{ W/m} \cdot \text{K} \), \( \alpha = 19.5 \times 10^{-6} \text{ m}^2/\text{s} \), \( \text{Pr} = 0.713 \).

ANALYSIS: (a) The ratio of the convection heat rates is

\[
\frac{q_{\text{hor}}}{q_{\text{vert}}} = \frac{\bar{h}_{\text{hor}}A_s \Delta T}{\bar{h}_{\text{vert}}A_s \Delta T} = \frac{\bar{h}_{\text{hor}}}{\bar{h}_{\text{vert}}}. \tag{1}
\]

To estimate coefficients, recognizing both sections have the same characteristics length, \( L = 0.1 \text{ m} \), with \( \text{Ra}_L = g \beta \Delta T L^3 / \nu \alpha \) find

\[
\text{Ra}_L = \frac{9.8 \text{ m/s}^2 \times (1/277 \text{ K}) (18 - (-10)) K (0.1 \text{ m})^3}{13.84 \times 10^{-6} \text{ m}^2/\text{s} \times 19.5 \times 10^{-6} \text{ m}^2/\text{s}} = 3.67 \times 10^6.
\]

The appropriate correlations for the sections are Eqs. 9.49 and 9.52 (with \( H/L = 30 \)),

\[
\bar{N}_u_L |_{\text{hor}} = 0.069 \text{Ra}_L^{1/3} \text{Pr}^{0.074}, \quad \bar{N}_u_L |_{\text{vert}} = 0.42 \text{Ra}_L^{1/4} \text{Pr}^{0.012} (H/L)^{-0.3}. \tag{3,4}
\]

Using Eqs. (3) and (4), the ratio of Eq. (1) becomes,

\[
\frac{q_{\text{hor}}}{q_{\text{vert}}} = \frac{0.069 \text{Ra}_L^{1/3} \text{Pr}^{0.074}}{0.42 \text{Ra}_L^{1/4} \text{Pr}^{0.012} (H/L)^{-0.3}} = \frac{0.069 (3.67 \times 10^6)^{1/3} (0.713)^{0.074}}{0.42 (3.67 \times 10^6)^{1/4} (0.713)^{0.012} (30)^{-0.3}} = 1.57. \tag{<}
\]

(b) The effect of the baffle in the vertical wall section is to reduce \( H/L \) from 30 to 15. Using Eq. 9.52, it follows,

\[
\frac{q_{\text{baf}}}{q} = \frac{\bar{h}_{\text{baf}}}{\bar{h}} = \left(\frac{H/L}{30}\right)^{-0.3} = \left(\frac{15}{30}\right)^{-0.3} = 1.23. \tag{<}
\]

That is, the effect of the baffle is to increase the convection heat rate.

COMMENTS: (1) Note that the heat rate for the horizontal section is 57% larger than that for the vertical section for the same \( (T_1 - T_2) \). This indicates the importance of heat losses from the ceiling or roofs in house construction. (2) Recognize that for Eq. 9.52, the \( \text{Pr} > 1 \) requirement is not completely satisfied. (3) What is the physical explanation for the result of part (b)?
PROBLEM 9.95

KNOWN: Double-glazed window of variable spacing L between panes filled with either air or carbon dioxide.

FIND: Heat transfer across window for variable spacing when filled with either gas. Consider these conditions (outside, T₁; inside, T₂): winter (-10, 20°C) and summer (35°C, 25°C).

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Radiation exchange is negligible, (3) Gases are at atmospheric pressure, (4) Perfect gas behavior.

PROPERTIES: Table A-4: Winter, \( \bar{T} = (−10 + 20) \, ^\circ \mathrm{C} / 2 = 288 \, \text{K} \), Summer, \( \bar{T} = (35 + 25) \, ^\circ \mathrm{C} / 2 = 303 \, \text{K} \):

<table>
<thead>
<tr>
<th>Gas</th>
<th>( \bar{T} )</th>
<th>( \alpha ) ( (\text{m}^2/\text{s} \times 10^6) )</th>
<th>( \nu ) ( (\text{m}^2/\text{s} \times 10^6) )</th>
<th>( k \times 10^3 ) ( (\text{W/m} \cdot \text{K}) )</th>
</tr>
</thead>
<tbody>
<tr>
<td>Air</td>
<td>288</td>
<td>20.5</td>
<td>14.82</td>
<td>24.9</td>
</tr>
<tr>

<td>11.2</td>
<td>8.55</td>
<td>16.78</td>
</tr>
</tbody>
</table>

ANALYSIS: The heat flux by convection across the window is

\[ q'' = h (T_1 - T_2) \]

where the convection coefficient is estimated from the correlation of Eq. 9.53 for large aspect ratios \( 10 < H/L < 40 \),

\[ \bar{N}_U_L = \bar{h}L/k = 0.046Ra_L^{1/4}. \]

Substituting numerical values for winter (w) and summer (s) conditions,

\[ Ra_{L,w,\text{air}} = 9.8 \times 10^6 \, (1/288K)(20−(−10)) \, KL^3 = 3.360 \times 10^9 \, L^3 / m^3 / s \]

\[ Ra_{L,s,\text{air}} = 8.724 \times 10^8 \, L^3 \]

\[ Ra_{L,w,\text{CO}_2} = 1.286 \times 10^{10} \, L^3 \]

\[ Ra_{L,s,\text{CO}_2} = 3.378 \times 10^9 \, L^3 \]

the heat transfer coefficients are

\[ \bar{h}_{w,\text{air}} = (0.0249 \, \text{W/m} \cdot \text{K} \cdot \text{L}) \times 0.046 \left( 3.360 \times 10^9 \, L^3 \right)^{1/4} = 0.276L^{-1/4} \]

\[ h_{s,\text{air}} = 0.209L^{-1/4} \]

\[ h_{w,\text{CO}_2} = 0.244L^{-1/4} \]

\[ h_{s,\text{CO}_2} = 0.186L^{-1/4} \]

For a separation distance such that \( H/L = 40 \), the maximum aspect ratio for the correlation, with \( H = 1.5 \, \text{m} \), \( L = 37.5 \, \text{mm} \) find

\[ q''_{w,\text{air}} = 18.8 \, \text{W/m}^2 \]

\[ q''_{s,\text{air}} = 4.7 \, \text{W/m}^2 \]

\[ q''_{w,\text{CO}_2} = 16.6 \, \text{W/m}^2 \]

\[ q''_{s,\text{CO}_2} = 4.2 \, \text{W/m}^2 \]

Using CO₂ rather than air reduces the heat loss/gain by approximately 12%. Note the winter heat rate for this window is nearly 4 times that for summer.
PROBLEM 9.96

KNOWN: Dimensions of double pane window. Thickness of air gap. Temperatures of room and ambient air.

FIND: (a) Temperatures of glass panes and heat rate through window, (b) Resistance of glass pane relative to smallest convection resistance.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Negligible glass pane thermal resistance, (3) Constant properties.

PROPERTIES: Table A-3, Plate glass: $k_p = 1.4 \text{ W/m-K}$. Table A-4, Air (p = 1 atm). $T_{f,i} = 287.6 \text{ K}$: $\nu_i = 14.8 \times 10^{-6} \text{ m}^2/\text{s}$, $k_i = 0.0253 \text{ W/m-K}$, $\alpha_i = 20.9 \times 10^{-6} \text{ m}^2/\text{s}$, $Pr_i = 0.710$, $\beta_i = 0.00348 \text{ K}^{-1}$. $T = (T_{s,i} + T_{s,o})/2 = 272.8 \text{ K}$: $\nu = 13.49 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 0.0241 \text{ W/m-K}$, $\alpha = 18.9 \times 10^{-6} \text{ m}^2/\text{s}$, $Pr = 0.714$, $\beta = 0.00367 \text{ K}^{-1}$. $T_{f,o} = 258.2 \text{ K}$: $\nu_o = 12.2 \times 10^{-6} \text{ m}^2/\text{s}$, $k_o = 0.0230 \text{ W/m-K}$, $\alpha = 17.0 \times 10^{-6} \text{ m}^2/\text{s}$, $Pr = 0.718$, $\beta_o = 0.00387 \text{ K}^{-1}$.

ANALYSIS: (a) The heat rate may be expressed as

$$q = q_o = \bar{h}_o H^2 (T_{s,o} - T_{\infty,o})$$

$$q = q_g = \bar{h}_g H^2 (T_{s,i} - T_{s,o})$$

$$q = q_i = \bar{h}_i H^2 (T_{\infty,i} - T_{s,i})$$

where $\bar{h}_o$ and $\bar{h}_i$ may be obtained from Eq. (9.26),

$$\bar{Nu}_H = \left[ 0.825 + \frac{0.387 Ra_H^{1/6}}{1 + (0.492/Pr)^{9/16}} \right]^{2/7}$$

with $Ra_H = g\beta_0 (T_{s,o} - T_{\infty,o}) H^3 / \alpha_0 \nu_o$ and $Ra_H = g\beta_i (T_{\infty,i} - T_{s,i}) H^3 / \alpha_i \nu_i$, respectively. Assuming $10^4 < Ra_L < 10^7$, $\bar{h}_g$ is obtained from

$$\bar{Nu}_L = \frac{0.42 Ra_L^{1/4} Pr^{0.012} (H/L)^{-0.3}}{0.3}$$

where $Ra_L = g\beta (T_{s,i} - T_{s,o}) L^3 / \alpha v$. A simultaneous solution to Eqs. (1)–(3) for the three unknowns yields

Continued …..
PROBLEM 9.96 (Cont.)

\[ T_{s,i} = 9.1^\circ C, \quad T_{s,o} = -9.6^\circ C, \quad q = 35.7 \text{ W} \]

where \( \bar{h}_i = 3.29 \text{ W} / \text{m}^2 \cdot \text{K}, \quad \bar{h}_o = 3.45 \text{ W} / \text{m}^2 \cdot \text{K} \) and \( \bar{h}_g = 1.90 \text{ W} / \text{m}^2 \cdot \text{K} \).

(b) The unit conduction resistance of a glass pane is \( R_{\text{cond}}^* = L_p / k_p = 0.00429 \text{ m}^2 \cdot \text{K} / \text{W} \), and the smallest convection resistance is \( R_{\text{conv},o}^* = (1/\bar{h}_o) = 0.290 \text{ m}^2 \cdot \text{K} / \text{W} \). Hence,

\[ R_{\text{cond}}^* << R_{\text{conv},\text{min}}^* \]

and it is reasonable to neglect the thermal resistance of the glass.

**COMMENTS:** (1) Assuming a heat flux of 35.7 W/m\(^2\) through a glass pane, the corresponding temperature difference across the pane is \( \Delta T = q^* (L_p / k_p) = 0.15^\circ C \). Hence, the assumption of an isothermal pane is good. (2) Equations (1) – (3) were solved using the IHT workspace and the temperature-dependent air properties provided by the software. The property values provided in the PROPERTIES section of this solution were obtained from the software.
**PROBLEM 9.97**

**KNOWN:** Top surface of an oven maintained at 60°C.

**FIND:** (a) Reduction in heat transfer from the surface by installation of a cover plate with specified air gap; temperature of the cover plate, (b) Effect of cover plate spacing.

**SCHEMATIC:**

![Diagram showing top surface with cover plate and heat transfer rates](image)

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Oven surface at $T_1 = T_s$ for both cases, (3) Negligible radiative exchange with surroundings and across air gap.

**PROPERTIES:** Table A.4, Air ($T_f = (T_s + T_\infty)/2 = 315$ K, 1 atm): $\nu = 17.40 \times 10^{-6}$ m$^2$/s, $k = 0.0274$ W/m·K, $\alpha = 24.7 \times 10^{-6}$ m$^2$/s; Table A.4, Air ($\overline{T} = (T_1 + T_2)/2$ and $T_{f2} = (T_2 + T_\infty)/2$): Properties obtained from Correlations Toolpad of IHT.

**ANALYSIS:** (a) The convective heat loss from the exposed top surface of the oven is $q_s = h \cdot A_s \cdot (T_s - T_\infty)$. With $L = A_s / P = (0.5 \text{ m})^2 / (4 \times 0.5 \text{ m}) = 0.125 \text{ m}$,

$$Ra_L = \frac{g \beta \Delta T L^3}{\nu \alpha} = \frac{9.8 \text{ m/s}^2 \left(1/315 \text{ K}\right) \left(60 - 23\right)^\circ \text{C} \left(0.125 \text{ m}\right)^3}{17.40 \times 10^{-6} \text{ m}^2/\text{s} \times 24.7 \times 10^{-6} \text{ m}^2/\text{s}^2} = 5.23 \times 10^6.$$

The appropriate correlation for a heated plate facing upwards, Eq. 9.30, is

$$\overline{Nu}_L = \frac{\overline{h} L}{k} = 0.54 \left( Ra_L \right)^{1/4} \quad 10^4 \leq Ra_L \leq 10^7$$

$$\overline{h} = \left( \frac{0.0274 \text{ W/m·K}}{0.125 \text{ m}} \right) \times 0.54 \left( 5.23 \times 10^6 \right)^{1/4} = 5.66 \text{ W/m}^2\cdot\text{K}$$

Hence, the heat rate for the exposed surface is

$$q_s = 5.66 \text{ W/m}^2\cdot\text{K} \left(0.5 \text{ m}\right)^2 \left(60 - 23\right)^\circ \text{C} = 52.4 \text{ W}.$$

With the cover plate, the surface temperature ($T_s = T_2$) is unknown and must be obtained by performing an energy balance at the top surface.

![Energy balance diagram](image)

Continued.....
PROBLEM 9.97 (Cont.)

Equating heat flow across the gap to that from the top surface, \( q_g = q_{cp} \). Hence, for a unit surface area,

\[
\bar{h}_g (T_1 - T_2) = \bar{h}_{cp} (T_2 - T_\infty)
\]

where \( \bar{h}_{cp} \) is obtained from Eq. 9.30 and \( \bar{h}_g \) is evaluated from Eq. 9.49.

\[
\frac{\bar{h}_g L}{k} = 0.069 \text{Ra}_L^{1/3} \Pr^{0.074}
\]

Entering this expression from the keyboard and Eq. 9.30 from the Correlations Toolpad, with the Properties Toolpad used to evaluate air properties at \( \bar{T} \) and \( T_{fs} \), IHT was used with \( L = 0.05 \, \text{m} \) to obtain

\[
T_2 = 35.4 ^\circ C \\
q_{cp} = 13.5 \, \text{W}
\]

where \( \bar{h}_g = 2.2 \, \text{W}/\text{m}^2\cdot\text{K} \) and \( \bar{h}_{cp} = 4.4 \, \text{W}/\text{m}^2\cdot\text{K} \). Hence, the effect of installing the cover plate creating the enclosure is to reduce the heat loss by

\[
\frac{q_s - q_{cp}}{q_s} \times 100 = \frac{52.4 - 13.5}{52.4} \times 100 = 74\%
\]

Note, however, that for \( L = 0.05 \, \text{m}, \, \text{Ra}_L = 2.05 \times 10^5 \) is slightly less than the lower limit of applicability for Eq. 9.49.

(b) If we use the foregoing model to evaluate \( T_2 \) and \( q_{cp} \) for \( 0.005 \leq L \leq 0.05 \, \text{m} \), we find that there is no effect. This seemingly unusual result is a consequence of the fact that, in Eq. 9.49, \( \overline{\text{Nu}}_L \propto \text{Ra}_L^{1/3} \), in which case \( \bar{h}_g \) is independent of \( L \). However, \( \text{Ra}_L \) and \( \text{Nu}_L \) do decrease with decreasing \( L \), eventually approaching conditions for which transport across the airspace is determined by conduction and not convection. If transport is by conduction, the heat rate must be determined from Fourier’s law, for which \( q_g = (k/L)(T_1 - T_2) \) and the equivalent, pseudo, Nusselt number is \( \overline{\text{Nu}}_L = \bar{h}_L/k = 1 \). If this expression is used to determine \( \bar{h}_g \) in the energy balance, \( q_{cp} \) increases with decreasing \( L \). The results would only apply if there is negligible advection in the airspace and hence for Rayleigh numbers less than 1708, which corresponds to \( L \approx 10.5 \, \text{mm} \). For this value of \( L, \, q_{cp} = 15.4 \, \text{W} \) exceeds that previously determined for \( L = 50 \, \text{mm} \). Hence, there is little variation in \( q_{cp} \) over the range \( 10.5 < L < 50 \, \text{mm} \). However, \( q_{cp} \) increases with decreasing \( L \) below 10.5 mm, achieving a value of 24.2 W for \( L = 5 \, \text{mm} \). Hence, a value of \( L \) slightly larger than 10.5 mm could be considered an optimum.

COMMENTS: Radiation exchange across the cavity and with the surroundings is likely to be significant and should be considered in a more detailed analysis.
PROBLEM 9.98

KNOWN: The sample compartment of an optical instrument in the form of a rectangular cavity; one face in contact with instrument cover maintained at 27°C; other face having 10-mm thick insulation pad in contact with oven wall maintained at 227°C.

FIND: Heat gain to the instrument, and average air temperature in the compartment.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible heat losses from the edges of the rectangular-cavity shaped compartment, and (3) Constant properties.

PROPERTIES: Table A-4, air (T_f = T_{air} = (T_i + T_c)/2 = 354 K, 1 atm): \( \nu = 2.132 \times 10^{-5} \text{ m}^2/\text{s}, \ k = 0.0303 \text{ W/m-K, } \alpha = 3.051 \times 10^{-5} \text{ m}^2/\text{s}, \ Pr = 0.699, \ \beta = 1/T_f. \)

ANALYSIS: The system comprised of the rectangular cavity and the insulating pad can be represented by the thermal circuit shown above. The heat gain to the instrument and the hot-side temperature of the cavity, \( T_i \), can be expressed as

\[
q = \frac{T_o - T_c}{R_{ins} + R_{cav}} \quad \frac{T_o - T_i}{R_{ins}} = \frac{T_i - T_c}{R_{cav}} \tag{1.2}
\]

The thermal resistance of the insulating pad is

\[
R_{ins} = \frac{L_i}{k_i A_s} = \frac{0.010 \text{ m}}{0.05 \text{ W/m-K} \times (0.15 \times 0.15) \text{ m}^2} = 8.89 \text{ K/W} \tag{3}
\]

The thermal resistance of the rectangular cavity is

\[
R_{cav} = 1/(\bar{h} A_s) \tag{4}
\]

where \( L_c \) is the cavity width and the average convection coefficient follows from Eq. 9.51 (since \( H/L_c = 15/10 = 1.5 \)),

\[
\bar{Nu}_L = \frac{\bar{h} L_c}{k} = 0.18 \left( \frac{Pr}{0.2 + Pr} \right)^{0.29} Ra_{Lc}^{0.29} \tag{5}
\]

\[
Ra_{Lc} = g \beta (T_i - T_c) L_c^3 / \alpha \nu \tag{6}
\]

where the properties are evaluated at the average cavity air temperature \( T_f = T_{air} = (T_i + T_c)/2 \)

\[
q = 10.4 \text{ W} \quad T_{air} = 134^\circ C \tag{7}
\]

COMMENTS: Other parameters resulting from the analyses are:

\[
\bar{Nu}_{Lc} = 14.3 \quad Ra_{Lc} = 4.57 \times 10^6 \quad \bar{h} = 4.33 \text{ W/m}^2\cdot\text{K} \quad R_{cav} = 10.28 \text{ K/W}
\]
PROBLEM 9.99

KNOWN: Rectangular cavity of two parallel, 0.5m square plates with insulated boundaries and with prescribed separation distance and surface temperatures.

FIND: Convective heat flux between surfaces for tilt angles of (a) 45° and (b) 75°.

SCHEMATIC:

ASSUMPTIONS: (1) Radiation exchange is negligible, (2) Cavity air is 1 atm.

PROPERTIES: Table A-4, Air (T_f = (T_1 + T_2)/2 = 300K, 1 atm): k = 0.0263 W/mK, ν = 15.89 × 10^{-6} m^2/s, Pr = 0.707, β = 1/T_f = 3.333 × 10^{-3} K^{-1}.

ANALYSIS: (a) The convective heat flux between the plates is q'' = h(T_1 - T_2) where h is estimated from the appropriate correlation with

\[
\text{Ra}_L = \frac{g \beta (T_1 - T_2) L^3}{\nu \alpha} = 9.8 \text{m/s}^2 \times 3.333 \times 10^{-3} \text{K}^{-1} (325 - 275) \text{K} (0.05 \text{m})^3 = 5.71 \times 10^5.
\]

For H/L = 0.5m/0.05m = 10 and τ < τ*, (τ* ≈ 64° from Table 9.4), Eq. 9.55 is suitable,

\[
\overline{\text{Nu}}_L = \overline{\text{Nu}}_L (\tau = 0) \left[ \frac{\text{Nu}_L (\tau = 90°)}{\text{Nu}_L (\tau = 0)} \right] \left( \frac{\tau}{\tau*} \right) \frac{(\sin \tau*)}{4 \tau*}.
\]

For \( \overline{\text{Nu}}_L (\tau = 90°) \), Eq. 9.50 is appropriate,

\[
\overline{\text{Nu}}_L (\tau = 90°) = 0.22 \left( \frac{\text{Pr}}{0.2 + \text{Pr}} \right)^{0.28} \left( \frac{H}{L} \right)^{1/4} = 0.22 \left( \frac{0.707}{0.2 + 0.707} \right)^{0.28} \left( \frac{5.71 \times 10^5}{10} \right)^{1/4} = 4.72.
\]

For \( \overline{\text{Nu}}_L (\tau = 0°) \), Eq. 9.49 is appropriate,

\[
\overline{\text{Nu}}_L (\tau = 0°) = 0.069 \text{Ra}_L^{1/3} \text{Pr}^{0.074} = 0.069 \times \left( 5.71 \times 10^5 \right)^{1/3} (0.707)^{0.074} = 5.58.
\]

Substituting numerical values into Eq. (1) with τ = 45°,

\[
\overline{\text{Nu}}_L = 5.58 \left[ 4.72/5.58 \right]^{45/64} (\sin 64°)^{45/4 \times 64} = 4.86
\]

\[
\overline{h} = \overline{\text{Nu}}_L \ k/L = 4.86 \times 0.0263 \text{W/m} \cdot \text{K}/0.05 \text{m} = 2.56 \text{W/m}^2 \cdot \text{K}.
\]

\[
q'' = 2.56 \text{W/m}^2 \cdot \text{K} (325 - 275) \text{K} = 128 \text{W/m}^2.
\]

(b) For τ = 75°, τ > τ*, the critical tilt angle, Eq. 9.56 is appropriate for estimating \( \overline{h} \).

\[
\overline{\text{Nu}}_L = \overline{\text{Nu}}_L (\tau = 90°) \left( \sin \tau \right)^{1/4} = 4.72 (\sin 75°)^{1/4} = 4.68
\]

\[
\overline{h} = \overline{\text{Nu}}_L \ k/L = 4.68 \times 0.0263 \text{W/m} \cdot \text{K}/0.05 \text{m} = 2.46 \text{W/m}^2 \cdot \text{K}.
\]

\[
q'' = 2.46 \text{W/m}^2 \cdot \text{K} (325 - 275) \text{K} = 123 \text{W/m}^2.
\]

COMMENTS: Note that \( \overline{\text{Nu}}_L (\tau = 0°) > \overline{\text{Nu}}_L (\tau = 90°) \). For the cavity conditions there is little change in \( \overline{h} \) for tilt angles, τ, from 45° to 90°.
PROBLEM 9.100

KNOWN: Dimensions and surface temperatures of a flat-plate solar collector.

FIND: (a) Heat loss across collector cavity, (b) Effect of plate spacing on the heat loss.

SCHEMATIC:

ASSUMPTIONS: Negligible radiation.

PROPERTIES: Table A.4, Air (\(\overline{T} = (T_1 + T_2)/2 = 323\) K): \(\nu = 18.2 \times 10^{-6} \text{ m}^2/\text{s}\), \(k = 0.028 \text{ W/m-K}\), \(\alpha = 25.9 \times 10^{-6} \text{ m}^2/\text{s}\), \(\beta = 0.0031 \text{ K}^{-1}\).

ANALYSIS: (a) Since \(H/L = 2\text{ m}/0.03\text{ m} = 66.7 > 12\), \(\tau < \tau^*\) and Eq. 9.54 may be used to evaluate the convection coefficient associated with the air space. Hence, \(q = \overline{h} A_s (T_1 - T_2)\), where \(\overline{h} = (k/L) \overline{Nu_L}\) and

\[
\overline{Nu_L} = 1 + 1.44 \left[1 - \frac{1708}{Ra_L \cos \tau}\right] \left[1 - \frac{1708(\sin 1.8\tau)^{1.6}}{Ra_L \cos \tau}\right] + \left[\frac{Ra_L \cos \tau}{5830}\right]^{1/3} - 1
\]

For \(L = 30\) mm, the Rayleigh number is

\[
Ra_L = \frac{g \beta (T_1 - T_2) L^3}{\alpha \nu} = \frac{9.8 \text{ m}/\text{s}^2 (0.0031 \text{ K}^{-1})(40^\circ \text{C})(0.03 \text{ m})^3}{25.9 \times 10^{-6} \text{ m}^2/\text{s} \times 18.2 \times 10^{-6} \text{ m}^2/\text{s}} = 6.96 \times 10^4
\]

and \(Ra_L \cos \tau = 3.48 \times 10^4\). It follows that \(\overline{Nu_L} = 3.12\) and \(\overline{h} = (0.028 \text{ W/m-K}/0.03 \text{ m})3.12 = 2.91 \text{ W/m}^2\text{-K}\). Hence,

\[
q = 2.91 \text{ W/m}^2\text{-K} \left(4 \text{ m}^2\right)\left(40^\circ \text{C}\right) = 466 \text{ W}
\]

(b) The foregoing model was entered into the workspace of IHT, and results of the calculations are plotted as follows.

Continued...
The plots are influenced by the fact that the third and second terms on the right-hand side of the correlation are set to zero at $L \approx 0.017$ m and $L \approx 0.011$ m, respectively. For the range of conditions, minima in the heat loss of $q \approx 410$ W and $q = 397$ W are achieved at $L \approx 0.012$ m and $L = 0.05$ m, respectively. Operation at $L \approx 0.02$ m corresponds to a maximum and is clearly undesirable, as is operation at $L < 0.011$ m, for which conditions are conduction dominated.

**COMMENTS:** Because the convection coefficient is low, radiation effects would be significant.
PROBLEM 9.101

KNOWN: Cylindrical 120-mm diameter radiation shield of Example 9.5 installed concentric with a 100-mm diameter tube carrying steam; spacing provides for an air gap of \( L = 10 \) mm.

FIND: (a) Heat loss per unit length of the tube by convection when a second shield of diameter 140 m is installed; compare the result to that for the single shield calculation of the example; and (b) The heat loss per unit length if the gap dimension is made \( L = 15 \) mm (rather than 10 mm). Do you expect the heat loss to increase or decrease?

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, and (b) Constant properties.

PROPERTIES: Table A-4, Air \((T_f = (T_s + T_\infty)/2 = 350 \) K, 1 atm): \( \nu = 20.92 \times 10^{-6} \) m\(^2\)/s, \( k = 0.030 \) W/m·K, \( Pr = 0.700 \).

ANALYSIS: (a) The thermal circuit representing the tube with two concentric cylindrical radiation shields having gap spacings \( L = 10 \) mm is shown above. The heat loss per unit length by convection is

\[
q' = \frac{T_1 - T_2}{R_{g1} + R_{g2}}
\]

where the \( R_g' \) represents the thermal resistance of the annular gap (spacing). From Eq. 9.58, 59 and 60, find

\[
R_g' = \frac{\ln(D_o/D_i)}{2\pi k_{\text{eff}}} \tag{2}
\]

\[
\frac{k_{\text{eff}}}{k} = 0.386\left( \frac{Pr}{0.861 + Pr} \right)^{1/4} \left( Ra_c^* \right)^{1/4} \tag{3}
\]

\[
Ra_c^* = \left[ \frac{\ln(D_o/D_i)}{4} \right]^4 Ra_L \tag{4}
\]

\[
Ra_L = \frac{g\beta(T_0 - T_1) L^3}{\alpha\nu} \tag{5}
\]

where the properties are evaluated at the average temperature of the bounding surfaces, \( T_f = (T_1 + T_o)/2 \). Recognize that the above system of equations needs to be solved iteratively by initial guess values of \( T_1 \), or solved simultaneously using equation-solving software with a properties library. The results are tabulated below.

Continued .....
(b) Using the foregoing relations, the analyses can be repeated with \( L = 15 \) mm, so that \( D_1 = 130 \) mm and \( D_2 = 160 \) mm. The results are tabulated below along with those from Example 9.5 for the single-shield configuration.

<table>
<thead>

</table>

**COMMENTS:**

(1) The effect of adding the second shield is to more than double the thermal resistance of the shields to convection heat transfer.

(2) The effect of gap increase from 10 to 15 mm for the two-shield configuration is slight. Increasing \( L \) allows for greater circulation in the annular space, thereby reducing the thermal resistance.

(3) Note the difference in thermal resistances for the annular spaces \( R_{g1}' \) of the one-and two-shield configurations with \( L = 10 \) mm. Why are they so different (0.7658 vs. 1.008 m·K/W, respectively)?

(4) See Example 9.5 for details on how to evaluate the properties for use with the correlation.
PROBLEM 9.102

KNOWN: Operating conditions of a concentric tube solar collector.

FIND: Convection heat transfer per unit length across air space between tubes.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Long tubes.

PROPERTIES: Table A-4, Air (T = 50°C, 1 atm): \( \nu = 18.2 \times 10^{-6} \text{ m}^2/\text{s} \), \( k = 0.028 \text{ W/m} \cdot \text{K} \), \( \alpha = 25.9 \times 10^{-6} \text{ m}^2/\text{s} \), \( \Pr = 0.71 \), \( \beta = 0.0031 \text{ K}^{-1} \).

ANALYSIS: For the annular region

\[
\text{Ra}_L = \frac{g \beta (T_s - T_\infty) L^3}{\nu \alpha} = \left( \frac{9.8 \text{ m/s}^2}{18.2 \times 10^{-6} \text{ m}^2/\text{s}} \right) \left( \frac{0.0031 \text{ K}^{-1}}{25.9 \times 10^{-6} \text{ m}^2/\text{s}} \right) \left( \frac{(70 - 30) \text{°C}}{(0.025 \text{ m})^3} \right)
\]

\( \text{Ra}_L = 4.03 \times 10^4 \).

Hence, from Eq. 9.60,

\[
\text{Ra}_c^* = \frac{\left[ \ln (0.15/0.10) \right]^4}{(0.025 \text{ m})^3 \left[ (0.10)^{-3/5} + (0.15)^{-3/5} \right]^5} \times 4.03 \times 10^4 = 3857.
\]

Accordingly, Eq. 9.59 may be used, in which case

\[
k_{\text{eff}} = 0.386 k \left( \frac{\Pr}{0.861 + \Pr} \right)^{1/4} \left( \text{Ra}_c^* \right)^{1/4}
\]

\[
k_{\text{eff}} = 0.386 \left( 0.028 \text{ W/m} \cdot \text{K} \right) \left( \frac{0.71}{0.861 + 0.71} \right)^{1/4} (3857)^{1/4} = 0.07 \text{ W/m} \cdot \text{K}.
\]

From Eq. 9.58, it then follows that

\[
q' = 2\pi k_{\text{eff}} \left( \frac{L}{\ln (D_o/D_i)} \right) (T_i - T_o) = 2\pi \left( 0.07 \text{ W/m} \cdot \text{K} \right) \left( \frac{70 - 30}{} \text{°C} \right) = 43.4 \text{ W/m}.
\]

COMMENTS: An additional heat loss is related to thermal radiation exchange between the inner and outer surfaces.
PROBLEM 9.103

KNOWN: Annulus formed by two concentric, horizontal tubes with prescribed diameters and surface temperatures is filled with water.

FIND: Convective heat transfer rate per unit length of the tubes.

SCHEMATIC:

\[ L = \frac{D_0 - D_i}{2} = 12.5 \text{ mm} \]

\[ T_i = 300 \text{ K}, \quad D_i = 50 \text{ mm} \]

\[ T_o = 350 \text{ K}, \quad D_o = 75 \text{ mm} \]

ASSUMPTIONS: Steady-state conditions.

PROPERTIES: Table A-6, Water (\( T_f = 325 \text{ K} \)): \( \rho = \frac{1}{1.013 \times 10^{-3}} \text{ m}^3/\text{kg} \), \( c_p = 4182 \text{ J/kg K} \), \( \mu = 528 \times 10^{-6} \text{ N\cdot s/m}^2 \), \( k = 0.645 \text{ W/m K} \), \( Pr = 3.42 \), \( \beta = 471.2 \times 10^{-6} \text{ K}^{-1} \).

ANALYSIS: From Eqs. 9.58 and 9.59,

\[
q' = \frac{2\pi k_{\text{eff}}}{\ln (D_0/D_1)} (T_i - T_o) \left( \frac{k_{\text{eff}}}{k} \right) = 0.386 \left( \frac{Pr}{0.861 + Pr} \right)^{1/4} \left( Ra_{\text{c}}^* \right)^{1/4}. \quad (1,2)
\]

From Eq. 9.60,

\[
Ra_{\text{c}}^* = \left[ \ln \left( \frac{D_o}{D_1} \right) \right]^4 \cdot \frac{Ra_L}{L^3} \left( \frac{D_i^{-3/5} + D_o^{-3/5}}{9.8 \text{ m/s}^2} \right)^5.
\]

The Rayleigh number follows from Eq. 9.25 using \( \nu = \mu/\rho \) and \( \alpha = k/\rho c_p \),

\[
Ra_L = \frac{g \beta (T_o - T_i) L^3}{\nu \alpha} = \frac{9.8 \text{ m/s}^2 \times 471.2 \times 10^{-6} \text{ K}^{-1} \times (350 - 300) \text{ K} \times \left( 12.5 \times 10^{-3} \text{ m} \right)^3}{528 \times 10^{-6} \text{ N\cdot s/m}^2 \times 1.013 \times 10^{-3} \text{ m}^3/\text{kg} \times 0.645 \text{ W/m K} \times 1.013 \times 10^{-3} \text{ m}^3/\text{kg} \times 4182 \text{ J/kg K}} = 5.396 \times 10^5.
\]

Using this value in Eq. (3), find

\[
Ra_{\text{c}}^* = \left[ \ln \left( \frac{75}{50} \right) \right]^4 \times 5.396 \times 10^5 / \left( 12.5 \times 10^{-3} \text{ m} \right)^3 \left( \left( 50 \times 10^{-3} \text{ m} \right)^{-3/5} + \left( 75 \times 10^{-3} \text{ m} \right)^{-3/5} \right)^5 = 5.164 \times 10^4
\]

and then evaluating Eq. (2), find

\[
\frac{k_{\text{eff}}}{k} = 0.386 \left( \frac{3.42}{0.861 + 3.42} \right)^{1/4} \left( 5.164 \times 10^4 \right)^{1/4} = 5.50
\]

\[ k_{\text{eff}} = 5.50 \times 0.645 \text{ W/m K} = 3.55 \text{ W/m K}. \]

The heat rate from Eq. (1) is then,

\[
q' = \frac{2\pi \times 3.55 \text{ W/m K}}{\ln (75/50)} \times (350 - 300) \text{ K} = 2.75 \text{ kW/m}. \]

COMMENTS: Note that the \( Ra_{\text{c}}^* \) value is within prescribed limits for Eq. 9.50 or Eq. (3). Note also the characteristic length in \( Ra_L \) is \( L = (D_o - D_i)/2 \), the annulus gap.
PROBLEM 9.104

KNOWN: Annulus formed by two concentric, horizontal tubes with prescribed diameters and surface temperatures is filled with nitrogen at 5 atm.

FIND: Convective heat transfer rate per unit length of the tubes.

SCHEMATIC:

ASSUMPTIONS: (1) Thermophysical properties $k$, $\mu$, and $Pr$, are independent of pressure, (2) Density is proportional to pressure, (3) Perfect gas behavior.

PROPERTIES: Table A-4, Nitrogen ($T = (T_i + T_o)/2 = 350K$, 5 atm): $k = 0.0293 \text{ W/mK}$, $\mu = 200 \times 10^{-7} \text{ N/s/m}^2$, $\rho (5 \text{ atm}) = 5 \rho (1 \text{ atm}) = 5 \times 0.9625 \text{ kg/m}^3 = 4.813 \text{ kg/m}^3$, $Pr = 0.711$, $\nu = \mu/\rho = 4.155 \times 10^{-6} \text{ m}^2/\text{s}$, $\alpha = k/\rho c = 0.0293 \text{ W/mK}/(4.813 \text{ kg/m}^3 \times 1042 \text{ J/kgK}) = 5.842 \times 10^{-6} \text{ m}^2/\text{s}$.

ANALYSIS: From Eqs. 9.58 and 9.59

$$ q' = \frac{2\pi k_{\text{eff}}}{\ln(D_o/D_i)}(T_o - T_i) $$

$$ k_{\text{eff}} = 0.386 \left( \frac{Pr}{0.861 + Pr} \right)^{1/4} \left( Ra_c^* \right)^{1/4}. \quad (1.2) $$

From Eq. 9.60,

$$ Ra_c^* = \left[ \frac{\ln(D_o/D_i)}{D_i} \right]^4 Ra_L / L^3 \left( D_i^{-3/5} + D_o^{-3/5} \right)^5. \quad (3) $$

The Rayleigh number, $Ra_L$, follows from Eq. 9.25, and $Ra_c^*$ from Eq. (3),

$$ Ra_L = \frac{g \beta (T_o - T_i) L^3}{\alpha \nu} = \frac{9.8 \text{ m/s}^2 (1/350K) (400 - 300) \text{ K} (0.025m)^3}{5.842 \times 10^{-6} \text{ m}^2/\text{s} \times 4.155 \times 10^{-6} \text{ m}^2/\text{s}} = 1.802 \times 10^6. $$

$$ Ra_c^* = \left[ \frac{\ln(250/200)}{200} \right]^4 \times 1.802 \times 10^6 / (0.025m)^3 \left( 0.20^{-3/5} + 0.25^{-3/5} \right)^5 \text{ m}^3 = 98,791 $$

and then evaluating Eq. (2),

$$ k_{\text{eff}} = 0.386 \left( \frac{0.711}{0.861 + 0.711} \right)^{1/4} (98,791)^{1/4} = 5.61. $$

Hence, the heat rate, Eq. (1), becomes

$$ q' = \frac{2\pi \times 5.61 \times 0.0293 \text{ W/mK}}{\ln(250/200)} (400 - 300) \text{ K} = 463 \text{ W/m}. \quad < $$

COMMENTS: Note that the heat loss by convection is nearly six times that for conduction. Radiation transfer is likely to be important for this situation. The effect of nitrogen pressure is to decrease $\nu$ which in turn increases $Ra_L$; that is, free convection heat transfer will increase with increase in pressure.
PROBLEM 9.105

KNOWN: Diameters and temperatures of concentric spheres.

FIND: Rate at which stored nitrogen is vented.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible radiation.

PROPERTIES: Liquid nitrogen (given): \( h_{fg} = 2 \times 10^5 \text{ J/kg} \); Table A-4, Helium (\( \bar{T} = (T_i + T_o)/2 = 180\text{K}, 1 \text{ atm})\): \( \nu = 51.3 \times 10^{-6} \text{ m}^2/\text{s} \), \( k = 0.107 \text{ W/m-K} \), \( \alpha = 76.2 \text{ m}^2/\text{s} \), \( \text{Pr} = 0.673 \), \( \beta = 0.00556 \text{ K}^{-1} \).

ANALYSIS: Performing an energy balance for a control surface about the liquid nitrogen, it follows that

\[ q = q_{\text{conv}} = \dot{m} h_{fg}. \]

From the Raithby and Hollands expressions for free convection between concentric spheres,

\[ q_{\text{conv}} = k_{\text{eff}} \pi \left( \frac{D_i D_o}{L} \right) (T_o - T_i) \]

\[ k_{\text{eff}} = 0.74 \nu \left[ \frac{\text{Pr}}{(0.861 + \text{Pr})} \right]^{1/4} \left( \text{Ra}_s \right)^{1/4} \]

where

\[ \text{Ra}_s = \frac{L}{(D_o D_i)^4 \left( D_i^{-7/5} + D_o^{-7/5} \right)^5} \]

\[ \text{Ra}_L = \frac{g \beta (T_o - T_i)}{\nu \alpha} = \frac{9.8 \text{ m/s}^2 \left( 0.00556 \text{ K}^{-1} \right) (206\text{K})(0.05\text{m})^3}{(51.3 \times 10^{-6} \text{ m}^2/\text{s})(76.2 \times 10^{-6} \text{ m}^2/\text{s})} = 3.59 \times 10^5 \]

\[ \text{Ra}_s = \frac{0.05m}{(1.10m^2)^4 \left[ 1+(1.1)^{-7/5} \right]^5} = 529 \]

\[ k_{\text{eff}} = 0.74 \left( 0.107 \text{ W/m-K} \right) \left[ 0.673/(0.861+0.673) \right]^{1/4} (529)^{1/4} = 0.309 \text{ W/m-K} \]

Hence,

\[ q_{\text{conv}} = \left( 0.309 \text{ W/m-K} \right) \pi \left( 1.10m^2 / 0.05m \right) 206 \text{ K} = 4399 \text{ W}. \]

The rate at which nitrogen is lost from the system is therefore

\[ \dot{m} = \frac{q_{\text{conv}}}{h_{fg}} = 4399 \text{ W}/2 \times 10^5 \text{ J/kg} = 0.022 \text{ kg/s}. \]

COMMENTS: The heat gain and mass loss are large. Helium should be replaced by a noncondensing gas of smaller \( k \), or the cavity should be evacuated.
PROBLEM 9.106

KNOWN: Concentric spheres with prescribed surface temperatures.

FIND: Convection heat transfer rate.

SCHEMATIC:

![Diagram of concentric spheres with surface temperatures](image)

ASSUMPTIONS: (1) Quiescent air in void space, (2) Density ~ pressure; other properties independent, (3) Perfect gas behavior.

PROPERTIES: Table A-4, Air ($T_f = 300K$, 3 atm): $\beta = 3.33 \times 10^{-3} K^{-1}$, $\nu = 1/3 \times 15.89 \times 10^{-6} m^2/s$, $k = 0.263 W/mK$, $\alpha = 1/3 \times 22.5 \times 10^{-6} m^2/s$, $Pr = 0.707$.

ANALYSIS: The heat transfer rate due to free convection is

$$q = k_{eff} \pi (D_i D_o / L) (T_i - T_o)$$

where

$$k_{eff} / k = 0.74 \left( \frac{Pr}{0.861 + Pr} \right)^{1/4} \left( Ra_s^{*} \right)^{1/4}$$

$$Ra_s^{*} = \left[ \frac{L}{(D_o D_i)^4} \left( \frac{Ra_L}{D_i^{-7/5} + D_o^{-7/5}} \right)^5 \right]$$

$$Ra_L = \frac{g \beta (T_i - T_o) L^3}{\nu \alpha}.$$  (9.25)

Substituting numerical values in the above expressions, find that

$$Ra_L = \frac{9.8 m/s^2 \times 3.333 \times 10^{-3} K^{-1} (325 - 275) K (12.5 \times 10^{-3})^3 m^3}{(1/3) 5.89 \times 10^{-6} m^2 / s (1/3) 22.5 \times 10^{-6} m^2 / s} = 80,928$$

$$Ra_s^{*} = \left[ \frac{(12.5 \times 10^{-3}) m}{(100 \times 10^{-3} \times 75 \times 10^{-3})^4 m^4} \cdot \frac{80,928}{\left( 75 \times 10^{-3} m^{-7/5} + (100 \times 10^{-3} m)^{-7/5} \right)^5 \right] = 330.1$$

$$k_{eff} / k = 0.74 \left( \frac{0.707}{0.861 + 0.707} \right)^{1/4} (330.1)^{1/4} = 2.58.$$  

Hence, the heat rate becomes

$$q = \left( 2.58 \times 0.263 \frac{W}{m \cdot K} \right) \pi \left( \frac{75 \times 10^{-3} m \times 100 \times 10^{-3} m}{12.5 \times 10^{-3} m} \right) (325 - 275) K = 64.0 W.$$  

COMMENTS: Note the manner in which the thermophysical properties vary with pressure. Assuming perfect gas behavior, $\rho \sim p$. Also, $k$, $\mu$, and $c_p$ are independent of pressure. Hence, $Pr$ is independent of pressure, but $v = \mu / \rho \sim p^{-1}$ and $\alpha = k / \rho c \sim p^{-1}$. 

PROBLEM 9.107

KNOWN: Cross flow over a cylinder with prescribed surface temperature and free stream conditions.

FIND: Whether free convection will be significant if the fluid is water or air.

SCHEMATIC:

ASSUMPTIONS: (1) Constant properties, (2) Combined free and forced heat transfer.

PROPERTIES: Table A-6, Water \((T_f = (T_\infty + T_s)/2 = 300\text{K})\): \(\nu = \mu v_f = 855 \times 10^{-6} \text{N} \cdot \text{s} / \text{m}^2 \times 1.003 \times 10^{-3} \text{m}^3 / \text{kg} = 8.576 \times 10^{-7} \text{m}^2 / \text{s}, \beta = 276.1 \times 10^{-6} \text{K}^{-1};\) Table A-4, Air \((300\text{K}, 1 \text{atm})\): \(\nu = 15.89 \times 10^{-6} \text{m}^2 / \text{s}, \beta = 1/T_f = 3.333 \times 10^{-3} \text{K}^{-1} .\)

ANALYSIS: Following the discussion of Section 9.9, the general criterion for delineating the relative significance of free and forced convection depends upon the value of \(Gr/Re^2\). If free convection is significant,

\[
\text{Gr}_D / \text{Re}_D^2 \geq 1
\]

where

\[
\text{Gr}_D = g \beta (T_\infty - T_s)D^3 / \nu^2 \quad \text{and} \quad \text{Re}_D = VD / \nu .
\]

(a) When the surrounding fluid is water, find

\[
\begin{align*}
\text{Gr}_D &= 9.8 \text{m}^2 / \text{s}^2 \times 276.1 \times 10^{-6} \text{K}^{-1} \times (35 - 20) \text{K} (0.05 \text{m})^3 / \left(8.576 \times 10^{-7} \text{m}^2 / \text{s}\right)^2 = 68,980 \\
\text{Re}_D &= 0.05 \text{m} / \text{s} \times 0.05 \text{m} / 8.576 \times 10^{-7} \text{m}^2 / \text{s} = 2915 \\
\text{Gr}_D / \text{Re}_D^2 &= 68,980 / 2915^2 = 0.00812 . \quad < 
\end{align*}
\]

We conclude that since \(\text{Gr}_D / \text{Re}_D^2 \ll 1\), free convection is not significant. It is apparent that forced convection dominates the heat transfer process.

(b) When the surrounding fluid is air, find

\[
\begin{align*}
\text{Gr}_D &= 9.8 \text{m}^2 / \text{s}^2 \times 3.333 \times 10^{-3} \text{K}^{-1} \times (35 - 20) \text{K} (0.05 \text{m})^3 / \left(15.89 \times 10^{-6} \text{m}^2 / \text{s}\right)^2 = 242,558 \\
\text{Re}_D &= 0.05 \text{m} / \text{s} \times 0.05 \text{m} / 15.89 \times 10^{-6} \text{m}^2 / \text{s} = 157 \\
\text{Gr}_D / \text{Re}_D^2 &= 242,558 / 157^2 = 9.8 . \quad < 
\end{align*}
\]

We conclude that, since \(\text{Gr}_D / \text{Re}_D^2 \gg 1\), free convection dominates the heat transfer process.

COMMENTS: Note also that for the air flow situation, surface radiation exchange is likely to be significant.
PROBLEM 9.108

KNOWN: Parallel air flow over a uniform temperature, heated vertical plate; the effect of free convection on the heat transfer coefficient will be 5% when \( \frac{Gr_L}{Re_L^2} = 0.08 \).

FIND: Minimum vertical velocity required of air flow such that free convection effects will be less than 5% of the heat rate.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Criterion for combined free-forced convection determined from experimental results.

PROPERTIES: Table A-4, Air (\( T_f = \frac{(T_s + T_\infty)}{2} = 315K, 1 \text{ atm})\): \( \nu = 17.40 \times 10^{-6} \text{ m}^2/\text{s}, \beta = 1/T_f \).

ANALYSIS: To delineate flow regimes, according to Section 9.9, the general criterion for predominately forced convection is that
\[
\frac{Gr_L}{Re_L^2} << 1.
\]
(1)

From experimental results, when \( \frac{Gr_L}{Re_L^2} \approx 0.08 \), free convection will be equal to 5% of the total heat rate.

For the vertical plate using Eq. 9.12,
\[
Gr_L = \frac{g \beta (T_1 - T_2) L^3}{\nu^2} = \frac{9.8 \times 10^{-6} \text{ m}^2/\text{s}^2 \times 1/315K \times (60 - 25)K \times (0.3 \text{ m})^3}{(17.40 \times 10^{-6} \text{ m}^2/\text{s})^2} = 9.711 \times 10^7.
\]
(2)

For the vertical plate with forced convection,
\[
Re_L = \frac{u_\infty L}{\nu} = \frac{u_\infty (0.3 \text{ m})}{17.4 \times 10^{-6} \text{ m}^2/\text{s}} = 1.724 \times 10^4 u_\infty.
\]
(3)

By combining Eqs. (2) and (3),
\[
\frac{Gr_L}{Re_L^2} = \left[ \frac{9.711 \times 10^7}{1.724 \times 10^4 u_\infty} \right]^2 = 0.08
\]
find that
\[
u_\infty = 2.02 \text{ m/s}.
\]

That is, when \( u_\infty \geq 2.02 \text{ m/s} \), free convection effects will not exceed 5% of the total heat rate.
PROBLEM 9.109

KNOWN: Vertical array of circuit boards 0.15m high with maximum allowable uniform surface temperature for prescribed ambient air temperature.

FIND: Allowable electrical power dissipation per board, \( q' \) [W/m], for these cooling arrangements: (a) Free convection only, (b) Air flow downward at 0.6 m/s, (c) Air flow upward at 0.3 m/s, and (d) Air flow upward or downward at 5 m/s.

SCHEMATIC:

ASSUMPTIONS: (1) Uniform surface temperature, (2) Board horizontal spacing sufficient that boundary layers don’t interfere, (3) Ambient air behaves as quiescent medium, (4) Perfect gas behavior.

PROPERTIES: Table A-4, Air \((T_f = (T_s + T_\infty)/2 \approx 315K, 1 \text{ atm}): \nu = 17.40 \times 10^{-6} \text{ m}^2/\text{s}, k = 0.0274 \text{ W/m} \cdot \text{K}, \alpha = 24.7 \times 10^{-6} \text{ m}^2/\text{s}, \text{Pr} = 0.705, \beta = 1/T_f.\)

ANALYSIS: (a) For free convection only, the allowable electrical power dissipation rate is

\[
q' = \bar{h}_L (2L)(T_s - T_\infty)
\]

where \(\bar{h}_L\) is estimated using the appropriate correlation for free convection from a vertical plate. Find the Rayleigh number,

\[
\text{Ra}_L = \frac{g\beta \Delta T L^3}{\nu \alpha} = \frac{9.8 \text{m/s}^2 (1/315K)(60 - 25) K(0.150m)^3}{17.4 \times 10^{-6} \text{ m}^2/\text{s} \times 24.7 \times 10^{-6} \text{ m}^2/\text{s}} = 8.551 \times 10^6.
\]

Since \(\text{Ra}_L < 10^9\), the flow is laminar. With Eq. 9.27 find

\[
\text{Nu}_L = \frac{\bar{h}_L}{k} = 0.68 + \frac{0.670\text{Ra}_L^{1/4}}{\left[1 + (0.492/\text{Pr})^{9/16}\right]^{4/9}} = 0.68 + \left[\frac{0.670\left[8.551 \times 10^6\right]^{1/4}}{\left[1 + (0.492/0.705)^{9/16}\right]^{4/9}}\right] = 28.47
\]

\[
\bar{h}_L = (0.0274 \text{W/m} \cdot \text{K}/0.150m) \times 28.47 = 5.20 \text{W/m}^2 \cdot \text{K}.
\]

Hence, the allowable electrical power dissipation rate is

\[
q' = 5.20 \text{W/m}^2 \cdot \text{K} (2 \times 0.150m)(60 - 25)^\circ \text{C} = 54.6 \text{W/m}.
\]

(b) With downward velocity \(V = 0.6 \text{ m/s}\), the possibility of mixed forced-free convection must be considered. With \(\text{Re}_L = VL/\nu\), find

\[
\left(\frac{Gr_L}{\text{Re}_L^2}\right) = \left(\frac{\text{Ra}_L}{\text{Re}_L^2}\right) = \left(\frac{8.551 \times 10^6/0.705}{(0.6 \text{m/s} \times 0.150m/17.40 \times 10^{-6} \text{m}^2/\text{s})^2}\right) = 0.453.
\]

Continued …..
Since \( \left( \frac{G_L}{Re_L^2} \right) \sim 1 \), flow is mixed and the average heat transfer coefficient may be found from a correlating equation of the form

\[
\overline{Nu}^n = \frac{Nu_L^n \pm Nu_N^n}{F}
\]  

(5)

where \( n = 3 \) for the vertical plate geometry and the minus sign is appropriate since the natural convection (N) flow opposes the forced convection (F) flow. For the forced convection flow, \( Re_L = 5172 \) and the flow is laminar; using Eq. 7.31,

\[
\overline{Nu}_F = 0.664 \left( \frac{Re_L^{1/2} Pr^{1/3}}{0.150m} \right) \left( \frac{5172}{0.705} \right)^{1/3} = 42.50.
\]  

(6)

Using \( Nu_N = 28.47 \) from Eq. (3), Eq. (5) now becomes

\[
\overline{Nu}^3 = \left( \frac{hL}{k} \right)^3 = (42.50)^3 - (28.47)^3 \quad \overline{Nu} = 37.72
\]

\[
\bar{h} = \left( \frac{0.0274 W/m \cdot K}{0.150m} \right) \times 37.72 = 6.89 W/m^2 \cdot K.
\]

Substituting for \( \bar{h} \) into the rate equation, Eq. (1), the allowable power dissipation with a downward velocity of 0.6 m/s is

\[
q' = 6.89 W/m^2 \cdot K \left( 2 \times 0.150m \right) (60 - 25)°C = 72.3 W/m. \quad <
\]

(c) With an upward velocity \( V = 0.3 \) m/s, the positive sign of Eq. (5) applies since the N-flow is assisting the F-flow. For forced convection, find

\[
Re_L = VL/\nu = 0.3 m/s \times 0.150m/\left( 17.40 \times 10^{-6} m^2 / s \right) = 2586.
\]

The flow is again laminar, hence Eq. (6) is appropriate.

\[
\overline{Nu}_F = 0.664 \left( \frac{Re_L}{0.150m} \right)^{1/2} \left( 0.705 \right)^{1/3} = 30.05.
\]

From Eq. (5), with the positive sign, and \( Nu_N \) from Eq. (4),

\[
\overline{Nu}^3 = (30.05)^3 + (28.47)^3 \quad \overline{Nu} = 36.88 \quad \text{and} \quad \bar{h} = 6.74 W/m^2 \cdot K.
\]

From Eq. (1), the allowable power dissipation with an upward velocity of 0.3 m/s is

\[
q' = 6.74 W/m^2 \cdot K \left( 2 \times 0.150m \right) (60 - 25)°C = 70.7 W/m. \quad <
\]

(d) With a forced convection velocity \( V = 5 \) m/s, very likely forced convection will dominate. Check by evaluating whether \( \left( \frac{G_L}{Re_L^2} \right) \ll 1 \) where \( Re_L = VL/\nu = 5 m/s \times 0.150m/(17.40 \times 10^{-6} m^2 / s) = 43,103. \) Hence,

\[
\left( \frac{G_L}{Re_L^2} \right) = \left( \frac{Ra_L}{Pr} \right) = \left( 8.551 \times 10^6 / 0.705 \right) / 43,103^2 = 0.007.
\]

The flow is not mixed, but pure forced convection. Using Eq. (6), find

\[
\bar{h} = \left( \frac{0.0274 W/m \cdot K}{0.150m} \right) 0.664 \left( \frac{43,103}{0.705} \right)^{1/3} = 22.4 W/m^2 \cdot K
\]

and the allowable dissipation rate is

\[
q' = 22.4 W/m^2 \cdot K \left( 2 \times 0.150m \right) (60 - 25)°C = 235 W/m. \quad <
\]

**COMMENTS:** Be sure to compare dissipation rates to see relative importance of mixed flow conditions.
PROBLEM 9.110

KNOWN: Horizontal pipe passing hot oil used to heat water.

FIND: Effect of water flow direction on the heat rate.

SCHEMATIC:

ASSUMPTIONS: (1) Uniform pipe surface temperature, (2) Constant properties.

PROPERTIES: Table A-6, Water (T_f = (T_s + T_∞)/2 ≈ 335K): ν = μ_f v_f = 4.625 × 10^(-7) m^2/s, k = 0.656 W/mK, α = k v_f/ρ = 1.595 × 10^(-7) m^2/s, Pr = 2.88, β = 535.5 × 10^(-6) K^(-1); Table A-6, Water (T_∞ = 310K): ν = μ_f v_f = 6.999 × 10^(-7) m^2/s, k = 0.028 W/mK, Pr = 4.62; Table A-6, Water (T_s = 358K): Pr = 2.07

ANALYSIS: The rate equation for the flow situations is of the form

q' = h (πD) (T_s - T_∞).

To determine whether mixed flow conditions are present, evaluate \( Gr_D / Re_D^2 \).

\[
Gr_D = \frac{g β ΔT D^3}{ν^2} = \frac{9.8 \text{ m/s}^2 \times 535.5 \times 10^{-6} \text{ K}^{-1} (85 - 37) \text{ K} (0.100\text{ m})^3}{(4.625 \times 10^{-7} \text{ m}^2/\text{s})^2} = 1.178 \times 10^9
\]

\[
Re_D = \frac{VD}{ν} = 0.5 \text{ m/s} \times 0.100\text{ m} / 6.999 \times 10^{-7} \text{ m}^2/\text{s} = 7.144 \times 10^4.
\]

It follows that \( Gr_D / Re_D^2 = 0.231 \): since this ratio is of order unity, the flow condition is mixed. Using Eq. 9.64, \( \overline{Nu}^n = \overline{Nu}_F \pm \overline{Nu}_N \) and for the three flow arrangements,

(a) Transverse flow: \( \overline{Nu}^4 = \overline{Nu}_F^4 + \overline{Nu}_N^4 \)

(b) Opposing flow: \( \overline{Nu}^3 = \overline{Nu}_F^3 - \overline{Nu}_N^3 \)

(c) Assisting flow: \( \overline{Nu}^3 = \overline{Nu}_F^3 + \overline{Nu}_N^3 \)

For natural convection from the cylinder, use Eq. 9.34 with \( Ra = Gr \cdot Pr \).

\[
\overline{Nu}_N = \left\{ 0.60 + \frac{0.387 Ra_D^{1/6}}{1 + (0.559/Pr)^{9/16}} \right\}^{8/27} \]

\[
\overline{Nu}_F = C \left( \frac{Re_D}{Pr} \right)^{1/4} \overline{Nu}_F^0 \]

For forced convection in cross flow over the cylinder, from Table 7-4 use

\[
\overline{Nu}_F = 0.26 \left( 7.144 \times 10^4 \right)^{0.6} (4.62)^{0.37} (4.62/2.07)^{1/4} = 457.5
\]

Continued …..
where \( n = 0.37 \) since \( \text{Pr} \leq 10 \). The results of the calculations are tabulated.

**COMMENTS:** Note that the flow direction has a minor effect (<6%) for these conditions.
**PROBLEM 9.111**

**KNOWN:** Diameter and surface temperature of long tube housing heat dissipating electronic components. Temperature of cooling water.

**FIND:** (a) Heat dissipation per unit length to quiescent water, (b) Percent enhancement for imposed cross flow.

**SCHEMATIC:**

**ASSUMPTIONS:** Constant properties evaluated at $T_f$.

**PROPERTIES:** *Table A-6*, Water (325K): $\rho = 987 \text{ kg/m}^3$, $\mu = 528 \times 10^{-6} \text{ kg/s/m}$, $\nu = \mu/\rho = 0.535 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 0.645 \text{ W/mK}$, $Pr = 3.42$, $\beta = 471 \times 10^{-6} \text{ K}^{-1}$.

**ANALYSIS:** (a) With

$$Ra_D = \frac{\beta g \Delta T D^3}{\nu^2} Pr = \frac{9.8 \text{ m/s}^2 \times 471 \times 10^{-6} \text{ K}^{-1}(50 \text{ K})(0.1 \text{ m})^3}{(0.535 \times 10^{-6} \text{ m}^2/\text{s})^2} = 2.76 \times 10^9$$

use the Churchill and Chu correlation

$$\overline{Nu}_D = \left[0.60 + \frac{0.387 Ra_D^{1/6}}{\left[1 + (0.559/Pr)^{9/16}\right]^{8/27}}\right]^2 = \left[0.60 + \frac{0.387 \left(2.76 \times 10^9\right)^{1/6}}{\left[1 + (0.559/3.42)^{9/16}\right]^{8/27}}\right]^2 = 191$$

$$h = \frac{\overline{Nu}_D (k/D)}{191(0.645 \text{ W/m} \cdot \text{K}/0.1 \text{ m}) = 1232 \text{ W/m}^2 \cdot \text{K}}$$

Hence, $$q' = \pi D h (T_s - T_\infty) = \pi (0.1 \text{ m})1232 \text{ W/m}^2 \cdot \text{K}(350 - 300)\text{ K} = 19.4 \text{kW/m}.$$  

(b) Using the Hilpert correlation (for which properties are evaluated at $T_f$), it follows that, for pure forced convection,

$$Re_D = \frac{VD}{\nu} = \frac{1 \text{ m/s} \times 0.1 \text{ m}}{0.535 \times 10^{-6} \text{ m}^2/\text{s}} = 1.87 \times 10^5.$$  

Hence, using the Hilpert correlation,

$$\overline{Nu}_{D,F} = 0.027 Re_D^{0.805} Pr^{1/3} = 0.027 \left(1.87 \times 10^5\right)^{0.805} (3.42)^{1/3} = 713.$$  

For mixed convection with $n = 4$,

$$\overline{Nu}^n = \overline{Nu}_F^n + \overline{Nu}_N^n = (713)^4 + (191)^4 = 2.59 \times 10^{11} \overline{Nu} = 714$$

$$h = \frac{\overline{Nu}(k/D)}{714(0.645 \text{ W/m} \cdot \text{K}/0.1 \text{ m})} = 4605 \text{ W/m}^2 \cdot \text{K}.$$  

Hence, $$q' = h\pi D (T_s - T_\infty) = 4605 \text{ W/m}^2 \cdot \text{K} \times \pi (0.1 \text{ m})(350 - 300)\text{ K} = 72.3 \text{kW/m}.$$  

The cross flow enhances the heat rate by a factor of $72.3/19.4 = 3.7$.

**COMMENTS:** (1) With $V = 1 \text{ m/s}$, heat transfer is dominated by forced convection.
PROBLEM 9.112

KNOWN: Horizontal square panel removed from an oven and cooled in quiescent or moving air.

FIND: Initial convection heat rates for both methods of cooling.

SCHEMATIC:

ASSUMPTIONS: (1) Quasi-steady state conditions, (2) Backside of plates insulated, (3) Air flow is in the length-wise (not diagonal) direction, (4) Constant properties, (5) Radiative exchange negligible.

PROPERTIES: Table A-4, Air (\(T_f = (T_\infty + T_s)/2 = 350K\), 1 atm): \(v = 20.92 \times 10^{-6} \text{ m}^2/\text{s}\), \(k = 0.030 \text{ W/mK}\), \(\alpha = 29.9 \times 10^{-6} \text{ m}^2/\text{s}\), \(\Pr = 0.700\), \(\beta = 1/T_f\).

ANALYSIS: The initial heat transfer rate from the plates by convection is given by the rate equation

\[
q_h = h A_s \left( T_f - T_\infty \right)
\]

Test for the existence of combined free-forced convection by calculation of the ratio \(Gr/L^2 \cdot Re/L\). Use the same characteristic length in both parameters, \(L = 250\text{mm}\), the side length.

\[
Gr_L = \frac{g \beta \Delta T L^3}{v^2} = \frac{9.8 \text{ m/s}^2 (1/350K) (125 - 29) \text{K} (0.250\text{m})^3}{\left(20.92 \times 10^{-6} \text{ m}^2/\text{s}\right)^2} = 9.597 \times 10^7
\]

\[
Re_L = u_\infty L/v = 0.5 \text{ m/s} \times 0.250\text{m}/\left(20.92 \times 10^{-6} \text{ m}^2/\text{s}\right) = 5.975 \times 10^3.
\]

Since \(Gr/L^2 \cdot Re/L^2 = 2.69\) flow is mixed. For the stationary plate, \(Ra_L = Gr_L \cdot Pr = 6.718 \times 10^7\) and Eq. 9.31 is the appropriate correlation,

\[
\overline{Nu} = \frac{h L}{k} = 0.15 Ra_L^{1/3} = 0.15 \left(6.718 \times 10^7\right)^{1/3} = 60.9
\]

\[
q = 7.31 \text{ W/m}^2 \cdot \text{K} \times (0.250\text{m})^2 (125 - 29) \text{K} = 43.9\text{W}.
\]

For the plate with moving air, \(Re_L = 5.975 \times 10^3\) and the flow is laminar.

\[
\overline{Nu} = 0.664 \left(Re_L^{1/2} \cdot Pr^{1/3}\right) = 0.664 \left(5.975 \times 10^3\right)^{1/2} (0.700)^{1/3} = 45.6.
\]

For combined free-forced convection, use the correlating equation with \(n = 7/2\).

\[
\overline{Nu} = \frac{7/2}{Nu_{F}^{7/2} + Nu_{N}^{7/2}} = (45.6)^{7/2} + (60.9)^{7/2}
\]

\[
\overline{h} = Nu k/L = 66.5(0.030\text{W/m} \cdot \text{K}/0.25\text{m}) = 7.99\text{W/m}^2 \cdot \text{K}
\]

\[
q = 7.99 \text{ W/m}^2 \cdot \text{K} \times (0.250\text{m})^2 (125 - 29) \text{K} = 47.9\text{W}.
\]

COMMENTS: (1) The conveyor method provides only slight enhancement of heat transfer.
PROBLEM 9.113

KNOWN: Wet garment at 25°C hanging in a room with still, dry air at 40°C.

FIND: Drying rate per unit width of garment.

SCHEMATIC:

ASSUMPTIONS: (1) Analogy between heat and mass transfer applies, (2) Water vapor at garment surface is saturated at $T_s$, (3) Perfect gas behavior of vapor and air.

PROPERTIES: Table A-4, Air ($T_f \approx (T_s + T_\infty)/2 = 305K$, 1 atm): $\nu = 16.39 \times 10^{-6} \text{ m}^2/\text{s}$; Table A-6, Water vapor ($T_s = 298K$, 1 atm): $p_{A,s} = 0.0317 \text{ bar}$, $\rho_{A,s} = 1/\nu = 0.02660 \text{ kg/m}^3$; Table A-8, Air-water vapor (305 K): $D_{AB} = 0.27 \times 10^{-4} \text{ m}^2/\text{s}$, $\text{Sc} = \nu/D_{AB} = 0.607$.

ANALYSIS: The drying rate per unit width of the garment is

$$m_A' = \overline{h}_m \cdot L \left( \rho_{A,s} - \rho_{A,\infty} \right)$$

where $\overline{h}_m$ is the mass transfer coefficient associated with a vertical surface that models the garment. From the heat and mass transfer analogy, Eq. 9.24 and Fig. 9.6 yield

$$\text{Sh}_L = 0.59 \left( \text{Gr}_L \text{ Sc} \right)^{1/4}$$

where $\text{Gr}_L = g\Delta \rho L^3/\rho v^2$ and $\Delta \rho = \rho_s - \rho_\infty$. Since the still air is dry, $\rho_\infty = p_{B,\infty}/R_B T_\infty$, where $R_B = \Re/ M_B = 8.314 \times 10^{-2} \text{ m}^3 \cdot \text{bar/kmol/K}/29 \text{ kg/kmol} = 0.00287 \text{ m}^3 \cdot \text{bar/kg} \cdot \text{K}$. With $p_{B,\infty} = 1 \text{ atm} = 1.0133 \text{ bar}$,

$$\rho_\infty = \frac{1.0133 \text{ bar}}{0.00287 \text{ m}^3 \cdot \text{bar/kg} \cdot \text{K} \times 293 \text{ K}} = 1.1280 \text{ kg/m}^3$$

The density of the air/vapor mixture at the surface is $\rho_s = \rho_{A,s} + \rho_{B,s}$. With $p_{B,s} = 1 \text{ atm} - p_{A,s} = 1.0133 \text{ bar} - 0.0317 \text{ bar} = 0.9816 \text{ bar}$,

$$\rho_{B,s} = \frac{p_{B,s}}{R_B T_s} = \frac{0.9816 \text{ bar}}{0.00287 \left( \text{m}^3 \cdot \text{bar/kg} \cdot \text{K} \right) \times 298 \text{ K}} = 1.1477 \text{ kg/m}^3$$

Hence, $\rho_s = (0.0266 + 1.1477) \text{ kg/m}^3 = 1.1743 \text{ kg/m}^3$ and $\rho = (\rho_s + \rho_\infty)/2 = 1.512 \text{ kg/m}^3$. The Grashof number is then

$$\text{Gr}_L = \frac{9.8 \text{ m/s}^2 \times (1.1743 - 1.1280) \text{ kg/m}^3 (1 \text{ m})^3}{1.1512 \text{ kg/m}^3 \times \left( 16.39 \times 10^{-6} \text{ m}^2/\text{s} \right)^2} = 1.467 \times 10^9$$

and $(\text{Gr}_L \text{ Sc}) = 8.905 \times 10^8$. The convection coefficient is then

$$\overline{h}_m = \frac{D_{AB} \text{ Sh}_L}{L} = \frac{0.27 \times 10^{-4} \text{ m}^2/\text{s}}{1 \text{ m}} \times 0.59 \left( 8.905 \times 10^8 \right)^{1/4} = 0.00275 \text{ m/s}$$

The drying rate is then

$$m_A' = 2.750 \times 10^{-3} \text{ m/s} 	imes 1.0 \text{ m} \times (0.0226 - 0) \text{ kg/m}^3 = 6.21 \times 10^{-5} \text{ kg/s} \cdot \text{m}. <$$

COMMENTS: Since $\rho_s > \rho_\infty$, the buoyancy driven flow descends along the garment.
**PROBLEM 9.114**

**KNOWN:** Circular pan of water at 37°C exposed to dry, still air at 17°C.

**FIND:** Evaporation rate and total heat transfer rate from the pan.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Dry room air, (2) Negligible radiation, (3) Water vapor and air behave as perfect gases.

**PROPERTIES:** 
- Table A-4, Air ($T = (T_s + T_\infty)/2 = 300K, 1\text{ atm}$): 
  - $\nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}$,
  - $k = 0.0263 \text{ W/m} \cdot \text{K}$,
  - $Pr = 0.707$,
  - $\beta = 1/T_f$;
- Table A-6, Water ($T_s = 310\text{K}$): 
  - $\rho_{A,s} = \rho_{A, sat} = 1/\gamma g = 0.04361 \text{ kg/m}^3$,
  - $p_{A,s} = 0.0622 \text{ bar}$, $h_{fg} = 2414 \text{ kJ/kg}$;
- Table A-8, Air-water vapor (1 atm, $T_f = 300\text{K}$): 
  - $D_{AB} \approx 0.26 \times 10^{-4} \text{ m}^2/\text{s}$,
  - $Sc = \nu/D_{AB} = 0.611$

**ANALYSIS:**

The evaporation rate and total heat transfer rate from the pan are

\[
\dot{m}_A = \dot{m}_{A,s} (\rho_{A,s} - \rho_{A,\infty}) = \dot{m}_{A,s} \rho_{A, sat} (T_s) = q = q_{\text{conv}} + q_{\text{evap}} = \dot{m}_{A,s} (T_s - T_\infty) + \dot{m}_A h_{fg}
\]  

(1,2)

where $A_s = \pi D^2/4$. The convection coefficients can be estimated from the free convection correlation for a horizontal, circular plate with $L = A_s/P = D/4 = 0.0563 \text{ m}$.

To determine the appropriate convection correlation, we must first determine $\rho_\infty$ and $\rho_s$. Since $\phi_\infty = 0$ and the gas constant for air is $R_B = \gamma M_B = 8.314 \times 10^{-2} \text{ m}^3 \cdot \text{bar/kmol} / 29 \text{ kg/kmol} = 0.00287 \text{ m}^3 \cdot \text{bar/kg-K}$,

\[
\rho_\infty = \frac{p_{B,\infty}}{R_B T_\infty} = \frac{1.0133 \text{ bar}}{0.00287 \text{ m}^3 \cdot \text{bar/kg} \cdot \text{K} \times 290 \text{ K}} = 1.2175 \text{ kg/m}^3
\]

At the surface, $\rho_s = \rho_{A,s} + \rho_{B,s}$. With $p_{B,s} = 1.0133 \text{ bar} - p_{A,s} = 0.9511 \text{ bar}$, $\rho_{B,s} = p_{B,s}/R_B T_s = 1.0690 \text{ kg/m}^3$ and $\rho_s = \rho_{A,s} + \rho_{B,s} = 0.0436 + 1.0690 \text{ kg/m}^3 = 1.1126 \text{ kg/m}^3$

From Eq. 9.65, with $\rho = (\rho_s + \rho_\infty)/2 = 1.1651 \text{ kg/m}^3$, the Grashof number is

\[
Gr_L = \frac{g (\rho_\infty - \rho_s) L^3}{\rho v^2} = \frac{9.8 \text{ m/s}^2 \left(0.0524 \text{ kg/m}^3 \right) \left(0.0563 \text{ m}^3 \right)^3}{1.1651 \text{ kg/m}^3 \left(15.89 \times 10^{-6} \text{ m}^2/\text{s} \right)^2} = 3.12 \times 10^5
\]

in which case $Ra_L = Gr_L Pr = 2.21 \times 10^5$ and $Gr_L Sc = 1.91 \times 10^5$. From Eq. 9.30,

\[
h = \left(\frac{k}{L} \right)^{0.54} Ra_L^{1/4} = \left(\frac{0.0263 \text{ W/m} \cdot \text{K}}{0.0563 \text{ m}} \right)^{0.54} \left(2.21 \times 10^5 \right)^{1/4} = 5.47 \text{ W/m}^2 \cdot \text{K}
\]

Continued ....
and from its mass transfer analog,

\[
h_m = \frac{D_{AB}}{L} 0.54 \left( \frac{Gr \cdot Sc}{0.0563 \text{ m}} \right)^{1/4} = \left( \frac{0.26 \times 10^{-4} \text{ m}^2 / \text{s}}{0.0563 \text{ m}} \right)^{0.54} \left( 1.91 \times 10^5 \right)^{1/4} = 0.00521 \text{ m/s}
\]

Substituting numerical values into the rate equations, Eqs. (1) and (2), find

\[
\dot{m}_A = 5.21 \times 10^{-3} \text{ m/s} \left( \pi \left( \frac{0.225 \text{ m}}{4} \right)^2 \right) \times 0.04361 \text{ kg/m}^3 = 9.034 \times 10^{-6} \text{ kg/s} = 3.25 \text{ g/h}
\]

\[
q = 5.47 \text{ W/m}^2 \cdot \text{K} \left( \pi \left( \frac{0.225 \text{ m}}{4} \right)^2 \right) (37 - 17) \text{ K} + 9.034 \times 10^{-6} \text{ kg/s} \times 2414 \times 10^3 \text{ J/kg}
\]

\[
q = (4.4 + 21.8) \text{ W} = 26.2 \text{ W}
\]

**COMMENTS:** As expected, the heat loss is more strongly influenced by the loss of latent energy.
PROBLEM 9.115

KNOWN: A water bath maintained at a uniform temperature of 37°C with top surface exposed to draft-free air and uniform temperature walls in a laboratory.

FIND: (a) The heat loss from the surface of the bath by radiation exchange with the surroundings; (b) Calculate the Grashof number using Eq. 9.65 with a characteristic length L that is appropriate for the exposed surface of the water bath; (c) Estimate the free convection heat transfer coefficient using the result for $Gr_L$ obtained in part (b); (d) Invoke the heat-mass analogy and use an appropriate correlation to estimate the mass transfer coefficient using $Gr_L$; calculate the water evaporation rate on a daily basis and the heat loss by evaporation; and (e) Calculate the total heat loss from the surface and compare relative contributions of the sensible, latent and radiative effects. Review assumptions made in your analysis, especially those relating to the heat-mass analogy.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Laboratory air is quiescent, (3) Laboratory walls are isothermal and large compared to water bath exposed surface, (4) Emissivity of the water surface is 0.96, (5) Heat-mass analogy is applicable, and (6) Constant properties.

PROPERTIES: 

- Table A-6, Water vapor ($T_\infty = 293$ K): $\rho_{A,\infty,\text{sat}} = 0.01693$ kg/m$^3$; ($T_s = 310$ K): $\rho_{A,s} = 0.04361$ kg/m$^3$, $h_{fg} = 2.414 \times 10^6$ J/kg; 
- Table A-4, Air ($T_\infty = 293$ K, 1 atm): $\rho_{B,\infty} = 1.194$ kg/m$^3$; ($T_s = 310$ K, 1 atm): $\rho_{B,s} = 1.128$ kg/m$^3$; ($T_f = (T_s + T_\infty)/2 = 302$ K, 1 atm): $\nu_B = 1.604 \times 10^{-5}$ m$^2$/s, $k = 0.0270$ W/m·K, $Pr = 0.706$; 
- Table A-8, Water vapor-air ($T_f = 302$ K, 1 atm): $D_{AB} = 0.24 \times 10^{-4}$ m$^2$/s (302/298)$^{3/2} = 2.65 \times 10^{-5}$ m$^2$/s.

ANALYSIS: (a) Using the linearized form of the radiation exchange rate equation, the heat rate and radiation coefficient can be estimated.

$$h_{rad} = \varepsilon \sigma (T_s + T_{\text{sur}}) \left( T_s^2 + T_{\text{sur}}^2 \right)$$ (1)

$$h_{rad} = 0.96 \sigma (310 + 298) \left( 310^2 + 298^2 \right) K^3 = 6.12 \text{ W/m}^2 \cdot \text{K}$$ <

$$q_{rad} = h_{rad} A_s (T_s - T_{\text{sur}})$$ (2)

$$q_{rad} = 6.12 \text{ W/m}^2 \cdot \text{K} \times (0.25 \times 0.50) \text{m}^2 \times (37 - 25) \text{K} = 9.18 \text{ W}$$

(b) The general form of the Grashof number, Eq. 9.65, applied to natural convection flows driven by concentration gradients

$$Gr_L = g \left( \rho_\infty - \rho_s \right) L^3 / \rho \nu^2$$ (3)

where $L$ is the characteristic length defined in Eq. 9.29 as $L = A_s / P$, where $A_s$ and $P$ are the exposed surface area and perimeter, respectively; $\rho_s$ and $\rho_\infty$ are the density of the mixture at the surface and in the quiescent fluid, respectively; and, $\rho$ is the mean boundary layer density, $(\rho_\infty + \rho_s)/2$, and $\nu$ is the kinematic viscosity of fluid B, evaluated at the film temperature $T_f = (T_s + T_\infty)/2$. Using the property values from above,

Continued …..
\[ \rho_s = \rho_{A,s} + \rho_{B,s} = (0.04361 + 1.128) \text{kg/m}^3 = 1.1716 \text{kg/m}^3 \]
\[ \rho_{\infty} = \rho_{A,\infty} + \rho_{B,\infty} = \phi_{\infty} \rho_{A,\infty,\text{sat}} + \rho_{B,\infty} \]
\[ \rho_{\infty} = (0.6 \times 0.01693 + 1.194) \text{kg/m}^3 = 1.2042 \text{kg/m}^3 \]
\[ \rho = \frac{\rho_s + \rho_{\infty}}{2} = 1.4601 \text{kg/m}^3 \]

Substituting numerical values in Eq. (3), find the Grashof number.
\[ \text{Gr}_L = \frac{9.8 \text{m/s}^2 (1.2042 - 1.1716) \text{kg/m}^3 \times (0.0833 \text{m})^3}{1.4601 \text{kg/m}^3 \left( 1.604 \times 10^{-5} \text{m}^2/\text{s} \right)^2} \]
\[ \text{Gr}_L = 4.916 \times 10^5 \]

where the characteristic length is defined by Eq. 9.29,
\[ L = \frac{A_s}{P} = \frac{(0.25 \times 0.5) \text{m}^2}{2(0.25 + 0.50) \text{m}} = 0.0833 \text{m} \]

(c) The free convection heat transfer coefficient for the horizontal surface, Eq. 9.30, for upper surface of heated plate, is estimated as follows:
\[ \text{Ra}_L = \text{Gr}_L \text{Pr}_L = 4.916 \times 10^5 \times 0.706 = 3.471 \times 10^5 \]
\[ \overline{\text{Nu}}_L = \frac{\bar{h}L}{k} = 0.54 \text{Ra}_L^{1/4} = 13.11 \]
\[ \bar{h} = 13.11 \times 0.0270 \text{ W/m K/0.0833 m} = 4.25 \text{ W/m}^2 \cdot \text{K} \]

(d) Invoking the heat-mass analogy, the mass transfer coefficient is estimated as follows,
\[ \text{Ra}_{L,m} = \text{Gr}_L \text{Sc} = 4.916 \times 10^5 \times 0.605 = 2.975 \times 10^5 \]

where the Schmidt number is given as
\[ \text{Sc} = \nu / D_{AB} = 1.604 \times 10^{-5} \text{m}^2/\text{s} / 2.65 \times 10^{-5} \text{m}^2/\text{s} = 0.605 \]

The correlation has the form
\[ \overline{\text{Sh}}_L = \frac{\bar{h}_{m,L}}{D_{AB}} = 0.54 \text{Ra}_{L,m}^{1/4} = 12.61 \]
\[ \bar{h}_{m} = 12.61 \times 2.65 \times 10^{-5} \text{m}^2/\text{s/0.0833 m} = 0.00401 \text{ m/s} \]

The water evaporation rate on a daily basis is
\[ \overline{n}_A = \bar{h}_{m} A_s \left( \rho_{A,\text{sat}} - \rho_{A,\infty} \right) \]
\[ \overline{n}_A = 0.00401 \text{ m/s} (0.25 \times 0.50) \text{m}^2 (0.04361 - 0.6 \times 0.01693) \text{kg/m}^3 \]

Continued …..
PROBLEM 9.115 (Cont.)

\[ nA = 1.677 \times 10^{-5} \text{ kg/s} = 1.45 \text{ kg/day} \] <

and the heat loss by evaporation is

\[ q_{\text{evap}} = nA \cdot h_{fg} = 1.677 \times 10^{-5} \text{ kg/s} \times 2.414 \times 10^{6} \text{ J/kg} = 40.5 \text{ W} \] <

(e) The convective heat loss is that of free convection,

\[ q_{\text{cv}} = hA_s (T_s - T_\infty) \]

\[ q_{\text{cv}} = 4.25 \text{ W/m}^2 \times (0.25 \times 0.50) \text{ m}^2 \times (37 - 20) \text{ K} = 9.02 \text{ W} \] <

In summary, the total heat loss from the surface of the bath, which must be supplied as electrical power to the bath heaters, is

\[ q_{\text{tot}} = q_{\text{rad}} + q_{\text{cv}} + q_{\text{evap}} \]

\[ q_{\text{tot}} = (9.18 + 9.02 + 40.5) \text{ W} = 59 \text{ W} \] <

The sensible heat losses are by convection \((q_{\text{rad}} + q_{\text{cv}})\), which represent 31% of the total; the balance is the latent loss by evaporation, 69%. 
PROBLEM 10.1

KNOWN: Water at 1 atm with T_s – T_{sat} = 10°C.

FIND: Show that the Jakob number is much less than unity; what is the physical significance of the result; does result apply to other fluids?

ASSUMPTIONS: (1) Boiling situation, T_s > T_{sat}.

PROPERTIES: Table A-5 and Table A-6, (1 atm):

<table>
<thead>
<tr>
<th></th>
<th>h_{fg} (kJ/kg)</th>
<th>c_{p,v} (J/kg⋅K)</th>
<th>T_{sat}(K)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Water</td>
<td>2257</td>
<td>2029</td>
<td>373</td>
</tr>
<tr>
<td>Ethylene glycol</td>
<td>812</td>
<td>2742*</td>
<td>470</td>
</tr>
<tr>
<td>Mercury</td>
<td>301</td>
<td>135.5*</td>
<td>630</td>
</tr>
<tr>
<td>R-12</td>
<td>165</td>
<td>1015*</td>
<td>243</td>
</tr>
</tbody>
</table>

* Estimated based upon value at highest temperature cited in Table A-5.

ANALYSIS: The Jakob number is the ratio of the maximum sensible energy absorbed by the vapor to the latent energy absorbed by the vapor during boiling. That is,

\[ Ja = \left( c_p \Delta T \right)_v / h_{fg} = c_{p,v} \Delta T_c / h_{fg} \]

For water with an excess temperature \( \Delta T_s = T_c - T_\infty = 10°C \), find

\[ Ja = \left( 2029 \text{ J/kg} \cdot \text{K} \times 10^3 \right) / 2257 \times 10^3 \text{ J/kg} = 0.0090. \]

Since \( Ja \ll 1 \), the implication is that the sensible energy absorbed by the vapor is much less than the latent energy absorbed during the boiling phase change. Using the appropriate thermophysical properties for three other fluids, the Jakob numbers are:

**Ethylene glycol:**

\[ Ja = \left( 2742 \text{ J/kg} \cdot \text{K} \times 10^3 \right) / 812 \times 10^3 \text{ J/kg} = 0.0338 \]

**Mercury:**

\[ Ja = \left( 135.5 \text{ J/kg} \cdot \text{K} \times 10^3 \right) / 301 \times 10^3 \text{ J/kg} = 0.0045 \]

**Refrigerant, R-12:**

\[ Ja = \left( 1015 \text{ J/kg} \cdot \text{K} \times 10^3 \right) / 165 \times 10^3 \text{ J/kg} = 0.0615 \]

For ethylene glycol and R-12, the Jakob number is larger than the value for water, but still much less than unity. Based upon these example fluids, we conclude that generally we’d expect Ja to be much less than unity.

COMMENTS: We would expect the same low value of Ja for the condensation process since \( c_{p,g} \) and \( c_{p,f} \) are of the same order of magnitude.
PROBLEM 10.2

KNOWN: Horizontal 20 mm diameter cylinder with $\Delta T_e = T_s - T_{sat} = 5^\circ C$ in saturated water, 1 atm.

FIND: Heat flux based upon free convection correlation; compare with boiling curve. Estimate maximum value of the heat transfer coefficient from the boiling curve.

SCHEMATIC:

\[
\begin{align*}
\Delta T_e &= 5^\circ C \\
T_s &= 105^\circ C
\end{align*}
\]

ASSUMPTIONS: (1) Horizontal cylinder, (2) Free convection, no bubble information.

PROPERTIES: Table A-6, Water (Saturated liquid, $T_f = (T_{sat} + T_s)/2 = 102.5$ $^\circ C = 375K$): $\rho = 956.9$ kg/m$^3$, $c_p, \nabla = 4220$ J/kg-K, $\mu = 274 \times 10^{-6}$ N-s/m$^2$, $k = 0.681$ W/m-K, $Pr = 1.70$, $\beta = 761 \times 10^{-6}$ K$^{-1}$.

ANALYSIS: To estimate the free convection heat transfer coefficient, use the Churchill-Chu correlation,

\[
\overline{Nu_D} = \frac{\overline{hD}}{k} = \left[ 0.60 + \frac{0.387 Ra_D^{1/6}}{1 + (0.559/Pr)^{9/16}} \right]^{2/7}
\]

Substituting numerical values, with $\Delta T = \Delta T_e = 5^\circ C$, find

\[
Ra_D = \frac{g \beta \Delta T D^3}{\nu \alpha} = \frac{9.8 \times 761 \times 10^{-6} \times 5^\circ C \times 0.020 m}{274 \times 10^{-6} \times 956.9 \times 1.686 \times 10^{-7}} = 6.178 \times 10^6
\]

where $\alpha = k/\rho c_p = (0.681$ W/m-K/956.9 kg/m$^3 \times 4220$ J/kg-K) = $1.686 \times 10^{-7}$ m$^2$/s. Note that $Ra_D$ is within the prescribed limits of the correlation. Hence,

\[
\overline{Nu_D} = \left[ 0.60 + \frac{0.387 \left(6.178 \times 10^6\right)^{1/6}}{1 + (0.559/1.70)^{9/16}} \right]^{2/7} = 27.22
\]

\[
\overline{h_{fc}} = \overline{Nu_D} \frac{k}{D} = \frac{27.22 \times 0.681 W/m \cdot K}{0.020 m} = 928 W/m^2 \cdot K.
\]

Hence, $q_s^* = h_{fc} \Delta T_e = 4640$ W/m$^2$

From the typical boiling curve for water at 1 atm, Fig. 10.4, find at $\Delta T_e = 5^\circ C$ that $q_s^* = 8.5 \times 10^3$ W/m$^2$

The free convection correlation underpredicts (by 1.8) the boiling curve. The maximum value of $h_{bc}$ can be estimated as

\[
h_{max} = q_{max} / \Delta T_e = 1.2 \times 10^6$ MW/m$^2$ /30$^\circ C = 40,000$ W/m$^2 \cdot K.
\]

COMMENTS: (1) Note the large increase in $h$ with a slight change in $\Delta T_e$.

(2) The maximum value of $h$ occurs at point P on the boiling curve.
**PROBLEM 10.3**

**KNOWN:** Spherical bubble of pure saturated vapor in mechanical and thermal equilibrium with its liquid.

**FIND:** (a) Expression for the bubble radius, (b) Bubble vapor and liquid states on a p-v diagram; how changes in these conditions cause bubble to collapse or grow, and (c) Bubble size for specified conditions.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Liquid-vapor medium, (2) Thermal and mechanical equilibrium.

**PROPERTIES:** Table A-6, Water (\(T_{\text{sat}} = 101^\circ \text{C} = 374.15\text{K}\)): \(p_{\text{sat}} = 1.0502\text{ bar}\); (\(T_{\text{sat}} = 100^\circ \text{C} = 373.15\text{K}\)): \(p_{\text{sat}} = 1.0133\text{ bar}\), \(\sigma = 58.9 \times 10^{-3}\text{ N/m}\).

**ANALYSIS:** (a) For mechanical equilibrium, the difference in pressure between the vapor inside the bubble and the liquid outside the bubble will be offset by the surface tension of the liquid-vapor interface. The force balance follows from the free-body diagram shown above (right),

\[
F_{\text{st}} = \left(\pi r_b^2\right) \Delta p = \left(p_i - p_o\right) \left(\pi r_b^2\right)
\]

\[
(2\pi r_b)\sigma = \left(\pi r_b^2\right)(p_i - p_o)
\]

\[
r_b = \frac{2\sigma}{(p_i - p_o)}
\]

Thermal equilibrium requires that the temperatures of the vapor and liquid be equal. Since the vapor inside the bubble is saturated, \(p_i = p_{\text{sat,v}}(T)\). Since \(p_o < p_i\), it follows that the liquid outside the bubble must be superheated; hence, \(p_o = p_{\ell}(T)\), the pressure of superheated liquid at \(T\). Hence, we can write,

\[
r_b = \frac{2\sigma}{p_{\text{sat,v}} - p_{\ell}}
\]

(b) The vapor [1] and liquid [2] states are represented on the following p-v diagram. Thermal equilibrium requires both the vapor and liquid to be at the same temperature [3]. But mechanical equilibrium requires that the outside liquid pressure be less than the inside vapor pressure [4]. Hence the liquid must be in a superheated state. That is, its saturation temperature, \(T_{\text{sat}}(p_o)\) [5] is less than \(T_{\text{sat}}(p_i)\); \(T_{\ell} = T_{\text{sat}}(p_o)\) and \(p_o = p_{\ell}\).

Continued …..
The equilibrium condition for the bubble is unstable. Consider situations for which the pressure of the surrounding liquid is greater or less than the equilibrium value. These situations are presented on portions of the p-v diagram

When $p'_o < p_o$, $T'_\ell < T_{sat,v}$ and heat must be transferred out of the bubble and vapor condenses. Hence, the bubble collapses.

A similar argument for the condition $p'_o > p_o$ leads to $T'_\ell > T_{sat,v}$ and heat is transferred into the bubble causing evaporation with the formation of vapor. Hence, the bubble begins to grow.

(c) Consider the specific conditions

$$T_{sat,v} = 101^\circ C$$
and

$$T'_\ell = T_{sat}(p_o) = 100^\circ C$$

and calculate the radius of the bubble using the appropriate properties in Eq. (2).

$$r_b = 2 \times 58.9 \times 10^{-3} \frac{N}{m} / (1.0502 - 1.0133) \text{bar} \times \left( 10^5 \frac{N}{m^2} / \text{bar} \right)$$

$$r_b = 0.032 \text{mm}.$$
**PROBLEM 10.4**

**KNOWN:** Long wire, 1 mm diameter, reaches a surface temperature of 126°C in water at 1 atm while dissipating 3150 W/m.

**FIND:** (a) Boiling heat transfer coefficient and (b) Correlation coefficient, \( C_{s,f} \), if nucleate boiling occurs.

**SCHEMATIC:**

![Schematic Image]

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Nucleate boiling.

**PROPERTIES:** Table A-6, Water (saturated, 1 atm): \( T_s = 100°C \), \( \rho_\ell = 1/\nu_f = 957.9 \text{ kg/m}^3 \), \( \rho_f = 1/\nu_g = 0.5955 \text{ kg/m}^3 \), \( c_{p,\ell} = 4217 \text{ J/kg-K} \), \( \mu_\ell = 279 \times 10^{-6} \text{ N-s/m}^2 \), \( Pr_\ell = 1.76 \), \( h_{fg} = 2257 \text{ kJ/kg} \), \( \sigma = 58.9 \times 10^{-3} \text{ N/m} \).

**ANALYSIS:** (a) For the boiling process, the rate equation can be rewritten as

\[
\bar{h} = \frac{q''_{s}}{(T_s - T_{sat})} = \frac{q'_{s}}{\pi D} / (T_s - T_{sat})
\]

\[
\bar{h} = \frac{3150 \text{ W/m}}{\pi \times 0.001 \text{ m}} / (126 - 100) \text{°C} = 1.00 \times 10^6 \text{ W/m}^2 / 26 \text{°C} = 38.600 \text{ W/m}^2 \cdot \text{K}.
\]

Note the heat flux is very close to \( q''_{max} \), and nucleate boiling does exist.

(b) For nucleate boiling, the Rohsenow correlation may be solved for \( C_{s,f} \) to give

\[
C_{s,f} = \left\{ \frac{\mu_\ell h_{fg}}{q'_{s}} \right\}^{1/3} \left[ \frac{g (\rho_\ell - \rho_f)}{\sigma} \right]^{1/6} \left( \frac{c_{p,\ell} \Delta T_e}{h_{fg} Pr_\ell^{n}} \right)
\]

Assuming the liquid-surface combination is such that \( n = 1 \) and substituting numerical values with \( \Delta T_e = T_s - T_{sat} \), find

\[
C_{s,f} = \left\{ \frac{279 \times 10^{-6} \text{ N-s/m}^2 \times 2257 \times 10^3 \text{ J/kg}}{1.00 \times 10^6 \text{ W/m}^2} \right\}^{1/3} \left[ \frac{9.8 \frac{m}{s^2} (957.9 - 0.5955) \frac{\text{kg}}{\text{m}^3}}{58.9 \times 10^{-3} \text{ N/m}} \right]^{1/6} \times
\]

\[
\left\{ \frac{4217 \text{ J/kg-K} \times 26 \text{K}}{2257 \times 10^3 \text{ J/kg} \times 1.76} \right\}
\]

\[
C_{s,f} = 0.017.<
\]

**COMMENTS:** By comparison with the values of \( C_{s,f} \) for other water-surface combinations of Table 10.1, the \( C_{s,f} \) value for the wire is large, suggesting that its surface must be highly polished. Note that the value of the boiling heat transfer coefficient is much larger than values common to single-phase convection.
PROBLEM 10.5

KNOWN: Nucleate pool boiling on a 10 mm-diameter tube maintained at $\Delta T_e = 10^\circ$C in water at 1 atm; tube is platinum-plated.

FIND: Heat transfer coefficient.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Nucleate pool boiling.

PROPERTIES: Table A-6, Water (saturated, 1 atm): $T_s = 100^\circ$C, $\rho_{\ell} = 1/\nu_f = 957.9$ kg/m$^3$, $\rho_v = 1/\nu_g = 0.5955$ kg/m$^3$, $c_{p,\ell} = 4217$ J/kg$\cdot$K, $\mu_{\ell} = 279 \times 10^{-6}$ N$\cdot$s/m$^2$, $Pr_{\ell} = 1.76$, $h_{fg} = 2257$ kJ/kg, $\sigma = 58.9 \times 10^{-3}$ N/m.

ANALYSIS: The heat transfer coefficient can be estimated using the Rohsenow nucleate-boiling correlation and the rate equation

$$h = \frac{q_s^*}{\Delta T_e} = \frac{\mu_{\ell} h_{fg}}{\Delta T_e} \left[ \frac{g (\rho_{\ell} - \rho_v)}{\sigma} \right]^{1/2} \left[ \frac{c_{p,\ell} \Delta T_e}{C_{s,f} h_{fg} Pr_{\ell}^n} \right]^3.$$

From Table 10.1, find $C_{s,f} = 0.013$ and $n = 1$ for the water-platinum surface combination. Substituting numerical values,

$$h = \frac{279 \times 10^{-6} \text{N} \cdot \text{s} / \text{m}^2 \times 2257 \times 10^3 \text{J} / \text{kg}}{10^\circ \text{K}} \left[ \frac{9.8 \text{m} / \text{s}^2 (957.9 - 0.5955) \text{kg} / \text{m}^3}{58.9 \times 10^{-3} \text{N} / \text{m}} \right]^{1/2} \times$$

$$\left[ \frac{4217 \text{J} / \text{kg} \cdot \text{K} \times 10^\circ \text{K}}{0.013 \times 2257 \times 10^3 \text{J} / \text{kg} \times 1.76} \right]^3$$

$$h = 13,690 \text{ W} / \text{m}^2 \cdot \text{K}.$$ <

COMMENTS: For this liquid-surface combination, $q_s^* = 0.137 \text{ MW/m}^2$, which is in general agreement with the typical boiling curve of Fig. 10.4. To a first approximation, the effect of the tube diameter is negligible.
PROBLEM 10.6

KNOWN: Water boiling on a mechanically polished stainless steel surface maintained at an excess temperature of 15°C; water is at 1 atm.

FIND: Boiling heat transfer coefficient.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Nucleate pool boiling occurs.

PROPERTIES: Table A-6, Saturated water (1 atm): \( T_{\text{sat}} = 100^\circ\text{C} \), \( \rho_{\ell} = 957.9 \text{ kg/m}^3 \), \( \rho_v = 0.596 \text{ kg/m}^3 \), \( c_{p,\ell} = 4217 \text{ J/kg} \cdot \text{K} \), \( \mu_\ell = 279 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 \), \( Pr_\ell = 1.76 \), \( \sigma = 58.9 \times 10^{-3} \text{ N/m} \), \( h_{fg} = 2257 \text{ kJ/kg} \).

ANALYSIS: The heat transfer coefficient can be expressed as

\[
q_s^* = \frac{\Delta T_e}{h_{\text{fg}} / T_e}
\]

where the nucleate pool boiling heat flux can be estimated using the Rohsenow correlation.

\[
q_s^* = \mu_\ell \ h_{fg} \left[ \frac{g (\rho_\ell - \rho_v)}{\sigma} \right]^{1/2} \left( \frac{c_{p,\ell} \Delta T_e}{C_{s,f} h_{fg} \ P_{r,\ell}^n} \right)^{3/2}.
\]

From Table 10.1, find for this liquid-surface combination, \( C_{s,f} = 0.013 \) and \( n = 1 \), and substituting numerical values,

\[
q_s^* = 279 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 \times 2257 \times 10^3 \text{ J/kg} \left[ \frac{9.8 \text{ m/s}^2 (957.9 - 0.596) \text{ kg/m}^3}{58.9 \times 10^{-3} \text{ N/m}} \right]^{1/2} \times \left( \frac{4217 \text{ J/kg} \cdot \text{K} \times 15^\circ\text{C}}{0.013 \times 2257 \text{ kJ/kg} \times 1.76} \right)^{3/2}.
\]

\[
q_s^* = 461.9 \text{ kW/m}^2.
\]

Hence, the heat transfer coefficient is

\[
h = 461.9 \times 10^3 \text{ W/m}^2 / 15^\circ\text{C} = 30,790 \text{ W/m}^2 \cdot \text{K}.
\]

COMMENTS: Note that this value of \( q_s^* \) for \( \Delta T_e = 15^\circ\text{C} \) is consistent with the typical boiling curve, Fig. 10.4.
PROBLEM 10.7

KNOWN: Simple expression to account for the effect of pressure on the nucleate boiling convection coefficient in water.

FIND: Compare predictions of this expression with the Rohsenow correlation for specified $\Delta T_e$ and pressures (2 and 5 bar) applied to a horizontal plate.

ASSUMPTIONS: (1) Steady-state conditions, (2) Nucleate pool boiling, (3) $C_{s,f} = 0.013$, $n = 1$.

PROPERTIES: Table A-6, Saturated water (2 bar): $\rho_\ell = 942.7$ kg/m$^3$, $c_{p,\ell} = 4244.3$ J/kg·K, $\mu_\ell = 230.7 \times 10^{-6}$ N·s/m$^2$, $Pr_\ell = 1.43$, $h_{fg} = 2203$ kJ/kg, $\sigma = 54.97 \times 10^{-3}$ N/m, $\rho_v = 1.1082$ kg/m$^3$; Saturated water (5 bar): $\rho_\ell = 914.7$ kg/m$^3$, $c_{p,\ell} = 4316$ J/kg·K, $\mu_\ell = 179 \times 10^{-6}$ N·s/m$^2$, $Pr_\ell = 1.13$, $h_{fg} = 2107.8$ kJ/kg, $\sigma = 48.4 \times 10^{-3}$ N/m, $\rho_v = 2.629$ kg/m$^3$.

ANALYSIS: The simple expression by Jakob [51] accounting for pressure effects is

$$h = C(\Delta T_e)^n (p/p_a)^{0.4}$$

where $p$ and $p_a$ are the system and standard atmospheric pressures. For a horizontal plate, $C = 5.56$ and $n = 3$ for the range $15 < q_s'' < 235$ kW/m$^2$. For $\Delta T_e = 10^\circ C$,

$$p = 2 \text{ bar} \quad h = 5.56 \left(\frac{10^3}{2\text{bar}/1.0133\text{bar}}\right)^{0.4} = 7.298 \text{ W/m}^2\cdot\text{K}, \quad q_s'' = 73 \text{ kW/m}^2$$

$$p = 5 \text{ bar} \quad h = 5.56 \left(\frac{10^3}{5\text{bar}/1.0133\text{bar}}\right)^{0.4} = 10.529 \text{ W/m}^2\cdot\text{K}, \quad q_s'' = 105 \text{ kW/m}^2$$

where $q_s'' = h\Delta T_e$. The Rohsenow correlation, Eq. 10.5, with $C_{s,f} = 0.013$ and $n = 1$, is of the form

$$q_s'' = \mu_\ell h_{fg} \left[\frac{g(\rho_\ell - \rho_v)}{\sigma}\right]^{1/2} \left[\frac{c_{p,\ell} \Delta T_e}{C_{s,f} h_{fg} Pr_\ell^n}\right]^3$$

$$p = 2 \text{ bar}: \quad q_s'' = 230.7 \times 10^{-6} \frac{\text{N} \cdot \text{s}}{\text{m}^2} \times 2203 \times 10^3 \frac{\text{J}}{\text{kg}} \left\{ \frac{9.8 \frac{\text{m}}{\text{s}^2} \left(942.7 - 1.082 \frac{\text{kg}}{\text{m}^3}\right)}{54.97 \times 10^{-3} \frac{\text{N}}{\text{m}}} \right\}^{1/2} \times \left\{ \frac{4244.3 \frac{\text{J}}{\text{kg} \cdot \text{K}} \times 10^\circ \text{K}}{0.013 \times 2203 \times 10^3 \frac{\text{J}}{\text{kg} \times 1.43^3}} \right\}^3$$

$$q_s'' = 232 \text{ kW/m}^2$$

$$p = 4 \text{ bar}: \quad q_s'' = 439 \text{ kW/m}^2$$

COMMENTS: For ease of comparison, the results with $p_a = 1.0133$ bar are:

<table>
<thead>
<tr>
<th>Correlation/p (bar)</th>
<th>1</th>
<th>2</th>
<th>4</th>
</tr>
</thead>
<tbody>
<tr>
<td>Simple</td>
<td>56</td>
<td>73</td>
<td>105</td>
</tr>
<tr>
<td>Rohsenow</td>
<td>135</td>
<td>232</td>
<td>439</td>
</tr>
</tbody>
</table>

Note that the range of $q_s''$ is within the limits of the Simple correlation. The comparison is poor and therefore the correlation is not to be recommended. By manipulation of the Rohsenow results, find that the $(p/p_a)^m$ dependence provides $m \approx 0.75$, compared to the exponent of 0.4 in the Simple correlation.
**PROBLEM 10.8**

**KNOWN:** Diameter of copper pan. Initial temperature of water and saturation temperature of boiling water. Range of heat rates \(1 \leq q \leq 100\) kW.

**FIND:** (a) Variation of pan temperature with heat rate for boiling water, (b) Pan temperature shortly after start of heating with \(q = 8\) kW.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Conditions of part (a) correspond to steady nucleate boiling, (2) Surface of pan corresponds to polished copper, (3) Conditions of part (b) correspond to natural convection from a heated plate to an infinite quiescent medium, (4) Negligible heat loss to surroundings.

**PROPERTIES:** Table A-6, saturated water \((T_{sat} = 100^\circ C)\): \(\rho_{\ell} = 957.9\) kg/m\(^3\), \(\rho_v = 0.60\) kg/m\(^3\), \(c_{p,\ell} = 4217\) J/kg K, \(\mu_{\ell} = 279 \times 10^{-6}\) N·s/m\(^2\), \(Pr_{\ell} = 1.76\), \(h_{fg} = 2.257 \times 10^6\) J/kg, \(\sigma = 0.0589\) N/M.

Table A-6, saturated water (assume \(T_s = 100^\circ C, T_f = 60^\circ C = 333\) K): \(\rho = 983\) kg/m\(^3\), \(\mu = 467 \times 10^{-6}\) N·s/m\(^2\), \(k = 0.654\) W/m·K, \(Pr = 2.99\), \(\beta = 523 \times 10^{-6}\) K\(^{-1}\). Hence, \(\nu = 0.475 \times 10^{-6}\) m\(^2\)/s, \(\alpha = 0.159 \times 10^{-6}\) m\(^2\)/s.

**ANALYSIS:** (a) From Eq. (10.5),

\[
\Delta T_s = T_s - T_{sat} = \frac{C_{s,f} h_{fg} Pr_{\ell}^n}{c_{p,\ell}} \left[ \frac{q_s / \mu_{\ell} h_{fg} A_s}{g (\rho_{\ell} - \rho_v) / \sigma} \right]^{1/3} \]

For \(n = 1.0\), \(C_{s,f} = 0.013\) and \(A_s = \pi D^2/4 = 0.0707\) m\(^2\), the following variation of \(T_s\) with \(q_s\) is obtained.

As indicated by the correlation, the surface temperature increases as the cube root of the heat rate, permitting large increases in \(q\) for modest changes in \(T_s\). For \(q = 1\) kW, \(T_s = 104.7^\circ C\), which is barely sufficient to sustain boiling.

(b) Assuming \(10^7 < \text{Ra}_L < 10^{11}\), the convection coefficient may be obtained from Eq. (9.31). Hence, with \(L = A_s/P = D/4 = 0.075\) m,

Continued ….
PROBLEM 10.8 (Cont.)

\[ h = \left( \frac{k}{L} \right)^{1/3} Ra_{L}^{1/3} = \left( \frac{0.654 \text{ W} / \text{m} \cdot \text{K}}{0.075 \text{ m}} \right)^{0.15} \left[ \frac{9.8 \text{ m} / \text{s}^{2} \times 523 \times 10^{-6} \text{ K}^{-1} (T_{s} - T_{i}) (0.075 \text{ m})^{3}}{0.475 \times 0.159 \times 10^{-12} \text{ m}^{4} / \text{s}^{2}} \right]^{1/3} \]

\[ = 1.308 (2.86 \times 10^{7})^{1/3} (T_{s} - T_{i})^{1/3} = 400 (T_{s} - T_{i})^{1/3} \]

With \( A_s = \pi D^2 / 4 = 0.0707 \text{ m}^2 \), the heat rate is then

\[ q = \bar{h} A_s (T_{s} - T_{i}) = (400 \text{ W} / \text{m}^2 \cdot \text{K}^{4/3}) 0.0707 \text{ m}^2 (T_{s} - T_{i})^{4/3} \]

With \( q = 8000 \text{ W},\)

\[ T_{s} = T_{i} + 69^\circ \text{C} = 89^\circ \text{C} \]

**COMMENTS:**

1. With \( (T_{s} - T_{i}) = 69^\circ \text{C}, \) \( Ra_{L} = 1.97 \times 10^9 \), which is within the assumed Rayleigh number range.
2. The surface temperature increases as the temperature of the water increases, and bubbles may nucleate when it exceeds 100^\circ\text{C}. However, while the water temperature remains below the saturation temperature, the bubbles will collapse in the subcooled liquid.
PROBLEM 10.9

KNOWN: Fluids at 1 atm: mercury, ethanol, R-12.

FIND: Critical heat flux; compare with value for water also at 1 atm.

ASSUMPTIONS: (1) Steady-state conditions, (2) Nucleate pool boiling.

PROPERTIES: Table A-5 and Table A-6 at 1 atm,

<table>
<thead>
<tr>
<th>Fluid</th>
<th>h&lt;sub&gt;fg&lt;/sub&gt; (kJ/kg)</th>
<th>ρ&lt;sub&gt;v&lt;/sub&gt; (kg/m&lt;sup&gt;3&lt;/sup&gt;)</th>
<th>ρ&lt;sub&gt;l&lt;/sub&gt; (N/m)</th>
<th>σ × 10&lt;sup&gt;3&lt;/sup&gt;</th>
<th>T&lt;sub&gt;sat&lt;/sub&gt; (K)</th>

<td>2257</td>
<td>0.596</td>
<td>957.9</td>
<td>58.9</td>
<td>373</td>
</tr>
</tbody>
</table>

ANALYSIS: The critical heat flux can be estimated by the modified Zuber-Kutateladze correlation, Eq. 10.7,

\[
q_{\text{max}}' = 0.149 h_{\text{fg}} \rho_v \left[ \frac{\sigma g (\rho_l - \rho_v)}{\rho_v^2} \right]^{1/4}.
\]

To illustrate the calculation procedure, consider numerical values for mercury.

\[
q_{\text{max}}' = 0.149 \times 301 \times 10^3 \text{J/kg} \times 3.90 \text{kg/m}^3 \times \left[ \frac{417 \times 10^{-3} \text{N/m} \times 9.8 \text{m/s}^2 (12,740 - 3.90) \text{kg/m}^3}{(3.90 \text{kg/m}^3)^2} \right]^{1/4}
\]

\[
q_{\text{max}}' = 1.34 \text{ MW/m}^2.
\]

For the other fluids, the results are tabulated along with the ratio of the critical heat fluxes to that for water.

<table>
<thead>
<tr>
<th>Fluid</th>
<th>q&lt;sub&gt;max&lt;/sub&gt; (MW/m&lt;sup&gt;2&lt;/sup&gt;)</th>

<td>0.241</td>
<td>0.19</td>
</tr>
<tr>
<td>Water</td>
<td>1.26</td>
<td>1.00</td>
</tr>
</tbody>
</table>

COMMENTS: Note that, despite the large difference between mercury and water properties, their critical heat fluxes are similar.
PROBLEM 10.10

KNOWN: Copper pan, 150 mm diameter and filled with water at 1 atm, is maintained at 115°C.

FIND: Power required to boil water and the evaporation rate; ratio of heat flux to critical heat flux; pan temperature required to achieve critical heat flux.

SCHEMATIC:

ASSUMPTIONS: (1) Nucleate pool boiling, (2) Copper pan is polished surface.

PROPERTIES: Table A-6, Water (1 atm): \( T_{\text{sat}} = 100°C, \rho_\ell = 957.9 \text{ kg/m}^3, \rho_v = 0.5955 \text{ kg/m}^3, \)
\( c_{p,\ell} = 4217 \text{ J/kg} \cdot \text{K}, \mu_\ell = 279 \times 10^{-6} \text{ N} \cdot \text{s/m}^2, \text{Pr}_\ell = 1.76, h_{fg} = 2257 \text{ kJ/kg}, \sigma = 58.9 \times 10^{-3} \text{ N/m}. \)

ANALYSIS: The power requirement for boiling and the evaporation rate can be expressed as follows,
\[
q_{\text{boil}} = q_s^* \cdot A_s \quad \text{and} \quad \dot{m} = q_{\text{boil}} / h_{fg}.
\]
The heat flux for nucleate pool boiling can be estimated using the Rohsenow correlation.
\[
q_s^* = \mu_\ell h_{fg} \left[ \frac{g (\rho_\ell - \rho_v)}{\sigma} \right]^{1/2} \left( \frac{c_{p,\ell} \Delta T_e}{C_{s,f} \ h_{fg} \ \text{Pr}_\ell} \right)^{3/2}.
\]
Selecting \( C_{s,f} = 0.013 \) and \( n = 1 \) from Table 10.1 for the polished copper finish, find
\[
q_s^* = 4.619 \times 10^5 \text{ W/m}^2.
\]
The power and evaporation rate are
\[
q_{\text{boil}} = 4.619 \times 10^5 \text{ W/m}^2 \times \frac{\pi}{4} (0.150m)^2 = 8.16kW
\]
\[
\dot{m}_{\text{boil}} = 8.16kW/2257 \times 10^3 \text{ J/kg} = 3.62 \times 10^{-3} \text{ kg/s} = 13\text{ kg/h}.
\]
The maximum or critical heat flux was found in Example 10.1 as
\[
q_{\text{max}} = 1.26 \text{ MW/m}^2.
\]
Hence, the ratio of the operating to maximum heat flux is
\[
\frac{q_s^*}{q_{\text{max}}} = 4.619 \times 10^5 \text{ W/m}^2 / 1.26 \text{ MW/m}^2 = 0.367.
\]
From the boiling curve, Fig. 10.4, \( \Delta T_e \approx 30°C \) will provide the maximum heat flux.
PROBLEM 10.11

KNOWN: Nickel-coated heater element exposed to saturated water at atmospheric pressure; thermocouple attached to the insulated, backside surface indicates a temperature $T_o = 266.4^\circ C$ when the electrical power dissipation in the heater element is $6.950 \times 10^7$ W/m$^3$.

FIND: (a) From the foregoing data, calculate the surface temperature, $T_s$, and the heat flux at the exposed surface, and (b) Using an appropriate boiling correlation, estimate the surface temperature based upon the surface heat flux determined in part (a).

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Water exposed to standard atmospheric pressure and uniform temperature, $T_{sat}$, and (3) Nucleate pool boiling occurs on exposed surface, (4) Uniform volumetric generation in element, and (5) Backside of heater is perfectly insulated.

PROPERTIES: Table A-6, Saturated water, liquid (100°C): $\rho_f = 1/\nu_f = 957.9$ kg/m$^3$, $c_{p,\ell} = c_{p,f} = 4.217$ kJ/kg·K, $\mu_\ell = \mu_f = 279 \times 10^{-6}$ N·s/m$^2$, $Pr_\ell = Pr_f = 1.76$, $h_{fg} = 2257$ kJ/kg, $\sigma = 58.9 \times 10^{-3}$ N/m; Saturated water, vapor (100°C): $\rho_v = 1/\nu_g = 0.5955$ kg/m$^3$.

ANALYSIS: (a) From Eq. 3.43, the temperature at the exposed surface, $T_s$, is

$$T_s = T_o - \frac{q_L^2}{2k} = 266.4^\circ C - \frac{6.95 \times 10^7 \text{ W/m}^3 (0.015 \text{ m})^2}{2 \times 50 \text{ W/m·K}}$$

$$T_s = 110.0^\circ C$$

The heat flux at the exposed surface is

$$q_L^* = \frac{q}{L} = 6.95 \times 10^7 \text{ W/m}^3 / 0.015 \text{ m} = 4.63 \times 10^9 \text{ W/m}^2$$

(b) Since $\Delta T_e = T_s - T_{sat} = (110 - 100)^\circ C = 10^\circ C$, nucleate pool boiling occurs and the Rohsenow correlation, Eq. 10.5, with $q_L^*$ from part (a) can be used to estimate the surface temperature, $T_{s,c}$.

$$q_L^* = \mu_\ell h_{fg} \left[ \frac{g(r_\ell - \rho_f)}{\sigma} \right]^{1/2} \left( \frac{c_{p,\ell} \Delta T_{e,c}}{C_{s,f} h_{fg} Pr_{\ell}^n} \right)^{3}$$

From Table 10.1, for the water-nickel surface-fluid combination, $C_{s,f} = 0.006$ and $n = 1.0$. Substituting numerical values, find $\Delta T_{e,c}$ and $T_{s,c}$. Continued ….
PROBLEM 10.11 (Cont.)

\[ 4.63 \times 10^9 \text{ W/m}^2 = 279 \times 10^{-6} \text{ N.s/m}^2 \times 2257 \times 10^3 \text{ J/kg} \]

\[ \times \left[ \frac{9.8 \text{ m/s}^2}{58.9 \times 10^{-3} \text{ N/m}} \left( 957.9 - 0.5955 \right) \text{ kg/m}^3 - \right]^{1/2} \]

\[ \times \left( \frac{4.217 \times 10^3 \text{ J/kg.K} \times \Delta T_{c,c}}{0.006 \times 2257 \times 10^3 \text{ J/kg} \times 1.76} \right)^3 \]

\[ \Delta T_{c,c} = T_{s,c} - T_{sat} = 9.1^\circ \text{C} \quad T_{s,c} = 109.1^\circ \text{C} \]

COMMENTS: From the experimental data, part (a), the surface temperature is determined from the conduction analyses as \( T_s = 110.0^\circ \text{C} \). Using the traditional nucleate boiling correlation with the experiential value for the heat flux, the surface temperature is estimated as \( T_{s,c} = 109.1^\circ \text{C} \). The two approaches provide excess temperatures that are 10.0 vs. 9.1°C, which amounts to nearly a 10% difference.
PROBLEM 10.12

KNOWN: Chips on a ceramic substrate operating at power levels corresponding to 50% of the critical heat flux.

FIND: (a) Chip power level and temperature rise of the chip surface, and (b) Compute and plot the chip temperature $T_s$ as a function of heat flux for the range $0.25 \leq q_s^* / q_{\text{max}} \leq 0.90$.

SCHEMATIC:

ASSUMPTIONS: (1) Nucleate boiling, (2) Fluid-surface with $C_{s,f} = 0.004$, $n = 1.7$ for Rohsenow correlation, (3) Backside of substrate insulated.

PROPERTIES: Table A-5, Refrigerant R-113 (1 atm): $T_{\text{sat}} = 321 \text{ K} = 48^\circ \text{C}$, $\rho = 1511 \text{ kg/m}^3$, $\rho_v = 7.38 \text{ kg/m}^3$, $h_v = 147 \text{ kJ/kg}$, $\sigma = 15.9 \times 10^{-3} \text{ N/m}$; R-113, sat. liquid (given, 321 K): $c_{p,\ell} = 983.8 \text{ J/kg} \cdot \text{K}$, $\mu = 5.147 \times 10^{-4} \text{ N} \cdot \text{s/m}^2$, $Pr = 7.183$.

ANALYSIS: (a) The operating power level (flux) is $0.50 q_{\text{max}}^*$, where the critical heat flux is estimated from Eq. 10.7 for nucleate pool boiling,

$$q_{\text{max}}^* = 0.149 h_{\text{fg}} \rho_v \left[ \frac{\sigma (\rho - \rho_v)}{\rho_v^2} \right]^{1/4}$$

$$q_{\text{max}} = 0.149 \times 147 \times 10^{-3} \frac{\text{J}}{\text{kg}} \times 7.38 \frac{\text{kg}}{\text{m}^3} \times 15.9 \times 10^{-3} \frac{\text{N}}{\text{m}} \times 9.8 \frac{\text{m}}{\text{s}^2} (1511 - 7.38) \frac{\text{kg}}{\text{m}^3} / \left( 7.38 \frac{\text{kg}}{\text{m}^3} \right)^2^{1/4}$$

$$q_{\text{max}} = 233 \frac{\text{kW}}{\text{m}^2}.$$  

Hence, the heat flux on a chip is $0.5 \times 233 \frac{\text{kW}}{\text{m}^2} = 116 \frac{\text{kW}}{\text{m}^2}$ and the power level is

$$q_{\text{chip}} = q_s^* \times A_s = 116 \times 10^3 \frac{\text{W}}{\text{m}^2} \times 25 \text{ mm}^2 \left( 10^{-3} \text{ m/mm} \right)^2 = 2.9 \text{ W}.$$  

To determine the chip surface temperature for this condition, use the Rohsenow equation to find $\Delta T_c = T_s - T_{\text{sat}}$ with $q_s^* = 116 \times 10^3 \frac{\text{W}}{\text{m}^2}$. The correlation, Eq. 10.5, solved for $\Delta T_c$ is

$$\Delta T_c = \frac{C_{s,f} h_{\text{fg}} \left( \frac{q_s^*}{\mu h_{\text{fg}}} \right)^{1/3} \left[ \frac{\sigma}{g (\rho - \rho_v)} \right]^{1/6}}{c_{p,\ell} \left( \frac{116 \times 10^3 \frac{\text{W}}{\text{m}^2}}{5.147 \times 10^{-4} \frac{\text{N} \cdot \text{s}}{\text{m}^2} \times 147 \times 10^3 \frac{\text{J}}{\text{kg}}} \right)^{1/3} \left( \frac{15.9 \times 10^{-3} \frac{\text{N}}{\text{m}}}{9.8 \frac{\text{m}}{\text{s}^2} (1511 - 7.38) \frac{\text{kg}}{\text{m}^3}} \right)^{1/6}} \times \frac{0.004 \times 147 \times 10^3 \frac{\text{J}}{\text{kg} \cdot \text{K}} (7.18)^{1.7}}{983.8 \frac{\text{J}}{\text{kg} \cdot \text{K}}} = 19.9^\circ \text{C}.$$  

Hence, the chip surface temperature is

Continued...
PROBLEM 10.12 (Cont.)

\[ T_s = T_{\text{sat}} + \Delta T_c = 48^\circ \text{C} + 19.9^\circ \text{C} \approx 68^\circ \text{C}. \]

(b) Using the \textit{IHT Correlations Tools, Boiling, Nucleate Pool Boiling -- Heat flux and Maximum heat flux}, the chip surface temperature, \( T_s \), was calculated as a function of the ratio \( \frac{q''}{q''_{\text{max}}} \). The required thermophysical properties as provided in the problem statement were entered directly into the IHT workspace. The results are plotted below.

![Graph showing chip temperature, \( T_s \), against the ratio \( \frac{q''}{q''_{\text{max}}} \).](image)

**COMMENTS:**

1. Refrigerant R-113 is attractive for electronic cooling since its boiling point is slightly above room temperature. The reliability of electronic devices is highly dependent upon operating temperature.

2. A copy of the \textit{IHT Workspace} model used to generate the above plot is shown below.

```plaintext
// Correlations Tool - Boiling, Nucleate pool boiling, Critical heat flux
q''_{\text{max}} = q_{\text{max}}_dprime_NPB(rhol,rhov,hfg,sigma,g)  // Eq 10.7

(Continued on next page)
PROBLEM 10.13

KNOWN: Saturated ethylene glycol at 1 atm heated by a chromium-plated heater of 200 mm diameter and maintained at 480K.

FIND: Heater power, rate of evaporation, and ratio of required power to maximum power for critical heat flux.

SCHEMATIC:

ASSUMPTIONS: (1) Nucleate pool boiling, (2) Fluid-surface, \( C_{s,f} = 0.010 \) and \( n = 1 \).

PROPERTIES: Table A-5, Saturated ethylene glycol (1atm): \( T_{\text{sat}} = 470\text{K} \), \( h_{fg} = 812 \text{kJ/kg} \), \( \rho_f = 1111 \text{kg/m}^3 \), \( \sigma = 32.7 \times 10^{-3} \text{N/m} \); Saturated ethylene glycol (given, 470K): \( \rho_v = 1.66 \text{kg/m}^3 \), \( \mu_v = 0.38 \times 10^{-3} \text{N.s/m}^2 \), \( c_{p,\ell} = 3280 \text{J/kg.K} \), \( Pr_{\ell} = 8.7 \), \( k_{\ell} = 0.15 \text{W/m.K} \).

ANALYSIS: The power requirement for boiling and the evaporation rate are \( q^*_{\text{boil}} = q^*_{s}A_s \) and \( \dot{m} = q_{\text{boil}} / h_{fg} \). Using the Rohsenow correlation,

\[
q^*_{s} = \mu_v h_{fg} \left[ \frac{g(\rho_\ell - \rho_v)}{\sigma} \right]^{1/2} \left( \frac{c_{p,\ell} \Delta T_e}{C_{s,f} h_{fg} Pr_{\ell}^n} \right)^3
\]

\[
q^*_{s} = 0.38 \times 10^{-3} \frac{\text{N.s}}{\text{m}^2} \times 812 \times 10^3 \frac{\text{J}}{\text{kg}} \times \left[ \frac{9.8 \text{m/s}^2 (1111 - 1.66) \text{kg/m}^3}{32.7 \times 10^{-3} \text{N/m}} \right]^{1/2} \left( \frac{3280 \text{J/kg.K} (480 - 470) \text{K}}{0.01 \times 812 \times 10^3 \frac{\text{J}}{\text{kg}} (8.7)^1} \right)^3
\]

\[
q^*_{s} = 1.78 \times 10^4 \text{W/m}^2
\]

\[
\dot{m} = 559 \text{W} / 812 \times 10^3 \text{J/kg} = 6.89 \times 10^{-4} \text{kg/s}.
\]

For this fluid, the critical heat flux is estimated from Eq. 10.7,

\[
q^*_{\text{max}} = 0.149 h_{fg} \rho_v \left[ \frac{\sigma g(\rho_\ell - \rho_v)}{\rho_v^2} \right]^{1/4}
\]

\[
q^*_{\text{max}} = 0.149 \times 812 \times 10^3 \frac{\text{J}}{\text{kg}} \times 1.66 \frac{\text{kg}}{\text{m}^3} \times \left[ \frac{32.7 \times 10^{-3} \text{N/m} \times 9.8 \text{m/s}^2 (1111 - 1.66) \text{kg/m}^3}{(1.66 \text{kg/m}^3)^2} \right]^{1/4}
\]

\[
q^*_{\text{max}} = 6.77 \times 10^5 \text{W/m}^2
\]

Hence, the ratio of the operating heat flux to the critical heat flux is,

\[
\frac{q^*_{s}}{q^*_{\text{max}}} = \frac{1.78 \times 10^4 \text{W/m}^2}{6.77 \times 10^5 \text{W/m}^2} = 0.026 \quad \text{or} \quad 2.6%.
\]

COMMENTS: Recognize that the results are crude approximations since the values for \( C_{s,f} \) and \( n \) are just estimates. This fluid is not normally used for boiling processes since it decomposes at higher temperatures.
PROBLEM 10.14

**KNOWN:** Copper tubes, 25 mm diameter × 0.75 m long, used to boil saturated water at 1 atm operating at 75% of the critical heat flux.

**FIND:** (a) Number of tubes, \( N \), required to evaporate at a rate of 750 kg/h; tube surface temperature, \( T_s \), for these conditions, and (b) Compute and plot \( T_s \) and \( N \) required to provide the prescribed vapor production as a function of the heat flux ratio, \( 0.25 \leq q_s''/q_{\text{max}}'' \leq 0.90 \).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Nucleate pool boiling, (2) Polished copper tube surfaces.

**PROPERTIES:** Table A-6, Saturated water (100°C): \( \rho_\ell = 957.9 \text{ kg/m}^3 \), \( c_{p,\ell} = 4217 \text{ J/kg} \cdot \text{K} \), \( \mu_\ell = 279 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 \), \( \Pr_\ell = 1.76 \), \( h_{fg} = 2257 \text{ kJ/kg} \), \( \sigma = 58.9 \times 10^{-3} \text{ N/m} \), \( \rho_v = 0.5955 \text{ kg/m}^3 \).

**ANALYSIS:** (a) The total number of tubes, \( N \), can be evaluated from the rate equations

\[
q = q_s''A_s = q_s'' N \pi DL \quad q = \dot{m}h_{fg} \quad N = \dot{m}h_{fg}/q_s'' \pi DL .
\]

The tubes are operated at 75% of the critical flux (1.26 MW/m², see Example 10.1). Hence, the heat flux is

\[
q_s'' = 0.75 q_{\text{max}}'' = 0.75 \times 1.26 \text{ MW/m}^2 = 9.45 \times 10^5 \text{ W/m}^2 .
\]

Substituting numerical values into Eq. (3), find

\[
N = 750 \text{ kg/h} \times 1.26 \times 10^3 \text{ J/kg} \left( 9.45 \times 10^5 \text{ W/m}^2 \times \pi \times 0.025 \text{ m} \times 0.75 \text{ m} \right) = 8.5 \approx 9 .
\]

To determine the tube surface temperature, use the Rohsenow correlation,

\[
\Delta T_e = C_{s,f} h_{fg} \left( \Pr_\ell^n \right) \left( \frac{q_s''}{\mu_\ell h_{fg}} \right)^{1/3} \left[ \frac{\sigma}{g (\rho_\ell - \rho_v)} \right]^{1/6} .
\]

From Table 10.1 for the polished copper-water combination, \( C_{s,f} = 0.013 \) and \( n = 1.0 \).

\[
\Delta T_e = \frac{0.013 \times 2257 \times 10^3 \text{ J/kg} \left( 1.76 \right)^1 \left( \frac{9.45 \times 10^5 \text{ W/m}^2}{279 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 \times 2257 \times 10^3 \text{ J/kg}} \right)^{1/3} \times \frac{58.9 \times 10^{-3} \text{ N/m}}{9.8 \text{ m/s}^2 \left( 957.9 - 0.5955 \right) \text{ kg/m}^3} \right]^{1/6} = 19.0^\circ \text{C} .
\]

Hence,

\[
T_s = T_{\text{sat}} + \Delta T_e = (100 + 19) ^\circ \text{C} = 119 ^\circ \text{C} .
\]

Continued...
(b) Using the IHT Correlations Tool, Boiling, Nucleate Pool Boiling, Heat flux and the Properties Tool for Water, combined with Eqs. (1,2,3) above, the surface temperature $T_s$ and $N$ can be computed as a function of $q_s''/q_{max}''$. The results are plotted below.

Note that the tube surface temperature increases only slightly (113 to 120°C) as the ratio $q_s''/q_{max}''$ increases. The number of tubes required to provide the prescribed evaporation rate decreases markedly as $q_s''/q_{max}''$ increases.

**COMMENTS:** (1) The critical heat flux, $q_{max}'' = 1.26$ MW/m$^2$, for saturated water at 1 atm is calculated in Example 10.1 using the Zuber-Kutateladze relation, Eq. 10.7. The IHT Correlation Tool, Boiling, Nucleate pool boiling, Maximum heat flux, with the Properties Tool for Water could also be used to determine $q_{max}''$. 
**PROBLEM 10.15**

**KNOWN:** Diameter and length of tube submerged in pressurized water. Flow rate and inlet temperature of gas flow through the tube.

**FIND:** Tube wall and gas outlet temperatures.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Uniform tube wall temperature, (3) Nucleate boiling at outer surface of tube, (4) Fully developed flow in tube, (5) Negligible flow work and potential and kinetic energy changes for tube flow, (7) Constant properties.

**PROPERTIES:**

- **Table A-6,** saturated water \( (p_{\text{sat}} = 4.37 \text{ bars}) \): \( T_{\text{sat}} = 420 \text{ K} \), \( h_{\text{fg}} = 2.123 \times 10^6 \text{ J/kg} \), \( \rho_{\ell} = 919 \text{ kg/m}^3 \), \( \rho_{\nu} = 2.4 \text{ kg/m}^3 \), \( \mu_{\ell} = 185 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 \), \( c_{p,\ell} = 4302 \text{ J/kg} \cdot \text{K} \), \( \text{Pr}_{\ell} = 2.123 \times 10^6 \text{ J/kg} \cdot \text{K} \), \( \sigma = 0.0494 \text{ N/m} \).
- **Table A-4,** air \( (p = 1 \text{ atm}, T_m = 700 \text{ K}) \): \( c_p = 1075 \text{ J/kg} \cdot \text{K} \), \( \mu = 339 \times 10^{-7} \text{ N} \cdot \text{s/m}^2 \), \( k = 0.0524 \text{ W/m} \cdot \text{K} \), \( \text{Pr} = 0.695 \).

**ANALYSIS:** From an energy balance performed for a control surface that bounds the tube, we know that the rate of heat transfer by convection from the gas to the inner surface must equal the rate of heat transfer due to boiling at the outer surface. Hence, from Eqs. (8.44), (8.45) and (10.5), the energy balance for a single tube is of the form

\[
\bar{h}A_s \left[ \frac{\Delta T_0 - \Delta T_i}{\ln \left( \frac{\Delta T_0}{\Delta T_i} \right)} \right] = A_s \mu_{\ell} h_{\text{fg}} \left( \frac{g \left( \rho_{\ell} - \rho_{\nu} \right)}{\sigma} \right)^{1/2} \left( \frac{c_{p,\ell} \Delta T_e}{C_{s,f} h_{\text{fg}} \text{Pr}_{\ell}^n} \right)^{3/2}
\]

where \( \bar{U} = \bar{h} \) and \( C_{s,f} = 0.013 \) and \( n = 1.0 \) from Table 10.1. The corresponding unknowns are the wall temperature \( T_s \) and gas outlet temperature, \( T_{m,o} \), which are also related through Eq. (8.43).

\[
\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp \left( -\frac{\pi DL}{\bar{h} \bar{m} c_p} \right)
\]

For \( \text{Re}_D = 4m/\pi D \mu = 119,600 \), the flow is turbulent, and with \( n = 0.3 \), Eq. (8.60) yields,

\[
\bar{h} = h_{\text{fd}} = \left( \frac{k}{D} \right) 0.023 \text{Re}_D^{4/5} \text{Pr}^{0.3} = \left( \frac{0.0524 \text{ W/m} \cdot \text{K}}{0.025 \text{m}} \right) 0.023 (119,600)^{4/5} (0.695)^{0.3} = 502 \text{ W/m}^2 \cdot \text{K}
\]

Solving Eqs. (1) and (2), we obtain

\[
T_s = 152.6^\circ \text{C}, \quad T_{m,o} = 166.7^\circ \text{C}
\]

**COMMENTS:** (1) The heat rate per tube is \( q = \bar{m} c_p (T_{m,i} - T_{m,o}) = 45,930 \text{ W} \), and the total heat rate is \( Nq = 229,600 \text{ W} \), in which case the rate of steam production is \( \dot{m}_{\text{steam}} = q/h_{\text{fg}} = 0.108 \text{ kg/s} \).

(2) It would not be possible to maintain isothermal tube walls without a large wall thickness, and \( T_s \), as well as the intensity of boiling, would decrease with increasing distance from the tube entrance. However the foregoing analysis suffices as a first approximation.
PROBLEM 10.16

KNOWN: Nickel wire passing current while submerged in water at atmospheric pressure.

FIND: Current at which wire burns out.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Pool boiling.

ANALYSIS: The burnout condition will occur when electrical power dissipation creates a surface heat flux exceeding the critical heat flux, \( q''_{\text{max}} \).

This burn out condition is illustrated on the boiling curve to the right and in Figure 10.6.

The criterion for burnout can be expressed as

\[
q''_{\text{max}} \cdot \pi D = q'_{\text{elec}} \quad q'_{\text{elec}} = I^2 R_e.
\]

That is,

\[
I = \left[ q''_{\text{max}} \pi D / R_e \right]^{1/2}.
\]

For pool boiling of water at 1 atm, we found in Example 10.1 that

\[
q''_{\text{max}} = 1.26 \text{MW/m}^2.
\]

Substituting numerical values into Eq. (3), find

\[
I = \left[ 1.26 \times 10^6 \text{W/m}^2 (\pi \times 0.001 \text{m}) / 0.129 \Omega / \text{m} \right]^{1/2} = 175 \text{A}.
\]

COMMENTS: The magnitude of the current required to burn out the 1 mm diameter wire is very large. What current would burn out the wire in air?
PROBLEM 10.17

KNOWN: Saturated water boiling on a brass plate maintained at 115°C.

FIND: Power required (W/m²) for pressures of 1 and 10 atm; fraction of critical heat flux at which plate is operating.

SCHEMATIC:

ASSUMPTIONS: (1) Nucleate pool boiling, (2) \( \Delta T_e = 15°C \) for both pressure levels.

PROPERTIES: Table A-6, Saturated water, liquid (1 atm, \( T_{sat} = 100°C \)): \( \rho_\ell = 957.9 \text{ kg/m}^3 \), \( c_{p,\ell} = 4217 \text{ J/kg} \cdot \text{K} \), \( \mu_\ell = 279 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 \), \( \Delta T_e = 15°C \) for both pressure levels; Table A-6, Saturated water, vapor (1 atm): \( \rho_v = 0.596 \text{ kg/m}^3 \); Table A-6, Saturated water, liquid (10 atm = 10.133 bar, \( T_{sat} = 453.4 \text{ K} = 180.4°C \)): \( \rho_\ell = 886.7 \text{ kg/m}^3 \), \( c_{p,\ell} = 4410 \text{ J/kg} \cdot \text{K} \), \( \mu_\ell = 149 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 \), \( Pr = 0.98 \), \( h_{fg} = 2012 \text{ kJ/kg} \); Table A-6, Saturated water, vapor (10 atm): \( \rho_v = 5.155 \text{ kg/m}^3 \).

ANALYSIS: With \( \Delta T_e = 15°C \), we expect nucleate pool boiling. The Rohsenow correlation with \( C_{s,f} = 0.006 \) and \( n = 1.0 \) for the brass-water combination gives

\[
q_s = \mu_\ell h_{fg} \left[ \frac{g (\rho_\ell - \rho_v)}{\sigma} \right]^{1/2} \left( \frac{c_{p,\ell} \Delta T_e}{C_{s,f} h_{fg} \rho_v \mu_\ell^n} \right)^{3/2}
\]

1 atm: \( q_s = 279 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 \times 2257 \times 10^{-3} \text{ J/kg} \left[ \frac{9.8 \text{ m/s}^2 (957.9 - 0.596) \text{ kJ/g} \cdot \text{m}^3}{58.9 \times 10^{-3} \text{ N/m}} \right]^{1/2} \times \left( \frac{4217 \text{ J/kg} \cdot \text{K} \times 15 \text{ K}}{0.006 \times 2257 \times 10^{-3} \text{ J/kg} \cdot 1.76} \right)^{3/2} = 4.70 \text{ MW/m}^2
\]

10 atm: \( q_s = 23.8 \text{ MW/m}^2 \)

From Example 10.1, \( q_{max} \text{ (1 atm)} = 1.26 \text{ MW/m}^2 \). To find the critical heat flux at 10 atm, use the correlation of Eq. 10.7,

\[
q_{max} = 0.149 h_{fg} \rho_v \left[ \frac{\sigma g (\rho_\ell - \rho_v)}{\rho_v^2} \right]^{1/4}.
\]

\( q_{max} \text{ (10 atm)} = 0.149 \times 2012 \times 10^{-3} \text{ J/kg} \times 5.155 \text{ kg/m}^3 \times \left[ \frac{42.2 \times 10^{-3} \text{ N/m} \times 9.8 \text{ m/s}^2 (886.7 - 5.16) \text{ kJ/g} \cdot \text{m}^3}{5.155 \text{ kg/m}^3} \right]^{1/4} = 2.97 \text{ MW/m}^2.
\]

For both conditions, the Rohsenow correlation predicts a heat flux that exceeds the maximum heat flux, \( q_{max} \). We conclude that the boiling condition with \( \Delta T_e = 15°C \) for the brass-water combination is beyond the inflection point (P, see Fig. 10.4) where the boiling heat flux is no longer proportional to \( \Delta T_e^3 \).

\[
q_s = q_{max} \text{ (1 atm)} \leq 1.26 \text{ MW/m}^2 \quad q_s = q_{max} \text{ (10 atm)} \leq 2.97 \text{ MW/m}^2.
\]
PROBLEM 10.18

KNOWN: Zuber-Kutateladze correlation for critical heat flux, $q_{\text{max}}^\ast$.

FIND: Pressure dependence of $q_{\text{max}}^\ast$ for water; demonstrate maximum value occurs at approximately $1/3 \ p_{\text{crit}}$; suggest coordinates for a universal curve to represent other fluids.

ASSUMPTIONS: Nucleate pool boiling conditions.

PROPERTIES: Table A-6, Water, saturated at various pressures; see below.

ANALYSIS: The Z-K correlation for estimating the critical heat flux, has the form

$$q_{\text{max}}^\ast = 0.149 \ \rho_v h_{fg} \left[ \frac{g \sigma (\rho_\ell - \rho_v)}{\rho_v^2} \right]^{1/4}$$

where the properties for saturation conditions are a function of pressure. The properties (Table A-6) and the values for $q_{\text{max}}^\ast$ are as follows:

</table>

The $q_{\text{max}}^\ast$ values are plotted as a function of $p/p_c$, where $p_c$ is the critical pressure. Note the rapid decrease of $h_{fg}$ and $\sigma$ with increasing pressure. The universal curve coordinates would be $q_{\text{max}}^\ast / q_{\text{max}}$ for $\left(1/3 \ p_{\text{crit}} \right)$ vs. $p / p_c$. 

![Image](image.png)
**PROBLEM 10.19**

**KNOWN:** Kutateladze’s dimensional analysis and the bubble diameter parameter.

**FIND:** (a) Verify the dimensional consistency of the critical heat flux expression, and (b) Estimate heater size with water at 1 atm required such that the Bond number will exceed 3, i.e., $Bo \geq 3$.

**ASSUMPTIONS:** Nucleate pool boiling.

**ANALYSIS:** (a) Kutateladze postulated that the critical flux was dependent upon four parameters, 

$$q_{\text{max}}^* = q_{\text{max}}^* \left( h_{fg}, \rho_v, \sigma, D_b \right)$$

where $D_b$ is the bubble diameter parameter having the form

$$D_b = \left[ \sigma / g (\rho_\ell - \rho_v) \right]^{1/2}. \quad (1)$$

The form of the critical heat flux expression was presumed to be

$$q_{\text{max}}^* = C h_{fg} \rho_v^{1/2} D_b^{-1/2} \sigma^{1/2} \quad (2)$$

where $C$ is a constant. It is not possible to derive this equation from a dimensional (Pi) analysis. We can only determine that the equation is dimensionally consistent. Using SI units, check Eq. (1) for $D_b$,

$$Db \Rightarrow \left[ (Nm^{-1})(m^{-1}s^2)(kg^{-1}m^3) \right]^{1/2} \Rightarrow \left[ N \left( \frac{s^2}{kg \cdot m^2} \right) m^3 \right]^{1/2} \Rightarrow [m]$$

and in Eq. (2) for $q_{\text{max}}^*$,

$$q_{\text{max}}^* \Rightarrow \left[ (J kg^{-1})(kg^{1/2}m^{-3/2})(m^{-1/2})(N^{1/2}m^{-1/2}) \right] \Rightarrow \left[ \frac{J}{s} \left( \frac{N \cdot s^2}{kg \cdot m} \right)^{1/2} m^{-2} \right] \Rightarrow \left[ \frac{W}{m^2} \right].$$

Hence, the equations are dimensionally consistent.

(b) The Bond number, $Bo$, is defined as the ratio of the characteristic length $L$ (width or diameter) of the heater surface to the bubble diameter parameter, $D_b$. That is, $Bo \equiv L/D_B$. The number squared is also indicative of the ratio of the buoyant to capillary forces. For water at 1 atm (see Example 10.1 for properties listing), Eq. (1) yields

$$D_b = \left[ \frac{58.9 \times 10^{-3} N}{m} / 9.8 \frac{m}{s^2} (957.9 - 0.5955) \frac{kg}{m^3} \right]^{1/2} = 0.0025m = 2.5mm.$$ 

Eq. 10.7 for the critical heat flux is appropriate for an “infinite” heater (Bo ≥ 3). To meet this requirement, the heater dimension must be

$$L \geq Bo \cdot D_b = 3 \times 2.5mm = 7.5mm.$$ 

**COMMENTS:** As the heater size decreases (Bo decreasing), the boiling curve no longer exhibits the characteristic $q_{\text{max}}^*$ and $q_{\text{min}}^*$ features. The very small heater, such as a wire, is enveloped with vapor at small $\Delta T_e$ and film boiling occurs.
PROBLEM 10.20

KNOWN: Lienhard-Dhir critical heat flux correlation for small horizontal cylinders.

FIND: Critical heat flux for 1 mm and 3 mm diameter horizontal cylinders in water at 1 atm.

SCHEMATIC:

ASSUMPTIONS: Nucleate pool boiling.

PROPERTIES: Table A-6, Water (1 atm): \( \rho_\ell = 957.9 \text{ kg/m}^3, \rho_v = 0.5955 \text{ kg/m}^3, \sigma = 58.9 \times 10^{-3} \text{ N/m} \).

ANALYSIS: The Lienhard-Dhir correlation for small horizontal cylinders is

\[
q'_{\text{max}} = q'_{\text{max},Z} \left[ 0.94 \left( \text{Bo} \right)^{-1/4} \right] \quad 0.15 \leq \text{Bo} \leq 1.2
\]

where \( q'_{\text{max},Z} \) is the critical heat flux predicted by the Zuber-Kutateladze correlation for the infinite heater (Eq. 10.6) and the Bond number is

\[
\text{Bo} = \frac{r}{D_b} = \frac{r}{\left[ \sigma / g \left( \rho_\ell - \rho_v \right) \right]^{1/2}}.
\]

Note the characteristic length is the cylinder radius. From Example 10.1, using Eq. 10.6,

\( q'_{\text{max},Z} = 1.11 \text{ MW/m}^2 \)

and substituting property values for water at 1 atm into Eq. (2),

\[
D_b = \left[ \frac{58.9 \times 10^{-3}}{m / \text{s}^2} \frac{N}{m} / \frac{m}{s^2} \frac{(957.9 - 0.5955) \text{ kg/m}^3}{\text{kg/m}^3} \right]^{1/2} = 2.51 \text{ mm}.
\]

Substituting appropriate values into Eqs. (1) and (2),

1 mm dia cylinder \( \text{Bo} = 0.5 \text{ mm}/2.51 \text{ mm} = 0.20 \)

\[ q'_{\text{max}} = 1.11 \text{ MW/m}^2 \left[ 0.94 (0.20)^{-1/4} \right] = 1.56 \text{ MW/m}^2. \]

3 mm dia cylinder \( \text{Bo} = 1.5 \text{ mm}/2.51 \text{ mm} = 0.60 \)

\[ q'_{\text{max}} = 1.11 \text{ MW/m}^2 \left[ 0.94 (0.60)^{-1/4} \right] = 1.19 \text{ MW/m}^2. \]

Note that for the 3 mm diameter cylinder, the critical heat flux is \( 1.19/1.11 = 1.07 \) times larger than the value for a very large horizontal cylinder.

COMMENTS: For practical purposes a horizontal cylinder of diameter greater than 3 mm can be considered as a very large one. The critical heat flux for a 1 mm diameter cylinder is 40% larger than that for the large cylinder.
PROBLEM 10.21

KNOWN: Boiling water at 1 atm pressure on moon where the gravitational field is 1/6 that of the earth.

FIND: Critical heat flux.

ASSUMPTIONS: Nucleate pool boiling conditions.

PROPERTIES: Table A-6, Water (1 atm): $T_{\text{sat}} = 100^\circ \text{C}$, $\rho_\ell = 957.9 \text{ kg/m}^3$, $\rho_\nu = 0.5955 \text{ kg/m}^3$, $h_{fg} = 2257 \text{ kJ/kg}$, $\sigma = 58.9 \times 10^{-3} \text{ N/m}$.

ANALYSIS: The modified Zuber-Kutateladze correlation for the critical heat flux is Eq. 10.7.

$$q_{\text{max}} = 0.149 \rho_\nu^{1/2} h_{fg} \left[ \sigma g \left( \rho_\ell - \rho_\nu \right) \right]^{1/4}.$$  

The relation predicts the critical flux dependency on the gravitational acceleration as

$$q_{\text{max}} \sim g^{1/4}.$$  

It follows that if $g_{\text{moon}} = (1/6) g_{\text{earth}}$ and recognizing $q_{\text{max,e}} = 1.26 \text{ MW/m}^2$ for earth acceleration (see Example 10.1),

$$q_{\text{max,moon}} = q_{\text{max,earth}} \left( g_{\text{moon}} / g_{\text{earth}} \right)^{1/4}$$

$$q_{\text{max,moon}} = 1.26 \frac{\text{MW}}{\text{m}^2} \left( \frac{1}{6} \right)^{1/4} = 0.81 \text{ MW/m}^2.$$  

COMMENTS: Note from the discussion in Section 10.4.5 that the $g^{1/4}$ dependence on the critical heat flux has been experimentally confirmed. In the nucleate pool boiling regime, the heat flux is nearly independent of the gravitational field.
PROBLEM 10.22

KNOWN: Concentric stainless steel tubes packed with dense boron nitride powder. Inner tube has heat generation while outer tube surface is exposed to boiling heat flux, \( q_s^* = C(T_s - T_{sat})^3 \). Saturation temperature of boiling liquid and temperature of the outer tube surface.

FIND: Expressions for the maximum temperature in the stainless steel (ss) tubes and in the boron nitride (bn).

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional (cylindrical) steady-state heat transfer in tubes and boron nitride.

ANALYSIS: Construct the thermal circuit shown above where \( R_{23} \) and \( R_{34} \) represent the resistances due to the boron nitride between \( r_2 \) and \( r_3 \) and to the outer stainless steel tube, respectively. From an overall energy balance,

\[
\dot{q}_{gen} = \dot{q}_{boil}.
\]

\[
\dot{q}_{boil} = \pi (r_2^2 - r_1^2) (2\pi r_4) C(T_s - T_{sat})^3.
\]

With prescribed values for \( T_{sat}, T_s \) and \( C \), the required volumetric heating of the inner stainless steel tube is

\[
\dot{q} = \frac{2r_4}{(r_2^2 - r_1^2)} C(T_s - T_{sat})^3.
\]

Using the thermal circuit, we can write expressions for the maximum temperature of the stainless steel (ss) and boron nitride (bn).

**Stainless steel:** \( T_{ss,\text{max}} \) occurs at \( r_1 \). Using the results of Section 3.4.2, the temperature distribution in a radial tube of inner and outer radii \( r_1 \) and \( r_2 \) is

\[
T(r) = -\frac{\dot{q}}{2k_{ss}} r^2 + C_1 \ln r + C_2
\]

for which the boundary conditions are

\[
\text{BC#1: } r = r_1 \quad \frac{dT}{dr} = 0 \quad 0 = -\frac{\dot{q}}{2k_{ss}} \frac{C_1}{r_1} + C_1 \quad \Rightarrow C_1 = \frac{\dot{q} r_1^2}{k_{ss}}
\]

Continued …..
PROBLEM 10.22 (Cont.)

BC#2: \( r = r_2 \) \( T(r_2) = T_2 \) \( T_2 = -\frac{\dot{q}}{2k_{ss}}r_2^2 + \frac{\dot{q}r_1^2}{k_{ss}}\ln r_2 + C_2 \)

\[ C_2 = T_2 + \frac{\dot{q}}{2k_{ss}}r_2^2 - \frac{\dot{q}r_1^2}{k_{ss}}\ln r_2 \]

Hence,

\[ T(r) = -\frac{\dot{q}}{2k_{ss}}(r^2 - r_2^2) + \frac{\dot{q}r_1^2}{k_{ss}}\ln (r/r_2) + T_2. \]

Using the thermal circuit, find \( T_2 \) in terms of known parameters \( T_s, T_{sat} \) and \( C \).

\[ \frac{T_2 - T_s}{R'_{23} + R'_{34}} = (2\pi r_4)C(T_s - T_{sat})^3. \]

Hence, the maximum temperature in the inner stainless steel tube \( (r = r_1) \) is

\[ T_{ss,max} = T(\eta_1) = -\frac{\dot{q}}{2k_{ss}}(\eta_1^2 - r_2^2) + \frac{\dot{q}r_1^2}{k_{ss}}\ln (\eta_1 / r_2) + T_s \]

\[ + (R'_{23} + R'_{34})(2\pi r_4)C(T_s - T_{sat})^3 \]

where from Eq. 3.27

\[ R'_{23} = \frac{\ln (r_3 / r_2)}{2\pi k_{bn}} \quad \quad \quad R'_{34} = \frac{\ln (r_4 / r_3)}{2\pi k_{ss}}. \]

*Boron nitride*: \( T_{bn,max} \) occurs at \( r_1 \). Hence

\[ T_{bn,max} = T(\eta) \]

as derived above for the inner stainless steel tube.
**PROBLEM 10.23**

**KNOWN:** Thickness and thermal conductivity of a silicon chip. Properties of saturated fluorocarbon liquid.

**FIND:** (a) Temperature at bottom surface of chip for a prescribed heat flux and 90% of CHF, (b) Effect of heat flux on chip surface temperatures; maximum allowable heat flux.

**SCHEMATIC:**

![Schematic Diagram]

- Silicon, $k_s = 135$ W/m·K
- $q'' = 5 \times 10^4$ W/m$^2$ or $C_1 q''_{max}$
- $N.B.\, Constants: C_{sf} = 0.005, n = 1.7$

**ASSUMPTIONS:**
1. Steady-state conditions
2. Uniform heat flux and adiabatic sides, hence one-dimensional conduction in chip
3. Constant properties
4. Nucleate boiling in liquid

**PROPERTIES:** Saturated fluorocarbon (given):
- $c_{p, \ell} = 1100$ J/kg·K, $h_{fg} = 84.400$ J/kg
- $\rho_\ell = 1619.2$ kg/m$^3$, $\rho_v = 13.4$ kg/m$^3$
- $\sigma = 8.1 \times 10^{-3}$ kg/s$^2$, $\mu_\ell = 440 \times 10^{-6}$ kg/m·s
- $Pr_\ell = 9.01$

**ANALYSIS:**
(a) Energy balances at the top and bottom surfaces yield

$$ T_s - T_{sat} = \frac{C_{s,f}h_{fg}Pr_\ell^{\frac{n}{6}}}{c_{p, \ell} \left(\frac{q''_s}{\mu_\ell h_{fg}}\right)^{\frac{1}{3}}} \left[\frac{\sigma}{g(\rho_\ell - \rho_v)}\right]^{\frac{1}{6}} $$

Hence, for $q''_s = 5 \times 10^4$ W/m$^2$,

$$ T_s - T_{sat} = \frac{0.005(84,400)}{1100} \left(\frac{5 \times 10^4}{440 \times 10^{-6} \times 84,400}ight)^{\frac{1}{3}} $$

$$ \times \left[\frac{8.1 \times 10^{-3}}{9.807 \times (1619.2 - 13.4) \times 10^{-6}}\right]^{\frac{1}{6}} = 15.9^\circ C $$

$$ T_s = (15.9 + 57) ^\circ C = 72.9^\circ C $$

From the rate equation,

$$ T_0 = T_s + \frac{q''_0L}{k_s} = 72.9^\circ C + \frac{5 \times 10^4 \times 0.0025}{135} = 73.8^\circ C $$

For a heat flux which is 90% of the critical heat flux ($C_1 = 0.9$), it follows that

$$ q''_0 = 0.9q''_{max} = 0.9 \times \frac{149h_{fg} \rho_v}{\frac{\sigma g(\rho_\ell - \rho_v)}{\rho_v^2}} = 0.9 \times 0.149 \times 84,400 \times 13.4 \times 10^{-6} \times 10^3 $$

Continued...
PROBLEM 10.23 (Cont.)

\[
q_o^* = 0.9 \times 15.5 \times 10^4 \text{ W/m}^2 = 13.9 \times 10^4 \text{ W/m}^2
\]

From the results of the previous calculation and the Rohsenow correlation, it follows that

\[
\Delta T_c = 15.9^\circ\text{C} \left( q_o^*/5 \times 10^4 \text{ W/m}^2 \right)^{1/3} = 15.9^\circ\text{C} \left( 13.9/5 \right)^{1/3} = 22.4^\circ\text{C}
\]

Hence, \( T_s = 79.4^\circ\text{C} \) and

\[
T_o = 79.4^\circ\text{C} + \frac{13.9 \times 10^4 \text{ W/m}^2 \times 0.0025 \text{m}}{135 \text{ W/m K}} = 82^\circ\text{C}
\]

(b) Using the energy balance equations with the Correlations Toolpad of IHT to perform the parametric calculations for \( 0.2 \leq C_1 \leq 0.9 \), the following results are obtained.

![Graph showing chip heat flux vs. temperature](image)

The chip surface temperatures, as well as the difference between temperatures, increase with increasing heat flux. The maximum chip temperature is associated with the bottom surface, and \( T_o = 80^\circ\text{C} \) corresponds to

\[
q_{o,\text{max}} = 11.3 \times 10^4 \text{ W/m}^2
\]

which is 73% of CHF (\( q_{\text{max}}^* = 15.5 \times 10^4 \text{ W/m}^3 \)).

**COMMENTS:** Many of today’s VLSI chip designs involve heat fluxes well in excess of 15 W/cm², in which case pool boiling in a fluorocarbon would not be an appropriate means of heat dissipation.
PROBLEM 10.24

KNOWN: Operating conditions of apparatus used to determine surface boiling characteristics.

FIND: (a) Nucleate boiling coefficient for special coating, (b) Surface temperature as a function of heat flux; apparatus temperatures for a prescribed heat flux; applicability of nucleate boiling correlation for a specified heat flux.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, steady-state conduction in the bar, (2) Water is saturated at 1 atm, (3) Applicability of Rohsenow correlation with \( n = 1 \).

PROPERTIES: *Table A.6*, saturated water (100°C): \( \rho_\ell = 957.9 \text{ kg/m}^3, \ c_{p,\ell} = 4217 \text{ J/kg·K}, \ \mu_\ell = 279 \times 10^{-6} \text{ N·s/m}^2, \ Pr_\ell = 1.76, \ h_{fg} = 2.257 \times 10^6 \text{ J/kg}, \sigma = 0.0589 \text{ N/m}, \ \rho_v = 0.5955 \text{ kg/m}^3.\)

ANALYSIS: (a) The coefficient \( C_{s,f} \) associated with Eq. 10.5 may be determined if \( q_s^* \) and \( T_s \) are known. Applying Fourier’s law between \( x_1 \) and \( x_2 \),

\[
q_s^* = q_{\text{cond}} = k \frac{T_2 - T_1}{x_2 - x_1} = 400 \text{ W/m·K} \times \frac{(158.6 - 133.7) \degree C}{0.015 \text{ m}} = 6.64 \times 10^5 \text{ W/m}^2
\]

Since the temperature distribution in the bar is linear, \( T_s = T_1 - (dT/dx)x_1 = T_1 - [(T_2 - T_1)/(x_2 - x_1)]x_1. \)

Hence,

\[
T_s = 133.7 \degree C - \left[ 24.9 \degree C/0.015 \text{ m} \right] 0.01 \text{ m} = 117.1 \degree C
\]

From Eq. 10.5, with \( n = 1 \),

\[
C_{s,f} = \frac{c_{p,\ell} \Delta T_e}{h_{fg} Pr_\ell} \left( \frac{\mu_\ell h_{fg}}{q_s^*} \right)^{1/3} \left[ \frac{g (\rho_\ell - \rho_v)}{\sigma} \right]^{1/6}
\]

\[
C_{s,f} = \frac{4217 \text{ J/kg·K} \left( 17.1 \degree C \right)}{2.257 \times 10^6 \text{ J/kg} \left( 1.76 \right)} \left( \frac{279 \times 10^{-6} \text{ kg/s·m} \times 2.257 \times 10^6 \text{ J/kg}}{6.64 \times 10^5 \text{ W/m}^2} \right)^{1/3} \left[ \frac{9.8 \text{ m/s}^2 \times 957.3 \text{ kg/m}^3}{0.0589 \text{ kg/s}^2} \right]^{1/6} = 0.0131
\]

(b) Using the appropriate IHT *Correlations* and *Properties* Toolpads, the following portion of the nucleate boiling regime was computed.

Continued...
For $q_s^* = 10^6 \text{ W/m}^2 = q_{\text{cond}}^*$, $T_s = 119.6^\circ \text{C}$ and $T_1 = 144.6^\circ \text{C}$ and $T_2 = 182.1^\circ \text{C}$.

With the critical heat flux given by Eq. 10.7,

$$q_{\text{max}}^* = 0.149 h_f g \rho_v \left[ \frac{\sigma g (\rho_l - \rho_v)}{\rho_v^2} \right]^{1/4}$$

$$q_{\text{max}} = 0.149 \left( 2.257 \times 10^6 \text{ J/kg} \right) 0.5955 \text{ kg/m}^3 \left[ \frac{0.0589 \text{ kg/s}^2 \times 9.8 \text{ m/s}^2 \times 957.3 \text{ kg/m}^3}{(0.5955 \text{ kg/m}^3)^2} \right]^{1/4}$$

$$q_{\text{max}}^* = 1.25 \times 10^6 \text{ W/m}^2$$

Since $q_s^* = 1.5 \times 10^6 \text{ W/m}^2 > q_{\text{max}}^*$, the heat flux exceeds that associated with nucleate boiling and the foregoing results can not be used.

**COMMENTS:** For $q_s^* > q_{\text{max}}^*$, conditions correspond to film boiling, for which $T_s$ may exceed acceptable operating conditions.
**PROBLEM 10.25**

**KNOWN:** Small copper sphere, initially at a uniform temperature, \( T_i \), greater than that corresponding to the Leidenfrost point, \( T_D \), suddenly immersed in a large fluid bath maintained at \( T_{sat} \).

**FIND:** (a) Sketch the temperature-time history, \( T(t) \), during the quenching process; indicate temperature corresponding to \( T_i, T_D, \) and \( T_{sat} \), identify regimes of film, transition and nucleate boiling and the single-phase convection regime; identify key features; and (b) Identify times(s) in this quenching process when you expect the surface temperature of the sphere to deviate most from its center temperature.

**SCHEMATIC:**

![Schematic Image]

**ANALYSIS:** (a) In the right-hand schematic above, the quench process is shown on the “boiling curve” similar to Figure 10.4. Beginning at an initial temperature, \( T_i > T_D \), the process proceeds as indicated by the arrows: film regime from i to D, transition regime from D to C, nucleate regime from C to A, and single-phase (free convection) from A to the condition when \( \Delta T_e = T_s - T_{sat} = 0 \). The quench process is shown on the temperature-time plot below and the boiling regimes and key temperatures are labeled.

The highest temperature-time change should occur in the nucleate pool boiling regime, especially near the critical flux condition, \( T_c \). The lowest temperature-time change will occur in the single-phase, free convection regime.

(b) The difference between the center and surface temperature will occur when \( \text{Bi} = \frac{h r_o}{3k} \geq 0.1 \). This could occur in regimes with the highest convection coefficients. For example, \( h = 10,000 \text{ W/m}^2\cdot\text{K} \) which might be the case for water in the nucleate boiling regime, C-A, \( \text{Bi} = 10,000 \text{ W/m}^2 \times \frac{0.010\text{m}}{3} \times 400 \text{ W/m} \cdot \text{K} = 0.08 \). For a sphere of larger dimension, in the nucleate and film pool boiling regimes, we could expect temperature differences between the center and surface temperatures since Bi might be greater than 0.1.
PROBLEM 10.26

KNOWN: A sphere (aluminum alloy 2024) with a uniform temperature of 500°C and emissivity of 0.25 is suddenly immersed in a saturated water bath maintained at atmospheric pressure.

FIND: (a) The total heat transfer coefficient for the initial condition; fraction of the total coefficient contributed by radiation; and (b) Estimate the temperature of the sphere 30 s after it has been immersed in the bath.

SCHEMATIC:

ASSUMPTIONS: (1) Water exposed to standard atmospheric pressure and uniform temperature, \( T_{\text{sat}} \), and (2) Lumped capacitance method is valid.

PROPERTIES: See Comment 2; properties obtained with IHT code.

ANALYSIS: (a) For the initial condition with \( T_s = 500°C \), film boiling will occur and the coefficients due to convection and radiation are estimated using Eqs. 10.9 and 10.11, respectively,

\[
\begin{align*}
\overline{\text{Nu}}_D &= \frac{\overline{h}_{\text{conv}} D}{k_v} = C \left[ \frac{g (\rho_g - \rho_v) h_{fg} D^3}{\eta_v k_v (T_s - T_{\text{sat}})} \right]^{1/4} \\
\overline{h}_{\text{rad}} &= \frac{\varepsilon \sigma (T_s^4 - T_{\text{sat}}^4)}{T_s - T_{\text{sat}}} 
\end{align*}
\]

where \( C = 0.67 \) for spheres and \( \sigma = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \). The corrected latent heat is

\[
h_{fg}' = h_{fg} + 0.8 c_{p,v} (T_s - T_{\text{sat}})
\]

The total heat transfer coefficient is given by Eq. 10.10a as

\[
\overline{h}^{4/3} = \overline{h}_{\text{conv}}^{4/3} + \overline{h}_{\text{rad}}^{4/3} \cdot \overline{h}^{1/3}
\]

The vapor properties are evaluated at the film temperature,

\[
T_r = \left( T_s + T_{\text{sat}} \right) / 2
\]

while the liquid properties are evaluated at the saturation temperature. Using the foregoing relations in IHT (see Comments), the following results are obtained.

\[
\begin{align*}
\overline{\text{Nu}}_D &= 226 \\
\overline{h}_{\text{conv}} (\text{W/m}^2 \cdot \text{K}) &= 867 \\
\overline{h}_{\text{rad}} (\text{W/m}^2 \cdot \text{K}) &= 12.0 \\
\overline{h} (\text{W/m}^2 \cdot \text{K}) &= 876
\end{align*}
\]

The radiation process contribution is 1.4% that of the total heat rate.

(b) For the lumped-capacitance method, from Section 5.3, the energy balance is

\[
-\overline{h} A_s (T_s - T_{\text{sat}}) = \rho_s V c_s \frac{dT_s}{dt}
\]

where \( \rho_s \) and \( c_s \) are properties of the sphere. To determine \( T_s(t) \), it is necessary to evaluate \( \overline{h} \) as a function of \( T_s \). Using the foregoing relations in IHT (see Comments), the sphere temperature after 30 s is

\[
T_s (30s) = 333°C.
\]

Continued …..
**PROBLEM 10.26 (Cont.)**

**COMMENTS:**
1. The Biot number associated with the aluminum alloy sphere cooling process for the initial condition is $Bi = 0.09$. Hence, the lumped-capacitance method is valid.
2. The IHT code to solve this application uses the film-boiling correlation function, the water property functions, and the lumped capacitance energy balance, Eq. (6). The results for part (a), including the properties required of the correlation, are shown at the outset of the code.

**PROBLEM 10.27**

**KNOWN:** Steel bar upon removal from a furnace immersed in water bath.

**FIND:** Initial heat transfer rate from bar.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Uniform bar surface temperature, (2) Film pool boiling conditions.

**PROPERTIES:** *Table A-6*, Water, liquid (1 atm, $T_{sat} = 100^\circ C$): $\rho_f = 957.9$ kg/m$^3$, $h_{fg} = 2257$ kJ/kg; *Table A-6*, Water, vapor ($T_f = (T_s + T_{sat})/2 = 550$K): $\rho_v = 31.55$ kg/m$^3$, $c_p,v = 4640$ J/kg K, $\mu_v = 18.6 \times 10^{-6}$ N·s/m$^2$, $k_v = 0.0583$ W/m·K.

**ANALYSIS:** The total heat transfer rate from the bar at the instant of time it is removed from the furnace and immersed in the water is

$$q_s = \overline{h} A_s (T_s - T_{sat}) = \bar{h} A_s \Delta T_e$$  \hspace{1cm} (1)

where $\Delta T_e = 455 - 100 = 355$K. According to the boiling curve of Figure 10.4, with such a high $\Delta T_e$, film pool boiling will occur. From Eq. 10.10,

$$\bar{h}^{4/3} = \bar{h}^{4/3}_{conv} + \bar{h}_{rad}^{1/3}$$ \hspace{1cm} (2)

To estimate the convection coefficient, use Eq. 10.9,

$$\overline{Nu}_D = \frac{\bar{h}_{conv} D}{k_v} = C \left[ \frac{g (\rho_f - \rho_v) h_{fg} D^3}{\nu_v k_v \Delta T_e} \right]^{1/4}$$  \hspace{1cm} (3)

where $C = 0.62$ for the horizontal cylinder and $h_{fg} = h_{fg} + 0.8 c_p,v (T_s - T_{sat})$. Find

$$\bar{h}_{conv} = \frac{0.0583 \text{ W/m·K}}{0.020 \text{ m}} - 0.62 \left[ \frac{9.8 \text{ m/s}^2 (957.9 - 31.55) \text{ kg/m}^3 \left[ \frac{2257 \times 10^3 + 0.8 \times 4640 \times 355}{18.6 \times 10^{-6}/31.55} \right] \text{ J/kg (0.020m)}^{3/4}}{1/4} \right]$$

$$\bar{h}_{conv} = 690 \text{ W/m}^2 \cdot \text{K}.$$

To estimate the radiation coefficient, use Eq. 10.11,

$$\bar{h}_{rad} = \frac{\epsilon \sigma (T_s^4 - T_{sat}^4)}{T_s - T_{sat}} = \frac{0.9 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left( 728^4 - 373^4 \right) K^4}{355 \text{K}} = 37.6 \text{ W/m}^2 \cdot \text{K}.$$

Substituting numerical values into the simpler form of Eq. (2), find

$$\bar{h} = \overline{(690 + 3/4 \times 37.6)} \text{ W/m}^2 \cdot \text{K} = 718 \text{ W/m}^2 \cdot \text{K}.$$

Using Eq. (1), the heat rate, with $A_s = \pi D L$, is

$$q_s = 718 \text{ W/m}^2 \cdot \text{K} (\pi \times 0.020 \text{m} \times 0.200 \text{m}) \times 355 \text{K} = 3.20 \text{kW}.$$  \hspace{1cm} (<)

**COMMENTS:** For these conditions, the convection process dominates.
PROBLEM 10.28

KNOWN: Electrical conductor with prescribed surface temperature immersed in water.

FIND: (a) Power dissipation per unit length, \( q'_s \) and (b) Compute and plot \( q'_s \) as a function of surface temperature \( 250 \leq T_s \leq 650 \, ^\circ C \) for conductor diameters of 1.5, 2.0, and 2.5 mm; separately plot the percentage contribution of radiation as a function of \( T_s \).

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Water saturated at 1 atm, (3) Film pool boiling.

PROPERTIES: Table A-6, Water, liquid (1 atm, \( T_{sat} = 100 \, ^\circ C \)): \( \rho_f = 957.9 \, kg/m^3 \), \( h_{fg} = 2257 \, kJ/kg \); Table A-6, Water, vapor (\( T_f = (T_s + T_{sat})/2 = 600 \, K \)): \( \rho_v = 72.99 \, kg/m^3 \), \( c_{p,v} = 8750 \, J/kg \cdot K \), \( \mu_v = 22.7\times10^{-6} \, N \cdot s/m^2 \), \( k_v = 0.0929 \, W/m \cdot K \).

ANALYSIS: (a) The heat rate per unit length due to electrical power dissipation is

\[
q'_s = \frac{q_s}{\ell} = \frac{A_s}{\ell} (T_s - T_{sat}) = \bar{h} \pi D \Delta T_e
\]

where \( \Delta T_e = (555 - 100) \, ^\circ C = 455 \, ^\circ C \). According to the boiling curve of Figure 10.4, with such a high \( \Delta T_e \), film pool boiling will occur. From Eq. 10.10,

\[
\bar{h}^{4/3} = \bar{h}_{conv}^{4/3} + \bar{h}_{rad}^{1/3} \quad \text{or} \quad \bar{h} = \bar{h}_{conv}^{3} + \frac{3}{4} \bar{h}_{rad}^{3} \quad \text{(if} \quad \bar{h}_{conv} > \bar{h}_{rad}).
\]

To estimate the convection coefficient, use Eq. 10.9.

\[
\frac{\bar{h}_{conv}D}{k_v} = C \left[ \frac{g (\rho_f - \rho_v) h_{fg} D^3}{\nu_v k_v \Delta T_e} \right]^{1/4}
\]

where \( C = 0.62 \) for the horizontal cylinder and \( h'_{fg} = h_{fg} + 0.8 c_{p,v} (T_s - T_{sat}) \). Find

\[
\bar{h}_{conv} = \frac{0.0929 \, W/m \cdot K}{0.002 \, m} \times \frac{9.8 \, m/s^2 (957.9 - 72.99) \, kg/m^3 [2257 \times 10^3 + 0.8 \times 8750 \times 455]}{(22.7 \times 10^{-6}/72.99) \, m^2/s \times 0.0929 \, W/m \cdot K \times 455 \, K}^{1/4}
\]

To estimate the radiation coefficient, use Eq. 10.11.

\[
\bar{h}_{rad} = \frac{\varepsilon \sigma (T_s^4 - T_{sat}^4)}{T_s - T_{sat}} = \frac{0.5 \times 5.67 \times 10^{-8}}{455 \, K} \left[ (828^4 - 373^4) \right] K^4 = 28 \, W/m^2 \cdot K
\]

Since \( \bar{h}_{conv} > \bar{h}_{rad} \), the simpler form of Eq. 10.10b is appropriate. Find,

\[
\bar{h} = (2108 + (3/4) \times 28) \, W/m^2 \cdot K = 2129 \, W/m^2 \cdot K
\]

Continued...
The heat rate is
\[ q' = 2129 \text{ W/m}^2 \cdot \text{K} \times \pi (0.002 \text{ m}) \times 455 \text{ K} = 6.09 \text{ kW/m}. \]

(b) Using the IHT Correlations Tool, Boiling, Film Pool Boiling, combined with the Properties Tool for Water, the heat rate, \( q' \), was calculated as a function of the surface temperature, \( T_s \), for conductor diameters of 1.5, 2.0 and 2.5 mm. Also, plotted below is the ratio (%) of \( \frac{q_{\text{rad}}'}{q'} \) as a function of surface temperature.

From the \( q' \) vs. \( T_s \) plot, note that the heat rate increases markedly with increasing surface temperatures, and, as expected the heat rate increases with increasing diameter. The discontinuity near \( T_s = 650^\circ \text{C} \) is caused by the significant changes in the thermophysical properties as the film temperature, \( T_f \), approaches the critical temperature, 647.3 K. From the \( \frac{q_{\text{rad}}'}{q'} \) vs. \( T_s \) plot, the maximum contribution by radiation is 2% and surprisingly doesn’t occur at the maximum surface temperature. By examining a plot of \( q_{\text{rad}}' \) vs. \( T_s \), we’d see that indeed \( q_{\text{rad}}' \) increases markedly with increasing \( T_s \); but \( q_{\text{conv}}' \) increases even more markedly so the relative contribution of the radiation mode actually decreases with increasing temperature for \( T_s > 350^\circ \text{C} \).
PROBLEM 10.29

KNOWN: Horizontal, stainless steel bar submerged in water at 25°C.

FIND: Heat rate per unit length of the bar.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Film pool boiling, (3) Water at 1 atm.

PROPERTIES: Table A-6, Water, liquid (1 atm, $T_{sat} = 100°C$): $\rho_f = 957.9$ kg/m$^3$, $h_{fg} = 2257$ kJ/kg; Table A-6, Water, vapor, ($T_f = (T_s + T_{sat})/2 = 450K$): $\rho_v = 4.81$ kg/m$^3$, $c_{p,v} = 2560$ J/kg·K, $\mu_v = 14.85 \times 10^{-6}$ N·s/m$^2$, $k_v = 0.0331$ W/m·K.

ANALYSIS: The heat rate per unit length is

$$q' = q_s / \ell = q_s \pi D = \bar{h} \pi D (T_s - T_{sat}) = \bar{h} \pi D \Delta T_e$$

where $\Delta T_e = (250 - 100)°C = 150°C$. Note from the boiling curve of Figure 10.4, that film boiling will occur. From Eq. 10.10,

$$\frac{4}{3} \frac{4}{3} \frac{1}{3} \frac{1}{3} \text{conv} \text{rad} \text{conv} \text{rad} \text{conv}$$

To estimate the convection coefficient, use Eq. 10.9,

$$\frac{\bar{Nu}}{D} = \frac{\bar{h}_{\text{conv}} D}{k_v} = C \left[ \frac{g \left( \rho_f - \rho_v \right) h_{fg} D^3}{v_v k_v \Delta T_e} \right]^{1/4}$$

where $C = 0.62$ for the horizontal cylinder and $h_{fg} = h_{fg} + 0.8c_{p,v}(T_s - T_{sat})$. Find

$$\bar{h}_{\text{conv}} = \frac{0.0331 \text{W/m} \cdot \text{K}}{0.050 \text{m}} \frac{9.8 \text{m/s}^2 (957.9 - 4.81) \text{kg/m}^3}{0.8 \times 2560 \text{J/kg} \cdot \text{K} \times 150 \text{K}} \left[ \frac{2257 \times 10^3 + 0.8 \times 2560 \text{J/kg} \cdot \text{K} \times 150 \text{K}}{14.85 \times 10^{-6} / 4.81} \right]^{1/4}$$

$$\bar{h}_{\text{conv}} = 273 \text{ W/m}^2 \cdot \text{K}.$$

To estimate the radiation coefficient, use Eq. 10.11,

$$\frac{\bar{h}_{\text{rad}}}{T_s - T_{sat}} = \frac{0.50 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left( 523^4 - 373^4 \right)}{150 \text{K}} = 1.1 \text{ W/m}^2 \cdot \text{K}.$$

Since $h_{\text{conv}} > h_{\text{rad}}$, the simpler form of Eq. 10.10 is appropriate. Find,

$$\bar{h} = \left[ 273 + (3/4) \times 111 \right] \text{ W/m}^2 \cdot \text{K} = 281 \text{ W/m}^2 \cdot \text{K}.$$

Using the rate equation, find

$$q' = 281 \text{ W/m}^2 \cdot \text{K} \times \pi \times (0.050 \text{m}) \times 150 \text{K} = 6.62 \text{kW/m}.$$

COMMENTS: The effect of the water being subcooled ($T = 25°C < T_{sat}$) is considered to be negligible.
**PROBLEM 10.30**

**KNOWN:** Heater element of 5-mm diameter maintained at a surface temperature of 350°C when immersed in water under atmospheric pressure; element sheath is stainless steel with a mechanically polished finish having an emissivity of 0.25.

**FIND:** (a) The electrical power dissipation and the rate of evaporation per unit length; (b) If the heater element were operated at the same power dissipation rate in the nucleate boiling regime, what temperature would the surface achieve? Calculate the rate of evaporation per unit length for this operating condition; and (c) Make a sketch of the boiling curve and represent the two operating conditions of parts (a) and (b). Compare the results of your analysis. If the heater element is operated in the power-controlled mode, explain how you would achieve these two operating conditions beginning with a cold element.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, and (2) Water exposed to standard atmospheric pressure and uniform temperature, T<sub>sat</sub>.

**PROPERTIES:** Table A-6, Saturated water, liquid (100°C): ρ<sub>ℓ</sub> = 957.9 kg/m<sup>3</sup>, c<sub>p,ℓ</sub> = 4217 J/kg·K, μ<sub>ℓ</sub> = 279×10<sup>−6</sup> N·s/m<sup>2</sup>, Pr<sub>ℓ</sub> = 1.76, h<sub>f,g</sub> = 2257 kJ/kg, h'<sub>f,g</sub> = h<sub>f,g</sub> + 0.80 c<sub>p,ℓ</sub> (T<sub>s</sub> − T<sub>sat</sub>) = 2905 kJ/kg, σ = 58.9 × 10<sup>−3</sup> N/m; Saturated water, vapor (100°C): ρ<sub>v</sub> = 0.5955 kg/m<sup>3</sup>; Water vapor (T<sub>f</sub> = 498 K): ρ<sub>v</sub> = 1/ν<sub>v</sub> = 12.54 kg/m<sup>3</sup>, c<sub>p,v</sub> = 3236 J/kg·K, k<sub>v</sub> = 0.04186 W/m·K, η<sub>v</sub> = 1.317 × 10<sup>−6</sup> m<sup>2</sup>/s.

**ANALYSIS:** (a) Since ΔT<sub>e</sub> > 120°C, the element is operating in the *film-boiling* (FB) regime. The electrical power dissipation per unit length is

\[ q'_s = \bar{h} (\pi D) (T_s - T_{sat}) \]  

(1)

where the total heat transfer coefficient is

\[ \bar{h}^{4/3} = \bar{h}_{conv}^{4/3} + \bar{h}_{rad}^{1/3} \]  

(2)

The convection coefficient is given by the correlation, Eq. 10.9, with C = 0.62,

\[
\frac{\bar{h}_{conv} D}{k_v} = C \left[ \frac{g (\rho_\ell - \rho_v) h_{f,g} D^3}{\eta_v k_v (T_s - T_{sat})} \right]^{1/4}
\]

(3)

\[
\bar{h}_{conv} = 0.62 \left[ \frac{9.8 \text{ m/s}^2 (833.9 - 12.54) \text{kg/m}^3 \times 2.905 \times 10^6 \text{J/kg} \cdot \text{K} (0.005 \text{ m})}{1.31 \times 10^{-6} \text{m}^2/\text{s} \times 0.04186 \text{ W/m} \cdot \text{K} (350 - 100) \text{K}} \right]^{1/4}
\]

\[
\bar{h}_{conv} = 626 \text{ W/m}^2 \cdot \text{K}
\]

The radiation coefficient, Eq. (10.11), with σ = 5.67 × 10<sup>−8</sup> W/m<sup>2</sup>·K<sup>4</sup>, is

Continued …..
PROBLEM 10.30 (Cont.)

\[
\bar{h}_{\text{rad}} = \frac{\varepsilon\sigma\left(T_s^4 - T_{\text{sat}}^4\right)}{(T_s - T_{\text{sat}})}
\]

\[
\bar{h}_{\text{rad}} = \frac{0.25\sigma\left(623^4 - 373^4\right)K^4}{(350 - 100)K} = 4.5 \text{ W/m}^2\cdot\text{K}
\]

Substituting numerical values into Eq. (2) for \(h\), and into Eq. (1) for \(q_s\), find

\[
\bar{h} = 630 \text{ W/m}^2\cdot\text{K}
\]

\[
q_s = 630 \text{ W/m}^2\cdot\text{K}(\pi\times0.005 \text{ m})(350 - 100) \text{ K} = 2473 \text{ W/m}
\]

\[
q_s^* = q_s' / \pi D = 0.157 \text{ MW/m}^2
\]

The evaporation rate per unit length is

\[
m_b' = q_s^* / h_{fg} = 3.94 \text{ kg/h/m}
\]

(b) For the same heat flux, \(q_s^* = 0.157 \text{ MW/m}^2\), using the Rohsenow correlation for the nucleate boiling (NB) regime, find \(\Delta T_e\), and hence \(T_s\).

\[
q_s^* = \mu_{\ell}h_{fg}\left[\frac{g(\rho_{\ell} - \rho_v)}{\sigma}\right]^{1/2}\left(\frac{c_{p,\ell} \Delta T_e}{C_{s,f} h_{fg} Pr_{\ell}^{1/3}}\right)^3
\]

where, from Table 10.1, for stainless steel mechanically polished finish with water, \(C_{s,f} = 0.013\) and \(n = 1.0\).

\[
0.157\times10^6 \text{ W/m}^2 = 279\times10^{-6} \text{ N} \cdot \text{s/m}^2 \times 2.257\times10^6 \text{ J/kg}
\]

\[
\times\left[\frac{9.8 \text{ m/s}^2(957.9 - 0.5955) \text{ kg/m}^3}{58.9\times10^{-3} \text{ N/m}}\right]^{1/2}
\]

\[
\times\left(\frac{4217 \text{ J/kg} \cdot \text{K} \times \Delta T_e}{0.013\times2.257\times10^6 \text{ J/kg} \times 1.76}\right)^3
\]

\[
\Delta T_e = T_s - T_{\text{sat}} = 10.5 \text{ K} \quad \text{ T_s = 110.5°C}
\]

The evaporation rate per unit length is

\[
m_b' = q_s^* (\pi D) h_{fg} = 3.94 \text{ kg/h/m}
\]

Continued …..
(c) The two operating conditions are shown on the boiling curve, which is fashioned after Figure 10.4. For FB the surface temperature is $T_s = 350^\circ C$ ($\Delta T_e = 250^\circ C$). The element can be operated at NB with the same heat flux, $q''_s = 0.157 \text{ MW/m}^2$, with a surface temperature of $T_s = 110^\circ C$ ($\Delta T_e = 10^\circ C$). Since the heat fluxes are the same for both conditions, the evaporation rates are the same.

If the element is cold, and operated in a power-controlled mode, the element would be brought to the NB condition following the arrow shown next to the boiling curve near $\Delta T_e = 0$. If the power is increased beyond that for the NB point, the element will approach the critical heat flux (CHF) condition. If $q''_s$ is increased beyond $q''_{\text{max}}$, the temperature of the element will increase abruptly, and the burnout condition will likely occur. If burnout does not occur, reducing the heat flux would allow the element to reach the FB point.
PROBLEM 10.31

KNOWN: Inner and outer diameters, outer surface temperature and thermal conductivity of a tube. Saturation pressure of surrounding water and convection coefficient associated with gas flow through the tube.

FIND: (a) Heat rate per unit tube length, (b) Mean temperature of gas flow through tube.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Uniform surface temperature, (3) Water is at saturation temperature, (4) Tube is horizontal.

PROPERTIES: Table A-6, saturated water, liquid (p = 1.523 bars): T\textsubscript{sat} = 385 K, ρ\textsubscript{f} = 950 kg/m\textsuperscript{3}, h\textsubscript{fg} = 2225 kJ/kg. Table A-6, saturated water, vapor (T\textsubscript{f} = 480 K): ρ\textsubscript{v} = 9.01 kg/m\textsuperscript{3}, c\textsubscript{p,v} = 2940 J/kg\cdot K, μ\textsubscript{v} = 15.9 \times 10\textsuperscript{-6} N\cdot s/m\textsuperscript{2}, k\textsubscript{v} = 0.0381 W/m\cdot K, v\textsubscript{v} = 1.77 \times 10\textsuperscript{-6} m\textsuperscript{2}/s.

ANALYSIS: (a) The heat rate per unit length is \( q' = h_o \pi D_o (T\textsubscript{s,o} - T\textsubscript{sat}) \), where \( h_o \) includes contributions due to convection and radiation in film boiling. With C = 0.62 and \( h\textsubscript{fg} = h\textsubscript{fg} + 0.80 \), \( c\textsubscript{p,v} (T\textsubscript{s,o} - T\textsubscript{sat}) = 2.67 \times 10\textsuperscript{6} J/kg \), Eq. 10.9 yields

\[
\bar{h}_{\text{conv},o} = \left( \frac{0.0381 W/m \cdot K}{0.03 m} \right) (1/2) \left[ \frac{9.8 m/s^2 (950 - 9) kg/m^3 \cdot 2.67 \times 10^6 J/kg (0.03 m)^3}{1.77 \times 10^{-6} m^2/s \cdot 0.0381 W/m \cdot K \cdot 190 K} \right]^{1/4} = 376 W/m^2 \cdot K
\]

From Eq. 10.11, the radiation coefficient is

\[
\bar{h}_{\text{rad},o} = \frac{0.30 \times 5.67 \times 10^{-8} W/m^2 \cdot K^4 (575^4 - 385^4) K^4}{(575 - 385) K} = 7.8 W/m^2 \cdot K
\]

From Eq. 10.10b, it follows that

\[
\bar{h}_o = \bar{h}_{\text{conv},o} + 0.75 \bar{h}_{\text{rad},o} = 382 W/m^2 \cdot K
\]

and the heat rate is

\[
q' = \bar{h}_o \pi D_o (T\textsubscript{s,o} - T\textsubscript{sat}) = 382 W/m^2 \cdot K (π \times 0.03m)(190 K) = 6840 W
\]

(b) From the thermal circuit, with \( R\textsubscript{conv,i} = (h_o \pi D_t)^{-1} = (500 W/m^2 \cdot K \times π \times 0.026 m)^{-1} = 0.0245 m \cdot K/W \) and \( R\textsubscript{cond} = \ell n \left( D_o / D_i \right) / 2\pi k_s = \ell n \left( 0.03 / 0.026 \right) / 2\pi (15 W/m \cdot K) = 0.00152 m \cdot K/W \),

\[
q' = \frac{T_m - T\textsubscript{s,o}}{R\textsubscript{conv,i} + R\textsubscript{cond}} = \frac{T_m - 575 K}{(0.0245 + 0.00152) m \cdot K/W}
\]

\[
T_m = 575 K + 6840 W/m \left( 0.0260 m \cdot K/W \right) = 753 K
\]

COMMENTS: Despite the large temperature of the gas, the rate of heat transfer is limited by the large thermal resistances associated with convection from the gas and film boiling. The resistance due to film boiling is \( R\textsubscript{fb} = (\pi D_o \bar{h}_o)^{-1} = 0.0278 m \cdot K/W \).
**PROBLEM 10.32**

**KNOWN:** Cylinder of 120 mm diameter at 1000K quenched in saturated water at 1 atm

**FIND:** Describe the quenching process and estimate the maximum heat removal rate per unit length during cooling.

**SCHEMATIC:**

[Diagram showing the quenching process with points A, B, C, D, and the boiling curves.

**ASSUMPTIONS:** Water exposed to 1 atm pressure, $T_{\text{sat}} = 100^\circ\text{C}$.

**ANALYSIS:** At the start of the quenching process, the surface temperature is $T_s(0) = 1000K$. Hence, $\Delta T_c = T_s - T_{\text{sat}} = 1000K - 373K = 627K$, and from the typical boiling curve of Figure 10.4, film boiling occurs.

As the cylinder temperature decreases, $\Delta T_c$ decreases, and the cooling process follows the boiling curve sketched above. The cylinder boiling process passes through the Leidenfrost point D, into the transition or unstable boiling regime ($D \to C$).

At point C, the boiling heat flux has reached a maximum, $q_{\text{max}}^* = 1.26 \text{ MW/m}^2$ (see Example 10.1). Hence, the heat rate per unit length of the cylinder is

$$ q_s = q_{\text{max}} = q_{\text{max}}^* (\pi D) = 1.26 \text{ MW/m}^2 [\pi (0.120\text{m})] = 0.475 \text{ MW/m}. $$

As the cylinder cools further, nucleate boiling occurs ($C \to A$) and the heat rate drops rapidly. Finally, at point A, boiling no longer is present and the cylinder is cooled by free convection.

**COMMENTS:** Why doesn’t the quenching process follow the cooling curve of Figure 10.3?
PROBLEM 10.33

KNOWN: Horizontal platinum wire of diameter of 1 mm, emissivity of 0.25, and surface temperature of 800 K in saturated water at 1 atm pressure.

FIND: (a) Surface heat flux, \( q^*_{s} \), when the surface temperature is \( T_s = 800 \) K and (b) Compute and plot on log-log coordinates the heat flux as a function of the excess temperature, \( \Delta T_e = T_s - T_{sat} \), for the range \( 150 \leq \Delta T_e \leq 550 \) K for emissivities of 0.1, 0.25, and 0.95; separately plot the percentage contribution of radiation as a function of \( \Delta T_e \).

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Film pool boiling.

PROPERTIES: Table A.6, Saturated water, liquid (\( T_{sat} = 100^\circ C, 1 \) atm): \( \rho = 957.9 \) kg/m\(^3\), \( h_{fg} = 2257 \) kJ/kg; Table A.6, Water, vapor (\( T_f = (T_s + T_{sat})/2 = (800 + 373)K/2 = 587 \) K): \( \rho_v = 58.14 \) kg/m\(^3\), \( c_{p,v} = 7065 \) J/kg\( \cdot \)K, \( \mu_v = 21.1 \times 10^{-6} \) N\( \cdot \)s/m\(^2\), \( k_v = 81.9 \times 10^{-3} \) W/m\( \cdot \)K.

ANALYSIS: (a) The heat flux is
\[
q^*_{s} = \bar{h}(T_s - T_{sat}) = \bar{h}\Delta T_e
\]
where \( \Delta T_e = (800 - 373)K = 427 \) indicative of film boiling. From 10.10,
\[
\bar{h}^{4/3} = \bar{h}_{conv}^{4/3} + \bar{h}_{rad}\bar{h}^{-1/3}
\]
or
\[
\bar{h} = \bar{h}_{conv} + (3/4)\bar{h}_{rad}
\]
if \( \bar{h}_{rad} < \bar{h}_{conv} \). Use Eq. 10.9 with \( C = 0.62 \) for a horizontal cylinder,
\[
\frac{\bar{h}_{conv}}{k_v} = \frac{C}{\bar{h}_{conv}D} = \frac{g(\rho_{\ell} - \rho_v)h_{fg}D^{3}}{v_kk_v(T_{s} - T_{sat})}^{1/4}
\]
\[
\bar{h}_{conv} \times 0.001 \text{m} = \frac{9.8 \text{m/s}^2(957.9 - 58.14) \text{kg/m}^3 \times 4670 \text{kJ/kg}(0.001 \text{m})^3}{(21.1 \times 10^{-6} \text{N}\cdot\text{s/m}^2/58.14 \text{kg/m}^3) \times 0.0819 \text{W/m}\cdot\text{K}(800 - 373) \text{K}}^{1/4}
\]
\[
\bar{h}_{conv} = 2155 \text{ W/m}^2\cdot\text{K}
\]
where \( h_{fg} = h_{fg} + 0.8c_{p,v}(T_{s} - T_{sat}) = 2257 \) kJ/kg + \( 0.8 \times 7065 \) J/kg\( \cdot \)K(800 - 373)K = 4670 kJ/kg. To estimate the radiation coefficient, use Eq. 10.11,
\[
\bar{h}_{rad} = \frac{\varepsilon\sigma(T_s^4 - T_{sat}^4)}{T_s - T_{sat}} = \frac{0.25\sigma(800^4 - 373^4)K^4}{(800 - 373)K} = 13.0 \text{ W/m}^2\cdot\text{K}.
\]
Since \( \bar{h}_{rad} < \bar{h}_{conv} \), use the simpler expression,
\[
\bar{h} = 2155 \text{ W/m}^2\cdot\text{K} + (3/4)13.0 \text{ W/m}^2\cdot\text{K} = 2165 \text{ W/m}^2\cdot\text{K}.
\]
Using the rate equation, find

Continued...
PROBLEM 10.33 (Cont.)

\[ q_s^* = 2165 \text{ W/m}^2 \cdot \text{K} (800 - 373) \text{ K} = 0.924 \text{ MW/m}^2. \]

(b) Using the *IHT Correlations Tool, Boiling, Film Pool Boiling*, combined with the *Properties Tool* for *Water*, the heat flux, \( q_s^* \), was calculated as a function of the excess temperature, \( \Delta T_e \) for emissivities of 0.1, 0.25 and 0.95. Also plotted is the ratio (%) of \( q_{\text{rad}}^*/q^* \) as a function of \( \Delta T_e \).

From the \( q_s^* \) vs. \( \Delta T_e \) plot, note that the heat rate increases markedly with increasing excess temperature. On the plot scale, the curves for the three emissivity values, 0.1, 0.25 and 0.95, overlap indicating that the overall effect of emissivity change on the total heat flux is slight. Also shown on the plot are the critical heat flux, \( q_{\text{max}}^* = 1.26 \text{ MW/m}^2 \), and the minimum heat flux, \( q_{\text{min}}^* = 18.9 \text{kW/m}^2 \), at the Leidenfrost point. These values are computed in Example 10.1. Note that only for the extreme value of \( \Delta T_e \) is the heat flux in film pool boiling in excess of the critical heat flux. The relative contribution of the radiation mode is evident from the \( q_{\text{rad}}^*/q_s^* \) vs. \( \Delta T_e \) plot. The maximum contribution by radiation is less than 3\% and surprisingly doesn’t occur at the maximum excess temperature. By examining a plot of \( q_{\text{rad}}^* \) vs. \( \Delta T_e \), we’d see that indeed \( q_{\text{rad}}^* \) increases markedly with increasing \( \Delta T_e \); however, \( q_{\text{conv}}^* \) increases even more markedly so that the relative contribution of the radiation mode actually decreases with increasing temperature for \( \Delta T_e > 250 \text{ K} \). Note that, as expected, the radiation heat flux, \( q_{\text{rad}}^* \), is proportional to the emissivity.

**COMMENTS:** Since \( q_s^* < q_{\text{max}}^* = 1.26 \text{ MW/m}^2 \), the prescribed condition can only be achieved in power-controlled heating by first exceeding \( q_{\text{max}}^* \) and then decreasing the flux to 0.924 MW/m\(^2\).
PROBLEM 10.34

KNOWN: Surface temperature and emissivity of strip steel.

FIND: Heat flux across vapor blanket.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Vapor/jet interface is at \( T_{sat} \) for \( p = 1 \) atm, (3) Negligible effect of jet and strip motion.

PROPERTIES: Table A-6, Saturated water (100°C): \( \rho_l = 957.9 \) kg/m\(^3\), \( h_{fg} = 2257 \) kJ/kg; Saturated water vapor (\( T_f = 640K \)): \( \rho_v = 175.4 \) kg/m\(^3\), \( c_{p,v} = 42 \) kJ/kg_K, \( \mu_v = 32 \times 10^{-6} \) N\( \cdot \)s/m\(^2\), \( k = 0.155 \) W/m\( \cdot \)K, \( \nu_v = 0.182 \times 10^{-6} \) m\(^2\)/s.

ANALYSIS: The heat flux is

\[ q_s'' = \bar{h} \Delta T_e \]

where \( \Delta T_e = 907 \) K \(-\) 373 K = 534 K

and \( \bar{h} = r^{4/3} = \bar{h}_{\text{conv}} + \frac{1}{3} \bar{h}_{\text{rad}} \) or \( \bar{h} = \bar{h}_{\text{conv}} + (3/4) \bar{h}_{\text{rad}} \).

With \( h_{fg} = h_{fg} + 0.80 c_{p,v} (T_s - T_{sat}) = 2.02 \times 10^7 \) J/kg

Equation 10.9 yields

\[ \bar{h}_{\text{conv}} = \frac{1}{0.182 \times 10^{-6} \text{m}^2/\text{s} (0.155 \text{ W/m}\cdot\text{K}) (907 - 373) \text{ K}^{-1}} \]

\[ = 6243. \]

Hence,

\[ \bar{h}_{\text{conv}} = \frac{1}{D} \frac{K}{0.155 \text{ W/m}\cdot\text{K}} = 968 \text{ W/m}^2 \cdot \text{K} \]

\[ \bar{h}_{\text{rad}} = \frac{\varepsilon \sigma (T_s^4 - T_{sat}^4)}{T_s - T_{sat}} = \frac{0.35 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K} \cdot (907^4 - 373^4) \text{ K}^4}{907 - 373} \text{ K} \]

\[ \bar{h}_{\text{rad}} = 24 \text{ W/m}^2 \cdot \text{K} \]

Hence,

\[ \bar{h} = 968 \text{ W/m}^2 \cdot \text{K} + (3/4) (24 \text{ W/m}^2 \cdot \text{K}) = 986 \text{ W/m}^2 \cdot \text{K} \]

And \( q_s'' = 986 \text{ W/m}^2 \cdot \text{K} (907 - 373) \text{ K} = 5.265 \times 10^5 \text{ W/m}^2 \).

COMMENTS: The foregoing analysis is a very rough approximation to a complex problem. A more rigorous treatment is provided by Zumbrunnen et al. In ASME Paper 87-WA/HT-5.
PROBLEM 10.35

KNOWN: Copper sphere, 10 mm diameter, initially at a prescribed elevated temperature is quenched in a saturated (1 atm) water bath.

FIND: The time for the sphere to cool (a) from $T_i = 130$ to $110^\circ$C and (b) from $T_i = 550$ to $220^\circ$C.

SCHEMATIC:

ASSUMPTIONS: (1) Sphere approximates lumped capacitance, (2) Water saturated at 1 atm.

PROPERTIES: Table A-1, Copper: $\rho = 8933$ kg/m$^3$; Table A.11, Copper (polished): $\varepsilon = 0.04$, typical value; Table A.4, Water: as required for the pool boiling correlations.

ANALYSIS: Treating the sphere as a lumped capacitance and performing an energy balance, see Eq. 5.14,

$$\dot{E}_{in} - \dot{E}_{out} = \dot{E}_{st} - q''_s \cdot A_s = \rho c_v \frac{dT}{dt}$$

For the sphere, $V = \pi D^3 / 6$ and $A_s = \pi D^2$. Using the IHT Lumped Capacitance Model to solve this differential equation, we need to specify (1) the specific heat of the copper sphere as a function sphere temperature; use IHT Properties Tool, Copper; and (2) the heat flux, $q''_s$, associated with the pool boiling processes; use IHT Correlations Tool, Boiling:

(a) Cooling from $T_i = 130^\circ$ to $110^\circ$: Nucleate pool boiling, Rohsenhow correlation, Eq. 10.5,

(b) Cooling from $T_i = 550$ to $220^\circ$C: Film Pool Boiling, Eq. 10.9 with $C = 0.67$ (sphere).

The thermophysical properties for water required of the correlations are provided by the IHT Tool, Properties-Water. The specific heat of copper as a function of sphere temperature is provided by the IHT Tool, Properties-Copper. The temperature-time histories for each of the cooling processes are plotted below.
Using the Explore feature in the IHT Plot Window, the elapsed times for the quench process were found as:

<table>
<thead>
<tr>
<th>Quench process</th>
<th>$T_i - T_f$ (°C)</th>
<th>Δt(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Nucleate pool boiling</td>
<td>130-110</td>
<td>0.76</td>
</tr>
<tr>
<td>Film pool boiling</td>
<td>550-220</td>
<td>13.5</td>
</tr>
</tbody>
</table>

**COMMENTS:**

(1) Comparing the elapsed times for the two processes, the nucleate pool boiling process cools 20°C in 0.76s (26.3°C/s) vs. 330°C in 13.5s (24.4°C/s) for the film pool boiling process.

(2) The IHT Workspace used to generate the temperature-time history for the nucleate pool boiling process is shown below.
PROBLEM 10.36

KNOWN: Saturated water at 1 atm is heated in cross flow with velocities 0 – 2 m/s over a 2 mm-diameter tube.

FIND: Plot the critical heat flux as a function of water velocity; identify the pool boiling and transition regions between the low and high velocity ranges.

SCHEMATIC:

ASSUMPTIONS: Nucleate boiling in the presence of external forced convection.

PROPERTIES: Table A-6, Water (1 atm): \(T_{\text{sat}} = 100^\circ\text{C}, \) \(\rho_\ell = 957.9 \text{ kg/m}^3, \rho_v = 0.5955 \text{ kg/m}^3, h_{fg} = 2257 \text{ kJ/kg, } \sigma = 58.9 \times 10^{-3} \text{ N/m.}\)

ANALYSIS: The Lienhard-Eichhorn correlations for forced convection boiling with cross flow over a cylinder are appropriate for estimating \(q_{\text{max}}', \) Eqs. 10.12 and 10.13.

Low Velocity

\[
q_{\text{max}}' = \frac{\rho_v h_{fg}}{\pi} \left[ 1 + \left( \frac{4\sigma}{\rho_v V^2 D} \right)^{1/3} \right] V
\]

\[
q_{\text{max}}' = \frac{1}{\pi} 0.5955 \frac{\text{kg}}{\text{m}^3} \times 2257 \times 10^3 \frac{\text{J}}{\text{kg}} \left[ 1 + \left( \frac{4 \times 58.9 \times 10^{-3} \text{ N/m}}{0.5955 \text{ kg/m}^3 \cdot 2 \cdot 0.002 \text{ m}} \right)^{1/3} \right] V
\]

\[
q_{\text{max}}' = 4.2782 \times 10^5 V + 2.921 \times 10^6 V^{1/3}
\]

High Velocity

\[
q_{\text{max}}' = \frac{\rho_v h_{fg}}{\pi} \left[ \frac{1}{169} \left( \frac{\rho_\ell}{\rho_v} \right)^{3/4} + \frac{1}{19.2} \left( \frac{\rho_\ell}{\rho_v} \right)^{1/2} \left( \frac{\sigma}{\rho_v V^2 D} \right)^{1/3} \right] V
\]

\[
q_{\text{max}}' = \frac{1}{\pi} 0.5955 \frac{\text{kg}}{\text{m}^3} \times 2257 \times 10^3 \frac{\text{J}}{\text{kg}} \left[ \frac{1}{169} \left( \frac{957.9}{0.5955} \right)^{3/4} + \right.
\]

\[
\left. \frac{1}{19.2} \left( \frac{957.9}{0.5955} \right)^{1/2} \left( \frac{58.9 \times 10^{-3} \text{ N/m}}{0.5955 \text{ kg/m}^3 \cdot 2 \cdot 0.002 \text{ m}} \right)^{1/3} \right] V
\]

\[
q_{\text{max}}' = 6.4299 \times 10^5 V + 3.280 \times 10^6 V^{1/3}
\]

Continued ….
PROBLEM 10.36 (Cont.)

The transition between the low and high velocity regions occurs when

\[
q'_{\text{max}} = \rho_v h_{fg} V \left[ \frac{0.275}{\pi} \left( \frac{\rho_f}{\rho_v} \right)^{1/2} + 1 \right]
\]

\[
q'_{\text{max}} = 0.5955 \frac{\text{kg}}{\text{m}^3} \times 2257 \times 10^3 \frac{\text{J}}{\text{kg}} V \left[ \frac{0.275}{\pi} \left( \frac{957.9}{0.5955} \right)^{1/2} + 1 \right] = 6.0627 \times 10^6 V.
\]  

For pool boiling conditions when the velocity is zero, the critical heat flux must be estimated according to the correlation for the small horizontal cylinder as introduced in Problem 10.22. If the cylinder were “large,” the critical heat flux would be 1.26 MW/m² as given by the Zuber-Kutateladze correlation, Eq. 10.7. Following the analysis of Problem 10.22, find \(Bo = 0.40\) and the critical heat flux for the “small” 2 mm cylinder is

\[
q''_{\text{max}} = 1.18 \times 1.26 \text{ MW/m}^2 = 1.49 \text{ W/m}^2.
\]

The graph below identifies four regions: pool boiling where \(q''_{\text{max}} = 1.49 \text{ MW/m}^2\) from \(V = 0\) to 0.15 m/s and the low velocity, transition and high velocity regimes.
PROBLEM 10.37

KNOWN: Saturated water at 1 atm and velocity 2 m/s in cross flow over a heater element of 5 mm diameter.

FIND: Maximum heating rate, \(q'\ [\text{W/m}]\).

SCHEMATIC:

ASSUMPTIONS: Nucleate boiling in the presence of external forced convection.

PROPERTIES: Table A-6, Water (1 atm): \(T_{\text{sat}} = 100^\circ \text{C}, \rho_{\ell} = 957.9 \text{ kg/m}^3, \rho_{\nu} = 0.5955 \text{ kg/m}^3, h_{\text{fg}} = 2257 \text{ kJ/kg}, \sigma = 58.9 \times 10^{-3} \text{ N/m}.

ANALYSIS: The Lienhard-Eichhorn correlation for forced convection with cross flow over a cylinder is appropriate for estimating \(q''_{\text{max}}\). Assuming high-velocity region flow, Eq. 10.13 with Eq. 10.14 can be written as

\[
\frac{q''_{\text{max}}}{\pi} = \frac{\rho_{\nu} h_{\text{fg}} V}{\frac{1}{169} \left( \frac{\rho_{\ell}}{\rho_{\nu}} \right)^{3/4} + \frac{1}{19.2} \left( \frac{\rho_{\ell}}{\rho_{\nu}} \right)^{1/2} \left( \frac{\sigma}{\rho_{\nu} V^2 D} \right)^{1/3}}.
\]

Substituting numerical values, find

\[
q''_{\text{max}} = \frac{1}{\pi} \frac{0.5955 \text{ kg/m}^3 \times 2257 \times 10^3 \text{ J/kg} \times 2 \text{ m/s}}{\left[ \frac{1}{169} \left( \frac{957.9}{0.5955} \right)^{3/4} + \frac{1}{19.2} \left( \frac{957.9}{0.5955} \right)^{1/2} \left( \frac{58.9 \times 10^{-3} \text{ N/m}}{0.5955 \text{ kg/m}^3 \times (2 \text{ m/s})^2 \times 0.005 \text{ m}} \right)^{1/3} \right]}
\]

\[q''_{\text{max}} = 4.331 \text{ MW/m}^2.\]

The high-velocity region assumption is satisfied if

\[
\frac{q''_{\text{max}}}{\rho_{\nu} h_{\text{fg}} V} = \frac{0.275 \left( \frac{\rho_{\ell}}{\rho_{\nu}} \right)^{1/2} + 1}{\frac{4.331 \times 10^6 \text{ W/m}^2}{0.5955 \text{ kg/m}^3 \times 2257 \times 10^3 \text{ J/kg} \times 2 \text{ m/s}}} = 1.61 < \frac{0.275 \left( \frac{957.9}{0.5955} \right)^{1/2} + 1}{\pi} = 4.51.
\]

The inequality is satisfied. Using the \(q''_{\text{max}}\) estimate, the maximum heating rate is

\[q'_{\text{max}} = q''_{\text{max}} \cdot \pi D = 4.331 \text{ MW/m}^2 \times \pi (0.005 \text{ m}) = 68.0 \text{ kW/m}.\]

COMMENTS: Note that the effect of the forced convection is to increase the critical heat flux by \(4.33/1.26 = 3.4\) over the pool boiling case.
PROBLEM 10.38

KNOWN: Correlation for forced-convection local boiling inside a vertical tube.

FIND: Boiling heat transfer rate per unit length of the tube.

SCHEMATIC:

\[ T_s - T_{\text{sat}} = 15^\circ\text{C} \]

ASSUMPTIONS: (1) Steady-state conditions, (2) Local boiling occurs when tube wall is 15°C above the saturation temperature.

ANALYSIS: From experimental results, the heat transfer coefficient can be estimated by the correlation

\[ h = 2.54 (\Delta T_e)^3 \exp\left(\frac{p}{15.3}\right) \quad \text{[W/m}^2\cdot\text{K]} \]

where \( \Delta T_e \) is the excess temperature, \( T_s - T_{\text{sat}} \) [K], and \( p \) is the pressure [bar]. The heat transfer rate per unit length is

\[ q' = \pi D h \Delta T_e. \]

Evaluating the heat transfer coefficient, find

\[ h = 2.54 (15\text{K})^3 \exp\left(4 \text{ bar}/15.3\right) = 11,134 \text{ W/m}^2\cdot\text{K}. \]

The heat rate is then.

\[ q' = \pi (0.050\text{m}) \times 11,134\text{W/m}^2\cdot\text{K} \times 15\text{K} = 26.2 \text{ kW/m}. \]

COMMENTS: The saturation temperature at 4 bar is \( T_{\text{sat}} = 406.5\text{K} \) according to Table A-6.
**PROBLEM 10.39**

**KNOWN:** Forced convection and boiling processes occur in a smooth tube with prescribed water velocity and surface temperature.

**FIND:** Heat transfer rate per unit length of the tube.

**SCHEMATIC:**

![Diagram](image)

**ASSUMPTIONS:** (1) Fully-developed flow, (2) Nucleate boiling conditions occur on inner wall of tube, (3) Forced convection and boiling effects can be separately estimated.

**PROPERTIES:** Table A-6, Water ($T_m = 95^\circ C = 368K$): $\rho_\ell = 1/\nu_\ell = 962 \text{ kg/m}^3$, $\rho_v = 1/\nu_g = 0.500 \text{ kg/m}^3$, $h_{fg} = 2270 \text{ kJ/kg}$, $c_{p,\ell} = 4212 \text{ J/kg} \cdot \text{K}$, $\mu_\ell = 296 \times 10^{-6} \text{ N} \cdot \text{s/m}^2$, $k_\ell = 0.678 \text{ W/m} \cdot \text{K}$, $Pr_\ell = 1.86$, $\sigma = 60 \times 10^{-3} \text{ N/m}$, $n_\ell = 3.08 \times 10^{-7} \text{ m}^2/\text{s}$.

**ANALYSIS:** Experimentation has indicated that the heat transfer rate can be estimated as the sum of the separate effects due to forced convection and boiling. On a per unit length basis, $q' = q_f + q_{boil}$.

For forced convection, $Re_D = u_mD / \nu_\ell = 1.5 \text{ m/s} \times 0.015 \text{ m} / 3.08 \times 10^{-7} \text{ m}^2 / \text{s} = 73,052$. Since $Re > 2300$, flow is turbulent and since fully developed, use the Dittus-Boelter correlation but with the 0.023 coefficient replaced by 0.019 and $n = 0.4$.

$$h = \frac{k}{D} Nu_D = \frac{0.678 \text{ W/m} \cdot \text{K}}{0.015 \text{ m}} \times 0.019 \left(73,052\right)^{4/5} \left(1.86\right)^{0.4} = 8563 \text{ W/m}^2 \cdot \text{K}.$$ $q_f = h\pi D (T_s - T_m) = 8,563 \text{ W/m}^2 \cdot \text{K} \cdot \pi \left(0.015 \text{ m}\right) (110 - 95)^\circ \text{C} = 6052 \text{ W/m}$.

For boiling, $\Delta T_e = (110 - 100)^\circ \text{C} = 10^\circ \text{C}$ and hence nucleate boiling occurs. From the Rohsenow equation, with $C_{sf} = 0.006$ and $n = 1.0$,

$$q_{boil} = \mu_\ell h_{fg} \left[ \frac{g \left( \rho_\ell - \rho_v \right)}{\sigma} \right]^{1/2} \left[ \frac{c_{p,\ell} \Delta T_e}{C_{sf} \ h_{fg} \ Pr_\ell^n} \right]^3$$

$$q_{boil} = 296 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 \times 2270 \times 10^3 \text{ J/kg} \left[ \frac{9.8 \text{ m/s}^2 (962 - 0.5) \text{ kg/m}^3}{60 \times 10^{-3} \text{ N/m}} \right]^{1/2} \left[ \frac{4212 \text{ J/kg} \cdot \text{K} \cdot \text{K} \times 10^3}{0.006 \times 2270 \times 10^3 \text{ J/kg} \times (1.86)^{1.0}} \right]^3$$

$$q_{boil} = 1.22 \times 10^6 \text{ W/m}^2 \quad q_{boil} = q_{boil} (\pi D) = 1.22 \times 10^6 \text{ W/m}^2 (\pi \times 0.015 \text{ m}) = 57,670 \text{ W/m}.$$ The total heat rate for both processes is $q' = (6052 + 57,670) \text{ W/m} = 6.37 \times 10^4 \text{ W/m}$.

**COMMENTS:** Recognize that this method provides only an estimate since the processes are surely coupled.
PROBLEM 10.40

KNOWN: Saturated steam condensing on the outside of a brass tube and water flowing on the inside of the tube; convection coefficients are prescribed.

FIND: Steam condensation rate per unit length of the tube.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions.

PROPERTIES: Table A-6, Water, vapor (0.1 bar): \( T_{\text{sat}} \approx 320\text{K}, h_{fg} = 2390 \times 10^3 \text{J/kg} \); Table A-1, Brass \( \bar{T} = (T_m + T_{\text{sat}})/2 = 300\text{K} \): \( k = 110 \text{W/m-K} \)

ANALYSIS: The condensation rate per unit length follows from Eq. 10.33 written as

\[
m' = q' / h'_{fg}
\]

where the heat rate follows from Eq. 10.32 using an overall heat transfer coefficient

\[
q' = U_o \cdot \pi D_o \left( T_{\text{sat}} - T_m \right)
\]

and from Eq. 3.31,

\[
U_o = \left[ \frac{1}{h_o} + \frac{D_o/2}{k} \log \left( \frac{D_o}{D_i} \right) + \frac{D_o}{D_i h_i} \right]^{-1}
\]

\[
U_o = \left[ \frac{1}{6800\text{W/m}^2\cdot\text{K}} + \frac{0.0095m}{110\text{W/m} \cdot \text{K}} \ln \frac{19}{16.5} + \frac{19}{16.5} + \frac{1}{5200\text{W/m}^2 \cdot \text{K}} \right]^{-1}
\]

\[
U_o = \left[ 147.1 \times 10^{-6} + 12.18 \times 10^{-6} + 192.3 \times 10^{-6} \right]^{-1} \text{W/m}^2 \cdot \text{K} = 2627\text{W/m}^2 \cdot \text{K}.
\]

Combining Eqs. (1) and (2) and substituting numerical values (see below for \( h'_{fg} \)), find

\[
m' = U_o \pi D_o \left( T_{\text{sat}} - T_m \right) / h'_{fg}
\]

\[
m' = 2627 \text{W/m}^2 \cdot \text{K} \pi (0.019m)(320-303)\text{K}/2410 \times 10^3 \text{J/kg} = 1.11 \times 10^{-3} \text{kg/s}. <
\]

COMMENTS: (1) Note from evaluation of Eq. (3) that the thermal resistance of the brass tube is not negligible. (2) From Eq. 10.26, with \( Ja = c_{p,l} (T_{\text{sat}} - T_s) / h_{fg}, h'_{fg} = h_{fg} [1 + 0.68Ja] \). Note from expression for \( U_o \), that the internal resistance is the largest. Hence, estimate \( T_{s,o} = T_o - (R_o/\Sigma R) (T_o - T_m) = 313\text{K} \). Hence,

\[
h'_{fg} = 2390 \times 10^3 \text{J/kg} \left[ 1 + 0.68 \times 4179 \text{J/kg-K} (320 - 313) \text{K} / 2390 \times 10^3 \text{J/kg} \right]
\]

\[
h'_{fg} = 2410 \text{kJ/kg}
\]

where \( c_{p,l} \) for water (liquid) is evaluated at \( T_f = (T_{s,o} + T_o)/2 \approx 317\text{K} \).
PROBLEM 10.41

KNOWN: Insulated container having cold bottom surface and exposed to saturated vapor.

FIND: Expression for growth rate of liquid layer, \( \delta(t) \); thickness formed for prescribed conditions; compare with vertical plate condensate for same conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Side wall effects are negligible and, (2) Vapor-liquid interface is at \( T_{\text{sat}} \), (3) Temperature distribution in liquid is linear, (4) Constant properties.

PROPERTIES: Table A-6, Saturated vapor (p = 1.0133 bar): \( T_{\text{sat}} = 100^\circ \text{C}, \rho_v = 0.596 \text{ kg/m}^3, h_{fg} = 2257 \text{ kJ/kg} \); Table A-6, Saturated liquid (\( T_f = 90^\circ \text{C} = 363 \text{K} \)): \( \rho_\ell = 1000 \text{ kg/m}^3, \mu_\ell = 313 \times 10^{-6} \text{ Ns/m}^2, k_\ell = 0.676 \text{ W/m K}, c_{p,\ell} = 4207 \text{ J/kg K} \).

ANALYSIS: Perform a surface energy balance on the interface (see above) recognizing that

\[
\dot{m}_\ell / A = \rho_\ell \frac{d\delta}{dt} \quad \text{from an overall mass rate balance on the liquid to obtain}
\]

\[
\dot{E}^\text{in} - \dot{E}^\text{out} = q^\text{cond} - q^\text{cond} = \frac{\dot{m}}{A} h_{fg} - k_\ell \frac{T_{\text{sat}} - T_s}{\delta} = \rho_\ell \frac{d\delta}{dt} h_{fg} - k_\ell \frac{T_{\text{sat}} - T_s}{\delta} = 0 \quad (1)
\]

where \( q^\text{cond} \) is the condensation heat flux and \( q^\text{cond} \) is the conduction heat flux into the liquid layer of thickness \( \delta \) with linear temperature distribution. Eq. (1) can be rewritten as

\[
\rho_\ell h_{fg} \frac{d\delta}{dt} = k_\ell \frac{T_{\text{sat}} - T_s}{\delta}.
\]

Separate variables and integrate with limits shown to obtain the liquid layer growth rate,

\[
\int_0^\delta \delta d\delta = \int_0^t \frac{k_\ell (T_{\text{sat}} - T_s)}{\rho_\ell h_{fg}} dt \quad \text{or} \quad \delta = \left[ \frac{2k_\ell (T_{\text{sat}} - T_s)}{\rho_\ell h_{fg}} \right]^t_0 \left( \frac{1}{2} \right).
\]

For the prescribed conditions, the liquid layer thickness and condensate formed in one hour are

\[
\delta (1\text{hr}) = \left[ 2 \times 0.676 \times \frac{W}{m \cdot K} \times (100 - 80)^\circ \text{C} \times 3600 \text{s/1000} \times \frac{2257 \times 10^3 \text{ J}}{\text{kg}} \right]^{1/2} = 6.57 \text{mm} < \]

\[
M(1\text{hr}) = \rho_\ell A \delta = 1000 \text{kg/m}^3 \times 200 \times 10^{-6} \text{ m}^2 \times 6.57 \times 10^{-3} \text{ m} = 1.314 \times 10^{-3} \text{kg}.
\]

Continued …..
PROBLEM 10.41 (Cont.)

The condensate formed on a vertical plate with the same conditions follows from Eq. 10.33,

\[ M_{vp} = \dot{m} \cdot t = \bar{h}_L A (T_{sat} - T_s) \cdot t / h_{fg}' \]

where \( h_{fg}' \) and \( \bar{h}_L \) follow from Eqs. 10.26 and 10.30, respectively.

\[ h_{fg}' = h_{fg} (1 + 0.68 \text{Ja}) = \frac{h_{fg} (1 + 0.68 \rho_c \Delta T / h_{fg})}{1 + 0.68 \rho_c \Delta T / h_{fg}} \]

\[ h_{fg}' = 2257 \times 10^3 \text{ J/kg} \left(1 + 0.68 \times 4207 \frac{\text{ J}}{\text{ kg} \cdot \text{ K}} (100 - 80) \text{ °C} / 2257 \times 10^3 \text{ J/kg} \right) = 2314 \text{ kJ/kg} \]

\[ \bar{h}_L = 0.943 \left[ g \rho_c (\rho_c - \rho_v) k_c^3 h_{fg} / \mu_c (T_{sat} - T_s) L \right]^{1/4} \]

\[ \bar{h}_L = 0.943 \left[ 9.8 \text{ m/s}^2 \times 1000 \text{ kg/m}^3 \left(100 - 0.596 \right) \text{ kg/m}^3 (0.676 \text{ W/m} \cdot \text{ K}) \right]^{1/4} \times 2314 \times 10^3 \text{ J/kg} / 313 \times 10^{-6} \text{ N} \cdot \text{s} / \text{ m}^2 (100 - 80) \text{ °C} \times 0.2 \text{ m} \]

\[ \bar{h}_L = 8155 \text{ W/m}^2 \cdot \text{ K.} \]

Hence,

\[ M_{vp} = 8155 \text{ W/m}^2 \cdot \text{ K} \times 200 \times 10^{-6} \text{ m}^2 (100 - 80) \text{ °C} \times 3600 \text{ s} / 2314 \times 10^3 \text{ J/kg} \]

\[ M_{vp} = 5.08 \times 10^{-2} \text{ kg.} \]

**COMMENTS:**

(1) Note that the condensate formed by the vertical plate is an order of magnitude larger. For the vertical plate the rate of condensate formation is constant. For the container bottom surface, the rate decreases with increasing time since the conduction resistance increases as the liquid layer thickness increases.

(2) For the vertical plate, assumed to be square 14.1 × 14.1 mm, the Reynolds number, Eq. 10.35 and 10.33, is

\[ \text{Re}_\delta = \frac{4 \dot{m} b}{\mu_c b} = \frac{4 \bar{h}_L A (T_{sat} - T_s)}{h_{fg}'} \]

\[ \text{Re}_\delta = \frac{4}{313 \times 10^{-6} \text{ N} \cdot \text{s} / \text{ m}^2 \times 14.1 \times 10^{-3} \text{ m}} \frac{8155 \text{ W/m}^2 \cdot \text{ K} \left(200 \times 10^{-6} \text{ m}^2 \right)(100 - 80) \text{ °C}}{2314 \text{ kJ/kg}} \]

\[ \text{Re}_\delta = 12.8. \]

Hence, using Eq. 10.30 to estimate \( \bar{h}_L \) is correct since, in fact, the film is laminar.
PROBLEM 10.42

KNOWN: Vertical tube experiencing condensation of steam on its outer surface.

FIND: Heat transfer and condensation rates.

SCHEMATIC:

ASSUMPTIONS: (1) Film condensation, (2) Negligible non-condensibles, (3) D/2 >> \( \delta \), vertical plate behavior.

PROPERTIES: Table A-6, Water, vapor (1.0133 bar): \( T_{\text{sat}} = 100^\circ \text{C} \), \( \rho_v = 0.596 \text{ kg/m}^3 \), \( h_fg = 2257 \text{ kJ/kg} \); Table A-6, Water, liquid (\( T_f = 97^\circ \text{C} \)): \( \rho_f = 960.6 \text{ kg/m}^3 \), \( \mu_f = 289 \times 10^{-6} \text{ N.s/m}^2 \), \( c_{p,f} = 4214 \text{ J/kg.K} \), \( k_l = 0.679 \text{ W/m.K} \)

ANALYSIS: The heat transfer and condensation rates are

\[
q = \frac{h_L}{\pi D L} \left( T_{\text{sat}} - T_s \right)
\]

where \( h_f' = h_f \left( 1 + 0.68J_a \right) \) and \( J_a = \frac{c_{p,f} \left( T_{\text{sat}} - T_s \right)}{h_f'}. \) Hence \( J_a = 4214 \text{ J/kg.K} \) \((100 - 94)\text{K/}2257 \times 10^3 \text{ J/kg} = 0.0112 \) and \( h_f' = 2274 \text{ kJ/kg} \). Assume laminar film condensation and use Eq. 10.31 to estimate \( h_L \),

\[
\overline{h}_L = \frac{0.679 \text{ W/m.K}}{1.0 \text{ m}} \left( \frac{960.6 \text{ kg/m}^3 \times 9.8 \text{ m/s}^2 \left( 960.6 - 0.596 \right) \text{ kg/m}^3 \times 2274 \times 10^3 \text{ J/kg} \times (1 \text{ m})^3}{289 \times 10^{-6} \text{ N.s/m}^2 \times 0.679 \text{ W/m.K} \left( 100 - 94 \right) \text{ K}} \right)^{1/4} = 7360 \text{ W/m}^2 \cdot \text{K}.
\]

Hence, \( q = 7360 \text{ W/m}^2 \cdot \text{K} \left( \pi \times 0.100 \text{m} \times 1 \text{m} \right) \left( 100 - 94 \right) \text{K} = 13.87 \text{kW}. \)

\[
\dot{m} = 13.9 \times 10^3 \text{ W}/2274 \times 10^3 \text{ J/kg} = 0.00610 \text{kg/s}.
\]

Check the laminar film assumption: \( \text{Re} = \frac{4 \dot{m} / \mu_f \cdot b}{\pi \times 0.00610 \text{ kg/s}/289 \times 10^{-6} \text{ N.s/m}^2 \times (\pi \times 0.100 \text{m})} = 269. \) Since \( 30 < \text{Re} < 1800 \), the flow is wavy, not laminar. By combining Eqs. 10.33 and 10.35 with 10.38 (see Example 10.3), find \( \text{Re} \),

\[
\frac{\text{Re}}{4 A_s \left( T_{\text{sat}} - T_s \right)} = \frac{1.08 \text{Re}^{1.22}}{1.52 \left( \sqrt{\frac{2}{\mu_f} / g} \right)^{1/3}}.
\]

Continued …..
PROBLEM 10.42 (Cont.)

\[
\frac{289 \times 10^{-6} \text{N} \cdot \text{s} / \text{m}^2 \times (\pi \times 0.10 \text{m}) \times 2274 \times 10^3 \text{J} / \text{kg}}{4 \times (\pi \times 0.10 \text{m} \times 1 \text{m}) \times (100 - 94) \text{K}} = \frac{1}{1.08 \text{Re}_\delta^{1.22} - 5.2} \left( \frac{289 \times 10^{-6}}{960.6} \right)^2 \frac{\text{m}^4}{\text{s}^2} \frac{1}{(9.8 \text{m/s})^2} \right)^{1/3} = 0.679 \text{W/m} \cdot \text{K}
\]

Solving, we obtain \( \text{Re}_\delta = 311 \). Using Eq. 10.38, find

\[
\frac{\bar{h}_L \left( \frac{V_f^2}{g} \right)^{1/3}}{k_f} = \frac{\text{Re}_\delta}{1.08 \text{Re}_\delta^{1.22} - 5.2}
\]

\( \bar{h}_L = 8.507 \text{W/m}^2 \cdot \text{K} \)

\[
q = 8.507 \text{W/m}^2 \cdot \text{K} \left( \pi \times 0.10 \text{m} \times 1 \text{m} \right) \left( 100 - 94 \right) \text{K} = 16.0 \text{kW}
\]

\[
m = 16.0 \times 10^3 \text{W} / 2274 \times 10^3 \text{J/kg} = 7.05 \times 10^{-3} \text{kg/s}
\]

**COMMENTS:** To determine whether the assumption \( D/2 >> \delta \) is satisfied, use Eq. 10.25 to estimate \( \delta(L) \approx 0.12 \text{mm} \). Despite the laminar film assumption, clearly the assumption is justified and the vertical plate correlation is applicable.
PROBLEM 10.43

KNOWN: Vertical tube experiencing condensation of steam on its outer surface.

FIND: Heat transfer and condensation rates.

SCHEMATIC:

ASSUMPTIONS: (1) Film condensation, (2) Negligible condensibles in steam, (3) \( D/2 >> \delta \), vertical plate behavior.

PROPERTIES: Table A-6, Water, vapor (1.5 bar): \( T_{\text{sat}} = 385 K \), \( \rho_v = 0.876 \text{ kg/m}^3 \), \( h_{fg} = 2225 \text{ kJ/kg} \); Table A-6, Water, (liquid \( T_f = 376 K \)): \( \rho_\ell = 956.2 \text{ kg/m}^3 \), \( c_{p,\ell} = 4220 \text{ J/kg} \cdot K \), \( \mu_\ell = 271 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 \), \( k_\ell = 0.681 \text{ W/m} \cdot \text{K} \).

ANALYSIS: The heat transfer and condensation rates are

\[
q = \bar{h}_L \left( \pi D L \right) (T_{\text{sat}} - T_s) \quad \text{and} \quad \dot{m} = \frac{q}{h'_{fg}}
\]

where \( h'_{fg} = h_{fg} \left( 1 + 0.68Ja \right) \) and \( Ja = \frac{c_{p,\ell} (T_{\text{sat}} - T_s)}{h_{fg}} \). Hence, \( Ja = 4220 \text{ J/kg} \cdot \text{K} \left( 385 - 367 \right) / 2225 \times 10^3 \text{ J/kg} = 0.0171 \) and \( h'_{fg} = 2277 \text{ kJ/kg} \). Assume the flow is wavy. Combine Eqs. 10.33 and 10.35 with 10.38, find \( \text{Re}_\delta \).

\[
\frac{\text{Re}_\delta \mu_\ell b h'_{fg}}{4 A_s (T_{\text{sat}} - T_s)} = \frac{\text{Re}_\delta}{1.08 \text{Re}_\delta^{1.22} - 5.2} \cdot \frac{k_\ell}{\left( \frac{v^2}{g} \right)^{1/3}}
\]

\[
\frac{271 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 \left( \pi \times 0.10 \text{m} \right) \times 2277 \times 10^3 \text{ J/kg}}{4 \times (\pi \times 0.10 \text{m} \times 1 \text{m}) (385 - 367) \text{ K}}
\]

\[
= \frac{1}{1.08 \text{Re}_\delta^{1.22} - 5.2} \cdot \frac{0.681 \text{ W/m} \cdot \text{K}}{\left[ \left( 271 \times 10^{-6} / 956.2 \right)^2 \text{ m}^4 / \text{s}^2 / 9.8 \text{ m/s}^2 \right]^{1/3}}
\]

\( \text{Re}_\delta = 832 \).

Using Eq. 10.38, find

\[
\frac{\bar{h}_L \left( \frac{v^2}{g} \right)^{1/3}}{k_\ell} = \frac{\text{Re}_\delta}{1.08 \text{Re}_\delta^{1.22} - 5.2}
\]

\( \bar{h}_L = 7.127 \text{ W/m}^2 \cdot \text{K} \).

\[
q = 7127 \text{ W/m}^2 \cdot \text{K} \left( \pi \times 0.1 \text{m} \times 1 \text{m} \right) (385 - 367) \text{ K} = 40.3 \text{ kW}<
\]

\[
\dot{m} = 40.3 \times 10^3 \text{ W} / 2277 \times 10^3 \text{ J/kg} = 0.0177 \text{ kg/s}\. <
\]

Continued .....
COMMENTS: Since $30 < \text{Re} < 1800$, the wavy flow film assumption is justified. By comparing these results with those of Problem 10.42, the effect of increased pressure on condensation can be seen.

<table>
<thead>
<tr>
<th>$p$ (bar)</th>

<td>18</td>
<td>7127</td>
<td>40.3</td>
</tr>
</tbody>
</table>

The effect of increasing the pressure from 1.01 to 1.5 bar is to increase the excess temperature three-fold, to decrease $\bar{h}_L$ by 16%, and to increase the rates by a factor of 2.5.
**PROBLEM 10.44**

**KNOWN:** Saturated steam at one atmosphere condenses on the outer surface of a vertical tube; water flow within tube experiences 4°C temperature rise.

**FIND:** Required flow rate to maintain tube wall at 94°C.

**SCHEMATIC:**

![Schematic Diagram]

**ASSUMPTIONS:** (1) Laminar wavy film condensation on a vertical surface, (2) Negligible concentration of non-condensible gases in the stream, (3) Thermal resistance of tube wall is negligible, (4) Water flow is fully developed, (5) Tube wall surface is at uniform temperature $T_s$.

**PROPERTIES:** Table A-6, Water (Assume $T_m ≈ 300K$): $c_p = 4179 \text{J/kg} \cdot \text{K}$, $\mu = 855 \times 10^{-6} \text{N} \cdot \text{s/m}^2$, $k = 0.613 \text{W/m} \cdot \text{K}$, Pr = 5.83.

**ANALYSIS:** From the results of Problem 10.42, the heat rate for laminar wavy condensation on the outside surface of the tube was found to be $q = 16.0 \text{kW}$. From an energy balance on the water flowing within the tube, the flow rate is

$$m = \frac{q}{c_p(T_{m,o} - T_{m,i})} = \frac{16.0 \times 10^3 \text{W} / 4179 \text{J/kg} \cdot \text{K} \times 4 \text{K}}{957 \text{kg/s}} = 0.957 \text{kg/s}.$$  

(1)

To determine the inlet temperature of the water, the rate equation is required.

$$q = UA \Delta T_{lm} \quad \text{with} \quad \frac{1}{h_i} + \frac{1}{h_0} = \frac{\Delta T_{lm} - \Delta T_2}{\ln(\Delta T_1 / \Delta T_2)}.$$  

(2,3,4)

From Problem 10.42, $h_o = 8507 \text{W/m}^2 \cdot \text{K}$. Evaluate $Re$ for the water flow using Eq. 8.6

$$Re = 4 \frac{m}{\pi D \mu} = 4 \times 0.957 \text{kg/s} / \pi \times 0.092 \text{m} \times 855 \times 10^{-6} \text{N} \cdot \text{s/m}^2 = 15,493.$$  

The flow is turbulent and since fully-developed, Eq. 8.60 is an appropriate correlation.

$$Nu = \frac{h_i D_i}{k} = 0.023 Re^{4/5} Pr^{0.4} = 0.023 \times (15,493)^{4/5} (5.83)^{0.4} = 104.7.$$  

$$h_i = Nu \cdot k / D_i = 104.7 \times 0.613 \text{W/m} \cdot \text{K} / 0.092 \text{m} = 69.8 \text{W/m}^2 \cdot \text{K}.$$  

Hence, $U = 1 / (1/698 + 1/8507) = 645 \text{ W/m}^2 \cdot \text{K}$. Substituting numerical values into the rate equation, Eq. (2), with $A = \pi D_1 L$, find

$$\Delta T_{lm} = q / UA = 16.0 \times 10^3 \text{W} / 645 \text{W/m}^2 \cdot \text{K} \times (\pi 0.092 \text{m} \times 1 \text{m}) = 85.6 \text{K}.$$  

Recalling now Eq. (4), note that $\Delta T_1 - \Delta T_2 = 4 \text{K}$ and that $T_{m,o} - T_{m,i} = 4 \text{K}$, hence,

$$85.6 \text{K} = 4 \text{K} / \ln \frac{94 - T_{m,i}}{94 - (T_{m,i} + 4)} \quad \text{giving} \quad T_{m,i} = 6.3^\circ \text{C}.$$  

**COMMENTS:** Note that the $T_m = 300K$ assumption is not reasonable and an iteration should be made. Also, it is likely that the thermal resistance of the tube wall is not negligible.
PROBLEM 10.45

KNOWN: Cooled vertical plate 500-mm high and 200-mm wide condensing saturated steam at 1 atm.

FIND: (a) Surface temperature, \( T_s \), required to achieve a condensation rate of \( \dot{m} = 25 \text{ kg/h} \), (b) Compute and plot \( T_s \) as a function of the condensation rate for the range \( 15 \leq \dot{m} \leq 50 \text{ kg/h} \), and (c) Compute and plot \( T_s \) for the same range of \( \dot{m} \), but if the plate is 200 mm high and 500 mm wide (vs. 500 mm high and 200 mm wide for parts (a) and (b)).

SCHEMATIC:

ASSUMPTIONS: (1) Film condensation, (2) Negligible non-condensables in steam.

PROPERTIES: Table A-6, Water, vapor (1.0133 bar): \( T_{\text{sat}} = 100^\circ \text{C} \), \( \rho_v = 0.5963 \text{ kg/m}^3 \), \( h_g = 2257 \text{ kJ/kg} \); Table A-6, Water, liquid (\( T_f \approx (74 + 100)^\circ \text{C}/2 \approx 360 \text{ K} \)): \( \rho_{\ell} = 967.1 \text{ kg/m}^3 \), \( c_{p,\ell} = 4203 \text{ J/kg} \cdot \text{K} \), \( \mu_{\ell} = 324 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 \), \( k_{\ell} = 0.674 \text{ W/m} \cdot \text{K} \).

ANALYSIS: (a) The surface temperature can be determined from the rate equation, Eq. 10.32, written as

\[
\frac{\dot{m}}{G_{06}} = \frac{T_{\text{sat}} - q/\overline{h}_L A_s}{T_{\text{sat}} - \dot{m}h_g'/h_{\ell} \sqrt{h}_L A_s}
\]

where \( h_g' = h_g (1 + 0.68 \text{ Ja}) \) and \( J_a = c_{p,\ell} (T_{\text{sat}} - T_s)/h_{\ell} \). To evaluate \( T_s \), we need values of \( h_L \) and \( h_g' \), both of which require knowledge of \( T_s \). Hence, we need to assume a value of \( T_s \) and iterate the solution until good agreement with calculated \( T_s \) value is achieved. Assume \( T_s = 74^\circ \text{C} \) and evaluate \( h_g' \) and \( \text{Re}_\delta \).

\[
h_g' = 2257 \text{ kJ/kg} \left( 1 + 0.68 \left[ \frac{4203 \text{ J/kg} \cdot \text{K} (100 - 74) \text{ K}}{2257 \times 10^3 \text{ J/kg}} \right] \right) = 2331 \text{ kJ/kg}
\]

\[
\text{Re}_\delta = 4\dot{m}/\mu_{\ell} b = 4 \times (25/3600) \text{ kg/s} / 324 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 \times 0.2 \text{ m} = 429.
\]

Since \( 30 < \text{Re}_\delta < 1800 \), the flow is wavy-laminar and Eq. 10.38 is appropriate,

\[
\overline{h}_L = \frac{0.674 \text{ W/m} \cdot \text{K}}{1.08 \text{Re}_\delta^{1/2} - 5.2 \left( \frac{\nu_{\ell}^2}{g} \right)^{1/3}}
\]

\[
\overline{h}_L = \frac{429}{108 (429)^{1/2} - 5.2 \left[ \frac{324 \times 10^{-6}}{967.1} \right]^{2/3} / 9.8 \text{ m/s}^2} = 7312 \text{ W/m}^2 \cdot \text{K}
\]

Hence, \( T_s = 100^\circ \text{C} - (25/3600) \frac{7312 \text{ W/m}^2 \cdot \text{K}}{2331 \times 10^3 \text{ J/kg}} \times (0.2 \times 0.5) \text{ m}^2 = 78^\circ \text{C} \). <

This value is to be compared to the assumed value of 74°C. See comment 1.

(b,c) Using the IHT Correlations Tool, Film Condensation, Vertical Plate for laminar, wavy-laminar and turbulent regions, combined with the Properties Tool for Water, the surface temperature \( T_s \) was

Continued...
calculated as a function of the condensation rate, $\dot{m}$, considering the two plate configurations as indicated in the plot below.

As expected the condensation rate increases with decreasing surface temperature. The plate with the shorter height ($L = 200$ mm vs $500$ mm) will have the thinner boundary layer and, hence, the higher average convection coefficient. Since both plate configurations have the same total surface area, the $200$-mm height plate will have the larger heat transfer and condensation rates. For the range of conditions examined, the condensate flow is in the wavy-laminar region.

COMMENTS: (1) With the IHT model developed for parts (b) and (c), the result for the part (a) conditions with $\dot{m} = 25$ kg/h is $T_s = 78.2^\circ C$ ($Re_\delta = 439$ and $\overline{h}_L = 7403$ W/m$^2 \cdot K$). Hence, the assumed value ($T_s = 74^\circ C$) required to initiate the analysis was a good one.

(2) A copy of the IHT Workspace model used to generate the above plot is shown below.
PROBLEM 10.46

KNOWN: Plate dimensions, temperature and inclination. Pressure of saturated steam.

FIND: (a) Heat transfer and condensation rates for vertical plate, (b) Heat transfer and condensation rates for inclined plate.

SCHEMATIC:

ASSUMPTIONS: (1) Conditions correspond to the turbulent film region, (2) Constant properties.

PROPERTIES: Table A-6, saturated vapor (p=1.0133 bars): $T_{\text{sat}} = 100^\circ\text{C}$, $\rho_v = 0.596 \text{ kg/m}^3$, $h_{fg} = 2257 \text{ kJ/kg}$. Table A-6, saturated liquid ($T_f = 75^\circ\text{C}$): $\rho_f = 975 \text{ kg/m}^3$, $\mu_f = 375 \times 10^{-6} \text{ N.s/m}^2$, $k_f = 0.668 \text{ W/m.K}$, $c_{p,f} = 4193 \text{ J/kg.K}$.

ANALYSIS: (a) Expressing $h_L$ in terms of $Re_\delta$ by combining Eqs. (10.33) and (10.35) and substituting into Eq. (10.38), it follows that

$$\frac{Re_\delta \mu_f h_{fg}}{4L(T_{\text{sat}} - T_s)} = \frac{Re_\delta}{1.08 Re_\delta^{1.22} - 5.2} \cdot \frac{k_f}{\left(\nu_f^2 / g\right)^{1/3}}$$

where, with $Ja = c_{p,\ell}(T_{\text{sat}} - T_s) / h_{fg} = 0.0929$, $h_{fg} = h_{fg} (1 + 0.68 Ja) = 2400 \text{ kJ/kg}$. From an iterative solution to Eq. (1), we obtain $Re_\delta = 2370$, and the assumption of a turbulent film is justified. From Eqs. (10.35) and (10.33) the condensation and heat rates are then

$$\dot{m} = \frac{\mu_f b Re_\delta}{4} = 0.444 \text{ kg/s} <$$

$$q = \dot{m} h_{fg} = 0.444 \text{ kg/s} \times 2.4 \times 10^6 \text{ J/kg} = 1.065 \times 10^6 \text{ W}$$

From Eq. (10.32), we also obtain $\overline{h}_L = q / [(bL)(T_{\text{sat}} - T_s)] = 5325 \text{ W/m}^2\cdot\text{K}$.

(b) With $\overline{h}_L(incl) = (\cos \theta)^{1/4} \overline{h}_L$, we obtain $\overline{h}_L(incl) = 0.917 \times 5325 \text{ W/m}^2\cdot\text{K} = 4880 \text{ W/m}^2\cdot\text{K}$. If the inclination reduces $\overline{h}_L$ by 8.73%, the heat and condensation rates are reduced by equivalent amounts. Hence,

$$\dot{m} = 0.407 \text{ kg/s}$$

$$q = 0.977 \times 10^6 \text{ W}$$

COMMENTS: The initial guess of a turbulent film region was motivated by the value of $L = 2\text{m}$, which was believed to be large enough for transition to turbulence. Note that the solution could also have been obtained by accessing the Film Condensation correlations of IHT, implementation of which does not require an assumption of flow conditions.
PROBLEM 10.47

KNOWN: Saturated ethylene glycol (1 atm) condensing on a vertical plate at 420K.

FIND: Heat transfer rate to the plate and condensation rate.

SCHEMATIC:

ASSUMPTIONS: (1) Film condensation, (2) Negligible non-condensible gases in vapor.

PROPERTIES: Table A-5, Ethylene glycol vapor (1 atm): \( T_{sat} = 470K \), \( \rho_v \approx 0 \text{ kg/m}^3 \), \( h_{fg} = 812 \text{ kJ/kg} \); Table A-5, Ethylene glycol, liquid (\( T_f = (T_s + T_{sat})/2 \)) \( \approx 445K \); use properties at upper limit of table 373K): \( \rho = 1058.5 \text{ kg/m}^3 \), \( c_p = 2742 \text{ J/kg} \cdot \text{K} \), \( \mu = 0.215 \times 10^{-2} \text{ N} \cdot \text{s/m}^2 \), \( k = 0.263 \text{ W/m} \cdot \text{K} \).

ANALYSIS: The heat transfer and condensation rates are given by Eqs. 10.32 and 10.33.

\[
L_{ss} \cdot h_{fg} \cdot q = - \frac{h_{fg}}{h_{fg}'} \cdot q = \frac{L_{ss} \cdot h_{fg}}{h_{fg}'} = \frac{h_{fg}}{h_{fg}'} \cdot \frac{L_{ss}}{L_{ss}'}.
\]

where \( h_{fg}' = h_{fg} (1 + 0.68 \text{ Ja}) \) and \( \text{Ja} = \frac{p}{h_{fg}} \cdot \frac{c_p}{h_{fg}} \cdot \frac{T_s}{T_f} \). Substituting property values at \( T_f = (T_s + T_{sat})/2 \), find \( h_{fg}' = 812 \text{ kJ/kg} (1 + 0.68 \{2742 \text{ J/kg} \cdot \text{K} (470 - 420) \text{K/812} \times 10^3 \text{ J/kg}\}) = 905 \text{ kJ/kg} \).

Assuming the flow is laminar, use Eq. 10.30 to evaluate \( \frac{h_{fg}}{h_{fg}'} \).

\[
\frac{h_{fg}}{h_{fg}'} = \left[ \frac{9.8 \text{ m/s}^2 \times 1058.5 \text{ kg/m}^3}{1058.5 - 0} \right] \times \frac{1058.5 - 0}{0.263 \text{ W/m} \cdot \text{K} \times 10^3 \text{ J/kg}} \times 9.8 \text{ m/s}^2 \times 1058.5 \text{ kg/m}^3 \times 0.215 \times 10^{-2} \text{ m/s}^2 (470 - 420) \text{K} \times 0.3 \text{m}.
\]

find \( \frac{h_{fg}}{h_{fg}'} = 1451 \text{ W/m}^2 \cdot \text{K} \). Using the rate equations, find

\[
q = 1451 \text{ W/m}^2 \cdot \text{K} (0.3 \times 0.1) \text{ m}^2 (470 - 420) \text{K} = 2.18 \text{ kW}
\]

\[
\dot{m} = 2.18 \times 10^3 \text{ W/9.05 \times 10^3 J/kg} = 0.002405 \text{ kg/s} = 8.66 \text{ kg/h}.
\]

Determine whether the flow is indeed laminar: \( \frac{Re}{\delta} = 4 \frac{\dot{m}}{\mu_b} \cdot \frac{b}{\dot{m}/10^3 \times 0.215 \times 10^{-2} \text{ m/s}^2 \times 0.1m = 44.7. \) Since 30 < \( \frac{Re}{\delta} < 1800 \), the flow is in the wavy-laminar region. Hence, the correlation of Eq. 10.38 is more appropriate. Combining Eq. 10.33 and 10.35 with 10.38 (see Example 10.3),

\[
\frac{Re}{\delta} \cdot \frac{h_{fg}'}{h_{fg}'} = \frac{Re}{\delta} \cdot k_{fg} \cdot \frac{L_{ss}'}{L_{ss}'} = \frac{Re}{\delta} \cdot \frac{k_{fg}}{L_{ss}'} = 1.08Re^{1.22 - 5.2} \left( \frac{v_{fg}}{g} \right)^{1/3}.
\]

\[
\text{Re} = 4 \frac{\dot{m}}{\mu_b} \cdot \frac{b}{\text{Re}^{1.22 - 5.2} \left( \frac{v_{fg}}{g} \right)^{1/3}} \text{ with } \text{Re} = 4 \times (0.3 \times 0.1) \text{ m}^2 (470 - 420) \text{K} = 1.08Re^{1.22 - 5.2} \left( \frac{0.215 \times 10^{-2} /1058.5}{4 / s^2 / 9.8 \text{ m/s}^2} \right)^{1/3}.
\]

find \( \text{Re} = 45 \) and using Eq. 10.38, find

\[
\frac{h_{fg}'}{h_{fg}'} = \frac{Re}{\delta} \cdot k_{fg} \cdot \frac{L_{ss}'}{L_{ss}'} = 1.470 \text{ W/m}^2 \cdot \text{K}.
\]

Hence,

\[
q = 2.21 \text{ kW}
\]

\[
\dot{m} = 2.44 \times 10^{-3} \text{ kg/s}.\]

COMMENTS: Note the wavy-laminar value of \( \text{Re} \) is within 1.3% of the laminar value.
PROBLEM 10.48

KNOWN: Vertical plate 2.5 m high at a surface temperature \( T_s = 54 \degree C \) exposed to steam at atmospheric pressure.

FIND: (a) Condensation and heat transfer rates, (b) Whether turbulent flow would still exist if the height were halved, and (c) Compute and plot the condensation rates for the two plate heights (2.5 m and 1.25 m) as a function of surface temperature for the range, \( 54 \leq T_s \leq 90 \degree C \).

SCHEMATIC:

ASSUMPTIONS: (1) Film condensation, (2) Negligible non-condensables in steam.

PROPERTIES: Table A-6, Water, vapor (1 atm): \( T_{sat} = 100 \degree C \), \( \rho_v = 0.596 \text{ kg/m}^3 \), \( h_{fg} = 2257 \text{ kJ/kg} \);
Table A-6, Water, liquid (\( T_f = (100 + 54) / 2 = 350 \) K): \( \rho_\ell = 973.7 \text{ kg/m}^3 \), \( k_\ell = 0.668 \text{ W/m-K} \), \( \mu_\ell = 365 \times 10^{-6} \text{ N-s/m}^2 \), \( c_{p,\ell} = 4195 \text{ J/kg-K} \), \( Pr_\ell = 2.29 \).

ANALYSIS: (a) The heat transfer and condensation rates are given by Eqs. 10.32 and 10.33,

\[
q' = \overline{h}_L L (T_{sat} - T_s) \quad \dot{m}' = q'/h_{fg}'
\]

where, from Eq. 10.26, with \( J_a = c_{p,\ell} (T_{sat} - T_s)/h_{fg} \),

\[
h_{fg}' = h_{fg} \left(1 + 0.68 \left[c_{p,\ell} (T_{sat} - T_s)/h_{fg}\right]\right)
\]

\[
h_{fg}' = 2257 \frac{\text{kJ}}{\text{kg}} \left(1 + 0.68 \left[\frac{4195 \text{J/kg-K}(100 - 54) \text{K}}{2257 \times 10^3 \text{J/kg}}\right]\right) = 2388 \text{kJ/kg}.
\]

Assuming turbulent flow conditions, Eq. 10.39 is the appropriate correlation,

\[
\frac{\overline{h}_L \left(V_\ell^2 / g\right)^{1/3}}{k_\ell} = \frac{\text{Re}_\delta}{8750 + 58 \text{Pr}^{-0.5} \left(\text{Re}_\delta^{0.75} - 253\right)} \quad \text{Re}_\delta > 1800
\]

Not knowing \( \text{Re}_\delta \) or \( \overline{h}_L \), another relation is required. Combine Eq. 10.33 and 10.35,

\[
\overline{h}_L = \frac{\dot{m}h_{fg}'}{A(T_{sat} - T)} = \left(\frac{\text{Re}_\delta \mu_\ell b}{4}\right) \frac{h_{fg}'}{A(T_{sat} - T)}. \quad (4)
\]

Substitute Eq. (4) for \( \overline{h}_L \) into Eq. (3), with \( A = bL \),

\[
\frac{\text{Re}_\delta \mu_\ell b h_{fg}'}{4(bL)(T_{sat} - T)} = \frac{\text{Re}_\delta}{8750 + 58 \text{Pr}^{-0.5} \left(\text{Re}_\delta^{0.75} - 253\right)} \left(V_\ell^2 / g\right)^{1/3}. \quad (5)
\]

Using appropriate properties with \( L = 2.5 \text{ m} \), find

Continued...
PROBLEM 10.48 (Cont.)

\[
\frac{365 \times 10^{-6} \text{N} \cdot \text{s/m}^2 \times 2388 \times 10^3 \text{J/kg}}{4 \times 2.5 \text{m}(100 - 54) \text{K}} = \frac{1}{8750 + 58(2.29)^{-0.5}(\text{Re}_{\delta}^{0.75} - 253)} \cdot \frac{0.668 \text{W/m} \cdot \text{K}}{\left(365 \times 10^{-6} / 973.7 \right)^2 \text{m}^4 / \text{s}^2 / 9.8 \text{m/s}^2} \]^{1/3}

\[
\text{Re}_{\delta} = 2979. 
\]

Note that \(\text{Re}_{\delta} > 1800\), so indeed the flow is turbulent, and using Eq. (4) or (3), find

\[
\bar{h}_L = 5645 \text{ W/m}^2 \cdot \text{K}.
\]

From the rate equations (1) and (2), the heat transfer and condensation rates are

\[
q' = 5645 \text{ W/m}^2 \cdot \text{K} \times 2.5 \text{m}(100 - 54) \text{K} = 649 \text{ kW/m} < \]

\[
\dot{m}' = 649 \times 10^3 \text{ W/m}/2388 \times 10^3 \text{ J/kg} = 0.272 \text{ kg/s} \cdot \text{m}.
\]

(b) If the height of the plate were halved, \(L = 1.25 \text{ m}\), Eq. (6) would only need to be modified for this new value. Using the calculated values for the LHS and the last term on the RHS, Eq. (6) becomes,

\[
3.78960 = \frac{1}{8750 + 58(2.29)^{-0.5}(\text{Re}_{\delta}^{0.75} - 253)} \times 27,493
\]

and after some manipulation, find

\[
\text{Re}_{\delta} = 1280.
\]

Since \(1800 > \text{Re}_{\delta}\), the flow is not turbulent, but wavy-laminar. Now the procedure follows that of Example 10.3. For \(L = 1.25 \text{ m}\) with wavy-laminar flow, Eq. 10.38 is the appropriate correlation. The calculations yield these results:

\[
\text{Re}_{\delta} = 1372 \quad \bar{h}_L = 5199 \text{ W/m}^2 \cdot \text{K}
\]

\[
q' = 299 \text{ kW/m} \quad \dot{m}' = 0.125 \text{ kg/s} \cdot \text{m}.
\]

Note that the height was decreased by a factor of 2 while the rates decreased by a factor of 2.2! Would you have expected this result?

(c) Using the IHT Correlation Tool, Film Condensation, Vertical Plate for laminar, wavy-laminar, and turbulent regions, combined with the Properties Tool for Water, the condensation rates were calculated as a function of the surface temperature considering the two plate heights indicated.
The condensation rate decreases nearly linearly with increasing surface temperature. The inflection in the upper curve (L = 2.5 m) corresponds to the flow transition at \( \text{Re}_\delta = 1800 \) between wavy-laminar and turbulent. For surface temperature lower than 76°C, the flow is turbulent over the 2.5 m plate. The flow over the 1.25 m plate is always in the wavy-laminar region. The fact that the 2.5 m plate experiences turbulent flow explains the height-rate relationship mentioned in the closing sentences of part (b).

**COMMENTS:** A copy of the IHT model used to generate the above plot is shown below.

```plaintext
/* Correlations Tool
   - Film Condensation, Vertical Plate, Laminar, wavy-laminar and turbulent regions: */
NuLbar = NuL_bar_FCO_VP(Redelta,PrL)     // Eq 10.37, 38, 39
NuLbar = hLbar * (nul^2 / g)^1/3 / kl

// Assigned Variables:
L = 1.25 // Height, m
b = 1 // Width, m

// Properties Tool - Water:
// Water property functions : T dependence, From Table A.6
// Units: T(K), p(bars);
xl = 0 // Quality (0=sat liquid or 1=sat vapor)
rhol = rho_Tx("Water",Tf,xl) // Density, kg/m^3
hfg = hfg_T("Water",Tsat) // Heat of vaporization, J/kg
cpl = cp_Tx("Water",Tf,xl) // Specific heat, J/kg-K
mul = mu_Tx("Water",Tf,xl) // Viscosity, N-s/m^2
nul = nu_Tx("Water",Tf,xl) // Kinematic viscosity, m^2/s
kl = k_Tx("Water",Tf,xl) // Thermal conductivity, W/m-K
PrL = Pr_Tx("Water",Tf,xl) // Prandtl number
```

PROBLEM 10.48 (Cont.)
PROBLEM 10.49

KNOWN: Two vertical plate configurations maintained at 90°C for condensing saturated steam at 1 atm: single plate $L \times w$ and two plates each $L/2 \times w$ where $L$ and $w$ are the vertical and horizontal dimensions, respectively.

FIND: Which case will provide the larger heat transfer or condensation rate.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible concentration of non-condensible gases in the steam.

PROPERTIES: Table A-6, Saturated water vapor (1 atm): $T_{\text{sat}} = 100^\circ \text{C}$, $\rho_v = (1/\nu_g) = 0.596 \text{ kg/m}^3$, $h_{fg} = 2257 \text{ kJ/kg}$; Saturated water ($T_f = (T_s + T_{\text{sat}})/2 = (90 + 100)^\circ \text{C}/2 = 95^\circ \text{C} = 368 \text{K}$): $\rho_\ell = (1/\nu_\ell) = 962 \text{ kg/m}^3$, $\mu_\ell = 296 \times 10^{-6} \text{ N}\cdot\text{s/m}^2$, $k_\ell = 0.678 \text{ W/m}\cdot\text{K}$, $c_{p,\ell} = 4212 \text{ J/kg}\cdot\text{K}$.

ANALYSIS: The heat transfer and condensation rates are

$$q = \overline{h}_L A_s (T_{\text{sat}} - T_s) \quad \dot{m} = q / h_{fg}$$

where, for the two cases,

$$\overline{h}_L,1 A_{s,1} = \overline{h}_L,1 (L)[L \times w] \quad \overline{h}_L,2 A_{s,2} = \overline{h}_L,2 (L/2)[2(L/2 \times w)]$$

and the average convection coefficients are evaluated at $L$ and $L/2$, respectively. Hence,

$$\frac{q_1}{q_2} = \frac{\dot{m}_1}{\dot{m}_2} = \frac{\overline{h}_L,1 (L)[L \times w]}{\overline{h}_L,2 (L/2)[2(L/2 \times w)]} = \frac{\overline{h}_L,1 (L)}{\overline{h}_L,2 (L/2)}.$$  

For laminar film condensation on both plates, using the correlation of Eq. 10.30, with $\overline{h}_L \propto L^{-1/4}$,

$$q_1 / q_2 = (L/[L/2])^{-1/4} = 0.84.$$  

Hence, case 2 is preferred and provides 16% more heat transfer.

When $Re_\delta = 30$ for case 1 with the given conditions, find from Eq. 10.37

$$\frac{\overline{h}_L}{k_\ell} \sim \left( \frac{296 \times 10^{-6} \text{ N}\cdot\text{s/m}^2 / 962 \text{ kg/m}^3}{9.8 \text{ m/s}^2} \right)^2 / 0.678 \text{ W/m}\cdot\text{K}$$

Continued ….
PROBLEM 10.49 (Cont.)

\[ \frac{\bar{h}_L \left( \frac{L}{g} \right)^{1/3}}{k_T} = 1.47 \Re^{-1/3} = 1.47(30)^{-1/3} \]

\[ \bar{h}_L = 15,061 \text{ W/m}^2 \cdot \text{K} \]

and then from Eq. 10.30,

\[ \bar{h}_L = 0.943 \left[ \frac{g \rho \ell (\rho \ell - \rho \nu)k_T^3 h_{fg}^*}{\mu \ell (T_{sat} - T_s) L} \right]^{1/4} \]

where

\[ h_{fg}^* = h_{fg} + 0.68 c_p \ell (T_{sat} - T_s) \]

\[ h_{fg} = 2257 \text{ kJ/kg} + 0.68 \times 4212 \text{ J/kg} \cdot \text{K} (100 - 90) \text{ K} = 2286 \text{ kJ/kg}, \]

\[ 15,061 \text{ W/m}^2 \cdot \text{K} = 0.943 \left[ \frac{9.8 \text{ m/s}^2 \times 962 \text{ kg/m}^3 (962 - 0.596) \text{ kg/m}^3 (0.678 \text{ W/m} \cdot \text{K})^3}{296 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 (100 - 90) \text{ K} L} \right]^{1/4} \]

\[ L = 34 \text{ mm}. \]

We can anticipate for other, larger values of L that the comparison of \( \bar{h}_L \) values cannot be so easily made. However, according to Figure 10.15, we expect the same behavior of \( \bar{h}_L \) in the wavy region and anticipate that indeed case 2 will provide the greater condensation rate. Note that in the turbulent region with the increase in \( \bar{h}_L \) with Re\_8, we cannot conclude with certainty which case is preferred.

COMMENTS: In dealing with single-phase, forced or free convection, we associate thin thermal boundary layers with higher heat transfer rates. For vertical plates, we would expect the shorter plate to have the higher convection heat transfer coefficient. The results of this problem suggest the same is true for condensation on the vertical plate.
PROBLEM 10.50

KNOWN: Number, diameter and wall temperature of condenser tubes in a square array. Pressure of saturated steam around tubes.

FIND: Rates of heat transfer and condensation per unit length of the array.

SCHEMATIC:

ASSUMPTIONS: (1) Laminar film condensation on tubes, (2) Negligible concentration of noncondensable gases in steam.

PROPERTIES: Table A-6, saturated vapor (\( p_{\text{sat}} = 0.105 \) bar): \( T_{\text{sat}} = 320 \) K = 47\(^\circ\)C, \( \rho_v = 0.0715 \) kg/m\(^3\), \( h_{fg} = 2390 \) kJ/kg. Table A-6, saturated liquid (\( T_f = 32 \)\(^\circ\)C = 305 K): \( \rho_\ell = 995 \) kg/m\(^3\), \( \mu_\ell = 769 \times 10^{-6} \) N\( \cdot \)s/m\(^2\), \( \kappa_\ell = 0.620 \) W/m\( \cdot \)K, \( c_{p,\ell} = 4178 \) J/kg\( \cdot \)K.

ANALYSIS: The average heat rate per unit length for a single tube is

\[
q_1' = \overline{h}_{D,N} (\pi D) (T_{\text{sat}} - T_s),
\]

where \( \overline{h}_{D,N} \) is obtained from Eq. 10.41. With \( J_a = c_{p,\ell} (T_{\text{sat}} - T_s) / h_{fg} = 0.052 \) and \( h_{fg}' = h_{fg} (1 + 0.68 J_a) = 1.04 (2.390 \times 10^6 \) J/kg) = 2.48 \times 10^6 \) J/kg,

\[
\overline{h}_{D,N} = 0.729 \left[ \frac{g \rho_\ell (\rho_\ell - \rho_v) k_\ell^3 h_{fg}'}{N \mu_\ell (T_{\text{sat}} - T_s) D} \right]^{1/4}
\]

The heat rate per unit length of the array is \( q' = N^2 q_1' \). Hence,

\[
q' = N^2 \overline{h}_{D,N} (\pi D) (T_{\text{sat}} - T_s) = 625 \times 3260 \) W/m\(^2\) \cdot \)K \( (\pi \times 0.025m) \) 30\(^\circ\)C = 4.79 \times 10^6 \) W/m

The corresponding condensation rate is \( \dot{m}' = \frac{q'}{h_{fg}'} = \frac{4.79 \times 10^6 \) W/m}{2.48 \times 10^6 \) J/kg} = 1.93 \) kg/s \( \cdot \)m

COMMENTS: Because of turbulence generation due to splashing from one tube to another in a vertical column, the foregoing value of \( \overline{h}_{D,N} \) is expected to underestimate the actual value of \( \overline{h}_{D,N} \) and hence to underpredict the heat and condensation rates.
PROBLEM 10.51

KNOWN: Tube wall diameters and thermal conductivity. Mean temperature and flow rate of water flow through tube. Pressure of saturated steam around tube.

FIND: (a) Rates of heat transfer and condensation per unit length, (b) Effect of flow rate on heat transfer.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible concentration of noncondensible gases in the steam, (2) Uniform tube surface temperatures, (3) Laminar film condensation, (4) Fully-developed internal flow, (5) Constant properties.

PROPERTIES: Table A-6, water (T_m = 290 K): µ = 0.00108 N⋅s/m², k = 0.598 W/m⋅K, Pr = 7.56. Table A-6, saturated vapor (p = 0.135 bar): T_sat = 325 K = 52°C, ρ_v = 0.0904 kg/m³, h_fg = 2378 kJ/kg. Table A-6, saturated liquid (T_f ≈ T_sat): ρ_f = 987 kg/m³, c_p, f = 4182 J/kg⋅K, µ_f = 528×10⁻⁶ N⋅s/m², k_f = 0.645 W/m⋅K.

ANALYSIS: (a) From the thermal circuit, the heat rate may be expressed as

\[ q' = \frac{T_{sat} - T_m}{R_{fc} + R_{cond} + R_{conv}'}, \]  

where,

\[ R_{cond}' = \frac{\ell n \left( D_o / D_i \right)}{2 \pi k_s} = 0.00152 \text{ m} \cdot \text{K} / \text{W} \]

The convection resistance is \( R_{conv}' = (\pi D_i h_i)^{-1} \). With Re_D = 4m / πD_iμ = 11,336, the flow is turbulent and the Dittus-Boelter correlation yields

\[ h_i = \left( \frac{k}{D_i} \right) 0.023 Re_D^{4/5} Pr^{0.4} = \left( \frac{0.598 \text{ W/m} \cdot \text{K}}{0.026 \text{ m}} \right) 0.023 \left( 11,336 \right)^{4/5} \left( 7.56 \right)^{0.4} = 2082 \text{ W/m}^2 \cdot \text{K} \]

The convection resistance is then

\[ R_{conv}' = (\pi D_i h_i)^{-1} = \left( \pi \times 0.026 \text{ m} \times 2082 \text{ W/m}^2 \cdot \text{K} \right)^{-1} = 0.00588 \text{ m} \cdot \text{K} / \text{W} \]

The resistance associated with the condensate film is \( R_{fc}' = (\pi D_o \bar{h}_o) \), where \( \bar{h}_o \) is given by Eq. 10.40. With C = 0.729,

\[ \bar{h}_o = C \left[ \frac{g \rho_f (\rho_f - \rho_v) k_s^3 h_{fg}'}{\mu_f (T_{sat} - T_{s,o}) D_o} \right]^{1/4} = 0.729 \left[ \frac{9.8 \text{ m/s}^2 \times 987 \text{ kg/m}^3}{0.026 \text{ m}} \left( 0.645 \text{ W/m} \cdot \text{K} \right)^3 h_{fg}'} \left[ \frac{528 \times 10^{-6} \text{ N/s/m}^2 (325 - T_{s,o}) \times 0.030 \text{m}}{ \right]^{1/4} \]

\[ \bar{h}_o = 462 \left( \frac{W^2 \cdot \text{kg}}{m^8 \cdot \text{K}^3 \cdot \text{s}} \right)^{1/4} \left( \frac{h_{fg}'}{325 - T_{s,o}} \right)^{1/4} \]

where \( h_{fg}' = h_{fg} + 0.68 c_{p, f} (T_{sat} - T_{s,o}) = 2.38 \times 10^6 \text{ J/kg} + 2844 \text{ J/kg} \cdot \text{K} \left( 325 - T_{s,o} \right) \)

The unknown surface temperature may be determined from an additional rate equation, such as

Continued …..
PROBLEM 10.51 (Cont.)

\[ q' = \frac{T_{s,o} - T_m}{R_{\text{cond}} + R_{\text{conv}}} \]  

(2)

Substituting the thermal resistances into Eqs. (1) and (2), an iterative solution yields

\[ T_{s,o} = 321.6 \, \text{K} = 48.6^\circ \text{C} \quad q' = 4270 \, \text{W/m} \]

The condensation rate is then

\[ \dot{m}_{\text{cond}}' = \frac{q'}{h_{fg}} = \frac{4270 \, \text{W/m}}{2.39 \times 10^6 \, \text{J/kg}} = 0.00179 \, \text{kg/s m} \cdot \text{h} \]

The corresponding values of the condensate convection coefficient and resistance are

\[ \bar{h}_o = 13,380 \, \text{W/m}^2 \cdot \text{K} \]

and \[ R_{fc}' = 0.000793 \, \text{m} \cdot \text{K/W} \]

Because \( R_{\text{conv}}' \) is much larger than \( R_{\text{cond}}' \) and \( R_{fc}' \), attention should be paid to reducing the convection resistance in order to increase the heat rate. The resistance to heat flow by convection is the limiting factor.

(b) The effects of varying the flow rate are shown below

![Graph](image)

The effect of increasing \( \dot{m} \) on \( q' \) is significant and is accompanied by a reduction in \( T_{s,o} \).

COMMENTS: (1) Use of the IHT convection and condensation correlations, as well as its temperature-dependent properties of water facilitated the numerical solution. (2) Evaluation of the film properties at \( T_{\text{sat}} \) is reasonable for part (a), since \( T_f = (T_{s,o} + T_{\text{sat}})/2 = 50.3^\circ \text{C} \approx T_{\text{sat}} \). However, with increasing \( \dot{m} \) and hence decreasing \( T_{s,o} \), the approximation would become inappropriate.
**PROBLEM 10.52**

**KNOWN:** Inner surface of a vertical thin-walled container of length L and diameter D experiences condensation of a saturated vapor. Container wall maintained at a uniform surface temperature by flowing cold water across its outer surface.

**FIND:** Expression for the time, \( t_f \), required to fill the container with condensate assuming the condensate film is laminar. Express your result in terms of D, L, \((T_{sat} - T_s)\), g and appropriate fluid properties.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Laminar film condensation on a vertical surface, (2) Uniform temperature container wall surface, and (3) Mass of liquid condensate in the laminar film negligible compared to liquid mass on bottom of container.

**ANALYSIS:** From an instantaneous mass balance on the container,

\[
\dot{m}(t) = \frac{dM}{dt}
\]  

Where \( \dot{m}(t) \) is the condensate rate and the liquid mass in the container, \( M \), is

\[
M = \rho_l \left( \pi D^2 / 4 \right) (L - x)
\]

The condensate rate from Eq. 10.33 can be expressed as

\[
\dot{m}(t) = \frac{q}{h'_{fg}} = \frac{\bar{h}_s A_s (T_{sat} - T_s)}{h'_{fg}}
\]

where the average film coefficient over the height 0 to \( x \) from Eq. 10.30 is,

\[
\bar{h}_s = 0.943 \left[ \frac{g \rho_l (\rho_l - \rho_v) k^3 h'_{fg}}{\mu_l (T_{sat} - T_s) x} \right]^{1/4}
\]

and the surface area over which condensation occurs is

\[
A_s = \pi Dx
\]

Continued...
Substituting Eqs (2-5) into Eq. (1),

\[
0.943 \left[ \frac{g \rho_\ell (\rho_\ell - \rho_v) k_\ell h_\ell g}{\mu_\ell (T_{sat} - T_s) L} \right]^{1/4} L^{1/4} (\pi D x) / h_\ell g = - \rho_\ell \left( \pi D^2 / 4 \right) \frac{dx}{dt} \tag{6}
\]

Separate variables and identify the limits of integration,

\[
\left[ 0.943 \left[ \frac{g \rho_\ell (\rho_\ell - \rho_v) k_\ell h_\ell g}{\mu_\ell (T_{sat} - T_s) L} \right]^{1/4} L^{1/4} (\pi D) \right] h_\ell g \rho_\ell \left( \pi D^2 / 4 \right) \int_0^{t_f} dt = - \int_{x=L}^0 x^{-3/4} dx \tag{7}
\]

The RHS integrates to

\[
- \left[ x^{1/4} / (1/4) \right]_L^0 = 4L^{1/4} \tag{8}
\]

and solving for \( t_f \),

\[
t_f = 4 \left[ \frac{\rho_\ell \left( \pi D^2 / 4 \right) L h_\ell g}{0.943 \left[ \frac{g \rho_\ell (\rho_\ell - \rho_v) k_\ell h_\ell g}{\mu_\ell (T_{sat} - T_s) L} \right]^{1/4} (\pi D L) (T_{sat} - T_s)} \right]^{<}
\]

**COMMENTS:** The numerator and denominator in the bracketed expression are of special significance. The numerator is product of the mass in the filled container and the latent heat of vaporization; that is, the total energy removed by the cold water. What is physical significance of the denominator? Can you interpret the time-to-fill, \( t_f \), expression in light of these terms?
PROBLEM 10.53

KNOWN: Tube of Problem 10.42 in horizontal position experiences condensation on its outer surface.

FIND: Heat transfer and condensation rates.

SCHEMATIC:

ASSUMPTIONS: (1) Laminar film condensation, (2) End effects negligible, (3) Negligible concentration of non-condensible gases in steam.

PROPERTIES: Table A-6, Water, vapor (1 atm): \( T_{sat} = 100^\circ C, \rho_v = 0.596 \text{ kg/m}^3, h_{fg} = 2257 \text{ kJ/kg}; \)
Table A-6, Water, liquid (\( T_f = (T_s + T_{sat})/2 = 370K \)): \( \rho_\ell = 960.6 \text{ kg/m}^3, c_{p,\ell} = 4214 \text{ J/kg-K}, \mu_\ell = 289 \times 10^{-6} \text{ N-s/m}^2, k_\ell = 0.679 \text{ W/m-K}. \)

ANALYSIS: From Eq. 10.32 with \( A = \pi D L \) and Eq. 10.33, the heat transfer and condensation rates are

\[
q = \bar{h}L \left( \pi D L \right) (T_{sat} - T_s)
\]

where from Eq. 10.26 with \( Ja = c_{p,\ell} \left( T_{sat} - T_s \right)/h_{fg} \), find

\[
h_{fg} = h_{fg} \left[ 1 + 0.68Ja \right] = 2257 \text{ kJ/kg} \left[ 1 + 0.68 \left[ 4214 \text{ J/kg-K} \left( 100 - 94 \right) \text{ K} / 2257 \times 10^3 \text{ J/kg} \right] \right] = 2274 \frac{\text{kJ}}{\text{kg}}.
\]

For laminar film condensation, Eq. 10.40 is the appropriate correlation for a cylinder with \( C = 0.729, \)

\[
\bar{h}_D = 0.729 \left[ \frac{g \rho_\ell (\rho_\ell - \rho_v) k^3 h_{fg}}{\mu_\ell (T_{sat} - T_s) D} \right]^{1/4}
\]

\[
\bar{h}_D = 0.729 \left[ \frac{9.8 \text{ m/s}^2 \times 960.6 \text{ kg/m}^3 \left( 960.6 - 0.596 \right) \text{ kJ/kg} \times 0.679 \text{ W/m-K} \times 2274 \times 10^3 \text{ J/kg}}{289 \times 10^{-6} \text{ N-s/m}^2 \times (100 - 94) \text{ K} \times 0.1 \text{ m}} \right]^{1/4}
\]

\[
\bar{h}_D = 10,120 \text{ W/m}^2 \cdot \text{K}.
\]

Hence, the heat transfer and condensation rates are

\[
q = 10,120 \text{ W/m}^2 \cdot \text{K} (\pi \times 0.1 \text{m} \times 1 \text{m}) (100 - 94) \text{ K} = 19.1 \text{kW} < \quad <
\]

\[
m = 19.1 \times 10^3 \text{ W/2274 \times 10^3 J/kg} \times 8.39 \times 10^{-3} \text{ kg/s}.
\]

COMMENTS: A comparison of the above results for the horizontal tube with those for a vertical tube (Problem 10.42) follows:

<table>
<thead>
<tr>
<th>Position</th>
<th>( \bar{h} ) ( \text{W/m}^2 \cdot \text{K} )</th>
<th>q(kW)</th>
<th>( \dot{m} \times 10^3 \text{ (kg/s)} )</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vertical</td>
<td>8,507</td>
<td>16.0</td>
<td>7.05</td>
</tr>
<tr>
<td>Horizontal</td>
<td>10,120</td>
<td>19.1</td>
<td>8.39</td>
</tr>
</tbody>
</table>

The rates are higher for the horizontal case. Why?
PROBLEM 10.54

KNOWN: Horizontal pipe passing through an air space with prescribed temperature and relative humidity.

FIND: Water condensation rate per unit length of the pipe.

SCHEMATIC:

ASSUMPTIONS: (1) Film condensation occurs on horizontal tube.

PROPERTIES: Table A-6, Water, vapor (T_∞ = 37°C = 310K): p_{A,sat} = 0.06221 bar; Table A-6, Water, vapor (p_A = φ · p_{A,sat} = 0.04666 bar): T_{A,sat} = 305K, ρ_v = 0.04 kg/m^3, h_{fg} = 2426 kJ/kg; Table A-6, Water, liquid (T_f = (T_s + T_{A,sat})/2 = 297K): ρ_ε = 997.2 kg/m^3, c_{p,ε} = 4180 J/kg·K, μ_ε = 917 × 10^{-6} N·s/m^2, k_ε = 0.609 W/m·K.

ANALYSIS: From Eq. 10.33, the condensate rate per unit length is

\[
\dot{m} = \frac{q'}{h_{fg}} = \frac{h_{L} (\pi D) (T_{sat} - T_s)}{h_{fg}}
\]

where, from Eq. 10.26, with \( J_a = c_{p,ε} \frac{(T_{sat} - T_s)}{h_{fg}} \),

\[
h_{fg} = h_{fg} \left[ 1 + 0.68c_{p,ε} \frac{(T_{sat} - T_s)}{h_{fg}} \right] = 2426 \left[ 1 + 0.68 \times 4180 \frac{J}{kg·K} \right] \frac{(305 - 288) K/2426 \times 10^{-3} J/kg}{}
\]

\[
h_{fg} = 2474 \text{ kJ/kg}.
\]

Note that \( T_{sat} = T_{A,sat} \) is the saturation temperature of the water vapor in air at 37°C having a relative humidity \( φ = 0.75 \). That is, \( T_{sat} = 305K \) while \( T_s = 15°C = 288K \). Assuming laminar film condensation on the horizontal pipe, it follows from Eq. 10.40 that,

\[
\bar{h}_D = 0.729 \left[ \frac{g \rho_ε (ρ_ε - ρ_v) k^3_ε h_{fg}^4}{μ_ε (T_{sat} - T_s) D} \right]^{1/4}
\]

\[
\bar{h}_D = 0.729 \left[ \frac{9.8 \text{ m/s}^2 \times 997.2 \text{ kg/m}^3 (997.2 - 0.04) \text{ kg/m}^3 \times 0.609 \text{ W/m·K} \times 10^{-3} \text{ J/kg}}{917 \times 10^{-6} \text{ N·s/m}^2 \times (305 - 288) \text{ K} \times 0.025 m} \right]^{1/4}
\]

\[
\bar{h}_D = 7925 \text{ W/m}^2·\text{K}.
\]

Hence, the condensate rate is,

\[
\dot{m}' = 7925 \text{ W/m}^2·\text{K} (π \times 0.025 m) (305 - 288) K/2474 \times 10^3 \text{ J/kg}
\]

\[
\dot{m}' = 4.28 \times 10^{-3} \text{ kg/s·m}.
\]

COMMENTS: The actual dropwise condensation rate exceeds the foregoing estimate.
**PROBLEM 10.55**

**KNOWN:** Horizontal tube, 50mm diameter, with surface temperature of 34°C is exposed to steam at 0.2 bar.

**FIND:** Estimate the heat transfer and condensation rates per unit length of the tube.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Laminar film condensation, (2) Negligible non-condensibles in steam.

**PROPERTIES:** *Table A-6*, Saturated steam (0.2 bar): $T_{\text{sat}} = 333\, \text{K}$, $\rho_v = 0.129\, \text{kg/m}^3$, $h_{fg} = 2358\, \text{kJ/kg}$; *Table A-6*, Water, liquid ($T_f = (T_s + T_{\text{sat}})/2 = 320\, \text{K}$): $\rho_\ell = 989.1\, \text{kg/m}^3$, $c_{p,\ell} = 4180\, \text{J/kg\cdot K}$, $\mu_\ell = 577 \times 10^{-6}\, \text{N\cdot s/m}^2$, $k_\ell = 0.640\, \text{W/m\cdot K}$.

**ANALYSIS:** From Eqs. 10.32 and 10.33, the heat transfer and condensate rates per unit length of the tube are

$$q' = \bar{h}_D (\pi D)(T_{\text{sat}} - T_s) \quad \text{and} \quad \dot{m}' = q' / h_{fg}$$

where from Eq. 10.26 with $J_a = c_{p,\ell} (T_{\text{sat}} - T_s) / h_{fg}$,

$$h_{fg} = h_{fg}[1 + 0.68\, J_a] = 2358\, \text{kJ/kg}\left[1 + 0.68 \times 4180\, \text{J/kg\cdot K}(333 - 307)\, \text{K}/2358 \times 10^3\, \text{J/kg}\right]$$

$$h_{fg}' = 2432\, \text{kJ/kg}.$$ 

For laminar film condensation, Eq. 10.40 is appropriate for estimating $\bar{h}_D$ with $C = 0.729$,

$$\bar{h}_D = 0.729 \left[ \frac{g \rho_\ell (\rho_\ell - \rho_v) k_\ell^3 h_{fg}'}{h_\ell (T_{\text{sat}} - T_s) D} \right]^{1/4}$$

$$\bar{h}_D = 0.729 \left[ \frac{9.8\, \text{m/s}^2 \times 989.1\, \text{kg/m}^3 (989.1 - 0.129) \, \text{kg/m}^3 (0.640\, \text{W/m\cdot K})^3 \times 2432 \times 10^3\, \text{J/kg}}{577 \times 10^{-6}\, \text{N\cdot s/m}^2 (333 - 307)\, \text{K} \times 0.050\text{m}} \right]$$

$$\bar{h}_D = 6926\, \text{W/m}^2\cdot\text{K}.$$ 

Hence, the heat transfer and condensation rates are

$$q' = 6926\, \text{W/m}^2\cdot\text{K}(333 - 307)\, \text{K} = 28.3\, \text{kW/m} <$$

$$\dot{m}' = 28.3 \times 10^3\, \text{W/m} / 2432 \times 10^{-3}\, \text{J/kg} = 1.16 \times 10^{-2}\, \text{kg/s\cdot m}. <$$
PROBLEM 10.56

KNOWN: Horizontal tube 1m long with surface temperature of 70°C used to condense steam at 1 bar.

FIND: Diameter required for condensation rate of 125 kg/h.

SCHEMATIC:

ASSUMPTIONS: (1) Laminar film condensation, (2) Negligible non-condensibles in steam.

PROPERTIES: Table A-6, Water, vapor (1 atm): \( T_{\text{sat}} = 100^\circ\text{C}, \rho_v = 0.596 \text{ kg/m}^3, h_{fg} = 2257 \text{ kJ/kg}; \)

Table A-6, Water, liquid (\( T_f = (T_s + T_{\text{sat}})/2 = 358\)K): \( \rho_\ell = 968.6 \text{ kg/m}^3, c_{p,\ell} = 4201 \text{ J/kg} \cdot \text{K}, \mu_\ell = 332 \times 10^{-6} \text{ N} \cdot \text{s/m}^2, k_\ell = 0.673 \text{ W/m} \cdot \text{K}. \)

ANALYSIS: From the rate equation, Eq. 10.33, with \( A = \pi D L \), the required diameter is

\[
D = \frac{m h_{fg}}{\pi L \overline{h}_D (T_{\text{sat}} - T_s)}
\]  

(1)

where from Eq. 10.26 with \( \text{Ja} = \frac{c_{p,\ell} (T_{\text{sat}} - T_s)}{h_{fg}} \),

\[
h_{fg} = h_{fg} (1 + 0.68 \text{Ja}) = 2257 \frac{\text{kJ}}{\text{kg}} \left(1 + 0.68 \frac{4201 \text{J/kg} \cdot \text{K} \times (100 - 70)}{2257 \times 10^3 \text{ J/kg}}\right) = 2343 \text{kJ/kg}. \]

(2)

Substituting numerical values, Eq. (1) becomes

\[
D = \frac{125 \text{ kg/s} \times 2343 \times 10^3 \frac{\text{J}}{\text{kg}}}{\pi \times 1 \text{m} \times \overline{h}_D (100 - 70) \text{K}} = 863.2 \overline{D}^{-1}. \]

(3)

The appropriate correlation for \( \overline{h}_D \) is Eq. 10.40 with \( C = 0.729 \),

\[
\overline{h}_D = 0.729 \left[ \frac{g \rho_\ell (\rho_\ell - \rho_v) k_\ell^3 h_{fg}^3}{\mu_\ell (T_{\text{sat}} - T_s) D} \right]^{1/4}. \]

(4)

Substitute Eq. (4) for \( \overline{h}_D \) into Eq. (3) and use numerical values,

\[
863.2 \text{ D}^{-1} = 0.729 \times \left[ \frac{9.8 \text{m/s}^2 \times 968.6 \text{kg/m}^3 (968.6 - 0.596) \text{kg/m}^3 \times 0.673 \text{W/m} \cdot \text{K}^3 \times 2343 \times 10^3 \text{J/kg}}{332 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 (100 - 70) \text{K} \times D} \right]^{1/4}
\]

\[
863.2 \text{ D}^{-1} = 3693.4 \text{ D}^{-1/4}
\]

\[
D = 0.144 \text{m} = 144 \text{mm}. \]

COMMENTS: Note for this situation Ja = 0.06.
PROBLEM 10.57

KNOWN: Saturated R-12 vapor at 1 atm condensing on the outside of a horizontal tube.

FIND: Tube surface temperature required for condensation rate of 50 kg/h.

SCHEMATIC:

ASSUMPTIONS: (1) Laminar film condensation, (2) Negligible non-condensibles in vapor.

PROPERTIES: Table A-5, R-12 Saturated vapor (1 atm): \( T_{\text{sat}} = 243 \text{K} \), \( \rho_v = 6.32 \text{ kg/m}^3 \), \( h_{fg} = 165 \text{ kJ/kg} \); Table A-5, R-12 Saturated liquid (\( T_f \approx 240 \text{K} \)): \( \rho_\ell = 1498 \text{ kg/m}^3 \), \( c_{p,\ell} = 892.3 \text{ J/kg} \cdot \text{K} \), \( \mu_\ell = 0.0385 \times 10^{-2} \text{ N} \cdot \text{s/m}^2 \), \( k_\ell = 0.069 \text{ W/m} \cdot \text{K} \).

ANALYSIS: The surface temperature or temperature difference can be written as follows from Eq. 10.33,

\[
\Delta T = T_{\text{sat}} - T_s = \frac{\dot{m} h_{fg}'}{\overline{h}_D} \pi D L \tag{1}
\]

where \( A = \pi D L \). To evaluate \( h_{fg}' \) and \( \overline{h}_D \), we require knowledge of \( T_s \) or \( \Delta T \). Assume a \( \Delta T = 10^\circ \text{C} \), then \( T_s = 233 \text{K} \) and \( T_f = (T_s + T_{\text{sat}})/2 = 240 \text{K} \). From Eq. 10.26 with \( J_a = \frac{c_{p,\ell} \Delta T}{h_{fg}'} \), find

\[
h_{fg}' = h_{fg} (1 + 0.68 J_a) = 165 \frac{\text{kJ}}{\text{kg}} \left[ 1 + 0.68 \times 892.3 \frac{\text{J}}{\text{kg} \cdot \text{K}} \times 10 \text{K} / 165 \times 10^3 \frac{\text{J}}{\text{kg}} \right] = 171 \text{kJ/kg}. \tag{2}
\]

The appropriate correlation for \( \overline{h}_D \) is Eq. 10.40 with \( C = 0.729 \); substitute properties and find \( \overline{h}_D \) in terms of \( \Delta T \).

\[
\overline{h}_D = 0.729 \left[ \frac{g \rho_\ell \left( \rho_\ell - \rho_v \right) k_\ell^3 h_{fg}'}{\mu_\ell (T_{\text{sat}} - T_s) D} \right]^{1/4}
\]

\[
\overline{h}_D = 0.729 \left[ \frac{9.8 \text{ m/s}^2 \times 1498 \text{ kg/m}^3 \left( 1498 - 6.32 \right) \text{ kg/m}^3 (0.069 \text{ W/m} \cdot \text{K})^3 \times 171 \times 10^3 \text{J/kg}}{0.0385 \times 10^{-2} \text{ N} \cdot \text{s/m}^2 \times \Delta T \times 0.010 \text{m}} \right]^{1/4}
\]

\[
\overline{h}_D = 3082 \Delta T^{1/4}. \tag{3}
\]

Substitute Eq. (3) into Eq. (1) for \( \overline{h}_D \), and solve for \( \Delta T \),

\[
\Delta T = \frac{50}{3600} \frac{\text{kg/s} \times 171 \times 10^3 \text{J/kg}}{\left( 3082 \Delta T^{1/4} \right) \pi \left( 0.010 \text{m} \right) \times 1 \text{m}}
\]

\[
\Delta T = 12.9 \text{K} \quad \text{or} \quad T_s = 230 \text{K}. \tag{<}
\]

COMMENTS: We used the assumed value of \( T_s \) or \( \Delta T \) only to evaluate properties. Our estimate for \( T_f = 240 \text{K} \) is to be compared to the calculated value of \( T_f = 236 \text{K} \). An iteration is probably not necessary.
PROBLEM 10.58

KNOWN: Saturation temperature and inlet flow rate of R-12. Diameter, length and temperature of tube.

FIND: Rate of condensation and outlet flow rate.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible concentration of noncondensables in vapor.

PROPERTIES: Given, R-12, saturated vapor: \( \rho_v = 6 \text{ kg/m}^3, \ h_{fg} = 160 \text{ kJ/kg}, \ \mu_v = 150 \times 10^{-7} \text{ N\cdot s/m}^2 \). Table A-5, R-12, saturated liquid (\( T_f = 300 \text{ K} \)): \( \rho_f = 1306 \text{ kg/m}^3, \ c_{p,\ell} = 978 \text{ J/kg\cdot K}, \ \mu_\ell = 0.0254 \text{ N\cdot s/m}^2, \ k_\ell = 0.072 \text{ W/m\cdot K} \).

ANALYSIS: The Reynolds number associated with the inlet vapor flow is \( \text{Re}_{v,i} = 4 \frac{m_{v,i}}{\pi \mu_v} = 0.04 \text{ kg/s}/\pi \times 0.025 \text{ m} \times 150 \times 10^{-7} \text{ N\cdot s/m}^2 = 33.95 < 35,000 \). Hence, the average convection coefficient may be obtained from Eq. 10.42, where \( h_{fg} = h_{fg} + 0.375 c_{p,\ell} (T_{sat} - T_s) = (1.6 \times 10^5 + 0.375 \times 978 \times 20) \text{ J/kg} = 1.67 \times 10^5 \text{ J/kg} \).

\[
\overline{h}_D = 0.555 \left[ \frac{g \rho_v (\rho_v - \rho_f) k_\ell^3 h_{fg}^2}{\mu_\ell (T_{sat} - T_s) D} \right]^{1/4} \approx 0.555 \left[ \frac{9.8 \text{ m/s}^2 (1306 \text{ kg/m}^3)^2 (0.072 \text{ W/m\cdot K})^3 1.67 \times 10^5 \text{ J/kg}}{0.0254 \text{ N\cdot s/m}^2 \times 20 \text{ K} \times 0.025 \text{ m}} \right]^{1/4}
\]

\( \overline{h}_D = 297 \text{ W/m}^2\cdot\text{K} \)

The heat rate is then

\[
q = \pi DL \overline{h}_D (T_{sat} - T_s) = \pi \times 0.025 \text{ m} \times 2 \text{ m} \times 297 \text{ W/m}^2\cdot\text{K} \times 20 \text{ K} = 933 \text{ W}
\]

and the condensation rate is

\[
\dot{m}_{cond} = \frac{q}{h_{fg}} = \frac{933 \text{ W}}{1.67 \times 10^5 \text{ J/kg}} = 0.0056 \text{ kg/s}
\]

The flow rate of vapor leaving the tube is then

\[
\dot{m}_{v,o} = \dot{m}_{v,i} - \dot{m}_{cond} = (0.0100 - 0.0056) \text{ kg/s} = 0.0044 \text{ kg/s}
\]
PROBLEM 10.59

KNOWN: Array of condenser tubes exposed to saturated steam at 0.1 bar.

FIND: (a) Condensation rate per unit length of square array, (b) Options for increasing the condensation rate.

SCHEMATIC:

ASSUMPTIONS: (1) Film condensation on tubes, (2) Negligible non-condensable gases in steam.

PROPERTIES: Table A.6, Saturated water vapor (0.1 bar): $T_{\text{sat}} \approx 320 \text{ K}$, $\rho_v = 0.072 \text{ kg/m}^3$, $h_{fg} = 2390 \text{ kJ/kg}$; Table A.6, Water, liquid ($T_f = (T_s + T_{\text{sat}})/2 = 310 \text{ K}$): $\rho_f = 993.1 \text{ kg/m}^3$, $c_{p,f} = 4178 \text{ J/kg} \cdot \text{K}$, $\mu_f = 695 \times 10^{-6} \text{ N} \cdot \text{s/m}^2$, $k_f = 0.628 \text{ W/m} \cdot \text{K}$.

ANALYSIS:

(a) From Eq. 10.33, the condensation rate for a $N \times N$ square array is

$$m' = \frac{m}{L} = \overline{h}_{D,N} \cdot N_t \left( \frac{\pi D}{T_{\text{sat}} - T_s} \right) / h_{fg}$$

where $\overline{h}_{D,N}$ is the average coefficient for the tubes in a vertical array of $N$ tubes. With $Ja = c_{p,f} \Delta T / h_{fg} = 4178 \text{ J/kg} \cdot \text{K} \times (320 - 300) \text{K}/2390 \times 10^3 \text{ J/kg} = 0.035$, Eq. 10.26 yields $h_{fg}' = h_{fg}(1 + 0.68 Ja) = 2390 \text{ kJ/kg}(1 + 0.68 \times 0.035) = 2447 \text{ kJ/kg}$.

For a vertical tier of $N = 10$ horizontal tubes, the average coefficient is given by Eq. 10.41,

$$\overline{h}_{D,N} = 0.729 \left[ \frac{g \rho_f (\rho_f - \rho_v) k_f^3 h_{fg}'}{N \mu_f (T_{\text{sat}} - T_s) D} \right]^{1/4}$$

$$\overline{h}_{D,N} = 0.729 \left[ \frac{9.8 \text{ m/s}^2 \times 993.1 \text{ kg/m}^3 \times (993.1 - 0.072) \text{ kg/m}^3 \times 0.628 \text{ W/m} \cdot \text{K} \times 2447 \times 10^3 \text{ J/kg}}{10 \times 695 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 \times (320 - 300) \text{K} \times 0.008 \text{m}} \right]^{1/4}$$

$$\overline{h}_{D,N} = 6210 \text{ W/m}^2 \cdot \text{K}.$$ 

Hence, the condensation rate for the entire array per unit tube length is

$$m' = 6210 \text{ W/m}^2 \cdot \text{K}(100) \pi \times 0.008 \text{m}(320 - 300) \text{K}/2447 \times 10^3 \text{ J/kg}$$

$$m' = 0.128 \text{ kg/s} \cdot \text{m} = 459 \text{ kg/h} \cdot \text{m}.$$  

(b) Options for increasing the condensation rate include reducing the surface temperature and/or the number of tubes in a vertical tier. By varying the temperature of cold water flowing through the tubes, it is feasible to maintain surface temperatures in the range $280 \leq T_s \leq 300 \text{ K}$. Using the Correlations and Properties Toolpads of IHT, the following results were obtained for $N = 10, 5$ and $2$, with $N_t = 100$ in each case. The results are based on properties evaluated at $p = 0.1 \text{ bar}$, for which the Properties Toolpad yielded $T_{\text{sat}} = 318.9 \text{ K}$.

Continued...
Clearly, there are significant benefits associated with reducing both $T_s$ and $N$.

**COMMENTS:** Note that, since $\bar{h}_{D,N} \propto N^{-1/4}$, the average coefficient decreases with increasing $N$ due to a corresponding increase in the condensate film thickness. From the result of part (a), the coefficient for the topmost tube is $\bar{h}_D = 6210 \text{ W/m}^2 \cdot \text{K}(10)^{1/4} = 11,043 \text{ W/m}^2 \cdot \text{K}$. 
PROBLEM 10.60

KNOWN: Thin-walled concentric tube arrangement for heating deionized water by condensation of steam.

FIND: Estimates for convection coefficients on both sides of the inner tube. Inner tube wall outlet temperature. Whether condensation provides fairly uniform inner tube wall temperature approximately equal to the steam saturation temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible thermal resistance of inner tube wall, (2) Internal flow is fully developed.

PROPERTIES: Deionized water (given): \( \rho = 982.3 \text{ kg/m}^3, c_p = 4181 \text{ J/kg} \cdot \text{K}, k = 0.643 \text{ W/m} \cdot \text{K}, \mu = 548 \times 10^{-6} \text{ N} \cdot \text{s/m}^2, Pr = 3.56; \) Table A-6, Saturated vapor (1 atm): \( T_{sat} = 100^\circ \text{C}, \rho_v = (1/\nu_g) = 0.596 \text{ kg/m}^3, h_{fg} = 2265 \text{ kJ/kg}; \) Table A-6, Saturated water (assume \( T_s \approx 75^\circ \text{C}, T_f = (75 + 100)^\circ \text{C}/2 = 360^\circ \text{K} \)): \( \rho_f = (1/\nu_f) = 967 \text{ kg/m}^3, \mu_f = 324 \times 10^{-6} \text{ N} \cdot \text{s/m}^2, k_f = 0.674 \text{ W/m} \cdot \text{K}, c_{p,f} = 4203 \text{ J/kg} \cdot \text{K}. \)

ANALYSIS: From an energy balance on the inner tube assuming a constant wall temperature,

\[
\overline{h_c} (T_{sat} - T_{s,o}) = h_i (T_{s,o} - T_{m,o})
\]

where \( \overline{h_c} \) and \( h_i \) are, respectively, the heat transfer coefficients for condensation (c) on a horizontal cylinder and internal (i) flow in a tube.

Condensation. From Eq. 10.40, for the horizontal tube,

\[
\overline{h_c} = 0.729 \left[ \frac{g \rho_f (\rho_f - \rho_v) k^3 h_{fg}}{\mu_f (T_{Sat} - T_s) D} \right]^{1/4}
\]

where \( h_{fg} = h_{fg} \left\{ 1 + 0.68 c_{p,f} (T_{sat} - T_s) / h_{fg} \right\} \)

\[
h_{fg} = 2265 \text{ kJ/kg} \left\{ 1 + 0.68 \times 4203 \text{ J/kg} \cdot \text{K} (100 - T_s) / 2265 \times 10^3 \text{ J/kg} \right\}
\]

\[
h_{fg} = 2265 \text{ kJ/kg} \left\{ 1 + 1.262 \times 10^{-3} (100 - T_s) \right\}
\]

\[
\overline{h_c} = 0.729 \left[ 9.8 \text{ m/s}^2 \times 967 \text{ kg/m}^3 (067 - 0.596) \text{ kg/m}^3 (0.674 \text{ W/m} \cdot \text{K})^3 \times \right.
\]

\[
2265 \left\{ 1 + 1.262 \times 10^{-3} (100 - T_s) \right\} \text{kJ/kg} / 324 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 (100 - T_s) 0.030 \text{ m}^{1/4}
\]

Continued …..
PROBLEM 10.60 (Cont.)

\[
\overline{h}_c = 2.843 \times 10^4 \left[ \frac{1 + 1.262 \times 10^{-3} (100 - T_s)}{100 - T_s} \right]^{1/4}.
\]

Internal flow. From Eq. 8.6, evaluating properties at \( T_m \), find

\[
Re_D = \frac{4\dot{m}}{\pi \mu D} = \frac{4 \times 5 \text{ kg/s}}{\pi \times 548 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 \times 0.03 \text{ m}} = 3.872 \times 10^5
\]

and for turbulent flow use the Colburn equation,

\[
Nu_D = \frac{h_i D}{k} = 0.023 \frac{Re_D^{0.8} \text{ Pr}^{1/3}}{D}
\]

\[
h_i = \frac{0.023 \times 0.643 \text{ W/m} \cdot \text{K}}{0.03 \text{ m}} \left(3.872 \times 10^5\right)^{0.8} \left(3.56\right)^{1/3} = 2.22 \times 10^4 \text{ W/m}^2 \cdot \text{K}.
\]

Substituting numerical values into the energy balance relation,

\[
2.843 \times 10^4 \left[ \frac{1 + 1.262 \times 10^{-3} (100 - T_{s,o})}{100 - T_{s,o}} \right]^{1/4} (100 - T_{s,o}) \text{K}
\]

\[
= 2.22 \times 10^4 \text{ W/m}^2 \cdot \text{K} (T_{s,o} - 60) \text{K}
\]

and by trial-and-error, find

\[
T_{s,o} \approx 75^\circ \text{C}.
\]

With this value of \( T_{s,o} \), find that

\[
\overline{h}_c = 1.29 \times 10^4 \text{ W/m}^2 \cdot \text{K}
\]

which is approximately half that for the internal flow. Hence, the tube wall cannot be at a uniform temperature. This could only be achieved if \( \overline{h}_c \nrighteq h_i \).
PROBLEM 10.61

KNOWN: Heat dissipation from multichip module to saturated liquid of prescribed temperature and properties. Diameter and inlet and outlet water temperatures for a condenser coil.

FIND: (a) Condensation and water flow rates. (b) Tube surface inlet and outlet temperatures. (c) Coil length.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions since rate of heat transfer from the module is balanced by rate of heat transfer to coil, (2) Fully developed flow in tube, (3) Negligible changes in potential and kinetic energy for tube flow.

PROPERTIES: Saturated fluorocarbon (T_{\text{sat}} = 57^\circ C, given): \( k_{\ell} = 0.0537 \text{ W/m}\cdot K, \) \( c_{p,\ell} = 1100 \text{ J/kg}\cdot K, \) \( h_{fg} = 84,400 \text{ J/kg}, \) \( r_{\ell} = 1619.2 \text{ kg/m}^3, \) \( \rho_{\ell} = 13.4 \text{ kg/m}^3, \) \( \sigma = 8.1 \times 10^{-3} \text{ kg/s}^2, \) \( \mu_{\ell} = 440 \times 10^{-6} \text{ kg/m}\cdot s, \) \( Pr_{\ell} = 9; \) Table A-6, Water, sat. liquid (\( T_{\text{m}} = 300K \)): \( \rho = 997 \text{ kg/m}^3, \) \( c_p = 4179 \text{ J/kg}\cdot K, \) \( \mu = 855 \times 10^{-6} \text{ N}\cdot s/\text{m}^2, \) \( k = 0.613 \text{ W/m}\cdot K, \) \( Pr = 5.83. \)

ANALYSIS: (a) With

\[
q = (q^*\times A)_{\text{module}} = 10^5 \text{ W/m}^2(0.1 \text{ m})^2 = 10^3 \text{ W}
\]

the condensation rate is

\[
\dot{m}_{\text{con}} = \frac{q}{h_{fg}} = \frac{10^3 \text{ W}}{84,400 \text{ J/kg}} = 0.0118 \text{ kg/s}
\]

and the required water flow rate is

\[
\dot{m} = \frac{q}{c_p(T_{m,o} - T_{m,i})} = \frac{1000 \text{ W}}{4179 \text{ J/kg}\cdot K(30 K)} = 7.98 \times 10^{-3} \text{ kg/s}.
\]

(b) The Reynolds number for flow through the tube is

\[
\text{Re}_D = \frac{4 \dot{m}}{\pi D \mu} = \frac{4 \times 7.98 \times 10^{-3} \text{ kg/s}}{\pi (0.01 \text{ m}) 855 \times 10^{-6} \text{ N}\cdot s/\text{m}^2} = 1188.
\]

Hence, the flow is laminar. Assuming a uniform wall temperature,

\[
h_1 = Nu_D k / D = 3.66(0.613 \text{ W/m}\cdot K/0.01 \text{ m}) = 224 \text{ W/m}^2\cdot K.
\]

Continued …..
PROBLEM 10.61 (Cont.)

For film condensation on the outer surface, Eq. 10.40 yields

\[
h_o = 0.729 \left( \frac{9.8 \text{ m/s}^2 \left( 1619.2 \text{ kg/m}^3 \right) \left( 1605.8 \text{ kg/m}^3 \right) \left( 0.0537 \text{ W/m} \cdot \text{K} \right)^3 84,400 \text{ J/kg}}{440 \times 10^{-6} \text{ kg/m} \cdot \text{s} \times 0.01 \text{ m} \left( T_{\text{sat}} - T_s \right)} \right)^{1/4}
\]

\[
h_o = 2150 (57 - T_s)^{-1/4}.
\]

From an energy balance on a portion of the tube surface,

\[
h_o (T_{\text{sat}} - T_s) = h_i (T_s - T_m)
\]

or

\[
2150 (57 - T_s)^{3/4} = 224 (T_s - T_m)
\]

At the entrance where \((T_{m,i} = 285\text{K})\), trial-and-error yields:

\[
T_{s,i} = 50.6^\circ \text{C}
\]

and at the exit where \((T_{m,o} = 315\text{K})\).

\[
T_{s,o} = 55.4^\circ \text{C}
\]

(c) From Eqs. 8.44 and 8.45,

\[
L = \frac{q}{h_i \pi D \Delta T_{\ell/m}}
\]

where

\[
\Delta T_{\ell/m} = \frac{(T_s - T_{m,i}) - (T_s - T_{m,o})}{\ln \left( \frac{(T_s - T_{m,i})}{(T_s - T_{m,o})} \right)} = \frac{41 - 11}{\ln (41/11)} = 22.8^\circ \text{C}
\]

\[
L = \frac{1000 \text{ W}}{(224 \text{ W/m}^2 \cdot \text{K}) \pi (0.01 \text{ m}) 22.8^\circ \text{C}} = 6.23 \text{ m}
\]

COMMENTS: Some control over system performance may be exercised by adjusting the water flow rate. By increasing \(m, (T_{m,o} - T_{m,i})\) is reduced for a prescribed \(q\). The value of \(h_i\) is increased substantially if the internal flow is turbulent.
PROBLEM 10.62

KNOWN: Saturated ethylene glycol vapor at 1 atm condensing on a sphere of 100 mm diameter having surface temperature of 150°C.

FIND: Condensation rate.

SCHEMATIC:

ASSUMPTIONS: (1) Laminar film condensation, (2) Negligible non-condensibles in vapor.

PROPERTIES: Table A-5, Saturated ethylene glycol, vapor (1 atm): \( T_{\text{sat}} = 470 \text{K}, \rho_v = 0 \text{ kg/m}^3, h_{fg} = 812 \text{ kJ/kg}; \) Table A-5, Ethylene glycol, liquid (\( T_f = 423 \text{K}, \) but use values at 373K, limit of data in table): \( \rho_\ell = 1058.5 \text{ kg/m}^3, c_{p,\ell} = 2742 \text{ J/kg-K}, \mu_\ell = 0.215 \times 10^{-2} \text{ N-s/m}^2, k_\ell = 0.263 \text{ W/m-K}. \)

ANALYSIS: The condensation rate is given by Eq. 10.33 as

\[
\dot{m} = \frac{q}{h'_{fg}} = \frac{h_L \left( \pi D^2 \right) \left( T_{\text{sat}} - T_s \right)}{h'_{fg}}
\]

where \( A = \pi D^2 \) for the sphere and \( h'_{fg} \), with \( J_a = c_{p,\ell} \Delta T / h_{fg} \), is given by Eq. 10.26 as

\[
h'_{fg} = h_{fg} \left( 1 + 0.68 J_a \right) = 812 \frac{\text{kJ}}{\text{kg}} \left( 1 + 0.68 \times 2742 \frac{\text{J}}{\text{kg-K}} \left( 470 - 423 \right) \text{K} / 812 \times 10^3 \text{ J/kg} \right) = 900 \text{ kJ/kg}.
\]

The average heat transfer coefficient for the sphere follows from Eq. 10.40 with \( C = 0.815 \),

\[
\bar{h}_D = 0.815 \left[ \frac{g \rho_\ell (\rho_\ell - \rho_v) k_\ell^3 h'_{fg}}{\mu_\ell (T_{\text{sat}} - T_s) D} \right]^{1/4}
\]

\[
\bar{h}_D = 0.815 \left[ \frac{9.8 \text{ m/s}^2 \times 1058.5 \text{ kg/m}^3 \left( 1058.5 - 0 \right) \text{ kg/m}^3 \left( 0.263 \text{ W/m-K} \right)^3 \times 900 \times 10^3 \text{ J/kg}}{0.215 \times 10^{-2} \text{ N-s/m}^2 \left( 470 - 423 \right) \text{ K} \times 0.100 \text{ m}} \right]^{1/4}
\]

\[
\bar{h}_D = 1674 \text{ W/m}^2 \cdot \text{K}.
\]

Hence, the condensation rate is

\[
\dot{m} = 1674 \text{ W/m}^2 \cdot \text{K} \times \pi \left( 0.100 \text{ m} \right)^2 \left( 470 - 423 \right) \text{ K} / 900 \times 10^3 \text{ J/kg}
\]

\[
\dot{m} = 2.75 \times 10^{-3} \text{ kg/s}.
\]

COMMENTS: Recognize this estimate is likely to be a poor one since properties were not evaluated at the proper \( T_f \) which was beyond the limit of the table.
Problem 10.63

known: Copper sphere of 10 mm diameter, initially at 50°C, is placed in a large container filled with saturated steam at 1 atm.

Find: Time required for sphere to reach equilibrium and the condensate formed during this period.

Schematic:

Assumptions: (1) Laminar film condensation, (2) Negligible non-condensibles in vapor, (3) Sphere is spacewise isothermal, (4) Sphere experiences heat gain by condensation only.

Properties: Table A-6, Saturated water vapor (1 atm): \( T_{\text{sat}} = 100°C, \rho_v = 0.596 \text{ kg/m}^3, \ h_{fg} = 2257 \text{ kJ/kg}; \) Table A-6, Water, liquid \( (T_f \approx (75 + 100)°C/2 = 360K): \) \( \rho_{\ell} = 967.1 \text{ kg/m}^3, \ c_{p,\ell} = 4203 \text{ J/kg.K}, \mu_\ell = 324 \times 10^{-6} \text{ N.s/m}^2, \ k_\ell = 0.674 \text{ W/m.K}; \) Table A-1, Copper, pure \( (\bar{T} = 75°C): \) \( \rho_{sp} = 8933 \text{ kg/m}^3, c_{p,sp} = 389 \text{ J/kg.K}. \)

Analysis: Using the lumped capacitance approach, an energy balance on the sphere provides,

\[
\dot{E}_{in} - \dot{E}_{out} = \dot{E}_{st}
\]

\[\dot{m}h_{fg}' = \bar{h}_D A_s (T_{\text{sat}} - T_s) = \rho_{sp} c_{p,sp} V_s \frac{dT_s}{dt}. \tag{1}\]

Properties of the sphere, \( \rho_{sp} \) and \( c_{p,sp}. \) Will be evaluated at \( \bar{T}_s = (50 +100)°C/2 = 75°C, \) while water (liquid) properties will be evaluated at \( \bar{T}_f = (\bar{T}_s + T_{\text{sat}})/2 = 87.5°C = 360K. \) From Eq. 10.26 with \( J_a = c_{p,\ell} \Delta T / h_{fg} \) where \( \Delta T = T_{\text{sat}} - \bar{T}_s, \) find

\[h_{fg}' = h_{fg} (1 + 0.68 J_a) = 2257 \frac{\text{kJ}}{\text{kg}} \left(1 + 0.68 \left[4203 \frac{\text{J}}{\text{kg} \cdot \text{K}} \times (100 - 75) \text{K}/2257 \times \times 10^3 \text{J/kg} \right]\right) = 2328 \frac{\text{kJ}}{\text{kg}}. \tag{2}\]

To estimate the time required to reach equilibrium, we need to integrate Eq. (1) with appropriate limits. However, to perform the integration, an appropriate relation for the temperature dependence of \( \bar{h}_D \) needs to be found. Using Eq. 10.40 with \( C = 0.815, \)

\[\bar{h}_D = 0.815 \left[ g \rho_{\ell} (\rho_{\ell} - \rho_v) k_{\ell}^3 h_{fg}' \right]^{1/4}. \tag{3}\]

Substitute numerical values and find,

\[
\bar{h}_D = 0.815 \left[ 9.8 \text{ m/s}^2 \times 967.1 \text{ kg/m}^3 \times (967.1 - 0.596) \text{ kg/m}^3 \times (0.674 \text{ W/m.K})^3 \times 2328 \times 10^3 \text{J/kg} \right]^{1/4} \]

\[
= \frac{324 \times 10^{-6} \text{ N.s/m}^2 \cdot (T_{\text{sat}} - T_s) \times 0.010}{30,707 \text{ W/m}^2 \cdot \text{K}^3/4}. \tag{3}\]

Continued …..
PROBLEM 10.63 (Cont.)

Substitute Eq. (3) into Eq. (1) for $h_D$ and recognize $V_s/A_s = \frac{1}{6} \pi D^3 / \pi D^2 = D/6$.

$$B(T_{\text{sat}} - T_s)^{-1/4} (T_{\text{sat}} - T_s) = \rho_{\text{sp}} c_{\text{p,sp}} \left( \frac{D}{6} \right) \frac{dT_s}{dt}.$$  

(4)

Note that $dT_s = - d(T_{\text{sat}} - T_s)$; letting $\Delta T \equiv T_{\text{sat}} - T_s$ and separating variables, the energy balance relation has the form

$$\int_0^t dt = - \frac{\rho_{\text{sp}} c_{\text{p,sp}} \left( \frac{D}{6} \right)}{B} \int \Delta T \left( \frac{d(\Delta T)}{dT_s} \right)$$

(5)

where the limits of integration have been identified, with $\Delta T_o = T_{\text{sat}} - T_i$ and $T_i = T_s(0)$. Performing the integration, find

$$t = - \frac{\rho_{\text{sp}} c_{\text{p,sp}} \left( \frac{D}{6} \right)}{B} \cdot \frac{1}{1 - 3/4} \left[ \Delta T^{1/4} - \Delta T_o^{1/4} \right].$$

Substituting numerical values with the limits, $\Delta T = 0$ and $\Delta T_o = 100-50 = 50^\circ C$,

$$t = - \frac{8933 \text{kg/m}^3 \times 389 \text{J/kg} \cdot \text{K} \times (0.010 \text{m/6})}{30,707 \text{ W/m}^2 \cdot \text{K}^{3/4}} \times 4 \left[ 0^{1/4} - 50^{1/4} \right] \text{K}^{1/4}$$

$$t = 2.0 \text{s}.$$  

To determine the total amount of condensate formed during this period, perform an energy balance on a time interval basis,

$$E_{\text{in}} - E_{\text{out}} = \Delta E = E_{\text{final}} - E_{\text{initial}}$$

$$E_{\text{in}} = \rho_{\text{sp}} c_{\text{p,sp}} V (T_{\text{final}} - T_{\text{initial}})$$

(6)

where $T_{\text{final}} = T_{\text{sat}}$ and $T_{\text{initial}} = T_i = T_s(0)$. Recognize that

$$E_{\text{in}} = M h_{fg}$$

(7)

where $M$ is the total mass of vapor that condenses. Combining Eqs. (6) and (7),

$$M = \frac{\rho_{\text{sp}} c_{\text{p,sp}} V}{h_{fg}} [T_{\text{sat}} - T_i]$$

$$M = \frac{8933 \text{kg/m}^3 \times 389 \text{J/kg} \cdot \text{K} \times (0.010 \text{m/6})}{2328 \times 10^3 \text{ J/kg}} \left[ 100 - 50 \right] \text{K}$$

$$M = 3.91 \times 10^{-5} \text{kg}.$$  

COMMENTS: The total amount of condensate could have been evaluated from the integral,

$$M = \int_0^t m dt = \int_0^t q \frac{dt}{h_{fg}} = \int_0^t \bar{h}_D A_s (T_{\text{sat}} - T_s) dt$$

$$h_{fg}$$

giving the same result, but with more effort.
**PROBLEM 10.64**

**KNOWN:** Saturated steam condensing on the inside of a horizontal pipe.

**FIND:** Heat transfer coefficient and the condensation rate per unit length of the pipe.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Film condensation with low vapor velocities.

**PROPERTIES:** Table A-6, Saturated water vapor (1.5 bar): \( T_{\text{sat}} \approx 385 \text{K} \), \( \rho_v = 0.88 \text{ kg/m}^3 \), \( h_{fg} = 2225 \text{ kJ/kg} \); Table A-6, Saturated water (\( T_f = (T_{\text{sat}} + T_s)/2 = 380\text{K} \)): \( \rho_\ell = 953.3 \text{ kg/m}^3 \), \( c_{p,\ell} = 4226 \text{ J/kg} \cdot \text{K}, \mu_\ell = 260 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 \), \( k_\ell = 0.683 \text{ W/m} \cdot \text{K} \).

**ANALYSIS:** The condensation rate per unit length follows from Eq. 10.33 with \( A = \pi D L \) and has the form

\[
\dot{m}' = \frac{\dot{m}}{L} = \frac{h_D (\pi D)(T_{\text{sat}} - T_s)}{h_{fg}}
\]

where \( h_D \) is estimated from the correlation of Eq. 10.42 with Eq. 10.43,

\[
h_D = 0.555 \left[ \frac{g \rho_\ell (\rho_\ell - \rho_v)^3 h_{fg}}{\mu_\ell (T_{\text{sat}} - T_s) D} \right]^{1/4}
\]

where

\[
h_{\ell g} = h_{fg} + \frac{3}{8} c_{p,\ell} (T_{\text{sat}} - T_s) = 2225 \times 10^3 \frac{\text{J}}{\text{kg}} + \frac{3}{8} \times 4226 \frac{\text{J}}{\text{kg} \cdot \text{K}} (385 - 373) \text{K}
\]

\[
h_{\ell g} = 2244 \text{kJ/kg}.
\]

Hence,

\[
h_D = 0.555 \left[ \frac{9.8 \text{m/s}^2 \times 953.3 \frac{\text{kg}}{\text{m}^3} \left(953.3 - 0.88\right) \frac{\text{kg}}{\text{m}^3} (0.683 \text{W/m} \cdot \text{K})^3 \times 2244 \times 10^3 \frac{\text{J}}{\text{kg}}}{260 \times 10^{-6} \text{N} \cdot \text{s/m}^2 (385 - 373) \text{K} \times 0.075 \text{m}} \right]^{1/4}
\]

\[
h_D = 7127 \text{W/m}^2 \cdot \text{K}.
\]

It follows that the condensate rate per unit length of the tube is

\[
\dot{m}' = 7127 \text{W/m}^2 \cdot \text{K} \left(\pi \times 0.075 \text{m}\right)(385 - 373) \text{K} / 2225 \times 10^3 \text{ J/kg} = 9.06 \times 10^{-3} \text{ kg/s} \cdot \text{m}.
\]
PROBLEM 10.65

KNOWN: Horizontal pipe passing through an air space with prescribed temperature and relative humidity.

FIND: Water condensation rate per unit length of pipe.

SCHEMATIC:

ASSUMPTIONS: (1) Drop-wise condensation, (2) Copper tube approximates well promoted surface.

PROPERTIES: Table A-6, Water vapor \( T_\infty = 37°C = 310K \): \( p_{A,sat} = 0.06221 \) bar; Table A-6, Water vapor \( p_A = \phi \cdot p_{a,sat} = 0.04666 \) bar: \( T_{sat} = 305K = 32°C, h_{fg} = 2426 \) kJ/kg; Table A-6, Water, liquid \( T_f = (T_s + T_{sat})/2 = 297K \): \( c_{p,l} = 4180 \) J / kg \cdot K.

ANALYSIS: From Eq. 10.33, the condensate rate per unit length is

\[
\dot{m}' = \frac{q'}{h'_{fg}} = \frac{h_L (\pi D)(T_{sat} - T_s)}{h'_{fg}}
\]

where from Eq. 10.26, with \( J_a = c_{p,l} (T_{sat} - T_s)/h_{fg} \),

\[
h'_{fg} = h_{fg} \left[ 1 + 0.68Ja \right] = 2426 \frac{kJ}{kg} \left[ 1 + 0.68 \times 4180J/kg \cdot K \times (305-288)K/2426kJ/kg \right]
\]

\[
h'_{fg} = 2474kJ/kg.
\]

Note that \( T_{sat} \) is the saturation temperature of the water vapor in air at 37°C having a relative humidity, \( \phi = 0.75 \). That is, \( T_{sat} = 305K \) and \( T_s = 15°C + 288K \). For drop-wise condensation, the correlation of Eq. 10.44 yields

\[
\overline{h}_{dc} = 51.104 + 2044T_{sat} \quad 22°C < T_{sat} < 100°C
\]

where the units of \( \overline{h}_{dc} \) and \( T_{sat} \) are W/m²·K and °C.

\[
\overline{h}_{dc} = 51.104 + 2044(32°C) = 116,510 \text{ W / m}^2 \cdot \text{K}.
\]

Hence, the condensation rate is

\[
\dot{m}' = 116,510 \text{ W / m}^2 \cdot \text{K} (\pi \times 0.025m)(305 - 288)K/2474\times10^3 \text{ J/kg}
\]

\[
\dot{m}' = 6.288 \times 10^{-2} \text{ kg/s · m}
\]

COMMENTS: From the result of Problem 10.54 assuming laminar film condensation, the condensation rate was \( \dot{m}'_{film} = 4.28 \times 10^{-3} \) kg/s · m which is an order of magnitude less than for the rate assuming drop-wise condensation.
PROBLEM 10.66

KNOWN: Beverage can at 5°C is placed in a room with ambient air temperature of 32°C and relative humidity of 75%.

FIND: The condensate rate for (a) drop-wise and (b) film condensation.

SCHEMATIC:

ASSUMPTIONS: (1) Condensation on top and bottom surface of can neglected, (2) Negligible non-condensibles in water vapor-air, and (b) For film condensation, film thickness is small compared to diameter of can.

PROPERTIES: Table A-6, Water vapor (T_{\infty} = 32°C = 305 K): p_{A,sat} = 0.04712 bar; Water vapor (p_{A} = \phi p_{A,sat} = 0.03534 bar): T_{sat} = 300 K = 27°C, h_{fg} = 2438 kJ/kg; Water, liquid (T_f = (T_s + T_{sat})/2 = 289 K): c_{p,\ell} = 4185 J/kg·K.

ANALYSIS: From Eq. 10.33, the condensate rate is

$$\dot{m} = \frac{q}{h'_{fg}} = \frac{h(\pi DL)(T_{sat} - T_s)}{h_{fg}}$$

where from Eq. 10.26, with Ja = c_{p,\ell} (T_{sat} - T_s)/h_{fg},

$$h'_{fg} = h_{fg} \left[1 + 0.68 \text{Ja}\right]$$

$$h'_{fg} = 2438 \text{kJ/kg} \left[1 + 0.68 \times 4185 \text{ J/kg·K} \left(300 - 278\right)\text{K} / 2438 \text{kJ/kg}\right]$$

$$h'_{fg} = 2501 \text{kJ/kg}$$

Note that T_{sat} is the saturation temperature of the water vapor in air at 32°C having a relative humidity of \(\phi_{\infty} = 0.75\).

(a) For drop-wise condensation, the correlation of Eq. 10.44 with T_{sat} = 300 K = 27°C yields

$$\bar{h} = \bar{h}_{dc} = 51,104 + 2044 \ T_{sat}$$

22°C < T_{sat} ≤ 100°C

where the units of \(\bar{h}_{dc}\) are W/m²·K and T_{sat} are °C,

$$\bar{h}_{dc} = 51,104 + 2044 \times 27 = 106,292 \ W / m^2 \cdot K$$

Hence, the condensation rate is

$$\dot{m} = 1.063 \times 10^5 \text{W/m}^2 \cdot K (\pi \times 0.065 \text{ m} \times 0.125 \text{ m}) (27 - 5) \text{K} / 2501 \text{kJ/kg}$$

$$\dot{m} = 0.0229 \text{kg/s}$$

Continued …..
(b) For film condensation, we used the IHT tool Correlations, Film Condensation, which is based upon Eqs. 10.37, 10.38 or 10.39 depending upon the flow regime. The code is shown in the Comments section, and the results are

\[
\text{Re}_\delta = 24, \text{ flow is laminar} \quad \dot{m} = 0.00136 \text{ kg/s}
\]

Note that the film condensation rate estimate is nearly 20 times less than for drop-wise condensation.

**COMMENTS:** The IHT code identified in part (b) follows:

PROBLEM 10.66 (Cont.)
PROBLEM 10.67

KNOWN: Surface temperature and area of integrated circuits submerged in a dielectric fluid of prescribed properties. Height and temperature of condenser plates.

FIND: (a) Heat dissipation by an integrated circuit, (b) Condenser surface area needed to balance heat load.

SCHEMATIC:

ASSUMPTIONS: (1) Nucleate pool boiling in liquid, (2) Laminar film condensation of vapor, (3) Negligible heat loss to surroundings.

PROPERTIES: Dielectric fluid (given, \( T_{\text{sat}} = 50^\circ C \)):
- \( \rho_\ell = 1700 \text{kg/m}^3 \)
- \( c_{p,\ell} = 1005 \text{J/kg} \cdot \text{K} \)
- \( \mu_\ell = 6.8 \times 10^{-4} \text{kg/s} \cdot \text{m} \)
- \( k_\ell = 0.062 \text{W/m} \cdot \text{K} \)
- \( Pr_\ell = 11 \)
- \( \sigma = 0.013 \text{kg/s}^2 \)
- \( h_{fg} = 1.05 \times 10^5 \text{J/kg} \)
- \( C_{s,f} = 0.004 \)
- \( n = 1.7 \)

ANALYSIS:
(a) For nucleate pool boiling,

\[
q_s = \mu_\ell h_{fg} \left( \frac{g (\rho_\ell - \rho_\ell)}{\sigma} \right)^{1/2} \left( \frac{c_{p,\ell} \Delta T_c}{C_{s,f} h_{fg} Pr_\ell^n} \right)^3 \approx 6.8 \times 10^{-4} \text{kg/s} \cdot \text{m} \left( 1.05 \times 10^5 \text{J/kg} \right)
\]

\[
\times \left[ \frac{9.8 \text{m/s}^2 \times 1700 \text{kg/m}^3}{0.013 \text{kg/s}^2} \right]^{1/2} \left[ \frac{1005 \text{J/kg} \cdot \text{K} \times 25 \text{K}}{0.004 \times 1.05 \times 10^5 \text{J/kg} \times 11^{1.7}} \right] = 84.530 \text{W/m}^2
\]

\[
q_s = A_c q_s = 84.530 \text{W/m}^2 \times 25 \times 10^{-6} \text{m}^2 = 2.11 \text{W}.
\]

(b) For laminar film condensation on a vertical surface,

\[
\frac{h_{fg}'}{h_{fg}} = 1 + 0.68 \frac{c_{p,\ell} \Delta T}{h_{fg}} = 1.05 \times 10^5 + 0.68 \left( 1005 \text{J/kg} \cdot \text{K} \times 35 \text{K} \right) = 1.29 \times 10^5 \text{J/kg}
\]

\[
\bar{Nu}_L = 0.943 \left[ \frac{9.8 \text{m/s}^2 \times 1700 \text{kg/m}^3}{6.8 \times 10^{-4} \text{kg/s} \cdot \text{m} \times 0.062 \text{W/m} \cdot \text{K} \times 35 \text{K}} \right]^{1/4} = 703
\]

\[
h_L = \left( k_\ell / L \right) \bar{Nu}_L = (0.062 \text{W/m} \cdot \text{K} \times 0.05 \text{m}) \times 703 = 872 \text{W/m}^2 \cdot \text{K}
\]

\[
q_c = h_L A_c (T_{\text{sat}} - T_c) = 872 \text{W/m}^2 \cdot \text{K} \times 35 \text{K} \times A_c = 30,500 A_c \left( \text{m}^2 \right)
\]

To balance the heat load, \( q_c = N q_s \).

\[
A_c = \frac{500 \times 2.11 \text{W}}{30,500 \text{W/m}^2} = 0.0346 \text{m}^2
\]

COMMENTS: (1) With \( A_c = 0.0346 \text{m}^2 \) and \( H = 0.05 \text{m} \), the total condenser width is \( W = A_c / H = 692 \text{mm} \). (2) With \( \dot{m}_c / b = \Gamma = q_c / h_{fg} \), \( W = 1055 \text{W} / 1.29 \times 10^5 \text{J/kg} \times 0.692 \text{m} = 0.0118 \text{kg/s} \cdot \text{m} \), \( \text{Reg}_b = 4 \Gamma / \mu_\ell = 4(0.0118 \text{kg/s} \cdot \text{m}) / 68 \times 10^{-4} \text{kg/s} \cdot \text{m} = 69.4 \).

Hence condensate film is in the laminar-wavy regime, and a more accurate estimate of \( A_c \) would require iteration.
PROBLEM 10.68

KNOWN: Thin-walled thermosyphon. Absorbs heat by boiling saturated water at atmospheric pressure on boiling section \( L_b \). Rejects heat by condensing vapor into a thick film which falls length of condensation section \( L_c \) back into boiling section.

FIND: (a) Mean surface temperature, \( T_{s,b} \), of the boiling surface if nucleate boiling flux is 30% critical flux, (b) Mean surface temperature, \( T_{s,c} \), of condensation section, and (c) Total condensation flow rate, \( \dot{m} \), in thermosyphon. Explain how to determine whether film is laminar, wavy-laminar or turbulent.

SCHEMATIC:

Assumptions: (1) Laminar film condensation occurs in condensation section which approximates a vertical plate, (2) Boiling and condensing section are separated by insulated length \( L_i \), (3) Top surface of condensation section is insulated, (4) For condensation, liquid properties evaluated at \( T_f = 90^\circ C \).

Properties: Table A-6, Saturated water (100°C): \( \rho_{\ell} = 1/\nu_f = 957.9 \text{ kg/m}^3 \), \( c_{p,\ell} = 4217 \text{ J/kg} \cdot \text{K} \), \( \mu_{\ell} = 279 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 \), \( \text{Pr}_{\ell} = 1.76 \), \( h_{fg} = 2257 \text{ kJ/kg} \), \( \sigma = 58.9 \times 10^{-3} \text{ N/m} \); Saturated vapor (100°C): \( \rho_v = 1/\nu_g = 0.5955 \text{ kg/m}^3 \); Saturated water (90°C): \( \rho_{\ell} = 1/\nu_f = 964.9 \text{ kg/m}^3 \), \( c_{p,\ell} = 4207 \text{ J/kg} \cdot \text{K} \), \( \mu_{\ell} = 313 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 \), \( k = 0.676 \text{ W/m K} \).

Analysis: (a) The heat flux for the boiling section is 30% the critical heat flux which at atmospheric pressure is

\[ q_{s,b}^* = 0.30q_{\text{max}}^* = 0.30 \times 1.26 \times 10^6 \text{ W/m}^2 = 3.78 \times 10^5 \text{ W/m}^2. \]

Using the Rohsenow correlation for nucleate boiling with \( T_{\text{sat}} = 100^\circ C \) and typical values for the surface of \( C_{s,f} = 0.0130 \text{ and } n = 1.0 \), find

\[ q_{s,b}^* = \mu_{\ell} h_{fg} \left[ \frac{g (\rho_{\ell} - \rho_v)}{\sigma} \right]^{1/2} \left[ \frac{c_{p,\ell} (T_{s,b} - T_{\text{sat}})}{C_{s,f} h_{fg} \text{Pr}_{\ell}^n} \right]^{3/2} \]

\[ 3.78 \times 10^5 \text{ W/m}^2 = 279 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 \times 2257 \times 10^3 \text{ J/kg} \times \]

\[ \left[ \frac{9.8 \text{ m/s}^2 (957.9 - 0.5955) \text{ kg/m}^3}{58.9 \times 10^{-3} \text{ N/m}} \right]^{1/2} \left[ \frac{4217 \text{ J/kg} \cdot \text{K} (T_{s,b} - 100)}{0.013 \times 2257 \times 10^3 \text{ J/kg} \cdot \text{K} \cdot 1.76^{1.0}} \right]^{3/2} \]

Continued …..
T_{s,b} = 114.0^\circ \text{C}.

(b) The heat transferred into the boiling section must be rejected by film condensation,

\[ q_c = q_b = q_{s,b}^* = \pi D^2 / 4 + \pi DL_b \]  
\[ q_c = 3.78 \times 10^5 \text{ W/m}^2 \left( \pi (0.020 \text{m})^2 / 4 + \pi (0.020 \text{m}) \times 0.020 \text{m} \right) = 592 \text{ W}. \]

The mean surface temperature can be determined from the rate equation

\[ q_c = h_{Lc} (\pi D L_c) (T_{\text{sat}} - T_{s,c}) \]

where the convection coefficient is determined from Eq. 10.30,

\[ h_{Lc} = 0.943 \left[ \frac{g \rho \ell (\rho \ell - \rho \nu) k^3 \ell h_{fg}'}{\mu \ell (T_{\text{sat}} - T_{s,c}) L_c} \right]^{1/4} \]

\[ \bar{h}_{Lc} = 0.943 \left[ \frac{9.8 \text{ m/s}^2 \times 964.9 \text{ kg/m}^3 \times (964.9 - 0.5955) \text{ kg/m}^3 \times 0.676 \text{ W/m} \cdot \text{K} \times 2257 \times 10^3 \text{ J/kg}}{313 \times 10^6 \text{ N} \cdot \text{s} / \text{m}^2 \times (100 - T_{s,c}) \times 0.040 \text{ m}} \right]^{1/4} \]

where \( h_{fg}' = h_{fg'} \left\{ 1 + 0.68 \cdot c_p \cdot \ell \left( T_{\text{sat}} - T_{s,c} \right) / h_{fg} \right\} \)

\[ h_{fg'} = 2257 \times 10^3 \text{ J/kg} \left\{ 1 + 0.68 \times 4207 \text{ J/kg} \cdot \text{K} \left( 100 - T_{s,c} \right) / 2257 \times 10^3 \text{ J/kg} \right\} = 2257 \times 10^3 \text{ J/kg}. \]

Hence,

\[ \bar{h}_{Lc} = 2.517 \times 10^4 (100 - T_{s,c})^{-1/4}. \]

Using the rate equation, now find \( T_{s,c} \) by trial-and-error,

\[ 592 \text{ W} = 2.517 \times 10^4 (100 - T_{s,c})^{-1/4} \left( \pi \times 0.020 \text{m} \times 0.040 \text{m} \right) (100 - T_{s,c}) \text{ K} \]

\[ 9.358 = (100 - T_{s,c})^{0.75} \]

\[ T_{s,c} = 80.3^\circ \text{C}. \]

(c) The condensation rate in the condenser section is

\[ \dot{m} = q_c / h_{fg'} = 592 \text{ W} / \left( 2257 \times 10^3 \text{ J/kg} \right) = 2.623 \times 10^{-4} \text{ kg/s} \]

and from Eq. 10.35,

\[ \text{Re}_\delta = \frac{4 \dot{m}}{\rho \ell b} = \frac{4 \dot{m}}{\mu \ell (\pi D)} = \frac{4 \times 2.623 \times 10^{-4} \text{ kg/s}}{313 \times 10^{-6} \text{ N} \cdot \text{s} / \text{m}^2 (\pi \times 0.020 \text{m})} = 53.3. \]

Since 30 < Re_\delta < 1800, we conclude the film is laminar-wavy.
**Problem 10.69**

**Known:** Thermosyphon configuration for cooling a computer chip of prescribed size.

**Find:** (a) Chip temperature and total power dissipation when chip operates at 90% of critical heat flux, (b) Required condenser length.

**Schematic:**

**Assumptions:** (1) Steady-state, (2) Saturated liquid/vapor conditions, (3) Negligible heat transfer from bottom of chip.

**Properties:** Fluorocarbon (prescribed): $T_{\text{sat}} = 57^\circ C$, $c_{p,\ell} = 1100$ J/kg·K, $h_g = 84,400$ J/kg, $\rho_\ell = 1619.2$ kg/m$^3$, $\rho_v = 13.4$ kg/m$^3$, $\sigma = 8.1 \times 10^{-3}$ kg/s$^2$, $\mu_\ell = 440 \times 10^6$ kg/m·s, $Pr_\ell = 9.01$, $k_\ell = 0.054$ W/m·K, $\nu_\ell = \mu_\ell / \rho_\ell = 0.272 \times 10^{-6}$ m$^2$/s.

**Analysis:** (a) With $q^* = 0.9$ $q_{\text{max}}^*$ and the critical heat flux given by Eq. 10.7, the chip power dissipation is

$$q = 0.9L_c^2 \times 0.149h_{fg}\rho_v \left[ \frac{\sigma \left( \rho_\ell - \rho_v \right)}{\rho_v^2} \right]^{1/4}$$

$$q = 0.9 \left(0.02 \text{ m}^2\right) \times 0.149 \left(84,400 \text{ J/kg}\right)13.4 \text{ kg/m}^3 \left[ \frac{0.0081 \text{ kg/s}^2 \left(9.8 \text{ m/s}^2\right) \left(1605.8 \text{ kg/m}^3\right)}{\left(13.4 \text{ kg/m}^3\right)^2} \right]^{1/4}$$

$$q_c = 0.9 \left(4 \times 10^{-4} \text{ m}^2\right)1.55 \times 10^5 \text{ W/m}^2 = 55.7 \text{ W}$$

With operation at $q^* = 1.40 \times 10^5$ W/m$^2$ in the nucleate boiling region, Eq. 10.5 yields

$$T = T_{\text{sat}} + \frac{C_{s,\ell} h_{fg} Pr_{\ell}^{1/3} \left(\frac{q^*}{\mu_\ell h_{fg}}\right)^{1/3} \left[ \frac{\sigma}{g \left( \rho_\ell - \rho_v \right)} \right]}{c_{p,\ell}}$$

$$T = 57^\circ C + \frac{0.005 \left(84,400 \text{ J/kg}\right) \left(9.01\right)^{1.7} \left(1.40 \times 10^5 \text{ W/m}^2\right)}{1100 \text{ J/kg·K} \left(4.4 \times 10^{-4} \text{ kg/m·s} \times 84,400 \text{ J/kg}\right)} \left[ \frac{0.0081 \text{ kg/s}^2 \left(9.8 \text{ m/s}^2\right) \left(1605.8 \text{ kg/m}^3\right)}{\left(13.4 \text{ kg/m}^3\right)^2} \right]^{1/6}$$

Continued...
PROBLEM 10.69 (Cont.)

\[ T = 57^\circ C + 22.4^\circ C = 79.4^\circ C \]

(b) The power dissipated by the chip must be balanced by the rate of heat transfer from the condensing section. Hence, with \( A = \pi DL \), Eq. 10.32 yields the requirement that

\[
\overline{h}_L L = \frac{q}{\pi D (T_{\text{sat}} - T_s)} = \frac{55.7 \text{ W}}{\pi (0.03 \text{ m})(32^\circ \text{C})} = 18.5 \text{ W/m K}
\]

To determine \( \overline{h}_L \), we combine Eqs. 10.33 and 10.35 to obtain \( \text{Re}_\delta = 4q/\mu \ell bh_{fg} \), where \( b = \pi D = 0.0942 \) m and \( h_{fg} = h_{fg} + 0.68c_p,T_s (T_{\text{sat}} - T_s) = 84,400 \text{ J/kg} + 0.68(1100 \text{ J/kg} \cdot \text{K})32^\circ \text{C} = 108,300 \text{ J/kg} \). Hence, \( \text{Re}_\delta = 4(55.7 \text{ W})/4.4 \times 10^4 \text{ kg/m-s}(0.0942 \text{ m})108,300 \text{ J/kg} = 49.6 \) and the condensate film is in the laminar-wavy region. Hence, from Eq. 10.38

\[
\overline{h}_L = \frac{k_\ell}{(\nu^2/g)^{1/3}} \frac{\text{Re}_\delta}{1.08 \text{Re}_\delta^{12/6} - 5.2} = \frac{0.054 \text{ W/m K} \times 0.409}{(0.272 \times 10^{-6} \text{ m}^2/\text{s})^2/9.8 \text{ m/s}^2}^{1/3} = 1130 \text{ W/m}^2\cdot\text{K}
\]

in which case,

\[
L = \frac{18.5 \text{ W/m K}}{1130 \text{ W/m}^2\cdot\text{K}} = 0.0164 \text{ m} = 16.4 \text{ mm}
\]

COMMENTS: The chip operating temperature \( T = 79.4^\circ \text{C} \) is not excessive, and the proposed scheme provides a compact means of cooling high performance chips.
**PROBLEM 10.70**

**KNOWN:** Copper plate, 2m × 2m, in a condenser-boiler section maintained at \( T_s = 100°C \) separates condensing saturated steam and nucleate-pool boiling of saturated liquid X.

**FIND:** (a) Rates of evaporation and condensation (kg/s) for the two fluids and (b) Saturation temperature \( T_{\text{sat}} \) and pressure \( p \) for the steam, assuming that film condensation occurs.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Isothermal copper plate.

**PROPERTIES:**
- **Fluid-X** (Given, 1 atm): \( T_{\text{sat}} = 80°C \), \( h_{fg} = 700 \text{ kJ/kg} \), portion of boiling curve shown above for operating condition, \( \Delta T_c = T_s - T_{\text{sat}} = (100 - 80)^°C = 20°C \), \( q_s^* = 5 \times 10^4 \text{ W/m}^2 \); *Table A.4*,
- **Water** (saturated, 1 atm): \( T_{\text{sat}} = 100°C \), \( h_{fg} = 2.25 \times 10^6 \text{ J/kg} \);
- **Water** (saturated, \( T_{\text{sat}} \)): as required in part (b);
- **Water** (saturated, \( T_f = (T_{\text{sat}} + T_s)/2 \)): as required in part (b).

**ANALYSIS:**

(a) For fluid-X, with \( \Delta T_c = T_s - T_{\text{sat}} = (100 - 80)^°C = 20 K \), the heat flux from the boiling curve is

\[
q_s^* = 50,000 \text{ W/m}^2
\]

and the heat rate from the copper plate section into liquid-X is

\[
q_s = q_s^* \times A_s = 50,000 \text{ W/m}^2 \times (2 \times 2) \text{ m}^2 = 200,000 \text{ W}
\]

From an energy balance around liquid-X, the evaporation rate for fluid-X is

\[
\dot{m}_X = \frac{q_s}{h_{fg,X}} = \frac{200,000 \text{ W}}{700,000 \text{ J/kg}} = 0.286 \text{ kg/s}
\]

The heat rate into the copper plate section from the steam is \( q_s = 200,000 \text{ W} \), and from an energy balance around the condensate film, the condensation rate for steam (w) is

\[
\dot{m}_w = \frac{q_s}{h_{fg,w}} = \frac{200,000 \text{ W}}{2.25 \times 10^6 \text{ J/kg}} = 0.0889 \text{ kg/s}
\]

where we are assuming that \( T_{\text{sat},w} \) is only a few degrees above \( T_s \) so that \( h_{fg} \approx h_{fg,w} \).

(b) The condensation heat rate, Eq. 10.32 can be expressed as

\[
q_s = \tilde{h}_L A_s (T_{\text{sat}} - T_s)
\]

and assuming laminar film condensation, Eq. 10.30,

\[
\tilde{h}_L = 0.943 \left[ \frac{g \rho_l (\rho_l - \rho_v) k_l^3 h_{fg}^*}{\mu_l k_l (T_{\text{sat}} - T_s)} \right]^{1/4}
\]

Continued...
Recognize that with \( q_s, A_s \) and \( T_s \) known, this relation can be used to determine \( T_{sat} \), and from the steam table, the corresponding \( p_{sat} \) can be found. The vapor properties \( (\gamma) \) are evaluated at \( T_{sat} \) while the liquid properties \( (\ell) \) are evaluated at the film temperature \( T_f = (T_{sat} + T_s)/2 \). An iterative solution is required, beginning by assuming a value for \( T_{sat} \), evaluate properties and check whether the rate equation returns the assumed value for \( T_{sat} \). Using the IHT Correlations Tool, Film Condensation, Vertical Plate for the laminar region, the results are

\[
T_{sat} = 381.7 \, \text{K} \quad \text{and} \quad p_{sat} = 1.367 \, \text{bar}
\]

for which \( \text{Re}_5 = 661 \), so that the flow is wavy-laminar, not laminar. Repeating the analysis but with the IHT Tool for the laminar, wavy-laminar, turbulent regions, the results with \( \text{Re}_5 = 652 \) are

\[
T_{sat} = 379.6 \, \text{K} \quad \text{and} \quad p_{sat} = 1.27 \, \text{bar}
\]

**COMMENTS:** A copy of the IHT model for determining \( T_{sat} \) and \( p_{sat} \) for part (b) is shown below.

```
// Correlations Tool -
//Film Condensation, Vertical Plate, laminar, wavy-laminar, turbulent regions
NuLbar = NuL_bar_FCO_VP(Redelta,PrI) // Eq 10.37, 38, 39
NuLbar = hLbar * (nuL^2 / g)^(1/3) / kl

// Assigned Variables:
L = 2 // Plate height, m
b = 2 // Plate width, m

//q = 200000 // Heat rate, W; required heat rate for suitable Tsat
```

```
// Water property functions : T dependence, From Table A.6
// Units: T(K), p(bars);

xl = 0 // Quality (0=sat liquid or 1=sat vapor)
pl = psat_T("Water", Tf) // Saturation pressure, bar
vl = v_Tx("Water",Tf,xl) // Specific volume, m^3/kg
rho = rho_Tx("Water",Tf,xl) // Density, kg/m^3
cp = cp_Tx("Water",Tf,xl) // Specific heat, J/kg·K
m = mu_Tx("Water",Tf,xl) // Viscosity, N·s/m^2
nul = nu_Tx("Water",Tf,xl) // Kinematic viscosity, m^2/s
kl = k_Tx("Water",Tf,xl) // Thermal conductivity, W/m·K
Pr = Pr_Tx("Water",Tf,xl) // Prandtl number
```

```
// Properties Tool - Water:
// Water property functions : T dependence, From Table A.6
// Units: T(K), p(bars);

xv = 1 // Quality (0=sat liquid or 1=sat vapor)
pv = psat_T("Water", Tsat) // Saturation pressure, bar
vv = v_Tx("Water",Tsat,xv) // Specific volume, m^3/kg
rho = rho_Tx("Water",Tsat,xv) // Density, kg/m^3
hfg = hfg_T("Water",Tsat) // Heat of vaporization, J/kg
cpv = cp_Tx("Water",Tsat,xv) // Specific heat, J/kg·K
muv = mu_Tx("Water",Tsat,xv) // Viscosity, N·s/m^2
nuv = nu_Tx("Water",Tsat,xv) // Kinematic viscosity, m^2/s
```

```
// Comments:
A copy of the IHT model for determining T_sat and p_sat for part (b) is shown below.
```
**PROBLEM 10.71**

**KNOWN:** Thin-walled container filled with a low boiling point liquid (A) at $T_{sat,A}$. Outer surface of container experiences laminar-film condensation with the vapor of a high-boiling point fluid (B). Laminar film extends from the location of the liquid-A free surface. The heat flux for nucleate pool boiling in liquid-A along the container wall is given as $q_{npb}'' = C(T_s - T_{sat,A})^3$, where $C$ is a known empirical constant.

**FIND:** (a) Expression for the average temperature of the container wall, $T_s$; assume that the properties of fluids A and B are known; (b) Heat rate supplied to liquid-A, and (c) Time required to evaporate all the liquid-A in the container, assuming that initially the container is filled, $y = L$.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Nucleate pool boiling occurs on the inner surface of the container with liquid-A, (2) Laminar film condensation occurs on the outer surface of the container with fluid-B over the liquid-A free surface, $y$, and (3) Negligible wall thermal resistance.

**ANALYSIS:** (a) Perform an energy balance on the control surface about the container wall along locations experiencing boiling (A) and condensation (B) as shown in the schematic above.

\[
\dot{E}_{in}'' - \dot{E}_{out}'' = 0 \\
q_{cond}'' - q_{npb}'' = 0
\]

\[
\bar{h}_y (\pi D y) (T_{sat,B} - T_s) - (\pi D y) C (T_s^3 - T_{sat,A}) = 0
\]

\[
\bar{h}_y (T_{sat,B} - T_s) = C (T_s - T_{sat,A})^3
\]

where $\bar{h}_y$ is the average convection coefficient for laminar film condensation over the surface length 0 to $y$. From Eq. 10.30 and 10.26,

Continued...
PROBLEM 10.71 (Cont.)

\[
\overline{h}_y = 0.943 \left[ \frac{g \rho_\ell (\rho_\ell - \rho_v) k_\ell^3 h_{fg}'}{\mu_\ell (T_{sat} - T_s) y} \right]_{B}^{1/4} \tag{3}
\]

\[
h_{fg}' = h_{fg,B} + 0.68c_p,B (T_{sat,B} - T_s) \tag{4}
\]

where the properties are for fluid-B.

(b) The heat flux supplied to liquid-A is, from Eq. (2), \( q_{\text{cond}}^{\ast} = q_{\text{npb}}^{\ast} \). Since \( \overline{h}_y \) is a function of \( y, T_s \) and, hence, the heat fluxes will be functions of \( y \), the height of liquid A in the container.

(c) To determine the dry-out time, \( t_f \), begin with an energy balance on the inside of the container (fluid-A). The heat transfer supplied to liquid-A results in an evaporation rate of liquid-A,

\[
q_{\text{npb}}^{\ast} (\pi D y) \frac{dM}{dt} h_{fg} = 0 \tag{4}
\]

where \( M \) is the mass of liquid-A in the container,

\[
M = \rho_{\ell,A} \left( \pi D^2 / 4 \right) y \tag{5}
\]

Substituting Eq. (5) into (4), separating variables and identifying integration limits, find

\[
C \left( T_s - T_{sat,A} \right)^3 (\pi D y) = \frac{d}{dt} \left[ \rho_{\ell,A} \left( \pi D^2 / 4 \right) y \right] h_{fg} \]

\[
\int_0^{t_f} dt = t_f = \frac{1}{C \pi D} \int_0^L \frac{dy}{\left( T_s - T_{sat,A} \right)^3} \tag{6}
\]

The definite integral could be numerically evaluated using values for \( T_s(y) \) obtained by solving Eq. (3).
PROBLEM 11.1

KNOWN: Initial overall heat transfer coefficient of a fire-tube boiler. Fouling factors following one year’s application.

FIND: Whether cleaning should be scheduled.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible tube wall conduction resistance, (2) Negligible changes in $h_c$ and $h_h$.

ANALYSIS: From Equation 11.1, the overall heat transfer coefficient after one year is

$$\frac{1}{U} = \frac{1}{h_i} + \frac{1}{h_o} + R_{f,i}^{*} + R_{f,o}^{*}.$$  

Since the first two terms on the right-hand side correspond to the reciprocal of the initial overall coefficient,

$$\frac{1}{U} = \frac{1}{400 \text{ W} / \text{m}^2 \cdot \text{K}} + (0.0015 + 0.0005) \text{ m}^2 \cdot \text{K} / \text{W} = 0.0045 \text{ m}^2 \cdot \text{K} / \text{W}$$

$$U = 222 \text{ W} / \text{m}^2 \cdot \text{K}.$$  

COMMENTS: Periodic cleaning of the tube inner surfaces is essential to maintaining efficient fire-tube boiler operations.
PROBLEM 11.2

KNOWN: Type-302 stainless tube with prescribed inner and outer diameters used in a cross-flow heat exchanger. Prescribed fouling factors and internal water flow conditions.

FIND: (a) Overall coefficient based upon the outer surface, $U_o$, with air at $T_o = 15^\circ C$ and velocity $V_o = 20$ m/s in cross-flow; compare thermal resistances due to convection, tube wall conduction and fouling; (b) Overall coefficient, $U_o$, with water (rather than air) at $T_o = 15^\circ C$ and velocity $V_o = 1$ m/s in cross-flow; compare thermal resistances due to convection, tube wall conduction and fouling; (c) For the water-air conditions of part (a), compute and plot $U_o$ as a function of the air cross-flow velocity for $5 \leq V_o \leq 30$ m/s for water mean velocities of $u_{m,i} = 0.2, 0.5$ and $1.0$ m/s; and (d) For the water-water conditions of part (b), compute and plot $U_o$ as a function of the water mean velocity for $0.5 \leq u_{m,i} \leq 2.5$ m/s for air cross-flow velocities of $V_o = 1, 3$ and $8$ m/s.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Fully developed internal flow,

PROPERTIES: Table A.1, Stainless steel, AISI 302 (300 K): $k_w = 15.1 \text{ W/m-K}$; Table A.6, Water ($\bar{T}_{m,i} = 348 \text{ K}$): $\rho_i = 974.8 \text{ kg/m}^3$, $\mu_i = 3.746 \times 10^{-4} \text{ N-s/m}^2$, $k_i = 0.668 \text{ W/m-K}$, $Pr_i = 2.354$; Table A.4, Air (assume $\bar{T}_{f,o} = 315 \text{ K}$, 1 atm): $k_o = 0.02737 \text{ W/m-K}$, $\nu_o = 17.35 \times 10^{-6} \text{ m}^2/\text{s}$, $Pr_o = 0.705$.

ANALYSIS: (a) For the water-air condition, the overall coefficient, Eq. 11.1, based upon the outer area can be expressed as the sum of the thermal resistances due to convection (cv), tube wall conduction (w) and fouling (f):

$$\frac{1}{U_o} A_o = R_{tot} = R_{cv,i} + R_{f,i} + R_w + R_{f,o} + R_{cv,o}$$

$$R_{cv,i} = \frac{1}{\bar{h}_i} A_i \quad \quad R_{cv,o} = \frac{1}{\bar{h}_o} A_o$$

$$R_{f,i} = R_{f,i}^* / A_i \quad \quad R_{f,o} = R_{f,o}^* / A_o$$

and from Eq. 3.28,

$$R_w = \ln \left( \frac{D_o}{D_i} \right) \left( \frac{2\pi Lk_w}{D_i} \right)$$

The convection coefficients can be estimated from appropriate correlations.

Continued...
PROBLEM 11.2 (Cont.)

Estimating \( h_i \): For internal flow, characterize the flow evaluating thermophysical properties at \( T_{m,i} \) with

\[
\operatorname{Re}_{D,i} = \frac{u_{m,i} D_i}{v_i} = \frac{0.5 \text{ m/s} \times 0.022 \text{ m}}{3.746 \times 10^{-4} \text{ N} \cdot \text{s} / \text{m}^2 / 974.8 \text{ kg} / \text{m}^3} = 28,625
\]

For the turbulent flow, use the Dittus-Boelter correlation, Eq. 8.60,

\[
\operatorname{Nu}_{D,i} = 0.023 \operatorname{Re}_{D,i}^{0.8} \operatorname{Pr}_{i}^{0.4}
\]

\[
\operatorname{Nu}_{D,i} = 0.023(28,625)^{0.8}(2.354)^{0.4} = 119.1
\]

\[
\overline{h}_i = \frac{\operatorname{Nu}_{D,i} k_i}{D_i} = 119.1 \times 0.668 \text{ W/m}^2 \cdot \text{K} / 0.022 \text{ m} = 3616 \text{ W/m}^2 \cdot \text{K}
\]

Estimating \( h_o \): For external flow, characterize the flow with

\[
\operatorname{Re}_{D,o} = \frac{V_o D_o}{v_o} = \frac{20 \text{ m/s} \times 0.027 \text{ m}}{17.35 \times 10^{-6} \text{ m}^2 / \text{s}} = 31,124
\]

evaluating thermophysical properties at \( T_{f,o} = (T_{s,o} + T_o)/2 \) when the surface temperature is determined from the thermal circuit analysis result,

\[
\left( \frac{T_{m,i} - T_o}{R_{tot}} \right) = \left( \frac{T_{s,o} - T_o}{R_{cv,o}} \right)
\]

Assume \( T_{f,o} = 315 \text{ K} \), and check later. Using the Churchill-Bernstein correlation, Eq. 7.57, find

\[
\overline{\operatorname{Nu}}_{D,o} = 0.3 + \frac{0.62 \operatorname{Re}_{D,o}^{1/2} \operatorname{Pr}_{o}^{1/3}}{\left[ 1 + (0.4/\operatorname{Pr}_{o})^{2/3} \right]^{1/4}} \left[ 1 + \left( \frac{\operatorname{Re}_{D,o}}{282,000} \right)^{5/8} \right]^{4/5}
\]

\[
\overline{\operatorname{Nu}}_{D,o} = 0.3 + \frac{0.62(31,124)^{1/2}(0.705)^{1/3}}{\left[ 1 + (0.4/0.705)^{2/3} \right]^{1/4}} \left[ 1 + \left( \frac{31,124}{282,000} \right)^{5/8} \right]^{4/5}
\]

\[
\overline{\operatorname{Nu}}_{D,o} = 102.6
\]

\[
\overline{h}_o = \frac{\overline{\operatorname{Nu}}_{D,o} k_o}{D_o} = 102.6 \times 0.02737 \text{ W/m} \cdot \text{K} / 0.027 \text{ m} = 104.0 \text{ W/m} \cdot \text{K}
\]

Using the above values for \( \overline{h}_i \), and \( \overline{h}_o \), and other prescribed values, the thermal resistances and overall coefficient can be evaluated and are tabulated below.

<table>
<thead>
<tr>
<th>( R_{cv,i} ) (K/W)</th>
<th>( R_{i,i} ) (K/W)</th>
<th>( R_w ) (K/W)</th>
<th>( R_{f,i} ) (K/W)</th>
<th>( R_{cv,o} ) (K/W)</th>

<td>0.00216</td>
<td>0.00236</td>
<td>0.1134</td>
<td>92.1</td>
<td>0.128</td>
</tr>
</tbody>
</table>

The major thermal resistance is due to outside (air) convection, accounting for 89% of the total resistance. The other thermal resistances are of similar magnitude, nearly 50 times smaller than \( R_{cv,o} \).

(b) For the water-water condition, the method of analysis follows that of part (a). For the internal flow, the estimated convection coefficient is the same as part (a). For an assumed outer film coefficient, \( T_{f,o} = 292 \text{ K} \), the convection correlation for the outer water flow condition \( V_o = 1 \text{ m/s} \) and \( T_o = 15^\circ \text{C} \), find
PROBLEM 11.2 (Cont.)

\[ \text{Re}_{D,o} = 26,260 \quad \text{Nu}_{D,o} = 220.6 \quad \bar{h}_o = 4914 \text{ W/m}^2 \cdot \text{K} \]

The thermal resistances and overall coefficient are tabulated below.

<table>
<thead>
<tr>
<th>( R_{cv,i} ) (K/W)</th>
<th>( R_{i,i} ) (K/W)</th>
<th>( R_w ) (K/W)</th>
<th>( R_{f,o} ) (K/W)</th>
<th>( R_{cv,o} ) (K/W)</th>
<th>( R_{tot} ) (K/W)</th>
<th>( U_o ) (W/m(^2) K)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.00436</td>
<td>0.00579</td>
<td>0.00216</td>
<td>0.00236</td>
<td>0.00240</td>
<td>0.0171</td>
<td>691</td>
</tr>
</tbody>
</table>

Note that the thermal resistances are of similar magnitude. In contrast with the results for the water-air condition of part (a), the thermal resistance of the outside convection process, \( R_{cv,o} \), is nearly 50 times smaller. The overall coefficient for the water-water condition is 7.5 times greater than that for the water-air condition.

(c) For the water-air condition, using the IHT workspace with the analysis of part (a), \( U_o \) was calculated as a function of the air cross-flow velocity for selected mean water velocities.

![Water (i) - air (o) condition](image)

The effect of increasing the cross-flow air velocity is to increase \( U_o \) since the \( R_{cv,o} \) is the dominant thermal resistance for the system. While increasing the water mean velocity will increase \( \bar{h}_i \), because \( R_{cv,i} \ll R_{cv,o} \), this increase has only a small effect on \( U_o \).

(d) For the water-water condition, using the IHT workplace with the analysis of part (b), \( U_o \) was calculated as a function of the mean water velocity for selected air cross-flow velocities.

![Water (i) - water (o) condition](image)

Because the thermal resistances for the convection processes, \( R_{cv,i} \) and \( R_{cv,o} \), are of similar magnitude according to the results of part (b), we expect to see \( U_o \) significantly increase with increasing water mean velocity and air cross-flow velocity.
PROBLEM 11.3

KNOWN: Copper tube with prescribed inner and outer diameters used in a shell-and-tube heat exchanger. Conditions prescribed for internal water flow and steam condensation on external surface.

FIND: (a) Overall heat transfer coefficient based upon the outer surface area, \( U_o \); compare thermal resistances due to convection, tube wall conduction and condensation, and (b) Compute and plot \( U_o \), water-side convection coefficient, \( h_i \), and steam-side convection coefficient, \( h_o \), as a function of the water flow rate for the range \( 0.2 \leq \dot{m}_i \leq 0.8 \) kg/s.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Fully developed internal flow.

PROPERTIES: Table A.1, Copper, pure (300 K): \( k_w = 401 \) W/m·K; Table A.6, Water (\( T_{m,i} = 298 \) K): \( \mu_i = 8.966 \times 10^{-4} \) N·s/m², \( k_i = 0.6102 \) W/m·K, \( Pr_i = 6.146 \). Table A.6, Water, (assume \( T_{s,o} = 351 \) K, \( T_{f,o} = 362 \) K): \( \rho_f = 965.7 \) kg/m³, \( c_p,f = 4205 \) J/kg·K, \( \mu_f = 3.172 \times 10^{-4} \) N·s/m², \( k_f = 0.6751 \) W/m·K; Table A.6 Water (\( T_{sat} = 373 \) K, 1 atm): \( \rho_v = 0.5909 \) kg/m³, \( h_{fg} = 2257 \) kJ/kg.

ANALYSIS: (a) The overall coefficient, Eq 11.1, based upon the outer surface area can be expressed as the sum of the thermal resistances due to convection (cv), tube wall conduction (w, see Eq. 3.28) and condensation (cnd):

\[
\frac{1}{U_o A_o} = R_{tot} = R_{cv} + R_w + R_{cnd}
\]

\[
R_{cv} = \frac{1}{h_i A_i}
\]

\[
R_w = \ln \left( \frac{D_o}{D_i} \right) / (2\pi L k_w)
\]

\[
R_{cnd} = 1 / h_o A_o
\]

The convection coefficients can be estimated from appropriate correlations.

Estimating \( h_i \): For internal flow, characterize the flow using thermophysical properties evaluated at \( T_{m,i} \) with

\[
Re_{D,i} = \frac{4\dot{m}_i}{\pi D_i \mu_i} = \frac{4 \times 0.2 \text{ kg/s}}{\pi \times 0.013 \text{ m} \times 8.966 \times 10^{-4} \text{ N/s·m}^2} = 21,847
\]

For turbulent flow, use the Dittus-Boelter correlation, Eq. 8.60,

\[
Nu_{D,i} = 0.023 Re_{D,i}^{0.8} Pr_i^{0.4} = 0.023 (21,847)^{0.8} (6.146)^{0.4} = 140.8
\]

\[
h_i = Nu_{D,i} k_i / D_i = 140.8 \times 0.6102 \text{ W/m·K} / 0.013 \text{ m} = 6610 \text{ W/m}^2·\text{K}
\]

Continued...
PROBLEM 11.3 (Cont.)

Estimating \( h_o \): For the horizontal tube, average convection coefficient for film condensation, Eq. 10.40, is

\[
h_o = 0.729 \left[ \frac{g \rho_f (\rho_f - \rho_v) k_f^2 h_{fg}}{\mu_v (T_{sat} - T_{s,o}) D_o} \right]^{1/4}
\]

\[
h_{fg} = h_{fg} + 0.68 \rho_f (T_{sat} - T_{s,o})
\]

The vapor (v) properties and \( h_{fg} \) are evaluated at \( T_{sat} \), while the liquid properties (\( \ell \)) are evaluated at the film temperature \( T_{f,o} = (T_{s,o} - T_{sat}) \)

where the surface temperature is determined from the thermal circuit analysis result,

\[
\frac{(T_{m,i} - T_{sat})}{R_{tot}} = \frac{(T_{s,o} - T_{sat})}{R_{cnd}}
\]

Assume \( T_{s,o} = 351 \text{ K} \) so that \( T_{f,o} = 362 \text{ K} \), and check later. Hence,

\[
h_o = 0.729 \left[ \frac{9.8 \text{ m/s}^2 \times 965.7 \text{ kg/m}^3 \times (965.7 - 0.5909) \text{ kg/m}^3 \times (0.6751 \text{ W/m K})^3 \times 2321 \text{ kJ/kg}}{3.172 \times 10^{-4} \text{ N s/m}^2 \times (373 - 351) \text{ K} \times 0.018 \text{ m}} \right]^{1/4}
\]

\[
h_o = 11,005 \text{ W/m}^2 \cdot \text{K}
\]

Using the above values for \( h_v, h_o \) and other prescribed values, the thermal resistances and overall coefficient can be evaluated and are tabulated below.

\[
\begin{array}{cccccc}
 & R_{cv} \times 10^3 & R_w \times 10^3 & R_{cnd} \times 10^3 & R_{sat} \times 10^3 & U_o \\
 & \text{(K/W)} & \text{(K/W)} & \text{(K/W)} & \text{(K/W)} & \text{(W/m}^2 \cdot \text{K)} \\
3.704 & 1.292 & 1.610 & 5.444 & 3249
\end{array}
\]

The largest resistance is that due to convection on the water-side. Interestingly, the wall thermal resistance for the pure copper, while the smallest for all the process, is still significant relative to that for the condensation process.

(b) The foregoing relations were entered into the IHT workspace along with the Correlations Tools for Forced Convection, Internal Flow, Turbulent Flow and for Film Condensation, Horizontal Cylinder with the appropriate Properties Tools for Air and Water. The coefficients \( U_o, h_i \) and \( h_o \) were computed and plotted as a function of the water flow rate.

Note that the overall coefficient increases nearly 50\% over the range of the water flow rate. The water-side coefficient increases markedly, by nearly a factor of 4, with increasing flow rate. The steam-side coefficient, \( h_o \), is larger than \( h_i \) by a factor of 2 at the lowest flow rate. However, \( h_o \) decreases with increasing water flow rate since the tube wall temperature, \( T_{s,o} \), decreases causing the water film thickness to increase with the net effect of reducing \( h_o \).
**PROBLEM 11.4**

**KNOWN:** Dimensions of heat exchanger tube with or without fins. Cold and hot side convection coefficients.

**FIND:** Cold side overall heat transfer coefficient without and with fins.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible fouling, (2) Negligible contact resistance between fins and tube wall, (3) \( h \) is not affected by fins, (4) One-dimensional conduction in fins, (5) Adiabatic fin tip.

**ANALYSIS:** From Eq. 11.1,

\[
\frac{1}{U_c} = \frac{1}{(\eta_0 h)_c} + \frac{D_t \ln \left( \frac{D_o}{D_i} \right)}{2k} + \frac{A_c}{(\eta_0 h A)_h}
\]

Without fins: \( \eta_{o,c} = \eta_{o,h} = 1 \)

\[
\frac{1}{U_c} = \frac{1}{8000 \text{ W/m}^2 \cdot \text{K}} + \frac{0.02 \text{ m} \ln \left( \frac{26}{20} \right)}{100 \text{ W/m} \cdot \text{K}} + \frac{1}{200 \text{ W/m}^2 \cdot \text{K}} 26
\]

\[
1/U_c = \left(1.25 \times 10^{-4} + 5.25 \times 10^{-5} + 3.85 \times 10^{-3}\right) \text{ m}^2 \cdot \text{K}/\text{W} = 4.02 \times 10^{-3} \text{ m}^2 \cdot \text{K}/\text{W}
\]

\[
U_c = 249 \text{ W/m}^2 \cdot \text{K}.
\]

With fins: \( \eta_{o,c} = 1, \eta_{o,h} = 1 - (A_f / A)(1 - \eta_f) \) Per unit length along the tube axis,

\[
A_f = N \left(2L_f + t\right) = 16(30 + 2) \text{ mm} = 512 \text{ mm}
\]

\[
A_h = A_f + (\pi D_o - 16t) = (512 + 81.7 - 32) \text{ mm} = 561.7 \text{ mm}
\]

With

\[
m = (2h/kt)^{1/2} = \left(400 \text{ W/m}^2 \cdot \text{K} / 50 \text{ W/m} \cdot \text{K} \times 0.002 \text{ m}\right)^{1/2} = 63.3 \text{ m}^{-1}
\]

\[
mL_f = \left(63.3 \text{ m}^{-1}\right)(0.015 \text{ m}) = 0.95
\]

and Eq. 11.4 yields

\[
\eta_f = \tanh \left(mL_f \right)/mL_f = 0.739/0.95 = 0.778.
\]

The overall surface efficiency is then

\[
\eta_o = 1 - (A_f / A_h)(1 - \eta_f) = 1 - \left(512/561.7\right)(1 - 0.778) = 0.798.
\]

Hence

\[
\frac{1}{U_c} = \left(1.25 \times 10^{-4} + 5.25 \times 10^{-5} + \frac{\pi (20)}{0.798(200)561.7}\right) \text{ m}^2 \cdot \text{K}/\text{W} = 8.78 \times 10^{-4} \text{ m}^2 \cdot \text{K}/\text{W}
\]

\[
U_c = 1138 \text{ W/m}^2 \cdot \text{K}.
\]
PROBLEM 11.5

FIND: Heat rate per unit length.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) One-dimensional conduction in strut, (4) Adiabatic outer surface conditions, (5) Negligible gas-side radiation, (6) Fully-developed internal flow, (7) Negligible fouling.

PROPERTIES: Table A-6, Water (300 K): \( k = 0.613 \, \text{W/mK} \), \( Pr = 5.83 \), \( \mu = 855 \times 10^{-6} \, \text{N} \cdot \text{s/m}^2 \).

ANALYSIS: The heat rate is

\[
q = \frac{(UA)}{c} \left( T_{m,h} - T_{m,c} \right)
\]

where

\[
\frac{1}{(UA)} = \frac{1}{(hA)} + R_w + \frac{1}{(\eta_0 hA)}
\]

\[
R_w = \frac{\ln \left( \frac{D_i,2}{D_i,1} \right)}{2\pi kL} = \frac{\ln (30/24)}{2\pi (50 \, \text{W/mK})} = 7.10 \times 10^{-4} \, \text{K/W}.
\]

With

\[
Re_D = \frac{4m}{\pi D_i,1 \mu} = \frac{4 \times 0.161 \, \text{kg/s}}{\pi (0.024 \, \text{m}) 855 \times 10^{-6} \, \text{N} \cdot \text{s/m}^2} = 9990
\]

internal flow is turbulent and the Dittus-Boelter correlation gives

\[
h_c = \left( \frac{k}{D_i,1} \right) 0.023Re_D^{4/5} Pr^{0.4} = \left( \frac{0.613 \, \text{W/mK}}{0.024 \, \text{m}} \right) 0.023(9990)^{4/5} (5.83)^{0.4} = 1883 \, \text{W/m}^2 \cdot \text{K}
\]

\[
(hA)_c^{-1} = \left( 1883 \, \text{W/m}^2 \cdot \text{K} \cdot \pi \times 0.024 \, \text{m} \right)^{-1} = 7.043 \times 10^{-3} \, \text{K/W}.
\]

Find the fin efficiency as

\[
\eta_0 = 1 - \left( \frac{A_f}{A} \right) (1 - \eta_f)
\]

\[
A_f = 8 \times 2 \, (L \cdot w) = 8 \times 2 \, (0.015 \, \text{m} \times 1 \, \text{m}) = 0.24 \, \text{m}^2
\]

\[
A = A_f + \left( \pi D_{i,2} - 8t \right) w = 0.24 \, \text{m}^2 + (\pi \times 0.03 \, \text{m} - 8 \times 0.003 \, \text{m}) = 0.31 \, \text{m}^2.
\]
PROBLEM 11.5 (Cont.)

From Eq. 11.4,
\[
\eta_f = \frac{\tanh (mL)}{mL}
\]
where
\[
m = \left[ \frac{2h}{kt} \right]^{1/2} = \left[ \frac{2 \times 100 \text{ W} / \text{m}^2 \cdot \text{K}}{50 \text{ W} / \text{m} \cdot \text{K} \times 0.003 \text{ m}} \right]^{1/2} = 36.5 \text{ m}^{-1}
\]
\[
mL = \left( \frac{2h}{kt} \right)^{1/2} \cdot L = 36.5 \text{ m}^{-1} \times 0.015 \text{ m} = 0.55
\]
\[
tanh \left[ \left( \frac{2h}{kt} \right)^{1/2} \cdot L \right] = 0.499.
\]

Hence
\[
\eta_f = 0.800 / 1.10 = 0.907
\]
\[
\eta_o = 1 - \left( \frac{A_f}{A} \right) (1 - \eta_f) = 1 - (0.24 / 0.31)(1 - 0.907) = 0.928
\]
\[
(\eta_o hA)_h^{-1} = \left( \frac{0.928 \times 100 \text{ W} / \text{m}^2 \cdot \text{K} \times 0.31 \text{ m}^2}{100 \text{ W} / \text{m} \cdot \text{K}} \right)^{-1} = 0.0347 \text{ K} / \text{W}.
\]

Hence
\[
(UA)_c^{-1} = \left( 7.043 \times 10^{-3} + 7.1 \times 10^{-4} + 0.0347 \right) \text{ K} / \text{W}
\]
\[
(UA)_c = 23.6 \text{ W} / \text{K}
\]

and
\[
q = 23.6 \text{ W} / \text{K} \times (800 - 300) \text{ K} = 11,800 \text{ W}
\]

for a 1 m long section.

COMMENTS: (1) The gas-side resistance is substantially decreased by using the fins \((A_f >> \pi D_i^2)\) and \(q\) is increased.

(2) Heat transfer enhancement by the fins could be increased further by using a material of larger \(k\), but material selection would be limited by the large \(T_{m,h}\).
PROBLEM 11.6

KNOWN: Condenser arrangement of tube with six longitudinal fins (k = 200 W/m·K). Condensing refrigerant temperature at 45°C flows axially through inner tube while water flows at 0.012 kg/s and 15°C through the six channels formed by the splines.

FIND: Heat removal rate per unit length of the exchanger.

SCHEMATIC:

ASSUMPTIONS: (1) No heat loss/gain to the surroundings, (2) Negligible kinetic and potential energy changes, (3) Negligible thermal resistance on condensing refrigerant side, $h_i \to \infty$, (4) Water flow is fully developed, (5) Negligible thermal contact between splines and inner tube, (6) Heat transfer from outer tube negligible.

PROPERTIES: Table A-6, Water ($T_c = 15°C = 288 K$): $\rho = 1000 \text{ kg/m}^3$, $k = 0.595 \text{ W/m·K}$, $\nu = \mu / \rho$ $= 1.138 \times 10^{-6}$ N·s/m$^2$/1000 kg/m$^3 = 1.138 \times 10^{-6}$ m$^2$/s, Pr = 8.06; Tube fins (given): $k = 200 \text{ W/m·K}$.

ANALYSIS: Following the discussion of Section 11.2,

$$q' = UA'(T_h - T_c)$$

$$\frac{1}{UA'} = R'_h + R'_w + R'_c = R'_w + \frac{1}{(\eta_h A')_c}$$

where $R'_h = 0$, due to the negligible thermal resistance on the refrigerant side (h), and

$$R'_w = \frac{\ln(D_2 / D_1)}{2\pi k} = \frac{\ln(14/10)}{2\pi (200 \text{ W/m·K})} = 2.678 \times 10^{-4} \text{ m·K/W}.$$ 

To estimate the thermal resistance on the water side (c), first evaluate the convection coefficient. The hydraulic diameter for a passage, where $A_c$ is the cross-sectional area of the passage is

$$D_{h,c} = \frac{4A_c}{P} = \frac{4\left[\pi\left(D_3^2 - D_2^2\right)/4 - 6(D_3 - D_2)t/2\right]}{(\pi D_2 - 6t)/6 + (\pi D_3 - 6t)/6 + 2(D_3 - D_2)/2}$$

$$D_{h,c} = \frac{4\left[\pi(50^2 - 14^2)/4 - 6(50 - 14)\right] \times 10^{-6} \text{ m}^2/6}{[(14\pi - 6\times 2)/6 + (50\pi - 6\times 2)/6 + (50 - 14)] \times 10^{-3} \text{ m}}$$

$$D_{h,c} = \frac{4 \times 2.656 \times 10^{-4} \text{ m}^2}{6.551 \times 10^{-2} \text{ m}} = 0.01622 \text{ m}.$$ 

Hence the Reynolds number is

Continued …..
PROBLEM 11.6 (Cont.)

\[
\text{Re}_{D,c} = \left[ \frac{(0.012 \text{ kg/s} / 6) / (1000 \text{ kg/m}^3 \times 2.656 \times 10^{-4} \text{ m}^2)}{1.138 \times 10^{-6} \text{ m}^2 / \text{s}} \right] \times 0.01622 \text{m} = 107
\]

and assuming the flow is fully developed,

\[
\text{Nu}_{D,c} = \frac{h_c D_{h,c}}{k} = 3.66
\]

\[
h_c = 3.66 \times 0.595 \text{ W/m} \cdot \text{K} / 0.01622 = 134 \text{ W/m}^2 \cdot \text{K}.
\]

The temperature effectiveness of the splines (fins) on the cold side is

\[
\eta_o = 1 - \frac{A_{f,c}}{A_c} (1 - \eta_f)
\]

where \(A_{f,c}\) and \(A_c\) are, respectively, the finned and total (fin plus prime) surface areas, while

\[
\eta_f = -\frac{\tanh \left( \frac{mL}{mL} \right)}{mL} = \frac{25.88 \times 10^{-1} \times 0.018}{25.88 \times 10^{-1} \times 0.018} = 0.4348 = 0.934.
\]

Hence

\[
\eta_o = 1 - \left( \frac{6(D_3 - D_2)}{6(D_3 - D_2) + (\pi D_2 - 6t)} \right) [1 - \eta_f]
\]

\[
\eta_o = 1 - \left( \frac{6(50-14)}{6(50-14) + (14\pi - 6 \times 2)} \right) (1 - 0.934) = 0.943
\]

\[
\frac{1}{\eta_o h\A_c} = \frac{1}{0.943 \times 134 \text{ W/m}^2 \cdot \text{K} \times 6(50-14) + (14\pi - 6 \times 2)} = 3.22 \times 10^{-2} \text{ m} \cdot \text{K/W}
\]

and the heat rate is

\[
q' = \frac{T_h - T_c}{R_w + 1 / (\eta_o h\A_c)}
\]

\[
q' = \frac{(45-15) K}{2.678 \times 10^{-4} \text{ m} \cdot \text{K/W} + 3.22 \times 10^{-2} \text{ m} \cdot \text{K/W}} = 924 \text{ W/m}.
\]

COMMENTS:

(1) The effective length of the fin representing the splines was conservatively estimated. The heat transfer by conduction through the splines to the outer tube and then by convection to the water was ignored.

(2) Without the splines, find \(D_h = (D_3 - D_2) = 36 \text{ mm}\) so that \(h_c = 60.5 \text{ W/m}^2 \cdot \text{K} \). The heat rate with \(A'_c = \pi D_2 \) is

\[
q' = (hA'_c)(T_h - T_c) = 60.5 \text{ W/m}^2 \cdot \text{K} (0.014\pi \text{ m})(45-15)K = 79 \text{ W/m}.
\]

The splines enhance the heat transfer rate by a factor of 924/79 = 11.7.
**PROBLEM 11.7**

**KNOWN:** Number, inner-and outer diameters, and thermal conductivity of condenser tubes. Convection coefficient at outer surface. Overall flow rate, inlet temperature and properties of water flow through the tubes. Flow rate and pressure of condensing steam. Fouling factor for inner surface.

**FIND:** (a) Overall coefficient based on outer surface area, \( U_o \), without fouling, (b) Overall coefficient with fouling, (c) Temperature of water leaving the condenser.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible flow work and kinetic and potential energy changes for water flow, (2) Fully-developed flow in tubes, (3) Negligible effect of fouling on \( D_i \).

**PROPERTIES:** Water (Given): \( c_p = 4180 \text{ J/kg} \cdot \text{K} \), \( \mu = 9.6 \times 10^{-4} \text{ N} \cdot \text{s/m}^2 \), \( k = 0.60 \text{ W/m} \cdot \text{K} \), \( Pr = 6.6 \).

*Table A-6,* Water, saturated vapor (\( p = 0.0622 \text{ bars} \)): \( T_{sat} = 310 \text{ K} \), \( h_{fg} = 2.414 \times 10^6 \text{ J/kg} \).

**ANALYSIS:**

(a) Without fouling, Eq. 11.5 yields

\[
\frac{1}{U_o} = \frac{1}{h_i} \left( \frac{D_o}{D_i} \right) + \frac{D_o \ln \left( \frac{D_o}{D_i} \right)}{2k_t} + \frac{1}{h_o}
\]

With \( Re_{D_i} = \frac{\dot{m}_1}{\pi D_i \mu} = 1.60 \text{ kg/s} / \left( \pi \times 0.025 \text{ m} \times 9.6 \times 10^{-4} \text{ N} \cdot \text{s/m}^2 \right) = 21,220 \), flow in the tubes is turbulent, and from Eq. 8.60

\[
h_i = \left( \frac{k}{D_i} \right) 0.023 \frac{Re^{4/5}}{D_i} Pr^{0.4} = \left( \frac{0.60 \text{ W/m} \cdot \text{K}}{0.025 \text{ m}} \right) 0.023 (21,200)^{4/5} (6.6)^{0.4} = 3400 \text{ W/m}^2 \cdot \text{K}
\]

\[
U_o = \left[ \frac{1}{3400} \left( \frac{28}{25} \right) + \frac{0.028 \ln \left( \frac{28}{25} \right)}{2 \times 110} + \frac{1}{10,000} \right]^{-1} \text{ W/m}^2 \cdot \text{K} = 2225 \text{ W/m}^2 \cdot \text{K}
\]

(b) With fouling, Eq. 11.5 yields

\[
U_o = \left[ 4.43 \times 10^{-4} + (D_o/D_i) R_{f,i}^{*} \right]^{-1} = \left( 5.55 \times 10^{-4} \right)^{-1} = 1800 \text{ W/m}^2 \cdot \text{K}
\]

(c) The rate at which energy is extracted from the steam equals the rate of heat transfer to the water, \( \dot{m}_h h_{fg} = \dot{m}_c c_p (T_{m,o} - T_{m,i}) \), in which case

\[
T_{m,o} = T_{m,i} + \frac{\dot{m}_h h_{fg}}{\dot{m}_c c_p} = 15^\circ \text{C} + \frac{10 \text{ kg/s} \times 2.414 \times 10^6 \text{ J/kg}}{400 \text{ kg/s} \times 4180 \text{ J/kg} \cdot \text{K}} = 29.4^\circ \text{C}
\]

**COMMENTS:** (1) The largest contribution to the thermal resistance is due to convection at the interior of the tube. To increase \( U_o \), \( h_i \) could be increased by increasing \( \dot{m}_1 \), either by increasing \( \dot{m}_c \) or decreasing \( N \). (2) Note that \( T_{m,o} = 302.4 \text{ K} < T_{sat} = 310 \text{ K} \), as must be the case.
PROBLEM 11.8

KNOWN: Diameter and inner and outer convection coefficients of a condenser tube. Thickness, outer diameter, and pitch of aluminum fins.

FIND: (a) Overall heat transfer coefficient without fins, (b) Effect of fin thickness and pitch on overall heat transfer coefficient with fins.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible tube wall conduction resistance, (2) Negligible fouling and fin contact resistance, (3) One-dimensional conduction in fin.

PROPERTIES: Table A.1, Aluminum (T = 300 K): $k = 237 \text{ W/m-K}$.

ANALYSIS: (a) With no fins, Eq. 11.1 yields

$$U = \left( h_i^{-1} + h_o^{-1} \right)^{-1} = \left( 2 \times 10^{-4} + 0.01 \right)^{-1} \text{ W/m}^2 \cdot \text{K} = 98.0 \text{ W/m}^2 \cdot \text{K} \quad <$$

(b) With fins and a unit tube length, Eqs. 11.1 and 11.3 yield

$$\frac{1}{U_i} = \pi D_i + \frac{1}{h_i \pi D_i} + \frac{1}{\eta_o h_o A_o'}$$

and $\eta_o = 1 - (A_f' / A_o')(1 - \eta_f')$. The total fin surface area per unit length is $A_f' = N' \pi \left( r_{oc}^2 - r_i^2 \right)$, where the number of fins per unit length is $N' = \text{1m} / \text{S(m)}$. The total outside surface area per unit length is $A_o' = A_f' + (1 - N' \pi) D_o$, and the fin efficiency is given by Eq. 3.91 or Fig. 3.19.

For $t = 0.0015 \text{ m}$ and $S = 0.0035 \text{ m}$, $r_{oc} = (D_o/2) + (t/2) = 0.01075 \text{ m}$, $N' \approx 286$, $A_f' = 0.163 \text{ m}^2 / \text{m}$, and $A_o' = (0.163 + 0.018) \text{ m}^2 / \text{m} = 0.181 \text{ m}^2 / \text{m}$. With $r_{oc} / r_i = 2.15$, $L_c = 0.00575 \text{ m}$, $A_p = 8.625 \times 10^{-6} \text{ m}^2$, and $L_c^{3/2} \left( h_o / k A_p \right)^{1/2} = 0.0964$, Fig. 3.19 yields $\eta_f \approx 0.99$. Hence, $\eta_o = 1 - (0.163/0.181)(0.01) = 0.99$ and

$$U_i = \left( \pi D_i / \eta_0 h_o A_o' \right)^{-1}$$

$$U_i = \left[ 2 \times 10^{-4} \text{ m}^2 \cdot \text{K/W} + \pi \times 0.01 \text{ m} / 0.99 \times 100 \text{ W/m}^2 \cdot \text{K} \times 0.181 \text{ m}^2 / \text{m} \right]^{-1} = 512 \text{ W/m}^2 \cdot \text{K} \quad <$$

We may use the IHT Extended Surface Model (Performance Calculations for a Circular Rectangular Fin Array) to consider the effect of varying $t$ and $S$. To maximize $N'$, the minimum allowable value of $t$...
S - t = 1.5 mm should be selected. It is then a matter of choosing between a large number of thin fins or a smaller number of thicker fins. Calculations were performed for the following options.

<table>
<thead>
<tr>
<th>t (mm)</th>
<th>S (mm)</th>
<th>N’</th>
<th>( U_i ) (W/m²-K)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2.5</td>
<td>400</td>
<td>640</td>
</tr>
<tr>
<td>2</td>
<td>3.5</td>
<td>286</td>
<td>512</td>

<tr>
<td>4</td>
<td>5.5</td>
<td>182</td>
<td>420</td>
</tr>
</tbody>
</table>

Since heat transfer increases with \( U_i \), the best configuration corresponds to \( t = 1 \) mm and \( S = 2.5 \) mm, which provides the largest airside surface area.

**COMMENTS:** The best performance is always associated with a large number of closely spaced fins, so long as the flow between adjoining fins is sufficient to maintain the convection coefficient.
**PROBLEM 11.9**

**KNOWN:** Operating conditions and surface area of a finned-tube, cross-flow exchanger.

**FIND:** Overall heat transfer coefficient.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Negligible kinetic and potential energy changes, (3) Constant properties, (4) Exhaust gas properties are those of air.

**PROPERTIES:** *Table A-6, Water (T_m = 87°C): \( \bar{c}_p = 4203 \text{ J/kg·K}; \) Table A-4, Air (T_m = 275°C): \( \bar{c}_p = 1040 \text{ J/kg·K}. \)

**ANALYSIS:** From the energy balance equations

\[
q = \dot{m}_c c_p, c \left( T_{c, o} - T_{c, i} \right) = 0.5 \text{ kg/s} \times 4203 \text{ J/kg·K} (150 - 25) \degree C = 2.63 \times 10^5 \text{ W}
\]

\[
T_{h, o} = T_{h, i} - \frac{q}{\dot{m}_h c_p, h} = 325 \degree C - \frac{2.63 \times 10^5 \text{ W}}{2 \text{ kg/s} \times 1040 \text{ J/kg·K}} = 198.6 \degree C.
\]

Hence

\[
U = \frac{q}{A \Delta T_{\ell, m}} \quad \text{where} \quad \Delta T_{\ell, m} = F \Delta T_{\ell, m, CF}.
\]

From Fig. 11.12, with

\[
P = \frac{t_o - t_i}{T_i - t_i} = \frac{150 - 25}{325 - 25} = 0.42, \quad R = \frac{T_i - T_o}{t_o - t_i} = \frac{325 - 198.6}{150 - 25} = 1.01, \quad F = 0.94
\]

\[
\Delta T_{\ell, m, CF} = \frac{(325 - 150) - (198.6 - 25)}{\ln \frac{325 - 150}{198.6 - 25}} = 174.3 \degree C.
\]

Hence

\[
U = \frac{q}{AF \Delta T_{\ell, m, CF}} = \frac{2.63 \times 10^5 \text{ W}}{10\text{ m}^2 \times 0.94 \times 174.3 \degree C} = 160 \text{ W/m}^2 \cdot \text{K.}
\]

**COMMENTS:** From the \( \varepsilon \) - NTU method, \( C_c = 2102 \text{ W/K}; C_h = 2080 \text{ W/K}; (C_{\min}/C_{\max}) \approx 1, \) \( q_{max} = 6.24 \times 10^5 \text{ W} \) and \( \varepsilon = 0.42. \) Hence, from Fig. 11.18, NTU \( \approx 0.75 \) and \( U \approx 156 \text{ W/m}^2 \cdot \text{K}. \)
PROBLEM 11.10

KNOWN: Heat exchanger with two shell passes and eight tube passes having an area 925 m²; 45,500 kg/h water is heated from 80°C to 150°C; hot exhaust gases enter at 350°C and exit at 175°C.

FIND: Overall heat transfer coefficient.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible losses to surroundings, (2) Negligible kinetic and potential energy changes, (3) Constant properties, (4) Exhaust gas properties are approximated as those of atmospheric air.

PROPERTIES: Table A-6, Water \( \left( T_c = \left( 80 + 150 \right)^\circ C / 2 = 388 K \right) \): \( c = c_{p,f} = 4236 \) J/kg⋅K.

ANALYSIS: The overall heat transfer coefficient follows from Eqs. 11.9 and 11.18 written in the form

\[
U = \frac{q}{AF\Delta T_{m,CF}}
\]

where \( F \) is the correction factor for the HXer configuration, Fig. 11.11, and \( \Delta T_{m,CF} \) is the log mean temperature difference (CF), Eqs. 11.15 and 11.16. From Fig. 11.11, find

\[
R = \frac{T_{h,i} - T_{h,o}}{T_{c,o} - T_{c,i}} = \frac{(350 - 175) \degree C}{(150 - 80) \degree C} = 2.5, \quad P = \frac{T_{c,o} - T_{c,i}}{T_{h,i} - T_{c,i}} = \frac{(150 - 80) \degree C}{(350 - 80) \degree C} = 0.26
\]

find \( F \approx 0.97 \). The log-mean temperature difference, Eqs. 11.15 and 11.17, is

\[
\Delta T_{m,CF} = \frac{\Delta T_1 - \Delta T_2}{\ln(\Delta T_1 / \Delta T_2)} = \frac{(350 - 150) \degree C - (175 - 80) \degree C}{\ln[(350 - 150)/(175 - 80)]} = 141.1 \degree C.
\]

From an overall energy balance on the cold fluid (water), the heat rate is

\[
q = m_c c \left( T_{c,o} - T_{c,i} \right)
\]

\[
q = 45,500 \text{kg/h} \times 1 \text{h} / 3600 \text{s} \times 4236 \text{J/kg} \cdot \text{K} \left( 150 - 80 \right) \degree C = 3.748 \times 10^6 \text{W}.
\]

Substituting values with \( A = 925 \) m², find

\[
U = \frac{3.748 \times 10^6 \text{W} / 925 \text{m}^2 \times 0.97 \times 141.1 \text{K}}{29.6 \text{W/m}^2 \cdot \text{K}} < \]

COMMENTS: Compare the above result with representative values for air-water exchangers, as given in Table 11.2. Note that in this exchanger, two shells with eight tube passes, the correction factor effect is very small, since \( F = 0.97 \).
**PROBLEM 11.11**

**KNOWN:** Dimensions and thermal conductivity of tubes with or without annular fins. Convection coefficients associated with condensation and natural convection at the inner and outer surfaces, respectively.

**FIND:** (a) Overall heat transfer coefficient \( U_i \) for aluminum and copper tubes without fins, (b) Value of \( U_i \) associated with adding aluminum fins.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible fouling and fin contact resistances, (2) One-dimensional conduction in fins.

**ANALYSIS:** (a) For unfinned, aluminum tubes of unit length, Eq. 11.5 yields

\[
\frac{1}{U_i} = \frac{1}{h_i} + \frac{D_i \ln (D_o / D_i)}{2k} + \frac{1}{h_o} \left( \frac{D_i}{D_o} \right) \\
U_i = \left[ \frac{1}{5000} + \frac{0.011 \ln (13/11)}{2 \times 180} + \frac{1}{10} \left( \frac{11}{13} \right) \right]^{-1} = \left( \frac{2 \times 10^{-4} + 5.1 \times 10^{-6} + 846 \times 10^{-4}}{11.8 \text{ W/m} \cdot \text{K}} \right)^{-1} = 11.8 \text{ W/m}^2 \cdot \text{K} <
\]

For copper the tube conduction resistance is reduced from \( 5.1 \times 10^{-6} \text{ m}^2 \cdot \text{K}/\text{W} \) to \( 2.3 \times 10^{-6} \), but \( U_i \) is essentially unchanged.

\[
U_i = 11.8 \text{ W/m}^2 \cdot \text{K} <
\]

(b) With fins and a unit tube length, Eqs. 11.1 and 11.3 yield

\[
\frac{1}{U_i} = \frac{1}{h_i} + \frac{D_i \ln (D_o / D_i)}{2k} + \frac{\pi D_i}{\eta_o h_o A'_o}
\]

and \( \eta_o = 1 - \left( \frac{A'_f}{A'_o} \right) (1 - \eta_f) \). The fin surface area is \( A'_f = N'2\pi \left( r_{fc}^2 - r_f^2 \right) \) and the total outer surface area is \( A'_o = A'_f + (1 - N')\pi D_o \). With \( t = 0.001 \text{m} \), \( r_{fc} = r_f + t/2 = (0.0125 + 0.0005) \text{m} = 0.0130 \text{m} \) and \( A'_f = 300 \text{ m}^{-1} (2\pi \left( 0.0130^2 - 0.0065^2 \right)) \text{m}^2 = 0.239 \text{m} \) and \( A'_o = 0.239 \text{m} + (1 - 0.300)\pi (0.0130m) = 0.268 \text{m} \). With \( r_{fc} = r_f + t/2 = 0.013 \text{m} \), \( L_c = (r_f - r_o) + t/2 = 0.0065 \text{m} \), \( r_{fc}/r_o = 2 \), \( A_p = L_c t = 3.25 \times 10^{-6} \text{ m}^2 \), and \( L_c^{3/2} \left( h_o / k A_p \right)^{1/2} = 0.0685 \). Fig. 3.19 yields \( \eta_f = 0.97 \). Hence, \( \eta_o = 1 - (0.293/0.268) (0.03) = 0.973 \), and

\[
U_i = \left[ \frac{1}{5000} + \frac{0.011 \ln (13/11)}{360} + \frac{\pi \times 0.011}{0.973 \times 10 \times 0.244} \right]^{-1}
\]

\[
= \left( \frac{2 \times 10^{-4} + 5.1 \times 10^{-6} + 145 \times 10^{-4}}{68.0 \text{ W/m}^2 \cdot \text{K}} \right)^{-1} = \text{68.0 W/m}^2 \cdot \text{K} <
\]

**COMMENTS:** There is significant advantage to installing fins on the outer surface, which has a much smaller convection coefficient. The thermal resistance at the outer surface has been reduced from 0.0846 to 0.0145 m²·K/W and could be reduced further by increasing \( D_f \) and/or \( N' \). However, the spacing between adjoining fins must not be so small as to restrict buoyancy driven flow in the associated air space.
**PROBLEM 11.12**

**KNOWN:** Properties and flow rates for the hot and cold fluid to a heat exchanger.

**FIND:** Which fluid limits the heat transfer rate of the exchanger?

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Constant properties, and (3) Negligible losses to the surroundings and kinetic and potential energy changes.

**ANALYSIS:** The properties and flow rates for the hot and cold fluid to the heat exchanger are tabulated below.

<table>
<thead>
<tr>
<th></th>
<th>Cold fluid</th>
<th>Hot fluid</th>
</tr>
</thead>
<tbody>
<tr>
<td>Density, kg/m$^3$</td>
<td>997</td>
<td>1247</td>
</tr>
<tr>
<td>Specific heat, J/kg⋅K</td>
<td>4179</td>
<td>2564</td>
</tr>
<tr>
<td>Thermal conductivity, W/m⋅K</td>
<td>0.613</td>
<td>0.287</td>
</tr>
<tr>
<td>Viscosity, N⋅s/m$^2$</td>
<td>8.55 × 10$^{-4}$</td>
<td>1.68 × 10$^{-4}$</td>
</tr>
<tr>
<td>Flow rate, m$^3$/h</td>
<td>14</td>
<td>16</td>
</tr>
</tbody>
</table>

The fluid which limits the heat transfer rate of the exchanger is the minimum fluid, $C_{\text{min}} = \frac{b}{c} g q_{\text{min}}$. For the hot and cold fluids, find

$$C_h = \dot{m}_h c_h = 16 \text{ m}^3/\text{h} \times 1247 \text{ kg/ m}^3 \times 2564 \text{ J/kg⋅K} \times \frac{\text{b h}}{3600\text{s} g} = 14.21 \text{ kW/ K}$$

$$C_c = \dot{m}_c c_c = 14 \text{ m}^3/\text{h} \times 997 \text{ kg/ m}^3 \times 4179 \text{ J/kg⋅K} \times \frac{\text{b h}}{3600\text{s} g} = 16.20 \text{ kW/ K}$$

Hence, the hot fluid is the minimum fluid,

$$C_{\text{min}} = C_h$$

For any exchanger, the heat rate is $q = \varepsilon q_{\text{max}}$ where $\varepsilon$ depends upon the exchanger type. The maximum heat rate is $q_{\text{max}} = C_{\text{min}} (T_{h,i} - T_{c,i})$. Hence, it is the conditions for the minimum fluid that limit the performance of the exchanger.
PROBLEM 11.13

KNOWN: Process (hot) fluid having a specific heat of 3500 J/kg K and flowing at 2 kg/s is to be cooled from 80°C to 50°C with chilled-water (cold fluid) supplied at 2.5 ks/g and 15°C assuming an overall heat transfer coefficient of 2000 W/m²-K.

FIND: The required heat transfer areas for the following heat exchanger configurations; (a) Concentric tube (CT) - parallel flow, (b) CT - counterflow, (c) Shell and tube, one-shell pass and 2 tube passes; (d) Cross flow, single pass, both fluids unmixed. Use the IHT Tools | Heat Exchanger models as your solution tool.

SCHEMATIC:

![Schematic of heat exchangers](image)

(a) Parallel flow hxer
(b) Counterflow hxer

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible losses to the surroundings and kinetic and potential energy changes, (3) Overall heat transfer coefficient remains constant with different configurations, and (4) Constant properties.

ANALYSIS: The IHT Tools | Heat Exchanger models are based upon the effectiveness-NTU method and suited for design-type problems. The table below summarizes the results of our analysis using the IHT models including model equations, figures, and the required heat transfer area. The cold fluid outlet temperature for all configurations is $T_{c,o} = 35.1°C$. The IHT code for the concentric tube, parallel flow heat exchanger is provided in the Comments.

</tbody>
</table>

COMMENTS: (1) Referring to the tabulated results, note that for the concentric tube exchangers, the area required for parallel flow is 17% larger than for counterflow. Under what circumstances would you choose to use the PF arrangement if the area has to be significantly larger?

(2) The shell-tube and crossflow exchangers require nearly the same heat transfer area. What are other factors that might influence your decision to select one type over the other for an application?

(3) Based upon area considerations only, the CF arrangement requires the smallest heat transfer area. What practical issues need to be considered in making a CF heat exchanger with a 2.6 m² area?

Continued …..
(4) The IHT code used for the concentric tube, parallel flow heat exchanger is shown below. Note the use of the water property function, $cp_{-}Tx$, and the intrinsic function, $Tfluidavg$, to provide the specific heat at the mean water (cold fluid) temperature.

PROBLEM 11.14

KNOWN: A shell and tube Hxer (two shells, four tube passes) heats 10,000 kg/h of pressurized water from 35°C to 120°C with 5,000 kg/h water entering at 300°C.

FIND: Required heat transfer area, $A_s$.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Negligible kinetic and potential energy changes, (3) Constant properties.

PROPERTIES: Table A-6, Water ($T_c = 350$ K): $c_p = 4195$ J/kg·K; Table A-6, Water (Assume $T_{h,o} \approx 150$°C, $h_{T,h} \approx 500$ K): $c_p = 4660$ J/kg·K.

ANALYSIS: The rate equation, Eq. 11.14, can be written in the form

$$A_S = \frac{q}{U \Delta T_{\ell,m}}$$

and from Eq. 11.18,

$$\Delta T_{\ell,m} = F \Delta T_{m,CF}$$

where

$$\Delta T_{m,CF} = \frac{\Delta T_1 - \Delta T_2}{\ell \ln \left( \frac{\Delta T_1}{\Delta T_2} \right)}.$$ (2,3)

From an energy balance on the cold fluid, the heat rate is

$$q = \dot{m}_c c_p (T_{c,o} - T_{c,i}) = \frac{10,000 \text{ kg/h}}{3600 \text{ s/h}} \times 4195 \text{ J/kg·K} \times (120 - 35) \text{ K} = 9.905 \times 10^5 \text{ W.}$$

From an energy balance on the hot fluid, the outlet temperature is

$$T_{h,o} = T_{h,i} - q / \dot{m}_h c_p,h = 300°C - 9.905 \times 10^5 \text{ W} / 5000 \text{ kg} / 3600 \text{ s} \times 4660 \text{ J/kg·K} = 147°C.$$ (1)

From Fig. 11.11, determine $F$ from values of $P$ and $R$, where $P = (120 - 35)°C/(300 - 35)°C = 0.32$, $R = (300 - 147)°C/(120-35)°C = 1.8$, and $F = 0.97$. The log-mean temperature difference based upon a $CF$ arrangement follows from Eq. (3); find

$$\Delta T_{\ell,m} = \left[ \frac{(300-120) - (147-35)}{147-35} \right] K / \ln \left( \frac{300-120}{147-35} \right) = 143.3K.$$ <

$$A_S = 9.905 \times 10^5 \text{ W} / 1500 \text{ W/m}^2 · \text{K} \times 0.97 \times 143.3 \text{ K} = 4.75 \text{ m}^2.$$ <

COMMENTS: (1) Check $T_h \approx 500$ K used in property determination; $T_h = (300 + 147)°C/2 = 497$ K.

(2) Using the NTU-$\epsilon$ method, determine first the capacity rate ratio, $C_{min}/C_{max} = 0.56$. Then

$$\epsilon \equiv \frac{q}{q_{max}} = \frac{C_{\max} (T_{c,o} - T_{c,i})}{C_{\min} (T_{h,i} - T_{c,i})} = \frac{1}{0.56} \times \frac{(120 - 35)°C}{(300 - 35)°C} = 0.57.$$ (1)

From Fig. 11.17, find that $NTU = AU/C_{\min} = 1.1$ giving $A_s = 4.7 \text{ m}^2$. 
PROBLEM 11.15

KNOWN: The shell and tube HXer (two shells, four tube passes) of Problem 11.14, known to have an area $4.75 \text{ m}^2$, provides $95^\circ \text{C}$ water at the cold outlet (rather than $120^\circ \text{C}$) after several years of operation. Flow rates and inlet temperatures of the fluids remain the same.

FIND: The fouling factor, $R_f$.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Negligible kinetic and potential energy changes, (3) Constant properties, (4) Thermal resistance for the clean condition is $R'_t = (1500 \text{ W/m}^2 \cdot \text{K})^{-1}$.

PROPERTIES: Table A-6, Water ($T_c = 338 \text{ K}$): $c_p = 4187 \text{ J/kg} \cdot \text{K}$; Table A-6, Water (Assume $T_{h,o} \approx 190^\circ \text{C}$, $T_{h} \approx 520 \text{ K}$): $c_p = 4840 \text{ J/kg} \cdot \text{K}$.

ANALYSIS: The overall heat transfer coefficient can be expressed as

$$U = \frac{1}{(R'_t + R''_f)} \quad \text{or} \quad R''_f = \frac{1}{U} - R'_t$$

(1)

where $R'_t$ is the thermal resistance for the clean condition and $R''_f$, the fouling factor, represents the additional resistance due to fouling of the surface. The rate equation, Eq. 11.14 with Eq. 11.18, has the form,

$$\Delta T_{\text{m,CF}} = \frac{(\Delta T_1 - \Delta T_2)}{\ell n(\Delta T_1 / \Delta T_2)}.$$  

(2)

From energy balances on the cold and hot fluids, find

$$q = \dot{m}_c c_{p,c} (T_{c,o} - T_{c,i}) = (10,000/3600 \text{ kg/s}) 4187 \text{ J/kg} \cdot \text{K} (95 - 35) \text{ K} = 6.978 \times 10^5 \text{ W}$$

$T_{h,o} = T_{h,i} - q / \dot{m}_h c_{p,h} = 300^\circ \text{C} - 6.978 \times 10^5 \text{ W} / (5000/3600 \text{ kg/s} \times 4840 \text{ J/kg} \cdot \text{K}) = 196.2^\circ \text{C}.$

The factor, $F$, follows from values of $P$ and $R$ as given by Fig. 11.11 with

$$P = (95 - 35) / (300 - 35) = 0.23 \quad \text{and} \quad R = (300 - 196) / (120 - 35) = 1.22$$

giving $F \approx 1$. Based upon CF arrangement,

$$\Delta T_{\text{m,CF}} = \left[ (300 - 95) - (196 - 35) \right] ^\circ \text{C} / \ell n\left[ (300 - 95) / (196.2 - 35) \right] = 182 \text{ K}.$$

Using Eq. (2), find now the overall heat transfer coefficient as

$$U = 6.978 \times 10^5 \text{ W} / 4.75 \text{ m}^2 \times 1 \times 182 \text{ K} = 806 \text{ W/m}^2 \cdot \text{K}.$$  

From Eq. (1), the fouling factor is

$$R''_f = \frac{1}{806 \text{ W/m}^2 \cdot \text{K}} - \frac{1}{1500 \text{ W/m}^2 \cdot \text{K}} = 5.74 \times 10^{-4} \text{ m}^2 \cdot \text{K/W}.$$  

COMMENTS: Note that the effect of fouling is to nearly double ($U_{\text{clean}}/U_{\text{fouled}} = 1500/806 = 1.9$) the resistance to heat transfer. Note also the assumption for $T_{h,o}$ used for property evaluation is satisfactory.
**PROBLEM 11.16**

**KNOWN:** Inner tube diameter ($D = 0.02$ m) and fluid inlet and outlet temperatures corresponding to design conditions for a concentric tube heat exchanger. Overall heat transfer coefficient ($U = 500\, \text{W/m}^2\text{K}$) and desired heat rate ($q = 3000\, \text{W}$). Cold fluid outlet temperature after three years of operation.

**FIND:** (a) Required heat exchanger length, (b) Heat rate, hot fluid outlet temperature, overall heat transfer coefficient, and fouling factor after three years.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to the surroundings and kinetic and potential energy changes, (2) Negligible tube wall conduction resistance, (3) Constant properties.

**ANALYSIS:** (a) The tube length needed to achieve the prescribed conditions may be obtained from Eqs. 11.14 and 11.15 where $\Delta T_1 = T_{h,i} - T_{c,o} = 80^\circ\text{C}$ and $\Delta T_2 = T_{h,o} - T_{c,i} = 120^\circ\text{C}$. Hence, $\Delta T_{lm} = (120 - 80)^\circ\text{C}/\ln(120/80) = 98.7^\circ\text{C}$ and

$$L = \frac{q}{(\pi D)U_{T_{lm}}} = \frac{3000\, \text{W}}{(\pi \times 0.02\, \text{m})500\, \text{W/m}^2\text{K} \times 98.7^\circ\text{C}} = 0.968\, \text{m}$$

(b) With $q = C_c(T_{c,o} - T_{c,i})$, the following ratio may be formed in terms of the design and 3 year conditions.

$$\frac{q}{q_3} = \frac{C_c(T_{c,o} - T_{c,i})}{C_c(T_{c,o} - T_{c,i})} = 60^\circ\text{C} - 45^\circ\text{C} = 1.333$$

Hence,

$$q_3 = q/1.33 = 3000\, \text{W}/1.333 = 2250\, \text{W}$$

Having determined the ratio of heat rates, it follows that

$$\frac{q}{q_3} = \frac{C_h(T_{h,i} - T_{h,o})}{C_h(T_{h,i} - T_{h,o})} = \frac{20^\circ\text{C}}{160^\circ\text{C} - T_{h,o}(3)} = 1.333$$

Hence,

$$T_{h,o}(3) = 160^\circ\text{C} - 20^\circ\text{C}/1.333 = 145^\circ\text{C}$$

With $\Delta T_{lm,3} = (125 - 95)/\ln(125/95) = 109.3^\circ\text{C}$,

$$U_3 = \frac{q_3}{(\pi DL)\Delta T_{lm,3}} = \frac{2250\, \text{W}}{\pi (0.02\, \text{m})0.968\, \text{m}(109.3^\circ\text{C})} = 338\, \text{W/m}^2\text{K}$$

Continued...
PROBLEM 11.16 (Cont.)

With \( U = \left[ \left( 1/h_1 \right) + \left( 1/h_o \right) \right]^{-1} \) and \( U_3 = \left[ \left( 1/h_1 \right) + \left( 1/h_o \right) + R_{f,c} \right]^{-1} \),

\[
R_{f,c} = \frac{1}{U_3} - \frac{1}{U} = \left( \frac{1}{338} - \frac{1}{500} \right) \text{m}^2 \cdot \text{K/W} = 9.59 \times 10^{-4} \text{m}^2 \cdot \text{K/W}
\]

COMMENTS: Over time fouling will always contribute to a degradation of heat exchanger performance. In practice it is desirable to remove fluid contaminants and to implement a regular maintenance (cleaning) procedure.
**PROBLEM 11.17**

**KNOWN:** Counterflow, concentric tube heat exchanger of Example 11.1; maintaining the outlet oil temperature of 60°C, but with variable rate of cooling water, all other conditions remaining the same.

**FIND:** (a) Calculate and plot the required exchanger tube length $L$ and water outlet temperature $T_{c,o}$ for the cooling water flow rate in the range 0.15 to 0.3 kg/s, and (b) Calculate $U$ as a function of the water flow rate assuming the water properties are independent of temperature; justify using a constant value of $U$ for the part (a) calculations.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible losses to the surroundings and kinetic and potential energy changes, (3) Overall heat transfer coefficient independent of water flow rate for this range, and (4) Constant properties.

**PROPERTIES:** *Table A-6*, Water $\left(T_c = 35^\circ C = 308 K\right)$: $c_p = 4178 J/kg \cdot K$, $\mu = 725 \times 10^{-6}$ N·s/m², $k = 0.625$ W/m·K, $Pr = 4.85$, *Table A-4*, Unused engine oil $\left(T_h = 353 K\right)$: $c_p = 2131 J/kg \cdot K$.

**ANALYSIS:** (a) The NTU-$\varepsilon$ method will be used to calculate the tube length $L$ and water outlet temperature $T_{c,o}$ using this system of equations in the IHT workspace:

**NTU relation, CF hxer, Eq. 11.30b**

$$NTU = \frac{1}{C_r - 1} \left(\varepsilon - 1\right) \left(\varepsilon C_r - 1\right)$$

$C_r = C_{\max} / C_{\min}$ (1, 2)

$$NTU = \frac{U \cdot A}{C_{\min}}$$ (3)

$A = \pi D_i \cdot L$ (4)

**Capacity rates, find minimum fluid**

$$C_h = \dot{m}_h \cdot c_h = 0.1 \frac{kg}{s} \times 2131 \frac{J}{kg \cdot K} = 213.1 \frac{W}{K}$$

$$C_c = \dot{m}_c \cdot c_c = (0.15 \text{ to } 0.30) \frac{kg}{s} \times 4178 \frac{J}{kg \cdot K} = 626.7 \text{ to } 1253 \frac{W}{K}$$ (5)

$$C_{\min} = C_h$$ (6)

**Effectiveness and maximum heat rate, Eqs. 11.19 and 11.20**

$$\varepsilon = \frac{q}{q_{\max}}$$ (7)

$$q_{\max} = C_{\min} (T_{h,i} - T_{c,i}) = C_c (T_{h,i} - T_{c,i})$$ (8)

Continued …..
PROBLEM 11.17 (Cont.)

\[ q = C_h (T_{h,i} - T_{h,o}) \]  \hspace{1cm} (9)

With the foregoing equations and the parameters specified in the schematic, the results are plotted in the graphs below.

(b) The overall coefficient can be written in terms of the inner (cold) and outer (hot) side convection coefficients,

\[ U = \frac{1}{1/h_i + 1/h_o} \]  \hspace{1cm} (10)

From Example 11.1, \( h_o = 38.4 \) W/m\(^2\)K, and \( h_i \) will vary with the flow rate from Eq. 8.60 as

\[ h_i = h_{i,b} \left( \frac{\dot{m}_i}{\dot{m}_{i,b}} \right)^{0.8} \]  \hspace{1cm} (11)

where the subscript \( b \) denotes the base case when \( \dot{m}_i = 0.2 \) kg/s. From these equations, the results are tabulated.

<table>
<thead>
<tr>
<th>( \dot{m}_c ) (kg/s)</th>
<th>( h_i ) (W/m(^2)K)</th>
<th>( h_o ) (W/m(^2)K)</th>
<th>( U ) (W/m(^2)K)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.15</td>
<td>1787</td>
<td>38.4</td>
<td>37.6</td>
</tr>
<tr>
<td>0.20</td>
<td>2250</td>
<td>38.4</td>
<td>37.8</td>
</tr>
<tr>
<td>0.25</td>
<td>2690</td>
<td>38.4</td>
<td>37.9</td>
</tr>
<tr>
<td>0.30</td>
<td>3112</td>
<td>38.4</td>
<td>37.9</td>
</tr>
</tbody>
</table>

Note that while \( h_i \) varies nearly 50%, there is a negligible effect on the value of \( U \).

COMMENTS: Note from the graphical results, that by doubling the flow rate (from 0.15 to 0.30 kg/s), the required length of the exchanger can be decreased by approximately 6%. Increasing the flow rate is not a good strategy for reducing the length of the exchanger. However, any increase in the hot-side (oil) convection coefficient would provide a proportional decrease in the length.
PROBLEM 11.18

KNOWN: Concentric tube heat exchanger with area of 50 m$^2$ with operating conditions as shown on the schematic.

FIND: (a) Outlet temperature of the hot fluid; (b) Whether the exchanger is operating in counterflow or parallel flow; or can’t tell from information provided; (c) Overall heat transfer coefficient; (d) Effectiveness of the exchanger; and (e) Effectiveness of the exchanger if its length is made very long

SCHEMATIC:

<table>
<thead>
<tr>
<th>Operating conditions</th>
<th>Hot fluid (h)</th>
<th>Cold fluid (c)</th>

<td>54</td>
</tr>
</tbody>
</table>

ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Negligible kinetic and potential energy changes, and (3) Constant properties.

ANALYSIS: From overall energy balances on the hot and cold fluids, find the hot fluid outlet temperature

$$q = C_c (T_{c,o} - T_{c,i}) = C_h (T_{h,i} - T_{h,o})$$  \hspace{1cm} (1)

$$3000 \text{ W/K} (54 - 30) \text{K} = 6000 (60 - T_{h,o}) \quad T_{h,o} = 48^\circ \text{C}$$ \hspace{1cm} <

(b) HXer must be operating in counterflow (CF) since $T_{h,o} < T_{c,o}$. See schematic for temperature distribution.

(c) From the rate equation with $A = 50 \text{ m}^2$, with Eq. (1) for $q$,

$$q = C_c (T_{c,o} - T_{c,i}) = U A \Delta T_{\ell m}$$  \hspace{1cm} (2)

$$\Delta T_{\ell m} = \frac{\Delta T_1 - \Delta T_2}{\ell_m (\Delta T_1 / \Delta T_2)} = \frac{(60 - 54) \text{K} - (48 - 30) \text{K}}{\ell_n (6/18)} = 10.9^\circ \text{C}$$  \hspace{1cm} (3)

$$3000 \text{ W/K} (54 - 30) \text{K} = U \times 50 \text{ m}^2 \times 10.9 \text{K}$$

$$U = 132 \text{ W}/\text{m}^2 \cdot \text{K}$$ \hspace{1cm} <

(d) The effectiveness, from Eq. 11.20, with the cold fluid as the minimum fluid, $C_c = C_{\min}$.

$$\varepsilon = \frac{q}{q_{\max}} = \frac{C_c (T_{c,o} - T_{c,i})}{C_{\min} (T_{h,i} - T_{c,i})} = \frac{(54 - 30) \text{K}}{(60 - 30) \text{K}} = 0.8$$ \hspace{1cm} <

(e) For a very long CF HXer, the outlet of the minimum fluid, $C_{\min} = C_c$, will approach $T_{h,i}$. That is,

$$q \rightarrow C_{\min} (T_{c,o} - T_{c,i}) \rightarrow q_{\max} \quad \varepsilon = 1$$ \hspace{1cm} <
**PROBLEM 11.19**

**KNOWN:** Specifications for a water-to-water heat exchanger as shown in the schematic including the flow rate, and inlet and outlet temperatures.

**FIND:** (a) Design a heat exchanger to meet the specifications; that is, size the heat exchanger, and (b) Evaluate your design by identifying what features and configurations could be explored with your customer in order to develop more complete, detailed specifications.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Negligible kinetic and potential energy changes, (3) Tube walls have negligible thermal resistance, (4) Flow is fully developed, and (5) Constant properties.

**ANALYSIS:** (a) Referring to the schematic above and using the rate equation, we can determine the value of the UA product required to satisfy the design requirements. Sizing the heat exchanger involves determining the heat transfer area, $A$ (tube diameter, length and number), and the associated overall convection coefficient, $U$, such that $U \times A$ satisfies the required UA product. Our approach has five steps: (1) Calculate the UA product: Select a configuration and calculate the required UA product; (2) Estimate the area, $A$: Assume a range for the overall coefficient, calculate the area and consider suitable tube diameter(s); (3) Estimate the overall coefficient, $U$: For selected tube diameter(s), use correlations to estimate hot- and cold-side convection coefficients and the overall coefficient; (4) Evaluate first-pass design: Check whether the $A$ and $U$ values ($U \times A$) from Steps 2 and 3 satisfy the required UA product; if not, then (5) Repeat the analysis: Iterate on different values for area parameters until a satisfactory match is made, $(U \times A) = UA$.

To perform the analysis, IHT models and tools will be used for the effectiveness-NTU method relations, internal flow convection correlations, and thermophysical properties. See the Comments section for details.

**Step 1 Calculate the required UA.** For the initial design, select a concentric tube, counterflow heat exchanger. Calculate UA using the following set of equations, Eqs. 11.30a,

$$
\varepsilon = \frac{1 - \exp[-\text{NTU}(1 - C_r)]}{1 - C_r \exp[-\text{NTU}(1 - C_r)]}
$$

$$
\text{NTU} = \frac{UA}{C_{\text{min}}}
$$

$$
C_r = \frac{C_{\text{min}}}{C_{\text{max}}}
$$

$$
\varepsilon = \frac{q}{q_{\text{max}}}
$$

$$
q_{\text{max}} = C_{\text{min}}(T_{h,i} - T_{c,i})
$$

where $C = \dot{m} c_p$, and $c_p$ is evaluated at the average mean temperature of the fluid, $T_m = (T_{m,i} + T_{m,o})/2$. Substituting numerical values, find

$$
\varepsilon = 0.464 \quad \text{NTU} = 0.8523 \quad q = 2.934 \times 10^6 \text{W} \quad T_{h,o} = 65.0^\circ \text{C}
$$

Continued ....
PROBLEM 11.19 (Cont.)

\[ UA = 9.62 \times 10^4 \text{ W/K} \]

*Step 2 Estimate the area, \( A \).* From Table 11.2, the typical range of \( U \) for water-to-water exchangers is \( 850 \text{ – } 1700 \text{ W/m}^2\cdot\text{K} \). With \( UA = 9.619 \times 10^4 \text{ W/K} \), the range for \( A \) is \( 57 \text{ – } 113 \text{ m}^2 \), where

\[ A = \pi D_i LN \]  \( (6) \)

where \( L \) and \( N \) are the length and number of tubes, respectively. Consider these values of \( D_i \) with \( L = 10 \text{ m} \) to describe the exchanger:

<table>
<thead>
<tr>
<th>Case</th>
<th>( D_i ) (mm)</th>
<th>( L ) (m)</th>
<th>( N )</th>
<th>( A ) (m(^2))</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>25</td>
<td>10</td>
<td>73-146</td>
<td>57-113</td>
</tr>
<tr>
<td>2</td>
<td>50</td>
<td>10</td>
<td>36-72</td>
<td>57-113</td>
</tr>
<tr>
<td>3</td>
<td>75</td>
<td>10</td>
<td>24-48</td>
<td>57-113</td>
</tr>
</tbody>
</table>

*Step 3 Estimate the overall coefficient, \( U \).* With the inner (hot) and outer (cold) fluids in the concentric tube arrangement, the overall coefficient is

\[ 1/U = 1/\overline{h}_i + 1/\overline{h}_o \]  \( (7) \)

and the \( \overline{h} \) are estimated using the Dittus-Boelter correlation assuming fully developed turbulent flow.

*Coefficient, hot side, \( \overline{h}_i \).* For flow in the inner tube,

\[ \text{Re}_D = \frac{4 \dot{m}_h}{\pi D_i \mu_h} \quad \dot{m}_h = \dot{m}_{\text{hi}} \cdot N \]  \( (8,9) \)

and the correlation, Eq. 8.60 with \( n = 0.3 \), is

\[ \overline{Nu}_D = \frac{\overline{h}_i D_i}{k} = 0.037 \text{Re}_D^{4/5} \text{Pr}_D^{0.3} \]  \( (10) \)

where properties are evaluated at the average mean temperature, \( \overline{T} = (T_{h} + T_{o})/2 \).

*Coefficient, cold side, \( \overline{h}_o \).* For flow in the annular space, \( D_o - D_i \), the above relations apply where the characteristic dimension is the hydraulic diameter,

\[ D_{h,o} = 4 A_{c,o} / P_o \quad A_{c,o} = \pi \left( D_o^2 - D_i^2 \right) / 4 \quad P_o = \pi \left( D_o + D_i \right) \]  \( (11-13) \)

To determine the outer diameter \( D_o \), require that the inner and outer fluid flow areas are the same, that is,

\[ A_{c,i} = A_{c,o} \quad \pi D_i^2 / 4 = \pi \left( D_o^2 - D_i^2 \right) / 4 \]  \( (14,15) \)

*Summary of the convection coefficient calculations.* The results of the analysis with \( L = 10 \text{ m} \) are summarized below.

Continued .....
For all these cases, the Reynolds numbers are above 10,000 and turbulent flow occurs.

**Step 4: Evaluate first-pass design.** The required UA product value determined in step 1 is $UA = 9.62 \times 10^4 \text{ W/K}$. By comparison with the results in the above table, note that the $U \times A$ values for cases 1a and 2a are, respectively, larger and smaller than that required. In this first-pass design trial we have identified the range of $D_i$ and $N$ (with $L = 10 \text{ m}$) that could satisfy the exchanger specifications. A strategy can now be developed in **Step 5** to iterate the analysis on values for $D_i$ and $N$, as well as with different $L$, to identify a combination that will meet specifications.

(b) What information could have been provided by the customer to simplify the analysis for design of the exchanger? Looking back at the analysis, recognize that we had to assume the exchanger configuration (type) and overall length. Will knowledge of the customer’s installation provide any insight? While no consideration was given in our analysis to pumping power limitations, that would affect the flow velocities, and hence selection of tube diameter.

**COMMENTS:** The IHT workspace with the relations for step 3 analysis is shown below, including summary of key correlation parameters. The set of equations is quite stiff so that good initial guesses are required to make the initial solve.

<tr>
<td>Oil</td>
<td>800</td>
<td>1900</td>
<td>(1 \times 10^{-5})</td>
<td>0.134</td>
<td>140</td>
</tr>
</tbody>
</table>

ANALYSIS: (a) With the outlet temperature, \(T_{c,o} = 60°C\), from an overall energy balance on the hot (oil) fluid, find

\[
q = \dot{m}_h c_h (T_{h,i} - T_{h,o}) = 0.1 \text{ kg/s} \times 1900 \text{ J/kg·K} \times (100 - 60)\text{°C} = 7600 \text{ W.}
\]

From an energy balance on the cold (water) fluid, find

\[
T_{c,o} = T_{c,i} + q / \dot{m}_c c_c = 30°C + 7600 \text{ W} / 0.1 \text{ kg/s} \times 4200 \text{ J/kg·K} = 48.1°C.
\]

(b) Using the LMTD method, the length of the CF heat exchanger follows from

\[
q = UA \Delta T_{\text{LMTD}} = U(\pi DL) \Delta T_{\text{LMTD}}
\]

where

\[
\Delta T_{\text{LMTD}} = \frac{\Delta T_1 - \Delta T_2}{\ln \left( \frac{\Delta T_1}{\Delta T_2} \right)} = \frac{(60 - 30)\text{°C} - (100 - 48.1)\text{°C}}{\ln(30/51.9)} = 40.0°C
\]

\[
L = \frac{7600 \text{ W} / 60 \text{ W/m}^2\cdot\text{K} \times (\pi \times 0.025\text{m}) \times 40.0°C}{40.3\text{m.}}
\]

COMMENTS: Using the \(\varepsilon\)-NTU method, find \(C_{\text{min}} = C_h = 190 \text{ W/K}\) and \(C_{\text{max}} = C_c = 420 \text{ W/K}\). Hence

\[
q_{\text{max}} = C_{\text{min}} (T_{h,i} - T_{c,i}) = 190 \text{ W} / K(100 - 30)K = 13,300 \text{ W}
\]

and \(\varepsilon = q / q_{\text{max}} = 0.571\). With \(C_r = C_{\text{min}} / C_{\text{max}} = 0.452\) and using Eq. 11.30b,

\[
\text{NTU} = \frac{UA}{C_{\text{min}}} = \frac{1}{C_r - 1} \ln \left( \frac{\varepsilon - 1}{\varepsilon C_r - 1} \right) = \frac{1}{0.452 - 1} \ln \left( \frac{0.571 - 1}{0.571 \times 0.452 - 1} \right) = 1.00
\]

so that with \(A = \pi DL\), find \(L = 40.3\text{ m.}\).
PROBLEM 11.21

KNOWN: Counterflow, concentric tube heat exchanger undergoing test after service for an extended period of time; surface area of 5 m² and design value for the overall heat transfer coefficient of $U_d = 38 \text{ W/m}^2\cdot\text{K}$.

FIND: Fouling factor, if any, based upon the test results of engine oil flowing at 0.1 kg/s cooled from 110°C to 66°C by water supplied at 25°C and a flow rate of 0.2 kg/s.

SCHEMATIC:

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible losses to the surroundings and kinetic and potential energy changes, (3) Constant properties.

**PROPERTIES:** *Table A-5*, Engine oil ($T_h = 361 \text{ K}$): $c = 2166 \text{ J/kg} \cdot \text{K}$; *Table A-6*, Water ($T_c = 304 \text{ K}$, assuming $T_{c,o} = 36^\circ \text{C}$): $c = 4178 \text{ J/kg} \cdot \text{K}$.

**ANALYSIS:** For the CF conditions shown in the Schematic, find the heat rate, $q$, from an energy balance on the hot fluid (oil); the cold fluid outlet temperature, $T_{c,o}$, from an energy balance on the cold fluid (water); the overall coefficient $U$ from the rate equation; and a fouling factor, $R$, by comparison with the design value, $U_d$.

*Energy balance on hot fluid*

$q = m_h c_h (T_{h,i} - T_{h,o}) = 0.1 \text{ kg/s} \times 2166 \text{ J/kg} \cdot \text{K} (110 - 66)\text{K} = 9530 \text{ W}$

*Energy balance on the cold fluid*

$q = m_c c_c (T_{c,o} - T_{c,i})$, find $T_{c,o} = 36.4^\circ \text{C}$

*Rate equation*

$q = UA \Delta T_{n,\text{CF}}$

$
\Delta T_{n,\text{CF}} = \frac{(T_{h,i} - T_{c,o}) - (T_{h,o} - T_{c,i})}{\ln\left[\frac{T_{h,i} - T_{c,o}}{T_{h,o} - T_{c,i}}\right]} = \frac{(110 - 36.4)^\circ \text{C} - (66 - 25)^\circ \text{C}}{\ln[73.6/41.0]} = 55.7^\circ \text{C}
$

$9530 \text{ W} = U \times 5 \text{ m}^2 \times 55.7^\circ \text{C}$

$U = 34.2 \text{ W/m}^2 \cdot \text{K}$

*Overall resistance including fouling factor*

$U = \frac{1}{\left[1/U_d + R_f^*\right]}$

$34.2 \text{ W/m}^2 \cdot \text{K} = \frac{1}{\left[1/38 \text{ W/m}^2 \cdot \text{K} + R_f^*\right]}$

$R_f^* = 0.0029 \text{ m}^2 \cdot \text{K/W}$
PROBLEM 11.22

KNOWN: Prescribed flow rates and inlet temperatures for hot and cold water; UA value for a shell-and-tube heat exchanger (one shell and two tube passes).

FIND: Outlet temperature of the hot water.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Constant properties, (3) Negligible kinetic and potential energy changes.

PROPERTIES: Table A-6, Water ($c_T = \frac{20 + 60}{2} = 40°C \approx 310$ K): $c_T = c_{p,f} = 4178$ J/kg·K; Water ($c_h = \frac{80 + 60}{2} = 70°C \approx 340$ K): $c_h = c_{p,f} = 4188$ J/kg·K.

ANALYSIS: From an energy balance on the hot fluid, the outlet temperature is

$$T_{h,o} = T_{h,i} - \frac{q}{\dot{m}_h c_h}.$$  

(1)

The heat rate can be written in terms of the effectiveness and $q_{max}$ as

$$q = \varepsilon q_{max} = \varepsilon C_{min} \left( T_{h,i} - T_{c,i} \right)$$  

(2)

where for this HXer, the cold fluid is the minimum fluid giving

$$q_{max} = \left( \dot{m}_c \right) c \left( T_{h,i} - T_{c,i} \right)$$

$$q_{max} = \left( \frac{5000}{3600} \right) \frac{kg}{s} \times 4178 \frac{J}{kg \cdot K} \left( 80 - 20 \right) ^°C = 348.2 \text{ kW}.$$  

The effectiveness can be determined from Figure 11.16 with

$$NTU = \frac{UA}{C_{min}} = \frac{11,600 \text{ W/K}}{\left( \frac{5000}{3600} \right) \frac{kg}{s} \times 4178 \frac{J}{kg \cdot K}} = 2.0$$

giving, $\varepsilon = 0.7$ for $C_r = C_{min}/C_{max} = \left( 5,000 \times 4178 \right) / \left( 10,000 \times 4188 \right) = 0.499$. Combining Eqs. (1) and (2), find

$$T_{h,o} = 80°C - \left( 0.7 \times 348.2 \times 10^3 \frac{W}{J} \right) / \left( 10,000 \times 3600 \right) \frac{kg}{s} \times 4188 \frac{J}{kg \cdot K} \left( 80 - 20 \right) ^°C = 348.2 \text{ kW}.$$  

$$T_{h,o} = (80 - 21.0) °C = 59°C.$$  

COMMENTS: (1) From an energy balance on the cold fluid, $q = \left( \dot{m}_c \right) c \left( T_{c,o} - T_{c,i} \right)$, find that $T_{c,o} = 62°C$. For evaluating properties at average mean temperatures, we should use $T_h = \frac{59 + 80}{2} = 70°C = 343$ K and $T_c = \frac{20 + 62}{2} = 41°C = 314$ K. Note from above that we have indeed assumed reasonable temperatures at which to obtain specific heats.

(2) We could have also used Eq. 11.31a to evaluate $\varepsilon$ using $C_r = 0.5$ and $NTU = 2$ to obtain $\varepsilon = 0.693$.  

<
**PROBLEM 11.23**

**KNOWN:** Flow rates and inlet temperatures for automobile radiator configured as a cross-flow heat exchanger with both fluids unmixed. Overall heat transfer coefficient.

**FIND:** (a) Area required to achieve hot fluid (water) outlet temperature, $T_{m,o} = 330$ K, and (b) Outlet temperatures, $T_{h,o}$ and $T_{c,o}$, as a function of the overall coefficient for the range, $200 \leq U \leq 400$ W/m$^2$·K with the surface area $A$ found in part (a) with all other heat transfer conditions remaining the same as for part (a).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings and kinetic and potential energy changes, (2) Constant properties.

**PROPERTIES:** Table A.6, Water ($\overline{T}_h = 365$ K): $c_{p,h} = 4209$ J/kg·K; Table A.4, Air ($\overline{T}_c = 310$ K): $c_{p,c} = 1007$ J/kg·K.

**ANALYSIS:** (a) The required heat transfer rate is

$$q = \dot{m}_h c_{p,h} \left( T_{h,i} - T_{h,o} \right) = 0.05 \text{ kg/s} \left( 4209 \text{ J/kg} \cdot \text{K} \right) 70 \text{ K} = 14,732 \text{ W}.$$

Using the $\varepsilon$-NTU method,

$$C_{\text{min}} = C_h = 210.45 \text{ W/K} \quad C_{\text{max}} = C_c = 755.25 \text{ W/K}.$$

Hence, $C_{\text{min}}/C_{\text{max}} = 0.279$ and

$$q_{\text{max}} = C_{\text{min}} \left( T_{h,i} - T_{c,i} \right) = 210.45 \text{ W/K} (100 \text{ K}) = 21,045 \text{ W}.$$

$$\varepsilon = \frac{q}{q_{\text{max}}} = \frac{14,732 \text{ W}}{21,045 \text{ W}} = 0.700.$$

Figure 11.18 yields $NTU \approx 1.5$, hence,

$$A = NTU \left( C_{\text{min}}/U \right) = 1.5 \times 210.45 \text{ W/K} / \left( 200 \text{ W/m}^2 \cdot \text{K} \right) = 1.58 \text{ m}^2.$$  

(b) Using the *IHT Heat Exchanger Tool for Cross-flow with both fluids unmixed* arrangement and the *Properties Tool* for Air and Water, a model was generated to solve part (a) evaluating the efficiency using Eq. 11.33. The following results were obtained:

$$A = 1.516 \text{ m}^2 \quad NTU = 1.441 \quad T_{c,o} = 319.5 \text{ K}$$

Using the model but assigning $A = 1.516 \text{ m}^2$, the outlet temperature $T_{h,o}$ and $T_{c,o}$ were calculated as a function of $U$ and the results plotted below.

Continued...
With a higher $U$, the outlet temperature of the hot fluid (water) decreases. A benefit is enhanced heat removal from the engine block and a cooler operating temperature. If it is desired to cool the engine with water at 330 K, the heat exchanger surface area and, hence its volume in the engine component could be reduced.

**COMMENTS:**

1. For the results of part (a), the air outlet temperature is

   $$ T_{c,o} = T_{c,i} + q/C_c = 300 \text{ K} + (14,732 \text{ W} / 755.25 \text{ W/K}) = 319.5 \text{ K}. $$

2. For the conditions of part (a), using the LMTD approach, $\Delta T_{lm} = 51.2 \text{ K}$, $R = 0.279$ and $P = 0.7$. Hence, Fig. 11.12 yields $F \approx 0.95$ and

   $$ A = q/FU \Delta T_{lm} = (14,732 \text{ W}) \left[ 0.95 \left( 200 \text{ W/m}^2 \cdot \text{K} \right) \right] = 1.51 \text{ m}^2. $$

3. The IHT workspace with the model to generate the above plot is shown below. Note that it is necessary to enter the overall energy balances on the fluids from the keyboard.

   ```
   // Heat Exchanger Tool - Cross-flow with both fluids unmixed:
   // For the cross-flow, single-pass heat exchanger with both fluids unmixed,
   eps = 1 - exp((1 / Cr) * (NTU^0.22) * (exp(-Cr * NTU^0.78) - 1)) // Eq 11.33
   // where the heat-capacity ratio is
   Cr = Cmin / Cmax
   // and the number of transfer units, NTU, is
   NTU = U * A / Cmin // Eq 11.25
   // The effectiveness is defined as
   eps = q / qmax
   qmax = Cmin * (Thi - Tci) // Eq 11.20
   // See Tables 11.3 and 11.4 and Fig 11.18
   // Overall Energy Balances on Fluids:
   q = mdoth * cph * (Thi - Tho)
   q = mdotc * cpc * (Tco - Tci)
   // Assigned Variables:
   Cmin = Ch // Capacity rate, minimum fluid, W/K
   Ch = mdoth * cph // Capacity rate, hot fluid, W/K
   mdoth = 0.05 // Flow rate, hot fluid, kg/s
   Thi = 400 // Inlet temperature, hot fluid, K
   Tho = 330 // Outlet temperature, hot fluid, K; specified for part (a)
   Cmax = Cc // Capacity rate, maximum fluid, W/K
   Cc = mdotc * cpc // Capacity rate, cold fluid, W/K
   mdotc = 0.75 // Flow rate, cold fluid, kg/s
   Tci = 300 // Inlet temperature, cold fluid, K
   U = 200 // Overall coefficient, W/m^2.K
   // Properties Tool - Water (h)
   // Water property functions :T dependence, From Table A.6
   // Units: T(K), p(bars);
   // xh = 0 // Quality (0=sat liquid or 1=sat vapor)
   rhoh = rho_Tx("Water",Tmh,xh) // Density, kg/m^3
   cph = cp_Tx("Water",Tmh,xh) // Specific heat, J/kg·K
   Tmh = Tfluid_avg(Thi,Tho)
   // Properties Tool - Air(c)
   // Air property functions : From Table A.4
   // Units: T(K); 1 atm pressure
   rhoc = rho_T("Air",Tmc) // Density, kg/m^3
   cpc = cp_T("Air",Tmc) // Specific heat, J/kg·K
   Tmc = Tfluid_avg(Tci,Tco)
   ```
**PROBLEM 11.24**

**KNOWN:** Flowrates and inlet temperatures of a cross-flow heat exchanger with both fluids unmixed. Total surface area and overall heat transfer coefficient for clean surfaces. Fouling resistance associated with extended operation.

**FIND:** (a) Fluid outlet temperatures, (b) Effect of fouling, (c) Effect of UA on air outlet temperature.

**SCHEMATIC:**

![Heat Exchanger Schematic](image)

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings and negligible kinetic and potential energy changes, (2) Constant properties, (3) Negligible tube wall resistance.

**PROPERTIES:** Air and gas (given): \( c_p = 1040 \text{ J/kg} \cdot \text{K} \).

**ANALYSIS:** (a) With \( C_{\text{min}} = C_h = 1 \text{ kg/s} \times 1040 \text{ J/kg} \cdot \text{K} = 1040 \text{ W/K} \) and \( C_{\text{max}} = C_c = 5 \text{ kg/s} \times 1040 \text{ J/kg} \cdot \text{K} = 5200 \text{ W/K} \), \( C_{\text{min}} /C_{\text{max}} = 0.2 \). Hence, \( \text{NTU} = UA/C_{\text{min}} = 35 \text{ W/m}^2\cdot\text{K}(25 \text{ m}^2)/1040 \text{ W/K} = 0.841 \) and Fig. 11.18 yields \( \varepsilon \approx 0.57 \). With \( C_{\text{min}}(T_{h,i} - T_{c,i}) = 1040 \text{ W/K}(500 \text{ K}) = 520,000 \text{ W} = q_{\text{max}} \), Eqs. (11.21) and (11.22) yield

\[
\begin{align*}
\varepsilon &= -\frac{h_{,o}}{h_{,i}} = -\frac{800 \text{ K}}{1040 \text{ W/K}} = 0.56 \\
\varepsilon &= +\frac{c_{,o}}{c_{,i}} = +\frac{300 \text{ K}}{5200 \text{ W/K}} = 0.058
\end{align*}
\]

(b) With fouling, the overall heat transfer coefficient is reduced to

\[
U_f = \left( U^{-1} + R_f^* \right)^{-1} = \left[ \left(0.029 + 0.004\right) \text{ m}^2 \cdot \text{K/W} \right]^{-1} = 30.3 \text{ W/m}^2 \cdot \text{K}
\]

This 13.4% reduction in performance is large enough to justify cleaning of the tubes. (c) Using the *Heat Exchangers* option from the IHT Toolpad to explore the effect of UA, we obtain the following result.

![Heat Exchanger Graph](image)

The heat rate, and hence the air outlet temperature, increases with increasing UA, with \( T_{c,o} \) approaching a maximum outlet temperature of 400 K as \( UA \to \infty \) and \( \varepsilon \to 1 \).

**COMMENTS:** Note that, for conditions of part (a), Eq. 11.33 yields a value of \( \varepsilon = 0.538 \), which reveals the level of approximation associated with reading \( \varepsilon \) from Fig. 11.18.
PROBLEM 11.25

KNOWN: Cooling milk from a dairy operation to a safe-to-store temperature, $T_{h,o} \leq 13^\circ C$, using ground water in a counterflow concentric tube heat exchanger with a 50-mm diameter inner pipe and overall heat transfer coefficient of 1000 W/m$^2$·K.

FIND: (a) The UA product required for the chilling process and the length $L$ of the exchanger, (b) The outlet temperature of the ground water, and (c) the milk outlet temperatures for the cases when the water flow rate is halved and doubled, using the UA product found in part (a)

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible heat loss to surroundings and kinetic and potential energy changes, and (3) Constant properties.

PROPERTIES: Table A-6, Water ($T_c = 287$ K, assume $T_{c,o} = 18^\circ C$): $\rho = 1000$ kg/m$^3$, $c_p = 4187$ J/kg·K; Milk (given): $\rho = 1030$ kg/m$^3$, $c_p = 3860$ J/kg·K.

ANALYSIS: (a) Using the effectiveness-NTU method, determine the capacity rates and the minimum fluid.

Hot fluid, milk:

$$\dot{m}_h = \rho_h \dot{V}_h = 1030 \text{ kg/m}^3 \times 250 \text{ liter/h} \times 10^{-3} \text{ m}^3/\text{liter} \times 1 \text{ h/3600 s = 0.0715 kg/s}$$

$$C_h = \dot{m}_h c_h = 0.0715 \text{ kg/s} \times 3860 \text{ J/kg·K} = 276 \text{ W/K}$$

Cold fluid, water:

$$C_c = \dot{m}_c c_c = 1000 \text{ kg/m}^3 \times (0.72/3600 \text{ m}^3/\text{s}) \times 4187 \text{ J/kg·K} = 837 \text{ W/K}$$

It follows that $C_{\text{min}} = C_h$. The effectiveness of the exchanger from Eqs. 11.19 and 11.21 is

$$\varepsilon = \frac{q}{q_{\text{max}}} = \frac{C_h (T_{h,i} - T_{h,o})}{C_{\text{min}} (T_{h,i} - T_{c,i})} = \frac{(38.6 - 13)K}{(38.6 - 10)K} = 0.895$$

The NTU can be calculated from Eq. 10.30b, where $Cr = C_{\text{min}}/C_{\text{max}} = 0.330$,

$$\text{NTU} = \frac{1}{C_r - 1} \left( \frac{\varepsilon - 1}{\varepsilon} \right)$$

$$\text{NTU} = \frac{1}{0.330 - 1} \left( \frac{0.895 - 1}{0.895 \times 0.330 - 1} \right) = 2.842$$

Continued …..
PROBLEM 11.25 (Cont.)

From Eq. 11.25, find UA

\[ [UA] = NTU \cdot C_{\text{min}} = 2.842 \times 276 \text{ W} / \text{K} = 785 \text{ W} / \text{K} \]

and the exchanger tube length with \( A = \pi DL \) is

\[ L = \frac{[UA]}{\pi DU} = \frac{785 \text{ W} / \text{K}}{\pi \times 0.050 \text{ m} \times 1000 \text{ W} / \text{m}^2 \cdot \text{K}} = 5.0 \text{ m} \]

(b) The water outlet temperature, \( T_{c,o} \), can be calculated from the heat rates,

\[ C_h \left( T_{h,i} - T_{h,o} \right) = C_c \left( T_{c,o} - T_{c,i} \right) \]

\[ 276 \text{ W} / \text{K} \left( 38.6 - 13 \right) \text{K} = 837 \text{ W} / \text{K} \left( T_{c,o} - 10 \right) \text{K} \]

\[ T_{c,o} = 18.4 \text{°C} \]

(c) Using the foregoing Eqs. (1 - 3) in the IHT workspace, the hot fluid (milk) outlet temperatures are evaluated with \( UA = 785 \text{ W/K} \) for different water flow rates. The results, including the hot fluid outlet temperatures, are compared to the base case, part (a).

<table>
<thead>
<tr>
<th>Case</th>
<th>( C_c , (\text{W/K}) )</th>
<th>( T_{c,o} , (\text{°C}) )</th>
<th>( T_{h,o} , (\text{°C}) )</th>
</tr>
</thead>
<tbody>
<tr>
<td>1, halved flow rate</td>
<td>419</td>
<td>14.9</td>
<td>25.6</td>
</tr>
<tr>
<td>Base, part (a)</td>
<td>837</td>
<td>13</td>
<td>18.4</td>
</tr>
<tr>
<td>2, doubled flow rate</td>
<td>1675</td>
<td>12.3</td>
<td>14.3</td>
</tr>
</tbody>
</table>

COMMENTS:  
(1) From the results table in part (c), note that if the water flow rate is halved, the milk will not be properly chilled, since \( T_{c,o} = 14.9 \text{°C} > 13 \text{°C} \). Doubling the water flow rate reduces the outlet milk temperature by less than 1°C.

(2) From the results table, note that the water outlet temperature changes are substantially larger than those of the milk with changes in the water flow rate. Why is this so? What operational advantage is achieved using the heat exchanger under the present conditions?

(3) The water thermophysical properties were evaluated at the average cold fluid temperature,

\[ T_c = \left( T_{c,i} + T_{c,o} \right) / 2 \].

We assumed an outlet temperature of 18°C, which as the results show, was a good choice. Because the water properties are not highly temperature dependent, it was acceptable to use the same values for the calculations of part (c). You could, of course, use the properties function in IHT that will automatically use the appropriate values.
PROBLEM 11.26

FIND: (a) Heat transfer area required for regenerator and corresponding heat recovery rate and outlet temperatures, (b) Annual energy and fuel cost savings.

SCHEMATIC:

ASSUMPTIONS: (a) Negligible heat loss to surroundings, (b) Constant properties.

PROPERTIES: Table A-6, water \( \overline{\rho}_w = 310 \text{K} \): \( c_p = 4178 \text{J/kg·K} \).

ANALYSIS: (a) With \( C_r = 1 \) and \( \varepsilon = 0.50 \) for one shell and two tube passes, Eq. 11.31c yields \( E = 1.414 \). With \( C_{\text{min}} = 5 \text{kg/s} \times 4178 \text{J/kg·K} = 20,890 \text{W/K} \), Eq. 11.31b then yields

\[
A = -\frac{C_{\text{min}}}{U} \ln \left[ \frac{(E-1)/(E+1)}{1+C^2_r} \right]^{1/2} = \frac{20,890 \text{W/K}}{2000 \text{W/m}^2·\text{K}} \ln \left( \frac{0.171}{1.414} \right) = 13.05 \text{m}^2
\]

With \( \varepsilon = 0.50 \), the heat recovery rate is then

\[
q = \varepsilon C_{\text{min}} (T_{h,i} - T_{c,i}) = 679,000 \text{W}
\]

and the outlet temperatures are

\[
T_{c,o} = T_{c,i} + \frac{q}{C_c} = 5^\circ\text{C} + \frac{679,000 \text{W}}{20,890 \text{W/K}} = 37.5^\circ\text{C}
\]

\[
T_{h,o} = T_{h,i} - \frac{q}{C_h} = 70^\circ\text{C} - \frac{679,000 \text{W}}{20,890 \text{W/K}} = 37.5^\circ\text{C}
\]

(b) The amount of energy recovered for continuous operation over 365 days is

\[
\Delta E = 679,000 \text{W} \times 365 \text{d/yr} \times 24 \text{h/d} \times 3600 \text{s/h} = 2.14 \times 10^{13} \text{J/yr}
\]

The annual fuel savings \( S_A \) is then

\[
S_A = \frac{\Delta E \times C_{\text{ng}}}{\eta} = \frac{2.14 \times 10^7 \text{MJ/yr} \times 0.0075 \text{MJ}}{0.9} = \$178,000/\text{yr}
\]

COMMENTS: (1) With \( C_c = C_h \), the temperature changes are the same for the two fluids, (2) A larger effectiveness and hence a smaller value of \( A \) can be achieved with a counterflow exchanger (compare Figs. 11.15 and 11.16 for \( C_r = 1 \)), (c) The savings are significant and well worth the cost of the heat exchanger. An additional benefit is that, with \( T_{h,o} \) reduced from 70 to 37.5°C, less energy is consumed by the refrigeration system used to restore it to 5°C.
**PROBLEM 11.27**

**KNOWN:** Heat exchanger in car operating between warm radiator fluid and cooler outside air. Effectiveness of heater is $\varepsilon \sim \dot{m}_{\text{air}}^{-0.2}$ since water flow rate is large compared to that of the air. For low-speed fan condition, heat warms outdoor air from $0^\circ\text{C}$ to $30^\circ\text{C}$.

**FIND:** (a) Increase in heat added to car for high-speed fan condition causing $\dot{m}_{\text{air}}$ to be doubled while inlet temperatures remain the same, and (b) Air outlet temperature for medium-speed fan condition where air flow rate increases 50% and heat transfer increases 20%.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat losses from heat exchanger to surroundings, (2) $T_{h,i}$ and $T_{c,i}$ remain fixed for all fan-speed conditions, (3) Water flow rate is much larger than that of air.

**ANALYSIS:** (a) Assuming the flow rate of the water is much larger than that of air, $C_{\text{min}} = C_c = \dot{m}_{\text{air}} c_{p,c}$. Hence, the heat rate can be written as

$$q = \varepsilon q_{\text{max}} = \varepsilon C_{\text{min}} \left( T_{h,i} - T_{c,i} \right) = \varepsilon \cdot \dot{m}_{\text{air}} c_{p,\text{air}} \left( T_{h,i} - T_{c,i} \right).$$

Taking the ratio of the heat rates for the high and low speed fan conditions, find

$$\frac{q_{hi}}{q_{lo}} = \frac{(\varepsilon \dot{m}_{\text{air}})_{hi}}{(\varepsilon \dot{m}_{\text{air}})_{lo}} \frac{(\dot{m}_{0.8})_{hi}}{(\dot{m}_{0.8})_{lo}} = 2.08 = 1.74$$

where we have used $\varepsilon \sim \dot{m}_{\text{air}}^{-0.2}$ and recognized that for the high speed fan condition, the air flow rate is doubled. Hence the heat rate is increased by 74%.

(b) Considering the medium and low speed conditions, it was observed that,

$$\frac{q_{\text{med}}}{q_{lo}} = 1.2 \quad \frac{(\dot{m}_{\text{air}})_{\text{med}}}{(\dot{m}_{\text{air}})_{lo}} = 1.5.$$

To find the outlet air temperature for the medium speed condition,

$$\frac{q_{\text{med}}}{q_{lo}} = \frac{\left[ \dot{m}_{\text{air}} c_{p,c} \left( T_{c,o} - T_{c,i} \right) \right]_{\text{med}}}{\left[ \dot{m}_{\text{air}} c_{p,c} \left( T_{c,o} - T_{c,i} \right) \right]_{lo}}$$

$$1.2 = \frac{1.5 \dot{m}_{\text{air}} c_{p,c} \left( T_{c,o} - 0^\circ\text{C} \right)}{\dot{m}_{\text{air}} c_{p,c} \left( 30^\circ\text{C} - 0^\circ\text{C} \right)}$$

$T_{c,o} = 24^\circ\text{C}$. 

<
PROBLEM 11.28

KNOWN: Counterflow heat exchanger formed by two brazed tubes with prescribed hot and cold fluid inlet temperatures and flow rates.

FIND: Outlet temperature of the air.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible loss/gain from tubes to surroundings, (2) Negligible changes in kinetic and potential energy, (3) Flow in tubes is fully developed since \( \frac{L}{D} = 40 \text{m}/0.030 \text{m} = 1333 \).

PROPERTIES: Table A-6, Water \((T_h = 335 \text{ K})\): \( c_h = c_{p,h} = 4186 \text{ J/kg}\cdot\text{K}, \mu = 453 \times 10^{-6} \text{ N} \cdot \text{s}/\text{m}^2, k = 0.656 \text{ W/m}\cdot\text{K}, Pr = 2.88 \); Table A-4, Air \((300 \text{ K})\): \( c_c = c_{p,c} = 1007 \text{ J/kg}\cdot\text{K}, \mu = 184.6 \times 10^{-7} \text{ N} \cdot \text{s}/\text{m}^2, k = 0.0263 \text{ W/m}\cdot\text{K}, Pr = 0.707 \); Table A-1, Nickel \((T = (23 + 85)\degree C/2 = 327 \text{ K})\): \( k = 88 \text{ W/m}\cdot\text{K} \).

ANALYSIS: Using the NTU - \( \varepsilon \) method, from Eq. 11.30a,

\[
\varepsilon = \frac{1 - \exp\left[-\text{NTU}(1 - C_T)\right]}{1 - C_T \exp\left[-\text{NTU}(1 - C_T)\right]}
\]

\( \text{NTU} = \frac{U\cdot A}{C_{\min}} \quad \text{and} \quad C_T = \frac{C_{\min}}{C_{\max}} \). \quad (1,2,3)

Estimate \( U A \) from a model of the tubes and flows, and determine the outlet temperature from the expression

\[
\varepsilon = C_c \left( T_{C,o} - T_{C,i} \right) / C_{\min} \left( T_{H,i} - T_{C,i} \right). \quad (4)
\]

Water-side: \( \text{Re}_D = \frac{4 \dot{m}_h}{\pi D \mu} = \frac{4 \times 0.04 \text{ kg/s}}{\pi \times 0.010 \text{m} \times 453 \times 10^{-6} \text{N} \cdot \text{s}/\text{m}^2} = 11,243 \).

The flow is turbulent and since fully developed, use the Dittus-Boelter correlation,

\[
\overline{\text{Nu}_h} = \bar{h}_h D / k = 0.023 \text{Re}_D^{0.8} \text{Pr}^{0.3} = 0.023(11,243)^{0.8}(2.88)^{0.3} = 54.99
\]

\[
\bar{h}_h = 54.99 \times 0.656 \text{ W/m} \cdot \text{K} / 0.01 \text{m} = 3,607 \text{ W/m}^2 \cdot \text{K}.
\]

Air-side: \( \text{Re}_D = \frac{4 \dot{m}_c}{\pi D \mu} = \frac{4 \times 0.120 \text{ kg/s}}{\pi \times 0.030 \text{m} \times 184.6 \times 10^{-7} \text{N} \cdot \text{s}/\text{m}^2} = 275,890 \).

The flow is turbulent and since fully developed, again use the correlation

\[
\overline{\text{Nu}_c} = \bar{h}_c D / K = 0.023 \text{Re}_D^{0.8} \text{Pr}^{0.4} = 0.023(275,890)^{0.8}(0.707)^{0.4} = 450.9
\]

\[
\bar{h}_c = 450.9 \times 0.0263 \text{ W/m} \cdot \text{K} / 0.030 \text{m} = 395.3 \text{ W/m}^2 \cdot \text{K}.
\]

Overall coefficient: From Eq. 11.1, considering the temperature effectiveness of the tube walls and the thermal conductance across the brazed region,

Continued …..
where $\eta_o$ needs to be evaluated for each of the tubes.

*Water-side temperature effectiveness:*  $A_h = \pi D_h L = \pi (0.010 \text{m}) 40 \text{m} = 1.257 \text{m}^2$

$$\eta_{o,h} = L_{f,h} = \tanh\left(\frac{m L_h}{m L_h}\right) = \left(\frac{h_h P / k A}{h_h / k t}\right)^{1/2} = 143.2 \text{m}^{-1}$$

and with $L_h = 0.5 \pi D_h$, $\eta_{o,h} = \tanh(143.2 \text{m}^{-1} \times 0.5 \pi \times 0.010 \text{m})/143.2 \text{m}^{-1} \times 0.5 \pi \times 0.010 \text{m} = 0.435$.

*Air-side temperature effectiveness:*  $A_c = \pi D_c L = \pi (0.030 \text{m}) 40 \text{m} = 3.770 \text{m}^2$

$$\eta_{o,c} = L_{f,c} = \tanh\left(\frac{m L_c}{m L_c}\right) = \left(\frac{395.3 \text{W} / \text{m}^2 \cdot \text{K} / 8.8 \text{W} / \text{m} \cdot \text{K} \times 0.002 \text{m}}{395.3 \text{W} / \text{m}^2 \cdot \text{K} / 8.8 \text{W} / \text{m} \cdot \text{K} \times 0.002 \text{m}}\right)^{1/2} = 47.39 \text{m}^{-1}$$

and with $L_c = 0.5 \pi D_c$, $\eta_{o,c} = \tanh(47.39 \text{m}^{-1} \times 0.5 \pi \times 0.030 \text{m})/47.39 \text{m}^{-1} \times 0.5 \pi \times 0.030 \text{m} = 0.438$.

Hence, the *overall heat transfer coefficient* using Eq. (5) is

$$\frac{1}{U_A} = \frac{1}{0.435 \times 3607 \text{W} / \text{m}^2 \cdot \text{K} \times 1.257 \text{m}^2} + \frac{1}{100 \text{W} / \text{m} \cdot \text{K} (40 \text{m})} + \frac{1}{0.438 \times 395.3 \text{W} / \text{m}^2 \cdot \text{K} \times 3.770 \text{m}^2}$$

$$U_A = \left[5.070 \times 10^{-4} + 2.50 \times 10^{-4} + 1.533 \times 10^{-3}\right]^{-1} \text{W} / \text{K} = 437 \text{W} / \text{K}.$$  

Evaluating now the *heat exchanger effectiveness* from Eq. (1) with

$$C_h = m_{h,c} c_h = 0.040 \text{kg/s} \times 4186 \text{J/kg} \cdot \text{K} = 167.4 \text{W} / \text{K} \leftarrow C_{\text{max}}$$

$$C_c = m_{c,c} c_c = 0.120 \text{kg/s} \times 1007 \text{J/kg} \cdot \text{K} = 120.8 \text{W} / \text{K} \leftarrow C_{\text{min}}$$

$$C_r = C_{\text{min}} / C_{\text{max}} = 0.722$$

$$\text{NTU} = \frac{U_A}{C_{\text{min}}} = \frac{437 \text{W} / \text{K}}{120.8 \text{W} / \text{K}} = 3.62$$

$$\varepsilon = \frac{1-\exp\left[-3.62(1-0.722)\right]}{1-0.722 \exp\left[-3.62(1-0.722)\right]} = 0.862$$

and finally from Eq. (4) with $C_{\text{min}} = C_c$.

$$\frac{0.862}{\frac{C_c (T_{c,o} - 23 \text{°C})}{C_c (85 - 23) \text{°C}}} \quad T_{c,o} = 76.4 \text{°C}$$

**COMMENTS:**

(1) Using overall energy balances, the water outlet temperature is

$$T_{h,o} = T_{h,i} + \left(\frac{C_c}{C_h}\right)(T_{c,o} - T_{c,i}) = 85 \text{°C} - 0.722(76.4 - 23) \text{°C} = 46.4 \text{°C}.$$  

(2) To initially evaluate the properties, we assumed that $T_h = 235 \text{ K}$ and $T_c = 300 \text{ K}$. From the calculated values of $T_{h,o}$ and $T_{c,o}$, more appropriate estimates of $T_h$ and $T_c$ are $338 \text{ K}$ and $322 \text{ K}$, respectively. We conclude that proper thermophysical properties were used for water but that the estimates could be improved for air.
PROBLEM 11.29

KNOWN: Twin-tube counterflow heat exchanger with balanced flow rates, \( \dot{m} = 0.003 \text{ kg/s} \). Cold airstream enters at 280 K and must be heated to 340 K. Maximum allowable pressure drop of cold airstream is 10 kPa.

FIND: (a) Tube diameter \( D \) and length \( L \) which satisfies the heat transfer and pressure drop requirements, and (b) Compute and plot the cold stream outlet temperature \( T_{c,o} \), the heat rate \( q \), and pressure drop \( \Delta p \) as a function of the balanced flow rate from 0.002 to 0.004 kg/s.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible heat loss to surroundings, (3) Average pressure of the airstreams is 1 atm, (4) Tube walls act as fins with 100% efficiency, (4) Fully developed flow.

PROPERTIES: Table A.4, Air (\( T_m = 310 \text{ K}, 1 \text{ atm} \)) : \( \rho = 1.128 \text{ kg/m}^3 \), \( c_p = 1007 \text{ J/kg K} \), \( \mu = 18.93 \times 10^{-6} \text{ m}^2/\text{s} \), \( k = 0.0270 \text{ W/m-K} \), \( Pr = 0.7056 \).

ANALYSIS: (a) The heat exchanger diameter \( D \) and length \( L \) can be specified through two analyses: (1) heat transfer based upon the effectiveness-NTU method to meet the cold air heating requirement and (2) pressure drop calculation to meet the requirement of 10 kPa. The heat transfer analysis begins by determining the effectiveness from Eq. 11.22, since \( C_{min} = C_{max} \) and \( C_r = 1 \),

\[
\varepsilon = \frac{q}{q_{max}} = \frac{C(T_{c,o} - T_{c,i})}{C(T_{h,i} - T_{c,i})} = \frac{(340 - 280) \text{ K}}{(360 - 280) \text{ K}} = 0.750 \quad (1)
\]

From Table 11.4, Eq. 11.29b for \( C_r = 1 \),

\[
NTU = \frac{\varepsilon}{1 - \varepsilon} = \frac{0.750}{1 - 0.750} = 3 \quad (2)
\]

where NTU, following its definition, Eq. 11.25, is

\[
NTU = \frac{\Delta A}{C_{min}} \quad (3)
\]

with

\[
C_{min} = \dot{m} c_p = 0.003 \text{ kg/s} \times 1007 \text{ J/kg K} = 3.021 \text{ K/W} \quad (4)
\]
and $1/UA$ represents the thermal resistance between the two fluids at $T_{m,h}$ and $T_{m,c}$ as illustrated in the above-right schematic. Since the tube walls are isothermal, it follows that

$$1/UA = 1/h_c A + 1/h_h A$$

and since the flow conditions are nearly identical $h_c = h_h$ so that

$$U = 0.5h$$

where the heat transfer area is

$$A = \pi DL$$

Hence, Eq. (3) can now be expressed as

$$3 = 0.5h (\pi DL) = 3.021K/W$$

$$hDL = 5.7697$$

Assuming an average mean temperature $T_{m,c} = 310K$, characterize the flow with

$$Re_D = \frac{4m}{\pi D \mu} = \frac{4 \times 0.003 kg/s}{\pi \times D \times 18.93 \times 10^{-6} m^2/s} = \frac{201.78}{D}$$

and assuming the flow is both turbulent and fully developed using the Dittus-Boelter correlation, Eq. 8.57, with $n = 0.4$,

$$Nu_D = 0.023 Re_D^{0.8} Pr^{0.4}$$

$$h_D = 0.023 \times 0.0270 W/m-K \left(201.78/D\right)^{0.8} \left(0.7056\right)^{0.4}$$

$$h_D^{0.8} = 0.0377$$

The pressure drop for fully developed flow, Eq. 8.22a, is

$$\Delta p = f \frac{pu_m^2}{2D} L$$

where the mean velocity is $u_m = \dot{m}/(\rho \pi D^2/4)$ so that

$$\Delta p = f \frac{4 \rho \left(\dot{m}/\rho \pi D^2\right) L}{2D} = \frac{2}{\pi^2} f \frac{m^2 \rho^2 L}{D^5}$$

$$\Delta p = \frac{2}{\pi^2} f \left(0.003 kg/s\right)^2 \left(1.128 kg/m^3\right) L$$

$$\Delta p = 2.3206 \times 10^{-6} f LD^{-5}$$

Recall that the pressure drop requirement is $\Delta p = 10 kPa = 10^4 N/m^2$, so that Eq. (12) can be rewritten as

$$fLD^{-5} = 4.3092 \times 10^{10}$$

Continued...
For the Reynolds number range, $3000 \leq \text{Re}_D \leq 5 \times 10^6$, Eq. 8.21 provides an estimate for the friction factor,

$$f = \left[ \frac{0.790}{\ln \left( \text{Re}_D \right)} - 1.64 \right]^{-2}$$

$$f = \left[ \frac{0.790}{\ln \left( 201.78/D \right)} - 1.46 \right]^{-2}$$

In the foregoing analysis, there are 4 unknowns ($D$, $L$, $f$, $\overline{h}$) and 4 equations (8, 10, 13, 14). Using the IHT workspace, find

$$D = 8.96 \text{ mm} \quad L = 3.52 \text{ m} \quad f = 0.02538 \quad \overline{h} = 182.9 \text{ W/m}^2 \cdot \text{K}$$

For this configuration, $\text{Re}_D = 22,520$ so the flow is turbulent and since $L/D = 3.52/0.00896 = 390 \gg 10$, the fully developed assumption is reasonable.

(b) The foregoing analysis entered into the IHT workspace was used to determine $T_{c,o}$, $q$ and $\Delta p$ as a function of the balanced flow rate, $\dot{m}$.

The outlet temperature of the cold air, $T_{c,o}$, is nearly insensitive to the flow rate. It follows that the heat rate, $q$, must be nearly proportional to the flow rate as can be seen in the $q$ vs. $\dot{m}$ plot above. The pressure drop varies with the mean velocity squared.
**PROBLEM 11.30**

**KNOWN:** Dimensions and thermal conductivity of twin-tube, counterflow heat exchanger. Contact resistance between tubes. Air inlet conditions for one tube and pressure of saturated steam in other tube.

**FIND:** Air outlet temperature and condensation rate.

**SCHEMATIC:**

![Schematic diagram of a heat exchanger with air and steam flows, showing dimensions and temperature differences.]

**ASSUMPTIONS:** (1) Negligible heat exchange with surroundings, (2) Negligible kinetic and potential energy and flow work changes, (3) Fully developed air flow, (4) Negligible fouling, (5) Constant properties.

**PROPERTIES:** Table A-4, air \( (\bar{T}_C = 325 \text{ K}, \ p = 5 \text{ atm}) \):  \( c_p = 1008 \text{ J/kg} \cdot \text{K}, \mu = 196.4 \times 10^{-7} \text{ N} \cdot \text{s/m} \cdot \text{K} \),  \( k = 0.0281 \text{ W/m} \cdot \text{K}, \ Pr = 0.703. \) Table A-6, sat. steam \( (p = 2.455 \text{ bar}) \):  \( T_{h,i} = T_{h,o} = 400 \text{ K}, \ h_{fg} = 2183 \text{ kJ/kg}. \)

**ANALYSIS:** With \( C_{max} \to \infty, C_r = 0 \) and Eqs. 11.22 and 11.36a yield

\[
\varepsilon = \frac{T_{c,o} - T_{c,i}}{T_{h,i} - T_{c,i}} = 1 - \exp(-\text{NTU}) \tag{1}
\]

From Eq. 11.1,

\[
\frac{1}{UA} = \frac{1}{(\eta_o h A)_c} + \frac{R'_i}{L} + \frac{1}{(\eta_o h A)_h} \tag{2}
\]

With \( \text{Re}_D = 4\dot{m}/\pi D_t \mu = 0.12 \text{ kg/s/\pi (0.05m)} 196.4 \times 10^{-7} \text{ N} \cdot \text{s/m}^2 = 38,900 \), the air flow is turbulent and the Dittus-Boelter correlation yields

\[
h_c = h_{fD} = \left( \frac{k}{D_i} \right) 0.023 \frac{\text{Re}_D^{4/5} \text{Pr}^{0.4}}{0.0281 \text{ W/m} \cdot \text{K} / 0.05m} \left( \frac{0.0281 \text{ W/m} \cdot \text{K}}{0.05m} \right) 0.023(38,900)^{4/5} (0.703)^{0.4} = 52.7 \text{ W/m}^2 \cdot \text{K}
\]

As shown on the inset, each tube wall may be modelled as two fins, each of length \( L_f = \pi D/2 = 0.0785 \text{m}. \) The total surface area for heat transfer is \( A_t = \pi D_t L = 0.785 \text{ m}^2 = A_c, \) which is equivalent to the surface area of the fins. With \( NA_f = A_f \) from Eq. 3.102, \( \eta_o = \eta_f. \) Because the outer surface of the tube is insulated, a wall thickness of 2t must be used in evaluating \( \eta_f. \) With \( m = (2h/ct)^{1/2} = (h/kt)^{1/2} = [52.7 \text{ W/m}^2 \cdot \text{K}/(60 \text{ W/m} \cdot \text{K} \times 0.004 \text{m})]^{1/2} = 14.8 \text{ m}^{-1} \), \( L_c = L_f \) for an adiabatic tip, and \( mL_f = 1.163, \) Eq. 3.89 yields

\[
\eta_f = \frac{\tanh mL_f}{mL_f} = \frac{0.821}{1.163} = 0.706 = \eta_{o,c}
\]

Continued ….
Similarly, for the steam tube, \( m = \frac{h}{k}\frac{1}{2} = \frac{[5,000 \text{ W/m}^2 \cdot \text{K}/(60 \text{ W/m} \cdot \text{K} \times 0.004 \text{m})]}{1/2} = 144.3 \text{ m}^{-1} \)
and \( mL_f = 11.33 \). Hence,

\[
\eta_f = \frac{\tanh mL_f}{mL_f} = \frac{1.00}{11.33} = 0.088 = \eta_{o,h}
\]

Substituting into Eq. (2),

\[
UA = \left[ \frac{1}{0.706 \times 52.7 \times 0.785} + \frac{0.01}{5} + \frac{1}{0.088 \times 5000 \times 0.785} \right]^{-1} \frac{W}{\text{K}} = 25.6 \frac{W}{\text{K}}
\]

Hence, with \( C_{\text{min}} = \left( \dot{m}_c p_c \right)_c = 0.03 \text{ kg/s} \times 1008 \text{ J/kg} \cdot \text{K} = 30.2 \text{ W/K}, \) \( NTU = UA/C_{\text{min}} = 0.847 \) and \( \varepsilon = 1 - \exp(-NTU) = 0.571 \). From Eq. (1), the air outlet temperature is then

\[
T_{c,o} = T_{c,i} + \varepsilon (T_{h,i} - T_{c,i}) = 17^\circ \text{C} + 0.571(127 - 17)\text{^\circ C} = 79.8^\circ \text{C}
\]

The rate of heat transfer to the air is

\[
q = \dot{m}_c p (T_{c,o} - T_{c,i}) = 0.03 \text{ kg/s} \times 1008 \text{ J/kg} \cdot \text{K} \times 62.8^\circ \text{C} = 1900 \text{ W}
\]

and the rate of condensation is

\[
\dot{m}_{\text{cond}} = \frac{q}{\dot{h}_{fg}} = \frac{1900 \text{ W}}{2.183 \times 10^6 \text{ J/kg}} = 8.70 \times 10^{-4} \text{ kg/s}
\]

**COMMENTS:**
1. With \( \bar{T}_c = 321.4 \text{ K}, \) the initial estimate of 325 K is reasonable and iteration on the property values is not necessary.
2. The major contribution to the total thermal resistance is due to air-side convection.
3. The foregoing results are independent of air pressure.
PROBLEM 11.31

KNOWN: Tube inner and outer diameters and longitudinal and transverse pitches for a cross-flow heat exchanger. Number of tubes in transverse plane. Water and gas flow rates and inlet temperatures. Water outlet temperature.

FIND: (a) Gas outlet temperature and number of longitudinal tube rows, (b) Effect of gas flowrate and inlet temperature on fluid outlet temperatures.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Negligible kinetic and potential energy changes, (3) Constant properties, (4) Negligible fouling.

PROPERTIES: Table A.6, Water (\( \bar{T}_c = 320 \text{ K} \)): \( c_p = 4180 \text{ J/kg-K}, \mu = 577 \times 10^{-6} \text{ N-s/m}^2, k = 0.640 \text{ W/m-K}, \text{Pr} = 3.77 \); Table A.4, Air (\( \bar{T}_h = 550 \text{ K} \)): \( c_p = 1040 \text{ J/kg-K}, \mu = 288.4 \times 10^{-7} \text{ N-s/m}^2, k = 0.0439 \text{ W/m-K}, \text{Pr} = 0.683, \rho = 0.633 \text{ kg/m}^3 \).

ANALYSIS: (a) The required heat transfer rate is

\[
q = \dot{m}_c c_p (T_{c,o} - T_{c,i}) = 50 \text{ kg/s (4180 J/kg-K) 60 K} = 1.254 \times 10^7 \text{ W}.
\]

Hence, with \( T_{h,o} = T_{h,i} - q/\dot{m}_h c_p (\text{h}) \),

\[
T_{h,o} = 700 \text{ K} - 1.254 \times 10^7 \text{ W/(40 kg/s x 1040 J/kg-K)} = 398.6 \text{ K}
\]

Use the \( \varepsilon - \text{NTU} \) method to compute the hot side HX surface area, \( A_H \). To calculate \( U_h \), we must find \( h_h \).

For the tube bank, \( S_D = 44.7 \text{ mm} > (S_T + D)/2 = 30 \text{ mm} \). Hence, with \( \rho V_{\text{max}} = [S_T/(S_T - D_o)] \rho V = [S_T/(S_T - D_o)](\dot{m}_h/WH) \),

\[
\begin{align*}
\rho V_{\text{max}} &= (40/20) \left[ 40 \text{ kg/s} / (2 \times 1.2 \text{ m}^2) \right] = 33.3 \text{ kg/s} \cdot \text{m}^2 \\
Re_{D,\text{max}} &= (\rho V_{\text{max}} D_o) / \mu = \left[ 33.3 \text{ kg/s} \cdot \text{m}^2 (0.02 \text{ m}) \right] / 288.4 \times 10^{-7} \text{ N-s/m}^2 = 23,116.
\end{align*}
\]

From the Zhukauskas correlation, with \( (\text{Pr}/\text{Pr}_s) \approx 1 \), and Table 7.7,

\[
\bar{N}u_D = 0.35 Re_D^{0.6} Pr^{0.36} = 0.35 (23,116)^{0.6} (0.683)^{0.36} = 127
\]

where it is assumed that \( N_L > 20 \). Hence,

\[
h_h = \bar{N}u_D (k/D_o) = 127 (0.0439 \text{ W/m-K}/0.02 \text{ m}) = 279 \text{ W/m}^2 \cdot \text{K}.
\]

From Eq. 11.1,

Continued...
PROBLEM 11.31 (Cont.)

\[
\frac{1}{U_h} = \frac{1}{h_c} \left( \frac{D_o}{D_i} \right) + \frac{D_o \ln \left( \frac{D_o}{D_i} \right)}{2k} \frac{1}{h_h} = \frac{1}{3000 \text{ W/m}^2 \cdot \text{K}} + \frac{0.02 \text{ m} \ln \left( \frac{20}{15} \right)}{60 \text{ W/m K}} + \frac{1}{279 \text{ W/m}^2 \cdot \text{K}}
\]

\[
\frac{1}{U_h} = \left( 4.44 \times 10^{-4} + 9.59 \times 10^{-5} + 3.58 \times 10^{-3} \right) \text{m}^2 \cdot \text{K/W} = 4.12 \times 10^{-3} \text{m}^2 \cdot \text{K/W}
\]

\[U_h = 243 \text{ W/m}^2 \cdot \text{K}.
\]

With \(C_h = C_{\text{min}} = 4.160 \times 10^4 \text{ W/K}\) and \(C_c = C_{\text{max}} = 2.09 \times 10^5 \text{ W/K}\), \(C_{\text{min}}/C_{\text{max}} = 0.199\) and \(q_{\text{max}} = C_{\text{min}}(T_{h,i} - T_{c,i}) = 4.16 \times 10^4 \text{ W}/(410 \text{ K}) = 1.71 \times 10^7 \text{ W}\). Hence, \(\epsilon = (q/q_{\text{max}}) = (1.254 \times 10^7 \text{ W}/1.71 \times 10^7 \text{ W}) = 0.735\). With \(C_{\text{min}}\) mixed and \(C_{\text{max}}\) unmixed, Eq. 11.35b gives \(\text{NTU} = 1.54\) and

\[A_h = \text{NTU} \left( \frac{C_{\text{min}}}{U_h} \right) = 1.54 \left( \frac{4.160 \times 10^4 \text{ W/K}}{243 \text{ W/m}^2 \cdot \text{K}} \right) = 264 \text{ m}^2.
\]

Hence, \(N_L = \frac{A_h}{(\pi D_o W) \pi T} = \frac{264 \text{ m}^2}{\pi (0.02)2(30)\text{m}^2} = 70\)

(b) Using the IHT Correlations, Heat Exchangers and Properties Toolpads to perform the parametric calculations, we obtain the following results for \(N_L = 90\).

Since \(h_h\) and hence \(U_h\) increases with \(m_{h,i}\), \(q\), and hence, \(T_{c,o}\), increases with increasing \(m_{h,i}\), as well as with increasing \(T_{h,i}\). Although \(q\) increases with \(m_{h,i}\), the proportionality is not linear (\(q \propto m_{h,i}^a\), where \(a < 1\)) and \((T_{h,i} - T_{h,o})\) must decrease with increasing \(m_{h,i}\), in which case \(T_{h,o}\) must increase. From the above results, it is clear that operation is restricted to \(m_{h,i} \geq 40 \text{ kg/s}\) and \(T_{h,i} \geq 700 \text{ K}\), if corrosion of the heat exchanger surfaces is to be avoided.

COMMENTS: To check the presumed value of \(h_c = 3000 \text{ W/m}^2 \cdot \text{K}\), compute

\[\text{Re}_D = \frac{4(m_{h,i}/N)}{\pi D_i \mu} = \frac{4(50 \text{ kg/s})/70 \times 30}{\pi (0.015 \text{ m}) 577 \times 10^{-6} \text{ N} \cdot \text{s/cm}^2} = 3500.
\]

Hence, \(\text{Nu}_D = 0.023 \text{Re}_D^{4/5} \text{Pr}^{0.4} = 0.023(3500)^{4/5} (3.77)^{0.4} = 26.8\)

\[h_c = (k/D) \text{Nu}_D = (0.640 \text{ W/m K}/0.015 \text{ m}) 26.8 = 1142 \text{ W/m}^2 \cdot \text{K}.
\]

Hence, the cold side convection coefficient has been overestimated and the calculations should be repeated using the smaller value of \(h_c\).
PROBLEM 11.32

KNOWN: Single pass, cross-flow heat exchanger with hot exhaust gases (mixed) to heat water (unmixed)

FIND: Required surface area.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Negligible kinetic and potential energy changes, (3) Exhaust gas properties assumed to be those of air.

PROPERTIES: Table A-6, Water ($\bar{T}_c = (80 + 30)°C/2 = 328$ K): $c_p = 4184$ J/kg·K; Table A-4, Air (1 atm, $T_h = (100 + 225)°C/2 = 436$ K): $c_p = 1019$ J/kg·K.

ANALYSIS: The rate equation for the heat exchanger follows from Eqs. 11.14 and 11.18. The area is given as

$$A = \frac{q}{U \Delta T_{\epsilon_m}} = \frac{q}{U F \Delta T_{\epsilon_m, CF}}$$  \hspace{1cm} (1)

where $F$ is determined from Fig. 11.13 using

$$P = \frac{80 - 30}{225 - 30} = 0.26 \quad \text{and} \quad R = \frac{225 - 100}{80 - 30} = 2.50 \quad \text{giving} \quad F = 0.92.$$  \hspace{1cm} (2)

From an energy balance on the cold fluid, find

$$q = \dot{m}_c c_c (T_{c,o} - T_{c,i}) = 3 \frac{kg}{s} \times 4184 \frac{J}{kg \cdot K} (80 - 30) K = 627,600 \ W.$$  \hspace{1cm} (3)

From Eq. 11.15, the LMTD for counter-flow conditions is

$$\Delta T_{\epsilon_m, CF} = \frac{\Delta T_1 - \Delta T_2}{\ln (\Delta T_1 / \Delta T_2)} = \frac{(225 - 80) - (100 - 30)}{\ln (145/70)} °C = 103.0°C.$$  \hspace{1cm} (4)

Substituting numerical values resulting from Eqs. (2-4) into Eq. (1), find the required surface area to be

$$A = 627,600 \ W / 200 \ W / m^2 \cdot K \times 0.92 \times 103.0 \ K = 33.1 \ m^2.$$  \hspace{1cm} <

COMMENTS: Note that the properties of the exhaust gases were not needed in this method of analysis. If the $\epsilon$-NTU method were used, find first $C_h/C_c = 0.40$ with $C_{min} = C_h = 5021 \ W/K$. From Eqs. 11.19 and 11.20, with $C_h = C_{min}, \epsilon = q/q_{max} = (T_{h,i} - T_{h,o})/(T_{h,i} - T_{c,i}) = (225 - 100)/(225 - 30) = 0.64$. Using Fig. 11.19 with $C_{min}/C_{max} = 0.4$ and $\epsilon = 0.64$, find $NTU = UA/C_{min} \approx 1.4$. Hence,

$$A = NTU \cdot C_{min} / U \approx 1.4 \times 5021 \ W/K / 200 \ W / m^2 \cdot K = 35.2 \ m^2.$$ 

Note agreement with above result.
PROBLEM 11.33

KNOWN: Concentric tube heat exchanger operating in parallel flow (PF) conditions with a thin-walled separator tube of 100-mm diameter; fluid conditions as specified.

FIND: (a) Required length for the exchanger; (b) Convection coefficient for water flow, assumed to be fully developed; (c) Compute and plot the heat transfer rate, \( q \), and fluid inlet temperatures, \( T_{h,i} \) and \( T_{c,i} \), as a function of the tube length for \( 60 \leq L \leq 400 \) m with the PF arrangement and overall coefficient \( U = 200 \text{ W/m}^2 \cdot \text{K} \), inlet temperatures \( T_{h,i} = 225^\circ \text{C} \) and \( T_{c,i} = 30^\circ \text{C} \), and fluid flow rates from Problem 11.23; (d) Reduction in required length relative to the value found in part (a) if the exchanger were operated in the counterflow (CF) arrangement; and (e) Compute and plot the effectiveness and fluid outlet temperatures as a function of tube length for \( 60 \leq L \leq 400 \) m for the CF arrangement of part (c).

SCHEMATIC:

ASSUMPTIONS: (1) No losses to surroundings, (2) Negligible kinetic and potential energy changes, (3) Separation tube has negligible thermal resistance, (4) Water flow is fully developed, (5) Constant properties, (6) Exhaust gas properties are those of atmospheric air.

PROPERTIES: Table A-4, Hot fluid, Air (1 atm, \( \bar{T} = (225 +100)^\circ \text{C} / 2 = 436 \text{ K} \)): \( c_p = 1019 \text{ J/kg} \cdot \text{K} \); Table A-6, Cold fluid, Water \( \bar{T} = (30 + 80)^\circ \text{C} / 2 = 328 \text{ K} \): \( \rho = 1/\nu = 985.4 \text{ kg/m}^3 \), \( c_p = 4183 \text{ J/kg} \cdot \text{K} \), \( k = 0.648 \text{ W/m} \cdot \text{K} \), \( \mu = 505 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 \), \( Pr = 3.58 \).

ANALYSIS: (a) From the rate equation, Eq. 11.14, with \( A = \pi D L \), the length of the exchanger is

\[
L = \frac{q}{U \cdot \pi D \cdot \Delta T_{n,PF}}. \tag{1}
\]

The heat rate follows from an energy balance on the cold fluid, using Eq. 11.7, find

\[
q = \dot{m}_c c_c \left( T_{c,o} - T_{c,i} \right) = 3 \text{ kg/s} \times 4183 \text{ J/kg} \cdot \text{K} \times (80 - 30) \text{ K} = 627.5 \times 10^3 \text{ W}. \tag{2}
\]

Using an energy balance on the hot fluid, find \( \dot{m}_h \) for later use.

\[
\dot{m}_h = \frac{q}{c_h \left( T_{h,i} - T_{h,o} \right)} = 627.5 \times 10^3 \text{ W} / 1019 \text{ J/kg} \cdot \text{K} \left( 225 - 100 \right) \text{ K} = 4.93 \text{ kg/s}.
\]

For parallel flow, Eqs. 11.15 and 11.16,

\[
\Delta T_{m,PF} = \frac{\Delta T_1 - \Delta T_2}{\ln \left( 225 - 30 \right) / (100 - 80)} = 76.8^\circ \text{C}.
\]

Substituting numerical values into Eq. (1), find

\[
L = \frac{627.5 \times 10^3 \text{ W} / 200 \text{ W/m}^2 \cdot \text{K} \times (\pi \times 0.1 \text{m})}{76.8 \text{ K}} = 130 \text{ m}.
\]

Continued...
PROBLEM 11.33 (Cont.)

(b) Considering the water flow within the separator tube, from Eq. 8.6,

\[
Re_D = 4\frac{m}{\pi \mu} = 4 \times 3 \text{ kg/s}/\left(\pi \times 0.1 \text{ m} \times 505 \times 10^{-6} \text{ N/s.m}^2\right) = 75,638.
\]

Since \(Re_D > 2300\), the flow is turbulent and since flow is assumed to be fully developed, use the Dittus-Boelter correlation with \(n = 0.4\) for heating,

\[
Nu_D = 0.023 \frac{Re_D^{0.8} Pr^{0.4}}{Pr^{0.8}} = 0.023 \left(75,638\right)^{0.8} \left(3.58\right)^{0.4} = 306.4
\]

\[
h = Nu_D \frac{k}{D} = 306.4 \times 0.648 \text{ W/m.K} / (0.1 \text{ m}) = 1985 \text{ W/m}^2 \cdot \text{K}.
\]

(c) Using the IHT Heat Exchanger Tool, Concentric Tube, Parallel Flow, Effectiveness relation, and the Properties Tool for Water and Air, a model was developed for the PF arrangement. With \(U = 200 \text{ W/m}^2 \cdot \text{K}\) and prescribed inlet temperatures, \(T_{h,i} = 225^\circ\text{C}\) and \(T_{c,i} = 30^\circ\text{C}\), the outlet temperatures, \(T_{h,o}\) and \(T_{c,o}\), and heat rate, \(q\), were computed as a function of tube length \(L\).

As the tube length increases, the outlet temperatures approach one another and eventually reach \(T_{h,o} = T_{c,o} = 85.6^\circ\text{C}\).

(d) If the exchanger as for part (a) is operated in counterflow (rather than parallel flow), the log mean temperature difference is

\[
\Delta T_{m,CF} = \frac{\Delta T_1 - \Delta T_2}{\ln \left(\frac{\Delta T_1}{\Delta T_2}\right)}
\]

\[
\Delta T_{m,CF} = \frac{(225 - 80) - (100 - 30)}{\ln (225 - 80)/100 - 30} = 103.0^\circ\text{C}.
\]

Using Eq. (1), the required length is

\[
L = 627.5 \times 10^3 \text{ W}/200 \text{ W/m}^2 \cdot \text{K} \times \pi \times 0.1 \text{ m} \times 103.0 \text{ K} = 97 \text{ m}.
\]

The reduction in required length of CF relative to PF operation is

Continued...
PROBLEM 11.33 (Cont.)

$$\Delta L = \left( \frac{L_{PF} - L_{CF}}{L_{PF}} \right) = \frac{(103 - 97)}{103} = 5.8\%$$

(e) Using the IHT Heat Exchanger Tool, Concentric Tube, Counterflow, Effectiveness relation, and the Properties Tool for Water and Air, a model was developed for the CF arrangement. For the same conditions as part (c), but CF rather than PF, the effectiveness and fluid outlet temperatures were computed as a function of tube length L.

![Counterflow arrangement graph]

Note that as the length increases, the effectiveness tends toward unity, and the hot fluid outlet temperature tends toward $T_{c,i} = 30^\circ C$. Remember the heat rate for an infinitely long CF heat exchanger is $q_{max}$ and the minimum fluid (hot in our case) experiences the temperature change, $T_{h,i} - T_{c,i}$.

**COMMENTS:**

(1) As anticipated, the required length for CF operations was less than for PF operation.

(2) Note that U is substantially less than $h_i$ implying that the gas-side coefficient must be the controlling thermal resistance.
**PROBLEM 11.34**

**KNOWN:** Cross-flow heat exchanger (both fluids unmixed) cools blood to induce body hypothermia using ice-water as the coolant.

**FIND:** (a) Heat transfer rate from the blood, (b) Water flow rate, \( \dot{V}_c \) (liter/min), (c) Surface area of the exchanger, and (d) Calculate and plot the blood and water outlet temperatures as a function of the water flow rate for the range, \( 2 \leq \dot{V} \leq 4 \) liter/min, assuming all other parameters remain unchanged.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible losses to the surroundings and kinetic and potential energy changes, (3) Overall heat transfer coefficient remains constant with water flow rate changes, and (4) Constant properties.

**PROPERTIES:** Table A-6, Water \((T_c = 280\,\text{K})\), \( \rho = 1000 \, \text{kg/m}^3 \), \( c = 4198 \, \text{J/kg} \cdot \text{K} \). Blood (given): \( \rho = 1050 \, \text{kg/m}^3 \), \( c = 3740 \, \text{J/kg} \cdot \text{K} \).

**ANALYSIS:** (a) The heat transfer rate from the blood is calculated from an energy balance on the hot fluid,

\[
\dot{m}_h = \rho_h \dot{V}_h = 1050 \, \text{kg/m}^3 \times (5 \, \text{liter/min} \times 1 \, \text{min} / 60 \, \text{s}) \times 10^{-3} \, \text{m}^3 / \text{liter} = 0.0875 \, \text{kg/s}
\]

\[
q = \dot{m}_h c_h (T_{h,i} - T_{h,o}) = 0.0875 \, \text{kg/s} \times 3740 \, \text{J/kg} \cdot \text{K} (37 - 25) \, \text{K} = 3927 \, \text{W} < (1)
\]

(b) From an energy balance on the cold fluid, find the coolant water flow rate,

\[
q = \dot{m}_c c_c (T_{c,o} - T_{c,i})
\]

\[
3927 \, \text{W} = \dot{m}_c \times 4198 \, \text{J/kg} \cdot \text{K} (15 - 0) \, \text{K} \quad \dot{m}_c = 0.0624 \, \text{kg/s}
\]

\[
\dot{V}_c = \dot{m}_c / \rho_c = 0.0624 \, \text{kg/s} / 1000 \, \text{kg/m}^3 \times 10^3 \, \text{liter/m}^3 \times 60 \, \text{s/min} = 3.74 \, \text{liter/min} <
\]

(c) The surface area can be determined using the effectiveness-NTU method. The capacity rates for the exchanger are

\[
C_h = \dot{m}_h c_h = 327 \, \text{W/K} \quad C_c = \dot{m}_c c_c = 262 \, \text{W/K} \quad C_{min} = C_c
\]

From Eq. 11.19 and 11.20, the maximum heat rate and effectiveness are

Continued .....
PROBLEM 11.34 (Cont.)

\[
q_{\text{max}} = C_{\min} \left( T_{h,i} - T_{c,i} \right) = 262 \text{ W/K} \left( 37 - 0 \right) \text{K} = 9694 \text{ W}
\]

\[
\varepsilon = \frac{q}{q_{\text{max}}} = \frac{3927}{9694} = 0.405
\]

For the cross flow exchanger, with both fluids unmixed, substitute numerical values into Eq. 11.33 to find the number of transfer units, NTU, where \( C_r = C_{\min} / C_{\max} \).

\[
\varepsilon = 1 - \exp \left\{ \left( \frac{1}{C_r} \right) \right\} ^{0.22} \left\{ \exp \left( -C_r \times \text{NTU}^{0.78} \right) - 1 \right\}
\]

\[
\text{NTU} = 0.691
\]

From Eq. 11.25, find the surface area, A.

\[
\text{NTU} = \frac{UA}{C_{\min}}
\]

\[
A = 0.691 \times 262 \text{ W/K} / 750 \text{ W/m}^2 \cdot \text{K} = 0.241 \text{ m}^2
\]

(d) Using the foregoing equations in the IHT workspace, the blood and water outlet temperatures, \( T_{h,o} \) and \( T_{c,o} \), respectively, are calculated and plotted as a function of the water flow rate, all other parameters remaining unchanged.

From the graph, note that with increasing water flow rate, both the blood and water outlet temperatures decrease. However, the effect of the water flow rate is greater on the water outlet temperature. This is an advantage for this application, since it is desirable to have the blood outlet temperature relatively insensitive to changes in the water flow rate. That is, if there are pressure changes on the water supply line or a slight miss-setting of the water flow rate controller, the outlet blood temperature will not change markedly.
**PROBLEM 11.35**

**KNOWN:** Steam at 0.14 bar condensing in a shell and tube HXer (one shell, two tube passes consisting of 130 brass tubes off length 2 m, D₁ = 13.4 mm, Dₒ = 15.9 mm). Cooling water enters at 20°C with a mean velocity 1.25 m/s. Heat transfer convection coefficient for condensation on outer tube surface is \( hₒ = 13,500 \text{ W/m}^2\cdot\text{K} \).

**FIND:** (a) Overall heat transfer coefficient, \( U \), for the HXer, outlet temperature of cooling water, \( T_{c,o} \), and condensation rate of the steam \( \dot{m}_h \); and (b) Compute and plot \( T_{c,o} \) and \( \dot{m}_h \) as a function of the water flow rate \( 10 \leq \dot{m}_c \leq 30 \text{ kg/s} \) with all other conditions remaining the same, but accounting for changes in \( U \).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Negligible kinetic and potential energy changes, (3) Constant properties, (4) Fully developed water flow in tubes.

**PROPERTIES:** *Table A-6*, Steam (0.14 bar): \( T_{\text{sat}} = T_h = 327 \text{ K} \), \( h_{fg} = 2373 \text{ kJ/kg} \); *Table A-6*, Water (Assume \( T_{c,o} \approx 44°C \) or \( cT \approx 305 \text{ K} \)): \( v_f = 1.005 \times 10^{-3} \text{ m}^3/\text{kg} \), \( c_p = 4178 \text{ J/kg} \cdot \text{K} \), \( \mu = 769 \times 10^{-6} \text{ N} \cdot \text{s}/\text{m}^2 \), \( k_f = 0.620 \text{ W/m} \cdot \text{K} \), \( Pr_f = 5.2 \); *Table A-1*, Brass - 70/30 (Evaluate at \( T = (T_h + T_c)/2 = 316 \text{ K} \)): \( k = 114 \text{ W/m} \cdot \text{K} \).

**ANALYSIS:** (a) The overall heat transfer coefficient based upon the outside tube area follows from Eq. 11.5,

\[
U_o = \left[ \frac{1}{h_o} + \frac{r_o}{k} \frac{r_o}{\eta} \frac{1}{h_i} \right]^{-1},
\]

Continued...
PROBLEM 11.35 (Cont.)

\[ h_i = \frac{k_f \cdot \text{Nu}_D}{D_i} = \frac{0.620 \text{W/m} \cdot \text{K}}{13.4 \times 10^{-3} \text{m}} \times 130.9 = 6057 \text{W/m}^2 \cdot \text{K}. \]

Substituting numerical values into Eq. (1), the overall heat transfer coefficient is

\[
U_o = \left[\frac{1}{13,500 \text{W/m}^2 \cdot \text{K}} + \left(\frac{15.9 \times 10^{-3} \text{m}}{115 \text{W/m} \cdot \text{K}}\right)\frac{15.9}{13.4} + \frac{15.9}{6057 \text{W/m}^2 \cdot \text{K}}\right]^{-1}
\]

\[
U_o = \left[7.407 \times 10^{-5} + 1.183 \times 10^{-5} + 19.590 \times 10^{-5}\right]^{-1} \text{W/m}^2 \cdot \text{K} = 3549 \text{W/m}^2 \cdot \text{K}.
\]

To find the outlet temperature of the water, we’ll employ the \( \epsilon \) – NTU method. From an energy balance on the cold fluid,

\[
T_{c,o} = T_{c,i} + \frac{q}{C_c}
\]

where the heat rate can be expressed as

\[
q = \epsilon q_{\text{max}} \quad q_{\text{max}} = C_{\text{min}} \left(T_{h,i} - T_{h,o}\right).
\]

The minimum capacity rate is that of the cold water since \( C_h \to \infty \). Evaluating, find

\[
C_{\text{min}} = C_c = \left(\bar{m}c_p\right)_c = 22.8 \text{kg/s} \times 4178 \text{J/kg} \cdot \text{K} = 95,270 \text{W/K}.
\]

where

\[
\bar{m}_c = (\rho \cdot A_u \cdot N) = 995.0 \text{kg/m}^3 \times \pi/4 \left(0.0134 \text{m}\right)^2 \times 1.25 \text{m/s} \times 130 = 22.8 \text{kg/s}
\]

To determine \( \epsilon \), use Fig. 11.16 (one shell and any multiple of tube passes) with

\[
\text{NTU} = \frac{U_o A_o}{C_{\text{min}}} = \frac{3549 \text{W/m}^2 \cdot \text{K} \left(\pi 0.0159 \text{m} \times 2 \text{m} \times 130 \times 2\right)}{95,270 \text{W/K}} = 0.968
\]

where 130 and 2 represent the number of tubes and passes, respectively, to find \( \epsilon \approx 0.62 \). Combining Eqs. (4) and (5) into Eq. (3), find

\[
T_{c,o} = T_{c,i} + \epsilon C_{\text{min}} \left(T_{h,i} - T_{c,i}\right)/C_c = 20^\circ \text{C} + 0.62(327 - 293) \text{K} = 41.1^\circ \text{C}.
\]

The condensation rate of the steam is given by

\[
\bar{m}_h = q/h_{fg}
\]

where the heat rate can be determined from Eq. (3) with \( T_{c,o} \),

\[
\bar{m}_h = C_c \left(T_{c,o} - T_{c,i}\right)/h_{fg} = 95,270 \text{W/K} / (41.1 - 20.0) \text{K} / 2373 \times 10^3 \text{J/kg} \cdot \text{K} = 0.85 \text{kg/s}.
\]

(b) Using the IHT Heat Exchanger Tool, All Exchangers, \( C_r = 0 \), and the Properties Tool for Water, a model was developed and the cold outlet temperature and condensation rate were computed and plotted.

Continued...
With increasing cold flow rate, the cold outlet temperature decreases as expected. The condensation rate increases with increasing cold flow rate. Note that $T_{c,o}$ and $\dot{m}_H$ are nearly linear with the cold flow rate.

**COMMENTS:** For part (a) analysis, note that the assumption $T_{c,o} = 44^\circ C$ used for evaluation of the cold fluid properties was reasonable. Using the IHT model of part (b), we found $T_{c,o} = 40.2^\circ C$ and $\dot{m}_H = 0.812$ kg/s.
PROBLEM 11.36

KNOWN: Shell-and-tube (one shell, two tube passes) heat exchanger design. Water flow rate and inlet temperature. Steam pressure and convection coefficient.

FIND: (a) Water outlet temperature, $T_{c,o}$; (b) $T_{c,o}$ as a function of flow rate, $\dot{m}_c$, for the range, $5 \leq \dot{m}_c \leq 20$ kg/s, with all other conditions remaining the same, but accounting for changes in the overall coefficient, $U$; and (c) Plot $T_{c,o}$ on the same graph considering fouling factors of $R_f^* = 0.0002$ and $0.0005$ m²·K/W

SCHEMATIC:

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings and kinetic and potential energy changes, (2) Negligible wall conduction and fouling resistances, (3) Constant properties.

**PROPERTIES:** Table A-6. Sat. water ($p = 1.0133$ bar): $T_{sat} = T = 373.1$ K; ($\bar{T}_c = 320$ K): $c_p = 4180$ J/kg·K, $\mu = 577 \times 10^{-6}$ N·s/m², $k = 0.640$ W/m·K, $Pr = 3.77$.

**ANALYSIS:** Using the NTU-effectiveness method, calculate for $U$ by finding $h_i$. With

$$Re_D = 4 \dot{m}/\pi D \mu = \left[4(10 \text{ kg/s})/100\right] \left[\pi (0.02 \text{ m})(577 \times 10^{-6} \text{ N·s/m}^2)\right] = 11,033$$

(1)

and using the Dittus-Boelter correlation,

$$Nu_D = 0.023 Re_D^{4/5} Pr^{0.4} = 0.023(11,033)^{4/5} (3.77)^{0.4} = 67.05$$

(2)

$$h_i = (k/D) Nu_D = (0.640 \text{ W/m·K}/0.02 \text{ m}) 67.05 = 2146 \text{ W/m}^2 \cdot \text{K}.$$ 

From Eq. 11.5

$$1/U = 1/h_i + 1/h_o = \left[(1/10,000)+(1/2146)\right] \text{m}^2 \cdot \text{K}/\text{W} = 5.66 \times 10^{-4} \text{ m}^2 \cdot \text{K}/\text{W}$$

(3)

$$U = 1766 \text{ W}/\text{m}^2 \cdot \text{K}.$$ 

The heat transfer surface area, capacity rates and NTU are

$$A = N(\pi D)2L = 100(\pi 0.02 \text{ m})2 \times 2 \text{ m} = 25.1 \text{ m}^2$$

$$C_{min} = C_c = 10 \text{ kg/s} (4180 \text{ J/kg·K}) = 41,800 \text{ W/K}$$

$$NTU = UA/C_{min} = 1766 \text{ W}/\text{m}^2 \cdot \text{K} \times 25.1 \text{ m}^2/41,800 \text{ W/K} = 1.06$$

From Eq. 11.36a

Continued...
PROBLEM 11.36 (Cont.)

\[ \varepsilon = 1 - \exp \left( -\text{NTU} \right) = 1 - \exp \left( -1.06 \right) = 0.654. \]  \hspace{1cm} (4)

With

\[ q_{\text{max}} = C_{\text{min}} \left( T_{h,i} - T_{c,i} \right) = 41,800 \text{ W/K} \left( 373.15 - 290 \right) \text{ K} = 3.48 \times 10^6 \text{ W} \]  \hspace{1cm} (5)

\[ q = \varepsilon q_{\text{max}} = 0.654 \left( 3.48 \times 10^6 \text{ W} \right) = 2.27 \times 10^6 \text{ W} \]

find

\[ T_{c,o} = T_{c,i} + \left( q / C_c \right) = 290 \text{ K} + \left( 2.27 \times 10^6 \text{ W} / 41,800 \text{ W/K} \right) = 344.4 \text{ K}. \]  \hspace{1cm} (6)

(b,c) Using the IHT Heat Exchanger Tool, All Exchangers, \( C_r = 0 \), the Properties Tool for Water and the Correlation Tool, Forced Convection, Internal Flow, for Turbulent, fully developed conditions, a model was developed following the foregoing analysis to compute and plot the outlet temperature \( T_{c,o} \) as a function of the cold fluid flow rate, \( m_{\text{c}} \). The expression for the overall coefficient, Eq.(1), was modified to include the fouling factor,

\[ 1 / U = 1 / h_i + R''_{f} + 1 / h_o. \]

![Graph showing outlet temperature as a function of water flow rate for different fouling factors.](image)

The effect of increasing the cold flow rate is to decrease the outlet temperature. The effect of the fouling resistance is to decrease the outlet temperature as well.

**COMMENTS:**

(1) For the part (a) analysis, \( \overline{T}_c = 317 \text{ K} \) and the initial guess of 320 K was reasonably good.

(2) In the analysis of parts (b,c), \( \text{Re}_{D_c} \) is as low as 4880, below the turbulent range (10,000) and above the laminar range (2300). We chose to treat the flow as turbulent.
PROBLEM 11.37

KNOWN: Saturated steam at 110°C condensing in a shell and tube heat exchanger (one shell pass, 2, 4, tube passes) with a UA value of 2.5 kW/K; cooling water enters at 40°C.

FIND: Cooling water flow rate required to maintain a heat rate of 150 kW; and (b) Calculate and plot the water flow rate required to provide heat rates over the range 130 to 160 kW, assuming that UA is independent of flow rate. Comment on the validity of the assumption.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Negligible kinetic and potential energy changes, (3) UA independent of flow rate, and (4) Constant properties.

PROPERTIES: Table A-6, Water (T_{m,c} = (T_{c,i} + T_{c,o})/2 = 49.5°C = 322.5 K): c_{p,c} = 4181 J/kg⋅K.

ANALYSIS: (a) For the shell-tube heat exchanger with any multiple of two-tube passes, from Eq. 11.36a with C_{r} = 0, using Eqs. 11.20 and 11.23,

\[ \varepsilon = 1 - \exp(-NTU) \]
\[ NTU = \frac{UA}{C_{\text{min}}} \]  

\[ \varepsilon = \frac{q}{q_{\text{max}}} \]
\[ q_{\text{max}} = C_{c} \left( T_{h,i} - T_{c,i} \right) \]

By combining the equations with C_{\text{min}} = C_{c} = \dot{m}_{c} c_{p,c},

\[ \frac{q}{\dot{m}_{c} c_{p,c} \left( T_{h,i} - T_{c,i} \right)} = 1 - \exp \left( -\frac{UA}{\dot{m}_{c} c_{p,c}} \right) \]

Substituting numerical values, and solving using IHT find

\[ \dot{m}_{c} = 1.89 \text{ kg/s} \]

The specific heat of the cold fluid, c_{p,c}, is evaluated at the average of the mean inlet and outlet temperatures, T_{m,c} = (T_{c,i} + T_{c,o})/2, with T_{c,o} determined from the energy balance equation,

\[ q = \dot{m} c_{p,c} \left( T_{c,o} - T_{c,i} \right). \]

(b) Solving the above system of equations in the IHT workspace, the graph below illustrates the water flow rate required to provide a range of heat rates.

Continued ….
COMMENTS: (1) The assumption that UA is constant with flow rate is a poor one. Because the heat transfer coefficient for condensation is so high, the overall coefficient is controlled by the waterside coefficient. Presuming the flow is turbulent, from the Dittus-Boelter correlation, we’d expect $U \propto \dot{m}_c^{0.8}$. Over the range of the graph above, $U$ will vary by approximately a factor of $(3.5/1)^{0.8} = 2.7$.

(2) If we considered UA to vary with the cold water flow rate as just described, make a sketch of $\dot{m}_c$ vs. $q$ and compare it to the graph above.
PROBLEM 11.38

KNOWN: Temperature, convection coefficient and condensation rate of saturated steam. Tube diameter for shell-and-tube heat exchanger with one shell pass and two tube passes. Velocity and inlet and maximum allowable exit temperatures of cooling water.

FIND: (a) Minimum number of tubes and tube length per pass, (b) Effect of tube-side heat transfer enhancement on tube length.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible heat exchange with surroundings, (2) Negligible flow work and kinetic and potential energy changes, (3) Negligible tube wall conduction and fouling resistance, (4) Constant properties, (5) Fully developed internal flow throughout.

PROPERTIES: Table A-6, Sat. water (340 K): $h_{fg} = 2.342 \times 10^6$ J/kg; Sat. water $(T_c = 22.5^\circ C \approx 295 \text{ K})$: $\rho = 998 \text{ kg/m}^3$, $c_p = 4181 \text{ J/kg-K}$, $\mu = 959 \times 10^{-6} \text{ N-s/m}^2$, $k = 0.606 \text{ W/m-K}$, $Pr = 6.62$.

ANALYSIS: (a) The required heat rate and the maximum allowable temperature rise of the water determine the minimum allowable flow rate. That is, with

\[
q = q_{\text{cond}} = \dot{m}_{\text{cond}} h_{fg} = 2.73 \text{ kg/s} \times 2.342 \times 10^6 \text{ J/kg} = 6.39 \times 10^6 \text{ W}
\]

\[
\dot{m}_{c,\text{min}} = \frac{q}{c_{p,c} (T_{c,o} - T_{c,i})} = \frac{6.39 \times 10^6 \text{ W}}{4181 \text{ J/kg-K}(15^\circ \text{C})} = 101.9 \text{ kg/s}
\]

With a specified flow rate per tube of $\dot{m}_{c,1} = \rho u m \pi D^2/4 = 998 \text{ kg/m}^3 \times 0.5 \text{ m/s} \times \pi (0.019 \text{ m})^2/4 = 0.141 \text{ kg/s}$, the minimum number of tubes is

\[
N_{\text{min}} = \frac{\dot{m}_{c,\text{min}}}{\dot{m}_{c,1}} = \frac{101.9 \text{ kg/s}}{0.141 \text{ kg/s}} = 720
\]

To determine the corresponding tube length, we must first find the required heat transfer surface area. With $Re_D = \rho u m D/\mu = 998 \text{ kg/m}^3 \times 0.5 \text{ m/s} \times 0.019 \text{ m}/959 \times 10^{-6} \text{ N-s/m}^2 = 9.886$, the Dittus-Boelter equation yields

\[
\overline{n} = (k/D)0.023 \left(Re_D^{4/5} Pr^{0.4}ight) = (0.606 \text{ W/m-K}/0.019 \text{ m}) \times (9.886)^{4/5} (6.62)^{0.4} = 2454 \text{ W/m}^2 \cdot \text{K}
\]

Continued ....
Hence, \( U = \left[ \frac{1}{h_i} + \frac{1}{h_0} \right]^{-1} = 1970 \text{ W/m}^2 \cdot \text{K} \)

With \( C_r = 0, C_{\text{min}} = \dot{m}_c c_{p,c} = 101.9 \text{ kg/s} \times 4181 \text{ J/kg.K} = 4.26 \times 10^5 \text{ W/K}, q_{\text{max}} = C_{\text{min}} (T_{h,i} - T_{c,i}) = 4.26 \times 10^5 \text{ W/K} (340 - 288) \text{ K} = 2.215 \times 10^7 \text{ W} \) and \( \varepsilon = q/q_{\text{max}} = 0.289 \), Eq. 11.36b yields \( NTU = -\ln (1 - \varepsilon) = -\ln (1 - 0.289) = 0.341 \). Hence the tube length per pass is

\[
L = \frac{A}{2N\pi D} = \frac{NTU \times C_{\text{min}}}{2N\pi DU} = \frac{0.341 \times 4.26 \times 10^5 \text{ W/K}}{2 \times 720 \times \pi (0.019 \text{ m}) 1970 \text{ W/m}^2 \cdot \text{K}} = 0.858 \text{ m} <
\]

(b) If the tube-side convection coefficient is doubled, \( \bar{h}_i = 4908 \text{ W/m}^2 \cdot \text{K} \) and \( U = 3292 \text{ W/m}^2 \cdot \text{K} \).

Since \( q, C_r, C_{\text{min}}, q_{\text{max}} \) and hence \( \varepsilon \) are unchanged, the number of transfer units is still \( NTU = 0.341 \). Hence, the tube length per pass is now

\[
L = \frac{NTU \times C_{\text{min}}}{2N\pi DU} = \frac{0.341 \times 4.26 \times 10^5 \text{ W/K}}{2 \times 720 \times \pi (0.019 \text{ m}) 3292 \text{ W/m}^2 \cdot \text{K}} = 0.513 \text{ m} <
\]

**COMMENTS:** Heat transfer enhancement for the flow with the smallest convection coefficient significantly reduces the size of the heat exchanger.
PROBLEM 11.39

KNOWN: Pressure and initial flow rate of water vapor. Water inlet and outlet temperatures. Initial and final overall heat transfer coefficients.

FIND: (a) Surface area for initial U and water flow rate, (b) Vapor flow rate for final U.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Negligible wall conduction resistance.

PROPERTIES: Table A-6, Sat. water ($T_c = 310$ K): $c_{p,c} = 4178$ J/kg·K; (p = 0.51 bars): $T_{sat} = 355$ K, $h_{fg} = 2304$ kJ/kg.

ANALYSIS: (a) The required heat transfer rate is

$$ q = \dot{m}_h h_{fg} = 1.5 \text{ kg/s} \left(2.304 \times 10^6 \text{ J/kg} \right) = 3.46 \times 10^6 \text{ W} $$

and the corresponding heat capacity rate for the water is

$$ C_c = C_{min} = q / \left( T_{c,o} - T_{c,i} \right) = 3.46 \times 10^6 \text{ W} / 40 \text{ K} = 86,400 \text{ W} / \text{ K}. $$

Hence,

$$ \epsilon = q / \left[ C_{min} \left( T_{h,i} - T_{c,i} \right) \right] = 3.46 \times 10^6 \text{ W} / 86,400 \text{ W} / \text{ K} \left(65 \text{ K} \right) = 0.62. $$

Since $C_{min}/C_{max} = 0$, Eq. 11.36b yields

$$ NTU = - \ln \left( 1 - \epsilon \right) = - \ln \left( 1 - 0.62 \right) = 0.97 $$

and

$$ A = NTU \left( C_{min} / U \right) = 0.97 \left( 86,400 \text{ W} / \text{ K} / 2000 \text{ W} / \text{ m}^2 \cdot \text{ K} \right) = 41.9 \text{ m}^2 $$

$$ \dot{m}_c = C_c / c_{p,c} = 86,400 \text{ W} / \text{ K} / 4178 \text{ J/kg} \cdot \text{ K} = 20.7 \text{ kg/s}. $$

(b) Using the final overall heat transfer coefficient, find

$$ NTU = UA / C_{min} = 1000 \text{ W} / \text{ m}^2 \cdot \text{ K} \left(41.9 \text{ m}^2 \right) / 86,400 \text{ W} / \text{ K} = 0.485. $$

Since $C_{min}/C_{max} = 0$, Eq. 11.36a yields

$$ \epsilon = 1 - \exp \left( - NTU \right) = 1 - \exp \left( -0.485 \right) = 0.384. $$

Hence,

$$ q = \epsilon C_{min} \left( T_{h,i} - T_{c,i} \right) = 0.384 \left( 86,400 \text{ W} / \text{ K} \right) 65 \text{ K} = 2.16 \times 10^6 \text{ W} $$

$$ \dot{m}_h = q / h_{fg} = 2.16 \times 10^6 \text{ W} / 2.304 \times 10^6 \text{ J/kg} = 0.936 \text{ kg/s}. $$

COMMENTS: The significant reduction (38%) in $\dot{m}_h$ represents a significant loss in turbine power. Periodic cleaning of condenser surfaces should be employed to minimize the adverse effects of fouling.
**PROBLEM 11.40**

**KNOWN:** Two-fluid heat exchanger with prescribed inlet and outlet temperatures of the two fluids.

**FIND:** (a) Whether exchanger is operating in parallel or counter flow, (b) Effectiveness of the exchanger when $C_c = C_{\text{min}}$.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to the surroundings, (2) Negligible kinetic and potential energy changes, (3) Cold fluid is minimum fluid.

**ANALYSIS:** (a) To determine whether operation is PF or CF, consider the temperature distributions. From the distributions we note that PF or CF operation is possible.

(b) The effectiveness of the exchanger follows from Eq. 11.20,

$$\varepsilon = \frac{q}{q_{\text{max}}}$$  \hspace{1cm} (1)

where from Eq. 11.19,

$$q_{\text{max}} = C_{\text{min}} \left( T_{h,i} - T_{c,i} \right).$$  \hspace{1cm} (2)

Since $C_{\text{min}} = C_c$ and performing an energy balance on the cold fluid, Eq. (1) with Eq. (2) becomes

$$\varepsilon = C_c \left( T_{c,o} - T_{c,i} \right) / C_{\text{min}} \left( T_{h,i} - T_{c,i} \right) = \left( T_{c,o} - T_{c,i} \right) / \left( T_{h,i} - T_{c,i} \right)$$

$$\varepsilon = \frac{(30-15) \degree C}{(65-15) \degree C} = 0.30.$$  \hspace{1cm} <

**COMMENTS:** If $T_{c,o}$ were greater than $T_{h,o}$, parallel-flow operation would not be possible.
**PROBLEM 11.41**

**KNOWN:** Concentric tube heat exchanger.

**FIND:** Length of the exchanger.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Negligible kinetic and potential energy changes, (3) Constant properties.

**PROPERTIES:** Table A-6, Water ($\overline{T}_c = (35 + 95)/2 = 338$ K): $c_p,T = 4188$ J/kg·K

**ANALYSIS:** From the rate equation, Eq. 11.14, with $A_o = \pi D_o L$,

$$L = \frac{q}{U_o \rho D_o \Delta T_{lm}}$$

The heat rate, $q$, can be evaluated from an energy balance on the cold fluid,

$$q = m_c c_c (T_{c,o} - T_{c,i}) = \frac{225 \text{ kg/h}}{3600 \text{ s/h}} \times 4188 \text{ J/kg·K} \times (95 - 35) \text{ K} = 15,705 \text{ W}.$$ 

In order to evaluate $\Delta T_{lm}$, we need to know whether the exchanger is operating in CF or PF. From an energy balance on the hot fluid, find

$$T_{h,o} = T_{h,i} - q / m_h c_h = 210^\circ\text{C} - 15,705 \text{ W} / \frac{225 \text{ kg/h}}{3600 \text{ s/h}} \times 2095 \frac{\text{ J}}{\text{ kg·K}} = 90.1^\circ\text{C}.$$ 

Since $T_{h,o} < T_{c,o}$ it follows that HXer operation must be CF. From Eq. 11.15,

$$\Delta T_{lm,CF} = \frac{\Delta T_1 - \Delta T_2}{\ln(\Delta T_1 / \Delta T_2)} = \frac{(210 - 95) - (90.1 - 35)}{\ln(115/55.1)} \approx 81.4^\circ\text{C}.$$ 

Substituting numerical values, the HXer length is

$$L = 15,705 \text{ W} / 550 \text{ W/m}^2 \cdot \text{K} \times (0.10 \text{ m}) \times 81.4 \text{ K} = 1.12 \text{ m}.$$ 

**COMMENTS:** The $\varepsilon$-NTU method could also be used. It would be necessary to perform the hot fluid energy balance to determine if CF operation existed. The capacity rate ratio is $C_{\text{min}}/C_{\text{max}} = 0.50$. From Eqs. 11.19 and 11.20 with $q$ evaluated from an energy balance on the hot fluid,

$$\varepsilon = \frac{T_{h,i} - T_{h,o}}{T_{h,i} - T_{c,i}} = \frac{210 - 90.1}{210 - 35} = 0.69.$$ 

From Fig. 11.15, find NTU $\approx 1.5$ giving

$$L = \text{NTU} \cdot \frac{C_{\text{min}}}{U_0 \pi D_o} \approx 1.5 \times 130.94 \frac{\text{W}}{\text{K}} / 550 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} \cdot \pi (0.10 \text{ m}) = 1.14 \text{ m}.$$ 

Note the good agreement in both methods.
PROBLEM 11.42

KNOWN: A very long, concentric tube heat exchanger having hot and cold water inlet temperatures, 85°C and 15°C, respectively; flow rate of hot water is twice that of the cold water.

FIND: Outlet temperatures for counterflow and parallel flow operation.

SCHEMATIC:

![Schematic](image)

ASSUMPTIONS: (1) Equivalent hot and cold water specific heats, (2) Negligible kinetic and potential energy changes, (3) No heat loss to surroundings.

ANALYSIS: The heat rate for a concentric tube heat exchanger with very large surface area operating in the counterflow mode is

$$ q = q_{\text{max}} = C_{\text{min}} (T_{h,i} - T_{c,i}) $$

where $C_{\text{min}} = C_c$. From an energy balance on the hot fluid,

$$ q = C_h (T_{h,i} - T_{h,o}). $$

Combining the above relations and rearranging, find

$$ T_{h,o} = -\frac{C_{\text{min}}}{C_h} (T_{h,i} - T_{c,i}) + T_{h,i} = -\frac{C_c}{C_h} (T_{h,i} - T_{c,i}) + T_{h,i}. $$

Substituting numerical values,

$$ T_{h,o} = -\frac{1}{2} (85 - 15)^\circ C + 85^\circ C = 50^\circ C. $$

For parallel flow operation, the hot and cold outlet temperatures will be equal; that is, $T_{c,o} = T_{h,o}$.

Hence,

$$ C_c (T_{c,o} - T_{c,i}) = C_h (T_{h,i} - T_{h,o}). $$

Setting $T_{c,o} = T_{h,o}$ and rearranging,

$$ T_{h,o} = \left( T_{h,i} + \frac{C_c}{C_h} T_{c,i} \right) / \left( 1 + \frac{C_c}{C_h} \right) $$

$$ T_{h,o} = \left( 85 + \frac{1}{2} \times 15 \right)^\circ C / \left( 1 + \frac{1}{2} \right) = 61.7^\circ C. $$

COMMENTS: Note that while $\varepsilon = 1$ for CF operation, for PF operation find $\varepsilon = q/q_{\text{max}} = 0.67$. 
**PROBLEM 11.43**

**KNOWN:** Saturation temperature and condensation rate of refrigerant. Frontal area of condenser and dependence of overall coefficient on inlet velocity. Operational range of the air inlet temperature.

**FIND:** (a) Required heat exchanger area and air outlet temperature for prescribed air inlet velocity and temperature, (b) Variation in air velocity needed to achieve prescribed condensation rate.

**SCHEMATIC:**

![Diagram of heat exchanger](image)

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Constant properties.

**PROPERTIES:** Given (R-12): \( h_{fg} = 1.35 \times 10^5 \) J/kg. Table A-4, air (\( T_{c,i} = 303 \) K): \( \rho_c = 1.17 \) kg/m\(^3\), \( c_{p,c} = 1007 \) J/kg\( \cdot \)K.

**ANALYSIS:** (a) With \( \dot{m}_c = \rho_c V A = 1.17 \) kg/m\(^3\) \( \cdot \)m/s \( = 0.25 \) m \( \cdot \)0.585 kg/s, \( \rho = \times \times = \)\( G_{06} \)\( \sqrt{m_c c p c} \)\( = 589 \) W/K. Hence, from Eq. (11.19), with \( T_{h,i} = T_{sat} \),

\[
q_{\text{max}} = C_{\text{min}} \left( T_{h,i} - T_{c,i} \right) = 589 \text{ W} / \text{K} (45 - 30) \text{ K} = 8,836 \text{ W}
\]

and with \( q = \dot{m}_h h_{fg} = 0.015 \) kg/s \( \times 1.35 \times 10^5 \) J/kg = 2025 W

\[
\varepsilon = \frac{q}{q_{\text{max}}} = \frac{2025}{8836} = 0.229
\]

From Eq. 11.36b we then obtain (for \( C_r = 0 \)),

\[
A = \frac{C_{\text{min}}}{U} \text{ NTU} = -\frac{C_{\text{min}}}{U} \ln \left( 1 - \varepsilon \right) = -\frac{589 \text{ W} / \text{K}}{50 \text{ W} / \text{m}^2 \cdot \text{K} \ln \left( 0.771 \right)} = 3.067 \text{ m}^2
\]

With \( q = C_{\text{min}} (T_{c,o} - T_{c,i}) \), the outlet temperature is

\[
T_{c,o} = T_{c,i} + \frac{q}{C_{\text{min}}} = 30^\circ \text{C} + \frac{2025 \text{ W}}{589 \text{ W} / \text{K}} = 33.4^\circ \text{C}
\]

(b) With \( q = 2025 \) W, \( A = 3.06 \) m\(^2\) and \( U = 50 \) W/m\(^2\)\( \cdot \)K \((V/2)^{0.7}\), the foregoing equations may be solved to obtain \( V \) as a function of \( T_{c,i} \).

Continued.....
With increasing $T_{c,i}$, the driving potential for heat transfer, $T_{h,i} - T_{c,i}$, decreases and a larger value of $U$, and hence $V$, is needed to maintain the required heat rate. For $27 \leq T_{c,i} \leq 38^\circ$C, $1.56 \leq V \leq 5.66$ m/s and $42.1 \leq U \leq 103.6$ W/m$^2$·K.

**COMMENTS:** The variation of $V$ with $T_{c,i}$ is nonlinear, and, in principle, $V \to \infty$ as $T_{c,i} \to T_{sat}$. 
**PROBLEM 11.44**

**KNOWN:** Conditions of oil and water for heat exchanger, one shell with 4 tube passes.

**FIND:** Length of exchanger tubes per pass, $L$; and (b) Compute and plot the effectiveness, $\varepsilon$, fluid outlet temperatures, $T_{h,o}$ and $T_{c,o}$, and water-side convection coefficient, $h_c$, as a function of the water flow rate for $5000 \leq \dot{m}_c \leq 15,000 \text{ kg/h}$ for the tube length found in part (a) with all other conditions remaining the same.

**SCHEMATIC:**

![Diagram of heat exchanger with oil and water flow paths]

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Negligible kinetic and potential energy changes, (3) Constant properties, (4) Fully-developed flow in tubes.

**PROPERTIES:** *Table A-1*, Brass (400 K): $k = 137 \text{ W/m}\cdot\text{K}$; *Table A-5*, Water (323 K): $\rho = 998.1 \text{ kg/m}^3$, $k = 0.643 \text{ W/m}\cdot\text{K}$, $c_p = 4182 \text{ J/kg}\cdot\text{K}$, $\mu = 548 \times 10^{-6} \text{ N}\cdot\text{s}/\text{m}^2$, $Pr = 3.56$.

**ANALYSIS:** (a) From an energy balance on the water, the heat rate required is

$$q = \dot{m}_c c_w \left( T_{c,o} - T_{c,i} \right) = 10,000/3600 \text{ kg/s} \times 4182 \text{ J/kg} \cdot \text{K} \left( 84 - 16 \right) \text{ C} = 789,933 \text{ W} \quad (1)$$

The required tube length may be obtained from Eqs. 11.14 and 11.15,

$$\frac{\Delta T_{m,CF}}{\Delta T_{m,CF}} = \left[ \left( 160 - 84 \right) \text{ C} - \left( 94 - 16 \right) \text{ C} \right] / \ell n \left( 160 - 84/94 - 16 \right) = 77.0 \text{ C} \quad (2)$$

From Fig. 11.10, $F = 0.86$ using $P = (84 - 16)/(160 - 16) = 0.47$ and $R = (160 - 94)/(84 - 16) = 0.97$. From Eq. 11.5,

$$U_o = \left[ \frac{1}{h_o} + \frac{\ell n \frac{r_o}{\eta}}{k} + \frac{\ell n \frac{r_o}{\eta}}{h_i} \right]^{-1}$$

where $h_i$ must be estimated from the appropriate correlation. With $N = 11$, the number of tubes,

$$Re_D = \frac{4\eta/N}{\pi D\mu} = \frac{4 \times (10,000/3600) \text{ kg/s} / (11)}{\pi \times 22.9 \times 10^{-3} \text{ m} \times 548 \times 10^{-6} \text{ N} \cdot \text{s} / \text{m}^2} = 25,621.$$  

For fully developed turbulent flow, the Dittus-Boelter correlation with $n = 0.4$ yields

$$Nu_D = h_i D/k = 0.023 Re_D^{0.8} Pr^{0.4} = 0.023 \left( 25,621 \right)^{0.8} \left( 3.56 \right)^{0.4} = 128.6 \quad (3.56)$$

$$h_i = Nu_D \left( k/D \right) = 128.6 \times 0.643 \text{ W/m} \cdot \text{K} / \left( 22.9 \times 10^{-3} \text{ m} \right) = 3610 \text{ W/m}^2 \cdot \text{K}.$$  

Continued...
PROBLEM 11.44 (Cont.)

$$U_0 = \left[ \frac{1}{400 \text{ W/m}^2 \cdot \text{K}} + \frac{25.4 \times 10^{-3} \text{ m}}{2 \times 137 \text{ W/m} \cdot \text{K}} \times \frac{25.4}{22.9} + \frac{25.4}{22.9} \times \frac{1}{3610 \text{ W/m}^2 \cdot \text{K}} \right]^{-1} = 355 \text{ W/m}^2 \cdot \text{K}.$$  

Returning now to Eq. (2), find $A_o$, then the length,

$$A_o = \pi D_o \times \text{No. of Passes} \times \text{No. of Tubes} = \pi \times 25.4 \times 10^{-3} \text{ m} \times 4 \times 11 \text{L} = 3.511 \text{ L}$$

$$L = \frac{789.933 \text{ W}}{3.511 \text{ m} \times 355 \text{ W/m}^2 \cdot \text{K} \times 0.86 \times 77.0^\circ \text{C}} = 9.6 \text{ m}$$

(b) Using the *IHT Heat Exchanger Tool, Shell and Tube, One-shell pass* and *N tube passes*, the *Correlation Tool, Forced Convection, Internal Flow for Turbulent, fully developed condition*, and the *Properties Tool* for *Water*, a model was developed using the effectiveness - NTU method to compute and plot $T_{c,o}$, $T_{h,o}$, $\epsilon$, and $h_i$ as a function of $\dot{m}_c$.

In order to avoid a boiling condition in the cold fluid, the cold flow rate should not be less than 8000 kg/h. As expected, $T_{c,o}$ and $T_{h,o}$ decrease and the internal convection coefficient increases nearly linearly with increasing flow rate. The effectiveness increases with increasing flow rate since the overall convection coefficient is increasing.

**COMMENTS:**

1. The thermal resistance of the brass tubes is negligible. Since $L/D_i = 400$, fully-developed conditions are reasonable.

2. In the analysis of part (b), you have to specify the capacity rate for the hot fluid in order to solve the model. From the analysis of part (a) using the model, we found $L = 9.56 \text{ m}$ and $C_h = 11,974 \text{ W/K}$.
PROBLEM 11.45

FIND: (a) Tube flow convection coefficient, $h_i$, (b) Tube length/pass required to achieve prescribed fluid outlet temperature, (c) Compute and plot the dielectric fluid outlet temperature, $T_{f,o}$, as a function of its flow rate $m_f$ for the range $4 \leq m_f \leq 6$ kg/s based upon the length/pass found in part (c), (d) the effect of $\pm 10\%$ change in the water flow rate, $m_w$, on $T_{f,o}$ and (e) the effect of $\pm 3^\circ C$ change in inlet water temperature, $T_{w,i}$ on $T_{f,o}$. For parts (c, d, e), account for any changes in the overall convection coefficient, while all other conditions remain the same.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible heat loss to surroundings, kinetic and potential energy changes, fouling and tube wall resistance; (2) Constant properties; (3) Fully developed flow, (4) Convection coefficient on shell side, $h_o$, remains constant for all operating conditions.

PROPERTIES: Coolant (given): $c_p = 1040$ J/kg·K, $\mu = 7.65 \times 10^{-4}$ kg/s·m, $k = 0.058$ W/m·K, Pr = 14;
Water (given): $c_p = 4200$ J/kg·K.

ANALYSIS: (a) For flow through a single tube,
$$ Re_D = \frac{4m_{f,t}}{\pi D \mu} = \frac{4(4.81 \text{ kg/s})/72}{\pi (0.01 \text{ m})7.65 \times 10^{-4} \text{ kg/s·m}} = 11,120 $$
and using the Dittus-Boelter correlation, find
$$ h_i = (k/D)(0.023 Re_D^{4/5} Pr^{0.3}) = 0.023 \frac{0.058 \text{ W/m·K}}{0.01 \text{ m}} (11,120)^{4/5} (14)^{0.3} = 508 \text{ W/m}^2 \cdot \text{K}.$$ 
(b) Find the capacity ratio
$$ C_f = m_f c_p f = 4.81 \text{ kg/s (1040 J/kg·K) = 5002 W/K} = C_{\text{min}} $$
$$ C_w = m_w c_p w = 2.5 \text{ kg/s (4200 J/kg·K) = 10,500 W/K} = C_{\text{max}} $$
hence, $C_f/C_{\text{max}} = 0.476$ and
$$ \varepsilon = \frac{q}{q_{\text{max}}} = \frac{C_f \left(T_{f,i} - T_{f,o}\right)}{C_f \left(T_{f,i} - T_{w,i}\right)} = \frac{(25 - 15)^\circ C}{(25 - 5)^\circ C} = 0.500.$$

Using Fig. 11.16 with $NTU = (UA/C_{\text{min}}) = (UN\pi D L/C_{\text{min}}) = 0.85$, Continued...
PROBLEM 11.45 (Cont.)

\[
U = \left( h_i^{-1} + h_o^{-1} \right)^{-1} = \left[ \left( 508 \right)^{-1} + \left( 10^4 \right)^{-1} \right] W/m^2 \cdot K = 483 W/m^2 \cdot K
\]

\[
L = 0.85 \left( 5002 \text{ W/K} \right) / 144\pi \left( 483 \text{ W/m}^2 \cdot \text{K} \right) = 0.01 \text{ m} = 1.95 \text{ m} .
\]

(c) Using the IHT Heat Exchanger Tool, Shell and Tube, One-shell pass and N-tube passes, and the Correlation Tool, Forced Convection, Internal Flow for Turbulent, fully developed conditions, a model was developed using the effectiveness-NTU method employed above to compute and plot \( T_{f,o} \) as a function of \( \dot{m}_f \).

![Graph showing the relationship between dielectric flow rate and outlet temperature.](image)

A change in the dielectric fluid flow rate of \( \pm 1 \text{ kg/s} \) causes approximately \( \pm 0.5^\circ \text{C} \) change in its outlet temperature.

(d) Using the above IHT model with the base conditions for part (c), the effect of a \( \pm 10\% \) change in the water flow rate from its design value, \( \dot{m}_w = 2.5 \text{ kg/s} \) (\( 2.25 \leq \dot{m}_w \leq 2.75 \text{ kg/s} \)) causes the dielectric fluid outlet temperature to change as

\[
T_{f,o} = 15 \pm 0.14^\circ \text{C}
\]

(e) Using the IHT model of part (c) with the base case conditions for part (c), the effect of a \( \pm 3^\circ \text{C} \) in the water inlet temperature from its design value, \( T_{c,i} = 5^\circ \text{C} \) (\( 2 \leq T_{c,i} \leq 8^\circ \text{C} \)) cause the dielectric fluid outlet temperature to change as

\[
T_{f,o} = 15 \pm 1.5^\circ \text{C}
\]

**COMMENTS:**

1. For the analyses of part (a), Eq. 11.31 yields NTU = 0.85 and \( q = 50 \text{ kW} \) and \( T_{w,o} = 9.76^\circ \text{C} \).

2. The results of the analyses provide operating performance information on the effect of changes due to dielectric fluid flow rate (\( \pm 1 \text{ kg/s of } \dot{m}_f \)), water fluid flow rate (\( \leq 10\% \) of \( \dot{m}_w \)) and water inlet temperature (\( \pm 3^\circ \text{C} \) of \( T_{w,i} \)) on the dielectric fluid outlet temperature, \( T_{f,o} \), supplied to the computer. The greatest effect on \( T_{f,o} \) is that by the input water temperature.
PROBLEM 11.46

KNOWN: Shell and tube heat exchanger with 135 tubes (one shell, double pass) of inner diameter 12.5 mm and surface area 47.5 m².

FIND: (a) Exchanger gas and water outlet temperatures, (b) Tube heat transfer coefficient, \( \overline{h}_t \), assuming fully developed flow, (c) Compute and plot the effectiveness and fluid outlet temperatures, \( T_{c,o} \) and \( T_{h,o} \) for the water flow rate range \( 6 \leq \dot{m}_c \leq 12 \text{ kg/s} \) with all other conditions remaining the same, and (d) Hot gas inlet temperature, \( T_{h,i} \), required to supply 10 kg/s of hot water with an outlet temperature of 42°C with all other conditions the same; determine also the effectiveness.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible heat lost to surroundings, (2) Negligible kinetic and potential energy changes, (3) Fully-developed conditions for internal flow of water in tubes, (4) Exhaust gas properties are those of air, and (5) The overall coefficient remains unchanged for the operating conditions examined.

PROPERTIES: Table A-6, Water (\( T_c \approx 300 \text{ K} \)): \( \rho = 997 \text{ kg/m}^3, \ c = 4179 \text{ J/kg} \cdot \text{K}, \ k = 0.613 \text{ W/m} \cdot \text{K}, \ \mu = 855 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 \), \( \text{Pr} = 5.83 \); Table A-4, Air (1 atm, \( T_h \approx 400 \text{ K} \)): \( \rho = 0.8711 \text{ kg/m}^3, \ c = 1014 \text{ J/kg} \cdot \text{K} \).

ANALYSIS: (a) Using the \( \varepsilon \)-NTU method, first find the capacity rates, \( C = \dot{m}_c c \frac{T_h}{G_0} \).

\[
\begin{align*}
C_c &= 6.5 \text{ kg/s} \times 4179 \text{ J/kg} \cdot \text{K} = 27,164 \text{ W/K} \\
C_h &= 5.0 \text{ kg/s} \times 1014 \text{ J/kg} \cdot \text{K} = 5,070 \text{ W/K}.
\end{align*}
\]

Recognize that \( C_h = C_{min} \) and determine

\[
\frac{C_{min}}{C_{max}} = \frac{C_h}{C_c} = \frac{5,070}{27,164} = 0.19 \\
\text{NTU} = \frac{AU}{C_{min}} = \frac{47.5 \text{ m}^2 \times 200 \text{ W/m}^2 \cdot \text{K}}{5,070 \text{ W/K}} = 1.87.
\]

From Fig. 11.16 for the shell and tube exchanger, find with \( \text{NTU} = 1.87 \) and \( C_{min}/C_{max} = 0.19 \) that \( \varepsilon = 0.78 \). From the definition of effectiveness,

\[
\varepsilon = \frac{q}{q_{\text{max}}} = \frac{C_h (T_{h,i} - T_{h,o})}{C_{min} (T_{h,i} - T_{c,i})} = \frac{200 - T_{h,o}}{200 - 15} = 0.78 \quad \text{or} \quad T_{h,o} = 55.7^\circ \text{C}.
\]

From energy balances on the two fluids, \( C_h (T_{h,i} - T_{h,o}) = C_c (T_{c,o} - T_{c,i}) \), find

\[
T_{c,o} = T_{c,i} + (C_h/C_c) (T_{h,i} - T_{h,o}) = 15^\circ \text{C} + 0.19 (200 - 55.7)^\circ \text{C} = 42.4^\circ \text{C}.
\]

(b) To estimate \( \overline{h}_t \) for the water, find first the Reynolds number. From Eq. 8.6,
PROBLEM 11.46 (Cont.)

\[
\text{Re}_{D_1} = \frac{4\dot{m}}{\pi D_1 \mu} = \frac{4\dot{m}_c}{N} = \frac{4 \times 6.5 \text{ kg/s} / 135}{\pi 12.5 \times 10^{-3} \text{ m} \times 855 \times 10^{-6} \text{ N/s} \cdot \text{m}^2} = 5736
\]

While the flow is fully developed and turbulent, \( \text{Re}_D = 10,000 \) such that Dittus-Boelter correlation is not strictly applicable. However, its use allows a first estimate.

\[
\overline{\text{Nu}}_{D_1} = \overline{\text{h}}_{D_1} / k = 0.023 \text{Re}_D^{4/5} \text{Pr}^{0.4} = 0.023 (5736)^{4/5} (5.83)^{0.4} = 47.3
\]

\[
\overline{\text{h}}_i = \overline{\text{Nu}}_D k / D_1 = 47.3 \times 0.613 \text{ W/m}^2 \cdot \text{K} / 12.5 \times 10^{-3} \text{ m} = 2320 \text{ W/m}^2 \cdot \text{K}.
\]

(c) Using the *IHT Heat Exchanger Tool, Shell and Tube, One-shell pass and N-tube passes*, and the prescribed properties, a model was developed following the analysis of part (a) to compute and plot \( \varepsilon \), \( T_{c,o} \), and \( T_{h,o} \) for a function of \( \dot{m}_c \).

\[
\text{Cold flow rate, } \dot{m}_{\text{dot}c} \text{ (kg/s)}
\]

The outlet temperatures decrease nearly linearly with increasing cold fluid flow rate; the decrease in the cold outlet temperature is nearly twice that of the hot fluid. The change in the effectiveness with increasing flow rate is only slightly increased.

(d) Using the above IHT model, the hot inlet temperature \( T_{h,i} \), required to provide \( \dot{m}_{c} = 10 \text{ kg/s} \) with \( T_{c,o} = 42^\circ \text{C} \) and the effectiveness for this operating condition are

\[
T_{h,i} = 74.4^\circ \text{C} \quad \varepsilon = 0.55
\]

**COMMENTS:**

1. Check that assumptions for \( \overline{T}_h \) and \( \overline{T}_c \) used in part (a) for evaluation of the fluid properties are satisfactory as \( \overline{T}_h = 400.7 \text{ K} \) and \( \overline{T}_c = 301.5 \text{ K} \).

2. From part (b), with \( \overline{\text{h}}_i = 2320 \text{ W/m}^2 \cdot \text{K} \) and \( U = 200 \text{ W/m}^2 \cdot \text{K} \), the shell-side convection coefficient is \( \overline{\text{h}}_o = 219 \text{ W/m}^2 \cdot \text{K} \). As such, \( U \) is controlled by shell-side conditions. Assuming \( U \) as a constant in part (c) with changes in \( \dot{m}_c \) is therefore reasonable. However, for part (d) with \( \dot{m}_h \) doubling, we should expect \( U \) to increase.
PROBLEM 11.47

KNOWN: Power output and efficiency of an ocean energy conversion system. Temperatures and overall heat transfer coefficient of shell-and-tube evaporator.

FIND: (a) Evaporator area, (b) Water flow rate.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Negligible kinetic and potential energy changes, (3) Constant properties.

PROPERTIES: Table A-6, Water ($\bar{T}_m = 296$ K): $c_p = 4181$ J/kg·K.

ANALYSIS: (a) The efficiency is

$$\eta = \frac{\dot{W}}{q} = \frac{2\text{MW}}{66.7\text{MW}} = 0.03.$$ 

Hence the required heat transfer rate is

$$q = \frac{2\text{MW}}{0.03} = 66.7\text{MW}.$$ 

Also

$$\Delta T_{\ell,\text{m,CF}} = \frac{(300 - 290) - (292 - 290)\degree C}{\frac{300 - 290}{292 - 290}} = 5\degree C$$ 

and, with $P = 0$ and $R = \infty$, from Fig. 11.10 it follows that $F = 1$. Hence

$$A = \frac{q}{UF\Delta T_{\ell,\text{m,CF}}} = \frac{6.67 \times 10^7 \text{W}}{1200 \text{ W/m}^2 \cdot \text{K} \times 1 \times 5\degree C}$$

$$A = 11,100 \text{ m}^2.$$ <

(b) The water flow rate through the evaporator is

$$\dot{m}_h = \frac{q}{c_p, h (T_{h,i} - T_{h,o})} = \frac{6.67 \times 10^7 \text{W}}{4181 \text{ J/kg} \cdot \text{K} (300 - 292)}$$

$$\dot{m}_h = 1994 \text{ kg/s}.$$ <

COMMENTS: (1) From the $\varepsilon$-NTU method, $(C_{\min}/C_{\max}) = 0$, $q_{\max} = 8.34 \times 10^7 \text{ W}$, $\varepsilon = 0.80$ and from Fig. 11.16, NTU = 1.65, giving $A = 11,500 \text{ m}^2$. (2) The required heat exchanger size is enormous due to the small temperature differences involved.
PROBLEM 11.48

KNOWN: Length and tube diameter for a shell-and-tube (one shell pass, multiple tube passes) heat exchanger. Flow rate and temperature of saturated steam. Condensation convection coefficient. Velocity and inlet and outlet temperatures of cooling water.

FIND: (a) Required number of tubes and if the heat exchanger length is not to exceed 1.5 m, the number of tube passes; (b) Compute and plot water outlet temperature $T_{c,o}$, and condensation rate, $\dot{m}_h$ as a function of the mean velocity for the range $0.5 \leq u_m \leq 3$ m/s, for the heat transfer area found from part (a), accounting for changes in the overall coefficient, but all other conditions remaining the same; and (c) Repeat the analysis of part (b) for tube diameters of 15 and 25 mm.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible heat loss to surroundings and changes in kinetic and potential energy, (2) Negligible tube wall conduction and fouling resistances, (3) Constant properties, and (4) The shell-side coefficient $\bar{h}_o$ remains unchanged for the operating conditions examined.

PROPERTIES: Table A.6, Sat. water (340 K): $h_{fg} = 2.342 \times 10^6$ J/kg; Sat. water ($\bar{T}_c = 297$ K): $\rho = 998$ kg/m$^3$, $c_p = 4180$ J/kg·K, $\mu = 917 \times 10^{-6}$ kg/s·m, $k = 0.609$ W/m·K, $Pr = 6.3$.

ANALYSIS: (a) The required heat rate is

$$q = \dot{m}_h h_{fg} = 2.73 \text{ kg/s} \left(2.342 \times 10^6 \text{ J/kg}\right) = 6.39 \times 10^6 \text{ W}.$$  

Hence, from conservation of energy,

$$\dot{m}_c = q \left[\frac{1}{c_p,c} (T_{c,o} - T_{c,i})\right] = 6.39 \times 10^6 \text{ W}/4180 \text{ J/kg·K} \left(12\text{K}\right) = 127.5 \text{ kg/s}.$$  

Hence the number of tubes is

$$N = \frac{\dot{m}_c}{\dot{m}_{c,i}} = \frac{\dot{m}_c}{\left(\pi D^2/4\right) \rho u_m} = 4 \times 127.5 \text{ kg/s}/\pi \left(0.019\text{m}\right)^2 998 \text{ kg}/\text{m}^3 \left(1.5 \text{ m/s}\right) = 300.$$  

To determine the heat transfer surface area $A$, use the $\varepsilon$ - NTU method. Find first

$$Re_D = \frac{\rho u_mD}{\mu} = 998 \text{ kg}/\text{m}^3 \left(1.5 \text{ m/s}\right) \left(0.019\text{m}\right)/917 \times 10^{-6} \text{ kg/s·m} = 31,017.$$  

and using the Dittus-Boelter equation,

$$h_i = \left(\frac{k}{D}\right)0.023 Re_D^{4/5} Pr^{0.4} = 0.609 \text{ W/m·K}/0.019\text{m} \times 0.023 \left(31,017\right)^{4/5} \left(6.3\right)^{0.4} = 6034 \text{ W}/\text{m}^2·\text{K}.$$  

$$U = \left[1/h_i + 1/h_o\right]^{-1} = \left[(1/6034) + (1/12,500)\right]^{-1} \text{ W}/\text{m}^2·\text{K} = 4070 \text{ W}/\text{m}^2·\text{K}. $$  

Continued...
PROBLEM 11.48 (Cont.)

With \( C_{\text{min}} = \dot{m}_{\text{c}} c_{p,c} = 127.5 \text{ kg/s}(5180 \text{ J/kg-K}) = 5.33 \times 10^5 \text{ W/K} \)

\[
\varepsilon = \frac{q}{q_{\text{max}}} = \frac{q}{C_{\text{min}} (T_{h,i} - T_{c,i})} = 6.39 \times 10^6 \text{ W/}5.33 \times 10^5 \text{ W/K} (49K) = 0.245 .
\]

Hence, with \( C_r = 0 \), Eq. 11.36b yields \( \text{NTU} = -\ln(1 - \varepsilon) = -\ln(1 - 0.245) = 0.281, \)

\[
A = \text{NTU} \left( \frac{C_{\text{min}}}{U} \right) = 0.281 \left( \frac{5.33 \times 10^5 \text{ W/K}}{4070 \text{ W/m}^2 \cdot \text{K}} \right) = 36.8 \text{ m}^2
\]

The tube length, \( L \), in terms of the number of tubes, \( N \), and passes, \( P \), is

\[ L = A/N \cdot P \pi D \]

and if \( P = 2 \),

\[ L = 36.8 \text{ m}^2 / 300 \times 2 \times \pi \times 0.019 \text{ m} = 1.03 \text{ m} \]

which is less than the maximum length 1.5 m.

(b) Using the IHT Heat Exchanger Tool, All Exchangers, \( C_r = 0 \), the Properties Tool for Water, and the Correlations Tool, Forced Convection, Internal Flow, for Turbulent fully developed conditions, a model was developed following the foregoing analysis to compute \( T_{c,o} \) and \( \dot{m}_{\text{H}} \) as a function of \( u_m \) with \( A = 36.8 \text{ m}^2 \) as determined from part (a). The plot is shown below with the results for part (c).

(c) The IHT model was used to compute and plot \( T_{c,o} \) and \( \dot{m}_{\text{H}} \) as a function of \( u_m \) for tube diameters of 15, 19, and 25 mm.

The effect of tube diameter on \( T_{c,o} \) as a function of the water flow rate is significant. As \( D \) increases at any flow rate, the outlet temperatures decreases. The effect of tube diameter on the condensation rate is slight. However, the condensation rate increases markedly as the water flow rate increases.
**PROBLEM 11.49**

**KNOWN:** Shell(1)-and-tube (two passes, \( p = 2 \)) heat exchanger for condensing saturated steam at \( 1 \) atm. Inlet cooling water temperature and mean velocity. Thin-walled tube diameter and length prescribed, as well as, convective heat transfer coefficient on outer tube surface, \( h_o \).

**FIND:** (a) Number of tubes/pass, \( N \), required to condense \( 2.3 \) kg/s of steam, (b) Outlet water temperature, \( T_{c,o} \), (c) Maximum condensation rate possible for same water flowrate and inlet temperature, and (d) Compute and plot \( T_{c,o} \) and the condensation rate, \( \dot{m}_h \), for water mean velocity, \( u_m \), in the range \( 1 \leq u_m \leq 5 \) ms/, using the heat transfer surface area found in part (a) assuming the shell-side convection coefficient remains unchanged.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Negligible kinetic and potential energy changes, (3) Negligible thermal resistance due to the tube walls.

**PROPERTIES:** *Table A.6*, Saturated steam (1 atm): \( T_{sat} = 100^\circ \text{C} \), \( h_{fg} = 2257 \text{ kJ/kg} \); Water (assume \( T_{c,o} \approx 25^\circ \text{C} \), \( mT = (T_h + T_c)/2 \approx 295 \text{ K} \)): \( \rho = 1/\nu = 998 \text{ kg/m}^3 \), \( c_c = c_{p,h} = 4181 \text{ J/kg} \cdot \text{K} \), \( \mu = \mu_f = 959 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 \), \( k = k_f = 0.606 \text{ W/m-K} \), \( Pr = Pr_f = 6.62 \).

**ANALYSIS:** (a) The heat transfer rate for the heat exchanger is

\[
q = \dot{m}_h h_{fg} = 2.3 \text{ kg/s} \times 2257 \times 10^3 \text{ J/kg} = 5.191 \times 10^6 \text{ W}
\]

Using the \( \epsilon \)-NTU method, evaluate the following parameters:

**Water-side heat transfer coefficient:**

\[
Re_D = \frac{u_m D}{\mu/\rho} = \frac{3.5 \text{ m/s} \times 0.014 \text{ m}}{959 \times 10^{-6} \text{ N} \cdot \text{s/m}^2/998 \text{ kg/m}^3} = 50,993
\]

\[
h_w = \frac{k D}{Nu D} = \frac{k}{D} 0.023 Re_D^{0.8} Pr^{1/3} = \frac{0.606 \text{ W/m-K}}{0.014 \text{ m}} \times 0.023 (50,993)^{0.8} (6.62)^{1/3} = 10.906 \text{ W/m}^2 \cdot \text{K}
\]

using the Colburn equation for fully developed turbulent conditions.

**Overall coefficient:**

\[
\bar{U} = \left( \frac{1}{h_i} + 1/h_o \right)^{-1} = \left( \frac{1}{10.906} + 1/21,800 \right)^{-1} = 7269 \text{ W/m}^2 \cdot \text{K}
\]

**Effectiveness relations:** With \( C_{min} = C_c \) and \( \dot{m}_c = \rho (\pi D^2/4) u_m N \),

\[
q = \epsilon \dot{m}_c = \epsilon C_{min} (T_{h,i} - T_{c,i})
\]

\[
C_{min} = \dot{m}_c c_c = 998 \text{ kg/m}^3 \left( \pi \times 0.014^2 \text{ m}^2/4 \right) \times 3.5 \text{ m/s} \times \text{N} \times 4181 \text{ J/kg} \cdot \text{K} = 2248 \text{ N}
\]

Continued...
PROBLEM 11.49 (Cont.)

\[ 5.191 \times 10^6 \text{W} = \varepsilon \times 2248 \text{N} (100 - 15) \text{K} \]
\[ \varepsilon N = 27.17 \]

From Eq. 11.36a with \( C_r = 0 \), the effectiveness is
\[ \varepsilon = 1 - \exp (-\text{NTU}) = 1 - \exp (-0.142) = 0.132 \]

where, using \( A_s = \pi \text{DLNP} \), NTU is evaluated as,
\[ \text{NTU} = \frac{UA_s}{C_{\min}} = \frac{7269 \text{W/m}^2 \cdot \text{K} \left( \pi \times 0.014 \text{m} \times 0.5 \text{m} \right) N \times 2}{2248 \text{N}} = 0.142 \]

Hence, using Eq. (7), the required number of tubes is
\[ N = \frac{27.17}{\varepsilon} = 205.8 \approx 206 \]

and the total surface area is
\[ A_s = \pi \text{DLNP} = \pi \times 0.014 \text{m} \times 0.5 \text{m} \times 206 \times 2 = 9.06 \text{m}^2 \]

(b) The water outlet temperature with \( C_{\min} = 2248 \text{N} = 463,090 \text{W/K} \),
\[ T_{c,o} = T_{c,i} + \frac{q}{C_{\min}} = 15^\circ \text{C} + 5.191 \times 10^6 \text{W} / 463,090 \text{W/K} = 26.1^\circ \text{C} \]

(c) The maximum condensation rate will occur when \( q = q_{\max} \). Hence
\[ \dot{m}_{h,\max} = \frac{q_{\max}}{h_{fg}} = \frac{C_{\min} \left( T_{h,i} - T_{c,i} \right)}{h_{fg}} = \frac{463,090 \text{W/K} (100 - 15) \text{K}}{2257 \times 10^3 \text{J/kg}} = 17.44 \text{kg/s} \]

(d) Using the IHT Heat Exchanger Tool, All Exchangers, \( C_r = 0 \), along with the Properties Tool for Water, the foregoing analysis was performed to obtain \( T_{h,o} \) and \( \dot{m}_{h} \) using the heat transfer surface area \( A_s = 9.06 \text{m}^2 \) (part a) as a function of \( u_m \).

![Graph](image)

Note that the condensation rate increases nearly linearly with the water mean velocity. The cold water outlet temperature decreases nearly linearly with \( u_m \). We should expect this behavior from energy balance considerations. Since \( h_h \) is nearly two times greater than \( h_c \), \( U \) is controlled by the water side coefficient. Hence \( U \) will increase with increasing \( u_m \).

**COMMENTS:** Note that the assumed value for \( T_{in} \) to evaluate water properties in part (a) was a good choice.
PROBLEM 11.50

KNOWN: Feed water heater (single shell, two tube passes) with inlet temperature 20°C supplies 10,000 kg/h of water at 65°C by condensing steam at 1.30 bar. Overall heat transfer coefficient is 2000 W/m²·K.

FIND: (a) Required area using LMTD and NTU approaches, (b) Steam condensation rate.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Negligible kinetic and potential energy changes, (3) Constant properties.

PROPERTIES: Table A-6, Steam (1.3 bar, saturated): \( T_h = 380.3 \) K, \( h_{fg} = 2238 \times 10^3 \) J/kg·K;
Table A-6, Water (\( T_c \) = 316 K): \( c_p = 4179 \) J/kg·K.

ANALYSIS: (a) Using the LMTD approach, from Eqs. 11.14 and 11.18,
\[
A = \frac{q}{UF\Delta T_{m,CF}} \quad \Delta T_{m,CF} = \left[ \Delta T_1 - \Delta T_2 \right] / \ln \left( \Delta T_1 / \Delta T_2 \right) \tag{1,2}
\]
\[
\Delta T_{m,CF} = \left[ (380.3 - 338) - (380.3 - 293) \right] K / \ln \left( \frac{380.3 - 338}{380.3 - 293} \right) = 62.1 K.
\]
Since \( T_h \) is uniform throughout the HXer, \( F = 1 \). From an energy balance on the cold fluid,
\[
q = \dot{m}_c c_p \left( T_{c,o} - T_{c,i} \right) = \frac{10,000 \text{kg}}{3600} \times \frac{4179}{\text{kg·K}} (338 - 293) \text{K} = 5.224 \times 10^5 \text{W}.
\]
Substituting numerical values into Eq. (1) find that
\[
A = 5.224 \times 10^5 \text{W} / 2000 \text{W/m}^2 \cdot \text{K} \times 1 \times 62.1 \text{K} = 4.21 \text{m}^2.
\]
Using the NTU approach, recognize that \( C_{\text{min}} = C_c \) and \( C_{\text{max}} = C_h \rightarrow \infty \) so that \( C_{\text{min}} / C_{\text{max}} = 0 \). The effectiveness, defined by Eq. 11.20, is
\[
\varepsilon \equiv \frac{q}{q_{\text{max}}} = \frac{C_c \left( T_{c,o} - T_{c,i} \right)}{C_{\text{min}} \left( T_{h,i} - T_{c,i} \right)} = \frac{338 - 293}{380.3 - 293} K = 0.515.
\]
From Fig. 11.16, with \( \varepsilon = 0.52 \) and \( C_{\text{min}} / C_{\text{max}} = 0 \), find NTU = 0.70. Hence,
\[
A = C_{\text{min}} \text{NTU} / U = \frac{10,000 \text{kg/s} \times 4179 \text{J/kg·K} \times 0.70}{2000 \text{W/m}^2 \cdot \text{K}} = 4.1 \text{m}^2.
\]
(b) The condensation rate of steam is
\[
\dot{m}_h = q / h_{fg} = 5.224 \times 10^5 \text{W} / \left( 2238 \times 10^3 \text{J/kg} \right) = 0.233 \text{ kg/s} = 840 \text{ kg/h}.
\]

COMMENTS: Note both methods of solution given the same result. Eq. 11.31 could have been used to obtain a more precise NTU value.
PROBLEM 11.51

KNOWN: Shell-and-tube HXer with one shell and one tube pass.

FIND: (a) Oil outlet temperature for prescribed conditions, (b) Effect of fouling and water flowrate on oil outlet temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Constant properties, (2) Negligible changes in kinetic and potential energies, (3) Negligible fouling and losses to surroundings, (4) Uniform tube outer surface temperature.

PROPERTIES: Table A.5, Engine oil (\(T_{th} \approx 350\) K): \( \rho_h = 854 \text{ kg/m}^3, c_{p,h} = 2118 \text{ J/kg} \cdot \text{K}, \mu_h = 0.0356 \text{ N} \cdot \text{s/m}^2, k_h = 0.318 \text{ W/m} \cdot \text{K}, Pr_h = 546; \ (T_s \approx 330\) K): \( \mu_s = 0.0836 \text{ N} \cdot \text{s/m}^2; \) Table A.6, Water (\(T_c \approx 320\) K): \( c_{p,c} = 4180 \text{ J/kg} \cdot \text{K}; \) Table A.1, Copper (\(T \approx 320\) K): \( k = 399 \text{ W/m} \cdot \text{K}.\)

ANALYSIS: (a) To determine the outlet temperature of the oil, we will need to know the overall heat transfer coefficient. From Eq. 11.5,

\[
\frac{1}{UA} = \frac{1}{h_i A_i} + \frac{\ln \left( \frac{D_o}{D_i} \right)}{2\pi L_t} + \frac{R_{f,o}^*}{A_o} - \frac{1}{h_o A_o}
\]

(1)

where \( h_o = 500 \text{ W/m}^2 \cdot \text{K} \) (water-side) and \( h_i \) (oil-side) must be estimated from an appropriate correlation. Using properties evaluated at an estimated average mean temperature \( \bar{T}_b = 350 \text{ K} \), find

\[
Re_{D,h} = \frac{4 \dot{m}_h D_i}{\pi D_i \mu_h} = \frac{4 \times (1 \text{ kg/s} / 100)}{\pi (0.006 \text{ m}) \times 0.0356 \text{ N} \cdot \text{s/m}^2} = 59.6
\]

(2)

Since \( Re_D < 2300 \), the flow is laminar. To assess flow conditions, evaluate

\[
Gz^{-1} = \frac{L/D_i}{Re_{D,h} Pr} = \frac{0.5 \text{ m}}{59.6 \times 546} = 0.00256
\]

(3)

Since \( Gz^{-1} < 0.05 \), the flow is characterized by combined entry length conditions (Fig. 8.9), and

\[
\overline{Nu}_D = 1.86 \left[ \frac{Re_D Pr}{L/D} \right]^{1/3} \left( \frac{\mu_h}{\mu_s} \right)^{0.14}
\]

(4)

where \( \left[ \right] \geq 2 \). To evaluate \( \mu_s \), assume \( T_s = 330 \text{ K} \). Hence,

\[
\overline{Nu}_D = 1.86 \left[ \frac{0.00256}{0.0356} \right]^{-1/3} \left[ \frac{0.0356}{0.0836} \right]^{0.14} = 1.86 \times 6.48 = 12.1
\]

Note that \( \left[ \right] = 6.48 > 2 \) as required. Hence, 

Continued...
With $R_{f,o}^*$ and $L_s = N_tL$, Eq. 1 yields

$$\frac{1}{UA} = \frac{1}{\pi N_t L} \left( \frac{1}{h_1 D_1} + \frac{\ln \left( D_o / D_1 \right)}{2k} + \frac{1}{h_o D_0} \right)$$

$$\frac{1}{UA} = \frac{1}{\pi \times 100 \times 0.5 \text{m}} \left[ \frac{1}{\left( 500 \text{ W/m}^2 \cdot \text{K} \times 0.008 \text{ m} \right)} + \ln \left( \frac{8}{6} \right) / \left( 2 \times 399 \text{ W/m} \cdot \text{K} \right) + \frac{1}{\left( 277 \text{ W/m}^2 \cdot \text{K} \times 0.006 \text{ m} \right)} \right]$$

$$\frac{1}{UA} = 6.366 \times 10^{-3} \left[ 0.2500 + 0.0003 + 0.6017 \right] = 5.424 \times 10^{-3} \text{ K/W}$$

$UA = 184 \text{ W/K}$

With knowledge of $UA$, we can now use the $\varepsilon$ - NTU method to obtain the oil outlet temperature, $T_{h,o}$. Find the capacity rates, $C = \dot{m} c_p$,

$$C_c = \dot{m} c_{p,c} = 2 \text{ kg/s} \times 4180 \text{ J/kg} \cdot \text{K} = 8360 \text{ W/K} = C_{\text{max}}$$

$$C_h = \dot{m} c_{p,h} = 1 \text{ kg/s} \times 2118 \text{ J/kg} \cdot \text{K} = 2118 \text{ W/K} = C_{\text{min}}$$

$$C_r = C_{\text{min}} / C_{\text{max}} = 2118 / 8360 = 0.253$$

From Eq. 11.25, find

$$NTU = UA / C_{\text{min}} = 184 \text{ W/K} / (2118 \text{ W/K}) = 0.0869.$$  \hspace{1cm} (6)

For this exchanger - one shell and one pass - there are no figures (11.14-19) or relations (Table 11.3) that can be directly used to evaluate $\varepsilon$. However, the HXer approximates a CF concentric tube HXer; hence, use Eq. 11.30a.

$$\varepsilon = \frac{1 - \exp \left[ -NTU \left( 1 - C_r \right) \right]}{1 - C_r \exp \left[ -NTU \left( 1 - C_r \right) \right]} = \frac{1 - \exp \left[ -0.0869 \left( 1 - 0.253 \right) \right]}{1 - 0.253 \exp \left[ -0.0869 \left( 1 - 0.253 \right) \right]} = 0.0824$$ \hspace{1cm} (7)

From the definition of effectiveness,

$$\varepsilon = \frac{q}{q_{\text{max}}} = \frac{C_h \left( T_{h,i} - T_{h,o} \right)}{C_{\text{min}} \left( T_{h,i} - T_{c,i} \right)}$$

$$T_{h,o} = T_{h,i} - \varepsilon \left( T_{h,i} - T_{c,i} \right) = 140^\circ \text{C} - 0.0824 \left( 140 - 15 \right) \text{C} = 129.7^\circ \text{C}$$

The foregoing result indicates that $T_{h} = 408 \text{ K}$, which is much larger than the assumed value of 350 K. Since the properties of oil depend strongly on temperature, they should be re-evaluated and the foregoing calculations repeated until convergence is achieved. Using the Correlations, Properties and Heat Exchangers Toolpads of IHT, we obtain $h_i = 226 \text{ W/m}^2 \cdot \text{K}$, $UA = 159 \text{ W/K}$, $\varepsilon = 0.064$, and $T_{h,o} = 132^\circ \text{C}$. Continued …..
PROBLEM 11.51 (Cont.)

(b) If the foregoing calculations are repeated with $R_{f,o}'' = 0.0003 \text{ m}^2 \cdot \text{K/W}$, there is only a slight increase in the oil outlet temperature to $T_{h,o} = 132.3\degree C$. The effect is small because the fouling resistance is approximately an order of magnitude smaller than the convection resistances. As shown below,

![Graph showing oil outlet temperature vs. water flowrate](image)

the effect of the water flowrate is also small, because, even for $\dot{m}_c = 1 \text{ kg/s}$, $T_{c,o}$ is only approximately $4.5\degree C$ larger than $T_{c,i}$. Although the effect of $\dot{m}_c$ on $h_o$ has not been considered, it would also be small since the water-side convection resistance is substantially larger than the oil side resistance.

**COMMENTS:** In Part (a), note that the Nusselt number for the oil entrance region flow is $12.1/3.66 \approx 3.3$ times that for fully developed flow.
PROBLEM 11.52

KNOWN: Shell-and-tube heat exchanger with one shell pass and 20 tube passes.

FIND: Average convection coefficient for the outer tube surface.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Negligible changes in kinetic and potential energies, (3) Constant properties, (4) Type of oil not specified, (5) Thermal resistance of tubes negligible; no fouling.

PROPERTIES: Table A-6, Water, liquid (T_h = 330 K): c_p = 4184 J/kg·K, k = 0.650 W/m·K, µ = 489 × 10^{-6} N·s/m^2, Pr = 3.15.

ANALYSIS: To find the average coefficient for the outer tube surface, h_o, we need to evaluate h_i for the internal tube flow and U, the overall coefficient. From Eq. 11.5,

\[ \frac{1}{UA} = \frac{1}{h_i A_i} + \frac{1}{h_o A_o} = \frac{1}{N_t \pi L \left[ \frac{1}{h_i D_i} + \frac{1}{h_o D_o} \right]} \]

where N_t is the total number of tubes. Solving for h_o,

\[ h_o = D_o^{-1} \left[ (UA)^{-1} N_t \pi L - 1 / h_i D_i \right]^{-1} \]  

Evaluate h_i from an appropriate correlation; begin by calculating the Reynolds number.

\[ \text{Re}_{D_i} = \frac{4 \dot{m}_h}{\pi D_i \mu} = \frac{4 \times 0.2 \text{ kg/s}}{\pi \times (0.020 \text{ m}) \times 489 \times 10^{-6} \text{ N·s/m}^2} = 26,038. \]

Hence, flow is turbulent and since L >> D_i, the flow is likely to be fully developed. Use the Dittus-Boelter correlation with n = 0.3 since T_s < T_m, Nu_D = 0.023 \text{ Re}^{4/5} \text{ Pr}^{0.3}

\[ h_i = \frac{k}{D} \cdot \frac{0.650 \text{ W/m·K} \times 0.023 (26,038)^{4/5} (3.15)^{0.3}}{3594 \text{ W/m}^2·\text{K}.} \]

To evaluate UA, we need to employ the rate equation, written as

\[ UA = \frac{q}{F \Delta T_{f,n,CF}} \]

where \[ q = \dot{m}_h \cdot c_{p,h} (T_{h,i} - T_{h,o}) = 0.2 \text{ kg/s} \times 4184 \text{ J/kg·K} \times (87 - 27)^\circ \text{C} = 50,208 \text{ W} \] and \[ \Delta T_{f,n,CF} = [\Delta T_1 - \Delta T_2]/\ell/n \ (\Delta T_1/\Delta T_2) = [(87 - 37) - (27 - 7)]^\circ \text{C}/\ell/n (87 - 37/27 - 7) = 32.7^\circ \text{C}. \] Find \[ F = 0.5 \] using Fig. 11.10 with \[ P = (27 - 87)/(7 - 87) = 0.75 \] and \[ R = (7 - 37)/(27 - 87) = 0.50. \] Substituting numerical values in Eqs. (3) and (1), find

\[ UA = 50,208 \text{ W}/0.5 \times 32.7^\circ \text{C} = 3071 \text{ W/K} \]

\[ h_o = (0.024m)^{-1} \left[ (3071 \text{ W/K})^{-1} \times 20 \times \pi \times 3m - 1/3594 \text{ W/m}^2·\text{K} \times 0.020m \right]^{-1} = 878 \text{ W/m}^2·\text{K}. \]

COMMENTS: Using the ε-NTU method: find C_h and C_c to obtain C_r = 0.5 and ε = 0.75. From Eq. 11.31b,c find NTU = 3.59 and UA = 3003 W/K.
PROBLEM 11.53

KNOWN: Engine oil cooled by air in a cross-flow heat exchanger with both fluids unmixed.

FIND: (a) Heat transfer coefficient on oil side of exchanger assuming fully-developed conditions and constant wall heat flux, (b) Effectiveness, and (c) Outlet temperature of the oil.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Negligible KE and PE changes, (3) Constant properties, (4) Oil flow and thermal conditions are fully developed, (5) Oil cooling process approximates constant wall flux conditions.

PROPERTIES: Table A-5, Engine oil (assume \( T_{h,o} \approx 45^\circ C \), \( T_T = (45 + 75)^\circ C/2 = 333 K \)): \( c_h = 2047 \text{ J/kg} \cdot \text{K}, \mu = 7.45 \times 10^{-2} \text{ N} \cdot \text{s/m}^2, k = 0.140 \text{ W/m} \cdot \text{K}; \) Table A-4, Air (assume \( T_{c,o} \approx 40^\circ C \), \( T_T = (30 + 40)^\circ C/2 = 308 K \), 1 atm): \( c_c = 1007 \text{ J/kg} \cdot \text{K}. \)

ANALYSIS: (a) For the oil side, using Eq. 8.6, find,

\[
\text{Re}_D = 4 \dot{m}_c / \pi D \mu = 4 \left( 0.026 \text{ kg/s} \right) / \left( 0.01 \text{ m} \right) = 44.4
\]

Since \( \text{Re}_D < 2000 \) the flow is laminar. For the fully-developed conditions with constant wall flux,

\[
\text{Nu}_D = \frac{h_D}{k} = 4.36, \quad h_D = 4.36 \frac{k}{D} = 4.36 \frac{0.140 \text{ W/m} \cdot \text{K}}{0.01 \text{ m}} = 61.0 \text{ W/m}^2 \cdot \text{K}.
\]

(b) The effectiveness can be determined by the \( \varepsilon \)-NTU method.

\[
C_h = \dot{m}_h c_h = 0.026 \text{ kg/s} \times 2047 \text{ J/kg} \cdot \text{K} = 53.22 \text{ W/K} \quad C_{\text{min}} = C_h
\]

\[
C_c = \dot{m}_c c_c = 0.53 \text{ kg/s} \times 1007 \text{ J/kg} \cdot \text{K} = 533.7 \text{ W/K} \quad C_{\text{min}} / C_{\text{max}} = 0.10
\]

\[
\text{NTU} = \frac{U A}{C_{\text{min}}} = 53 \text{ W/m}^2 \cdot \text{K} \times 1 \text{ m}^2 / 53.22 \text{ W/K} = 1.00.
\]

Using Fig. 11.18, with \( C_{\text{min}} / C_{\text{max}} = 0.1 \) and \( \text{NTU} = 1 \), find \( \varepsilon \approx 0.64. \)

(c) From Eqs. 11.20 and 11.19,

\[
\varepsilon = \frac{q}{q_{\text{max}}} = \frac{C_h \left( T_{h,i} - T_{h,o} \right)}{C_{\text{min}} \left( T_{h,i} - T_{c,i} \right)} = \frac{T_{h,i} - T_{h,o}}{T_{h,i} - T_{c,i}}.
\]

Solving for \( T_{h,o} \) and substituting numerical values, find

\[
T_{h,o} = T_{h,i} - \varepsilon \left( T_{h,i} - T_{c,i} \right) = 75^\circ C - 0.64(75 - 30)^\circ C = 46.2^\circ C.
\]

COMMENTS: Note that the \( T_h \) value at which the oil properties were evaluated is reasonable.
PROBLEM 11.54

KNOWN: Shell-tube heat exchanger with one shell and single tube pass; Tube side: exhaust gas with specified flow rate and temperature change; Shell side: supply of saturated water at 11.7 bar; Tube dimensions and thermal conductivity, and fouling resistance on gas side, \( R_{f,h} \), specified.

FIND: Number of tubes and their length if the gas velocity is not to exceed \( u_{m,i} = 25 \text{ m/s} \).

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible losses to the surroundings and kinetic and potential energy changes, (3) Negligible water-side thermal resistance, (4) Exhaust gas properties are those of atmospheric air, (5) Gas-side flow is fully developed, and (6) Constant properties.

PROPERTIES: 
- **Table A-4**, Air \((\overline{T_h} = 581 \text{ K})\): \( \rho = 0.600 \text{ kg} /\text{m}^3 \), \( c = 1047 \text{ J} / \text{kg} \cdot \text{K} \), \( v = 4.991 \times 10^{-5} \text{ m}^2 / \text{s} \), \( k = 0.0457 \text{ W} / \text{m} \cdot \text{K} \), \( Pr = 0.684 \).
- **Table A-6**, Water (11.7 bar, saturated): \( T_c = 460 \text{ K} = 187 \text{°C} \).

ANALYSIS: We’ll employ the NTU-\( \varepsilon \) method to design the exchanger. Since \( C_r = 0 \), use Eq. 11.36b.

\[
\text{NTU} = -\ell n(1 - \varepsilon)
\]

where the effectiveness can be evaluated from Eqs. 11.19 and 11.20.

\[
C_{\text{min}} = C_h = \dot{m}_h \ c_h = 2 \text{ kg} / \text{s} \times 1047 \text{ J} / \text{kg} \cdot \text{K} = 2094 \text{ W} / \text{K}
\]

\[
\varepsilon = \frac{C_h \ (T_{h,i} - T_{h,o})}{C_{\text{min}} \ (T_{h,i} - T_{c,i})} = \frac{(400 - 215) \text{°C}}{(400 - 187) \text{°C}} = 0.868
\]

\[
\text{NTU} = -\ell n(1 - 0.868) = 2.029
\]

From Eq. 11.25,

\[
UA = C_{\text{min}} \cdot \text{NTU} = 2094 \text{ W} / \text{K} \times 2.029 = 4249 \text{ W} / \text{K}
\]  \hspace{1cm} (1)

Considering the gas-side flow rate and velocity criteria, find the number of tubes required as

\[
\dot{m}_h = N \cdot \rho_h \cdot A_c \cdot u_{m,i} = N \cdot \rho_h \left( \pi D_i^2 / 4 \right) u_{m,i}
\]
PROBLEM 11.54 (Cont.)

\[ 2 \text{ kg/s} = N \times 0.6009 \text{ kg/m}^3 \times \pi (0.050 \text{ m})^2 / 4 \times 25 \text{ m/s} \]

\[ N = 67.8 \text{ tubes, specify 68} \]

The overall coefficient, considering the convection process, fouling resistance and the tube thermal resistance, is evaluated as

\[ U_i = 1/ \left[ R'_{f,i} + R''_{cv,i} + R''_{cd,t} \right] = 56.4 \text{ W/m}^2 \cdot \text{K} \]

\[ R'_{f,i} = 0.0015 \text{ m}^2 \cdot \text{K} / \text{W} \]

\[ R''_{cv,i} = 1/ h_i = 1/62 \text{ W/m}^2 \cdot \text{K} = 0.0161 \text{ m}^2 \cdot \text{K} / \text{W} \]

\[ R''_{cd,t} = \frac{D_i \ln (D_o / D_i)}{2k} = \frac{0.050 \text{ m} \ln (58/50)}{2 \times 40 \text{ W/m} \cdot \text{K}} = 9.28 \times 10^{-5} \text{ m}^2 \cdot \text{K} / \text{W} \]

where the gas-side convection coefficient estimate is explained in the Comments section. Substituting numerical values, determine the required tube length

\[ [UA] = U_i \cdot A_i = U_i \left( N \pi D_i L \right) \]

\[ 4249 \text{ W/K} = 56.4 \text{ W/m}^2 \cdot \text{K} \times 68 \times \pi \times 0.050 \text{ m} \times \text{L} \]

\[ L = 7.1 \text{ m} \]

COMMENTS: (1) Is the assumption of negligible water-side thermal resistance reasonable? Explain why.

(2) Knowing the tube gas-side velocity, the usual convection correlation calculation methodology is followed. The flow is turbulent, \( \text{Re}_{D_i} = 2.5 \times 10^4 \), and assuming fully developed flow, use the Dittius-Boelter correlation, Eq. 8.60, to find \( \text{Nu}_{D_i} = 67.8 \) and \( h_i = 62.0 \text{ W/m}^2 \cdot \text{K} \).
**PROBLEM 11.55**

**KNOWN:** Hot and cold gas flow rates and inlet temperatures of a recuperator. Overall heat transfer coefficient. Desired cold gas outlet temperature.

**FIND:** (a) Required surface area, (b) Effect of surface area on cold-gas outlet temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Negligible kinetic and potential energy and flow work changes, (3) Constant properties.

**PROPERTIES:** Given: \( c_{p,c} = c_{p,h} = 1040 \, \text{W/m} \cdot \text{K} \).

**ANALYSIS:** (a) With \( C_{\text{min}} = C_c = 6.2 \, \text{kg/s} \times 1040 \, \text{J/kg} \cdot \text{K} = 6,448 \, \text{W/K} \), \( C_{\text{max}} = C_h = 6.5 \, \text{kg/s} \times 1040 \, \text{J/kg} \cdot \text{K} = 6,760 \, \text{W/K} \), \( C_r = C_{\text{min}} / C_{\text{max}} = 0.954 \), \( q = C_c (T_{c,o} - T_{c,i}) = 6,448 \, \text{W/K} (200 \, \text{K}) = 1.29 \times 10^6 \, \text{W} \), \( q_{\text{max}} = C_{\text{min}} (T_{h,i} - T_{c,i}) = 6,448 \, \text{W/K} (400 \, \text{K}) = 2.58 \times 10^6 \, \text{W} \), and \( \varepsilon = q / q_{\text{max}} = 0.50 \), Fig. 11.18 yields \( \text{NTU} \approx 1.10 \). Hence

\[
A = \frac{\text{NTU} \times C_{\text{min}}}{U} = \frac{1.10 \times 6,448 \, \text{W/K}}{100 \, \text{W/m}^2 \cdot \text{K}} = 70.9 \, \text{m}^2 < \]

(b) Using the Heat Exchanger option of IHT, the following result was obtained

The air outlet temperature increases, of course, with increasing heat exchanger area, but the approach to the maximum possible outlet temperature, \( T_{h,i} \), is slow and the heat exchanger size needed to achieve a large outlet temperature may be prohibitively expensive.
PROBLEM 11.56

KNOWN: Inlet temperature and flow rates for a concentric tube heat exchanger. Hot fluid outlet temperature.

FIND: (a) Maximum possible heat transfer rate and effectiveness, (b) Preferred mode of operation.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state operation, (2) Negligible KE and PE changes, (3) Negligible heat loss to surroundings, (4) Fixed overall heat transfer coefficient.

PROPERTIES: Table A-5, Ethylene glycol ($T_m = 80^\circ$C): $c_p = 2650$ J/kg·K; Table A-6, Water ($T_m \approx 30^\circ$C): $c_p = 4178$ J/kg·K.

ANALYSIS: (a) Using the $\varepsilon$-NTU method, find

$$ C_{\text{min}} = C_h = \dot{m}_h \, c_{p,h} = (0.5 \, \text{kg/s}) (2650 \, \text{J/kg·K}) = 1325 \, \text{W/K}. $$

Hence from Eqs. 11.19 and 11.6,

$$ q_{\text{max}} = C_{\text{min}} (T_{h,i} - T_{c,i}) = (1325 \, \text{W/K})(100 - 15) \, ^\circ\text{C} = 1.13 \times 10^5 \, \text{W}. $$

$$ q = \dot{m}_h \, c_{p,h} (T_{h,i} - T_{h,o}) = 0.5 \, \text{kg/s} (2650 \, \text{J/kg·K})(100 - 60) \, ^\circ\text{C} = 0.53 \times 10^5 \, \text{W}. <$$

Hence from Eq. 11.20,

$$ \varepsilon = \frac{q}{q_{\text{max}}} = \frac{0.53 \times 10^5}{1.13 \times 10^5} = 0.47. $$

(b) From Eq. 11.7,

$$ T_{c,o} = T_{c,i} + \frac{q}{\dot{m}_c \, c_{p,c}} = 15 + \frac{0.53 \times 10^5}{0.5 \, \text{kg/s} \times 4178 \, \text{J/kg·K}} = 40.4^\circ\text{C}. $$

Since $T_{c,o} < T_{h,o}$, a parallel flow mode of operation is possible. However, with $(C_{\text{min}}/C_{\text{max}}) = (\dot{m}_h \, c_{p,h}/\dot{m}_c \, c_{p,c}) = 0.63$,

$$ \text{Fig. 11.14} \rightarrow (\text{NTU})_{\text{PF}} = 0.95 \quad \text{Fig. 11.15} \rightarrow (\text{NTU})_{\text{CF}} \approx 0.75. $$

Hence from Eq. 11.15

$$ (A_{\text{CF}} / A_{\text{PF}}) = (\text{NTU})_{\text{CF}} / (\text{NTU})_{\text{PF}} = (0.75/0.95) = 0.79. $$

Because of the reduced size requirement, and hence capital investment, the counterflow mode of operation is preferred.
**PROBLEM 11.57**

**KNOWN:** Single-pass, cross-flow heat exchanger with both fluids (water) unmixed; hot water enters at 90°C and at 10,000 kg/h while cold water enters at 10°C and at 20,000 kg/h; effectiveness is 60%.

**FIND:** Cold water exit temperature, \( T_{c,o} \).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Negligible kinetic and potential energy changes, (3) Constant properties.

**PROPERTIES:** *Table A-6*, Water (\( T_c = (10 + 40)°C/2 = 300 \text{ K})\): \( c_c = 4179 \text{ J/kg} \cdot \text{K} \); *Table A-6*, Water (\( \bar{T}_h = (90 + 60)°C/2 = 350 \text{ K})\): \( c_h = 4195 \text{ J/kg} \cdot \text{K} \).

**ANALYSIS:** From an energy balance on the cold fluid, Eq. 11.7, the outlet temperature can be expressed as

\[
T_{c,o} = T_{c,i} + \frac{q}{\dot{m}_c C_c}.
\]

The heat rate can be written in terms of the effectiveness and \( q_{\text{max}} \). Using Eqs. 11.20 and 11.19,

\[
q = \varepsilon q_{\text{max}} = \varepsilon C_{\text{min}} (T_{h,i} - T_{c,i}).
\]

By inspection, it can be noted that the hot fluid is the minimum capacity fluid. Substituting numerical values,

\[
q = \varepsilon (\dot{m}_h c_h) (T_{h,i} - T_{c,i})
\]

\[
q = 0.60 \times (10,000 \text{ kg/h/3600 s/h}) \times 4195 \text{ J/kg} \cdot \text{K} \times (90 - 10)°C = 559.3 \times 10^3 \text{ W}.
\]

The exit temperature of the cold water is then

\[
T_{c,o} = 10°C + 559.3 \times 10^3 \text{ W/3600 kg/s} \times 4179 \text{ J/kg} \cdot \text{K} = 34.1°C.
\]

**COMMENTS:** (1) The properties of the cold fluid should be evaluated at \( T = (T_{c,o} + T_{c,i})/2 = (34.1 + 10)°C/2 = 295 \text{ K} \). Note the analysis assumed \( \bar{T}_c = 300 \text{ K} \), hence little error is incurred. For best precision, one should check \( \bar{T}_h \) and \( C_h \).

(2) From Fig. 11.18, the value of NTU could be determined. First evaluate the term

\[
C_{\text{min}} / C_{\text{max}} = \frac{\dot{m}_h C_h}{\dot{m}_c C_c} = \frac{10,000 \times 4195}{20,000 \times 4179} = 0.50
\]

and with \( \varepsilon = 0.60 \), find NTU = 1.2.
PROBLEM 11.58

KNOWN: Hxer consisting of 32 tubes in 0.6m square duct. Hot water enters tubes at 150°C with mean velocity 0.5 m/s. Atmospheric air at 10°C enters exchanger with volumetric flow rate of 1 m³/s. Heat transfer coefficient on tube outer surfaces is 400 W/m²⋅K.

FIND: Outlet temperatures of the fluids, $T_{c,o}$ and $T_{h,o}$.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Negligible potential and kinetic energy changes, (3) Constant properties, (4) Hxer is a single-pass, cross-flow type with one fluid mixed (air) and the other unmixed (water), (5) Tube water flow is fully developed, (6) Negligible thermal resistance due to tube wall.

PROPERTIES: Table A-4, Air ($T_{c,i} = 10°C = 283 K, 1 \text{ atm}$): $\rho = 1.2407 \text{ kg/m}^3; \text{ Table A-4, Air (assume } T_{c,o} \approx 40°C, \overline{T}_c = (10 + 40)^\circ C/2 = 298 \text{ K, 1 atm}): c_p = 1007 \text{ J/kg} \cdot \text{K}; \text{ Table A-6, Water (assume } T_{h,o} \approx 140°C, \overline{T}_h = (140 + 150)^\circ C/2 = 418 \text{ K}): \rho = 1/\nu_f = 1/1.0850 \times 10^{-3} \text{ m}^3/\text{kg}, c_p = 4297 \text{ J/kg} \cdot \text{K}, \mu_f = 188 \times 10^{-6} \text{ N} \cdot \text{s}/\text{m}^2, k_f = 0.688 \text{ W/m} \cdot \text{K}, Pr_f = 1.18.$

ANALYSIS: Using the $\varepsilon$-NTU method, first find the capacity rates.

$$C_h = \dot{m}_h c_{p,h} = \left( \rho A_c u_m \right)_h N \cdot c_{p,h}$$

$$C_h = \frac{1}{1.0850 \times 10^{-3} \text{ m}^3/\text{kg}} \times \frac{\pi}{4} \left(10.2 \times 10^{-3} \text{ m} \right)^2 \times 0.5 \text{ m/s} \times 32 \times 4297 J/\text{kg} \cdot \text{K} = 5178 \text{ W/K}$$

$$C_c = \dot{m}_c c_{p,c} = \left( \rho V \right)_c c_{p,c} = 1.2407 \frac{\text{kg}}{\text{m}^3} \times 1 \text{ m}^3/\text{s} \times 1007 \text{ J/kg} \cdot \text{K} = 1249 \frac{\text{W}}{\text{K}}. \quad (1.2)$$

Note that the cold fluid is the minimum fluid, $C_c = C_{min}$. The overall heat transfer coefficient follows from Eq. 11.5,

$$U_o A_o = \left[ \frac{1}{h_i A_i} + \frac{1}{h_o A_o} \right]^{-1} \quad (3)$$

where $h_i$ must be estimated from an appropriate internal flow correlation. The Reynolds number for water flow is

$$Re_D = \frac{\rho u_m D_i}{\mu} = \frac{1/1.0850 \times 10^{-3} \text{ m}^3/\text{kg}}{188 \times 10^{-6} \text{ N} \cdot \text{s}/\text{m}^2} \times 0.5 \text{ m/s} \times \left(10.2 \times 10^{-3} \text{ m} \right) = 25,002. \quad (4)$$

Continued …..
The flow is turbulent and since \( \frac{L}{D_i} = \frac{0.6\text{m}}{10.2 \times 10^{-3}\text{m}} = 59 \), fully developed conditions may be assumed. The Dittus-Boelter correlation with \( n = 0.3 \) is appropriate.

\[
\text{Nu}_D = \frac{h_i D_i}{k} = 0.023 \text{Re}^{0.8} \Pr^{0.3} = 0.023(25,002)^{0.8}(1.18)^{0.3} = 79.7
\]

\[
h_i = \frac{k}{D_i} \text{Nu}_D = \frac{0.688\text{W/m} \cdot \text{K}}{10.2 \times 10^{-3}\text{m}} \times 79.7 = 5376\text{W/m}^2 \cdot \text{K}.
\]

Substituting numerical values into Eq. (3), find

\[
U_o = \left[ \left( \frac{12.5\text{mm}}{10.2\text{mm}} \right) \frac{1}{5376\text{W/m}^2 \cdot \text{K}} + \frac{1}{400\text{W/m}^2 \cdot \text{K}} \right]^{-1} = 366.6\text{W/m}^2 \cdot \text{K}.
\]

It follows from Eq. 11.25, with \( A_o = N(\pi D_o L) \), that

\[
\text{NTU} = \frac{U_o A_o}{C_{\text{min}}} = 366.6 \frac{W}{m^2 \cdot K} \times \left( \frac{32 \times \pi \times 12.5 \times 10^{-3}\text{m} \times 0.6\text{m}}{1249 \frac{W}{K}} \right) = 0.22.
\]

From Fig. 11.19, noting that \( C_{\text{min}} = C_c \) is the mixed fluid (solid curves),

\[
\frac{C_{\text{mixed}}}{C_{\text{unmixed}}} = \frac{C_{\text{min}}}{C_{\text{max}}} = \frac{C_c}{C_h} = \frac{1249\text{W/K}}{5178\text{W/K}} = 0.24
\]

and with \( \text{NTU} = 0.22 \) find \( \varepsilon \approx 0.19 \). From the definition of effectiveness, Eq. 11.20,

\[
\varepsilon = \frac{q}{q_{\text{max}}} = \frac{C_c (T_{c,o} - T_{c,i})}{C_{\text{min}} (T_{h,i} - T_{c,i})}
\]

\[
T_{c,o} = T_{c,i} + \varepsilon (T_{h,i} - T_{c,i}) = 10^\circ\text{C} + 0.19(150 - 10)^\circ\text{C} = 36.6^\circ\text{C}.
\]

Equating the energy balances on both fluids,

\[
C_c (T_{c,o} - T_{c,i}) = C_h (T_{h,i} - T_{h,o})
\]

or

\[
T_{h,o} = T_{h,i} - \frac{C_c}{C_h} (T_{c,o} - T_{c,i})
\]

\[
T_{h,o} = 150^\circ\text{C} - \frac{1249\text{W/K}}{5178\text{W/K}} (36.6 - 10)^\circ\text{C} = 143.5^\circ\text{C}.
\]

**COMMENTS:**

1. Note that the assumptions of \( T_{h,o} \) and \( T_{c,o} \) used in evaluating properties are reasonable.

2. Note that to calculate \( \dot{m}_c \) from \( V \), the density at \( 10^\circ\text{C} \) is more appropriate than at \( T_c \).
**PROBLEM 11.59**

**KNOWN:** Flow rates and inlet temperatures of exhaust gases and combustion air used in a cross-flow (one fluid mixed) heat exchanger. Overall heat transfer coefficient. Desired air outlet temperature.

**FIND:** Required heat exchanger surface area.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Negligible heat loss to surroundings, (3) Negligible kinetic and potential energy changes, (4) Constant properties, (5) Gas properties are those of air.

**PROPERTIES:** Table A-4, Air ($\bar{T}_m = 700$ K, 1 atm): $c_p = 1075$ J/kg·K.

**ANALYSIS:** From Eqs. 11.6 and 11.7,

$$T_{h,o} = T_{h,i} - \frac{m_c c_{p,c}}{m_h c_{p,h}} (T_{c,o} - T_{c,i}) = 1100K - \frac{10 \text{ kg/s}}{15 \text{ kg/s}} (850 - 300) \text{K} = 733K.$$  

From Eqs. 11.15, 11.17 and 11.18,

$$\Delta T_{\text{lm}} = F \frac{(T_{h,i} - T_{c,o}) - (T_{h,o} - T_{c,i})}{\ln [(T_{h,i} - T_{c,o}) / (T_{h,o} - T_{c,i})]} = F \frac{250 - 433}{\ln (250/433)} = F \times 333K.$$  

From Fig. 11.13, with $R = (300 - 850)/(733 - 1100) = 1.50$ and $P = (733 - 1100)/(300 - 1100) = 0.46$, $F = 0.73$. With

$$q = m_h c_{p,h} (T_{h,i} - T_{h,o}) = 15 \text{kg/s} \times 1075 \text{J/kg·K} (367 \text{K}) = 5.92 \times 10^6 \text{W}$$  

it follows from Eq. 11.14 that

$$A = \frac{5.92 \times 10^6 \text{W}}{100 \text{W/m}^2 \cdot \text{K} \times 0.73 (333 \text{K})} = 243 \text{m}^2.$$  

**COMMENTS:** Using the effectiveness-NTU method, from Eq. 11.22

$$\varepsilon = \frac{T_{c,o} - T_{c,i}}{T_{h,i} - T_{c,i}} = \frac{(850 - 300) \text{K}}{(1100 - 300) \text{K}} = 0.688.$$  

Hence, with $C_{\text{mixed}}/C_{\text{unmixed}} = C_c/C_h = 0.67$, Fig. 11.19 gives NTU $\approx 2.3$. From Eq. 11.25,

$$A = \frac{\text{NTU} C_{\text{min}}}{U} = 2.3 \frac{10 \text{ kg/s} \times 1075 \text{J/kg·K}}{100 \text{ W/m}^2 \cdot \text{K}} = 247 \text{m}^2.$$
**PROBLEM 11.60**

**KNOWN:** Dimensions, configuration and material of a single-pass, cross-flow heat exchanger. Inlet conditions of inner and outer flow. Fouling factor of inner surface.

**FIND:** (a) Percent fuel savings for prescribed conditions, (b) Effect of UA on air outlet temperature and fuel savings.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings and potential and kinetic energy changes, (2) Air properties are those of atmospheric air at 300 K, (3) Gas properties are those of atmospheric air at 1400 K, (4) Tube wall temperature may be approximated as 800 K for treating variable property effects.

**PROPERTIES:** Table A.4, Air (1 atm, T = 300 K): \( \nu = 15.89 \times 10^{-6} \text{ m}^2/\text{s}, c_p = 1007 \text{ J/kg} \cdot \text{K}, k = 0.0263 \text{ W/m} \cdot \text{K}, Pr = 0.707 \); (T = 1400 K): \( \mu = 530 \times 10^{-7} \text{ kg/s} \cdot \text{m}, c_p = 1207 \text{ J/kg} \cdot \text{K}, k = 0.091 \text{ W/m} \cdot \text{K}, Pr = 0.703 \); (T = 800 K): \( \mu = 370 \times 10^{-7} \text{ kg/s} \cdot \text{m}, Pr = 0.709 \).

**ANALYSIS:** (a) With capacity rates of \( C_c = \dot{m}_c c_p, c = 1 \text{ kg/s} \times 1007 \text{ J/kg} \cdot \text{K} = 1007 \text{ W/K} = C_{\min} \) and \( C_h = h_p, h_m c = 1.05 \text{ kg/s} \times 1207 \text{ J/kg} \cdot \text{K} = 1267 \text{ W/K} = C_{\max} \), \( C_{\min}/C_{\max} = 0.795 \). The overall coefficient is

\[
\frac{1}{UA} = \frac{1}{h_i A_i} + \frac{R_{f,i}}{A_i} + \frac{\ln \left( D_o/D_i \right)}{(2\pi kL) N} + \frac{1}{h_o A_o}.
\]

For flow through a single tube,

\[
Re_D = \frac{4\dot{m}_h}{N\pi D_i \mu} = \frac{4 \times 1.05 \text{ kg/s}}{80\pi \left( 0.055 \text{ m} \right) 530 \times 10^{-7} \text{ kg/s} \cdot \text{m}} = 5733.
\]

Assuming fully developed turbulent flow throughout and using the Sieder-Tate correlation,

\[
Nu_D = 0.027 Re_D^{4/5} Pr^{1/3} \left( \mu/\mu_s \right)^{0.14} = 0.027 \left( 5733 \right)^{4/5} \left( 0.055/0.703 \right)^{1/3} \left( 530/370 \right)^{0.14} = 25.6
\]

\[
h_i = Nu_D k/D_i = 25.6 \left( 0.091 \text{ W/m} \cdot \text{K} \right)/0.055 \text{ m} = 42.4 \text{ W/m}^2 \cdot \text{K}.
\]

For flow over the tube bank,

\[
V_{\text{max}} = \left[ S_T / \left( S_T - D_o \right) \right] V = \left[ 0.12 \text{ m} / (0.12 - 0.08) \text{ m} \right] 1 \text{ m/s} = 3 \text{ m/s}
\]

\[
Re_{D,\text{max}} = \frac{V_{\text{max}} D_o}{\nu} = \frac{3 \text{ m/s} (0.08 \text{ m})}{15.89 \times 10^{-6} \text{ m}^2/\text{s}} = 15,100
\]

From the Zhukauskas correlation for a tube bank,

\[
\bar{Nu}_D = 0.27 \left( 15,100 \right)^{0.63} \left( 0.707 \right)^{0.36} \left( 0.707/0.709 \right)^{1/4} = 102.3
\]

\[
\bar{h}_o = \bar{Nu}_D \left( k/D_o \right) = 102.3 \left( 0.0263 \text{ W/m} \cdot \text{K} \right)/0.08 \text{ m} = 33.6 \text{ W/m}^2 \cdot \text{K}.
\]

Hence, based on the inner surface, the **overall coefficient** is

Continued...
PROBLEM 11.60 (Cont.)

\[
\frac{1}{U_i} = \frac{1}{h_i} + R_{f,i} + \frac{D_i \ln\left(\frac{D_o}{D_i}\right)}{2k} + \frac{D_i}{D_o h_o}
\]

\[
\frac{1}{U_i} = \left[0.0236 + 0.0002 + \frac{0.055 \ln\left(\frac{0.08}{0.055}\right)}{40} + \frac{0.055}{0.08 \times 33.6}\right] \text{m}^2 \cdot \text{K}/\text{W}
\]

\[
U_i = \left[(0.0236 + 0.0002 + 0.0005 + 0.0246) \text{m}^2 \cdot \text{K}/\text{W}\right]^{-1} = 22.3 \text{W}/\text{m}^2 \cdot \text{K}.
\]

Hence, \((UA)_i = U_i N \pi D_i L = 22.3 \text{W}/\text{m}^2 \cdot \text{K} \times 80\pi (0.055 \text{m})1.4 \text{m} = 432 \text{W}/\text{K}\). The number of transfer units is then \(NTU = \frac{UA}{C_{\text{min}}} = 432 \text{W}/\text{K}/1007 \text{W}/\text{K} = 0.429\), and with \(C_{\text{mixed}}/C_{\text{unmixed}} = C_c/C_h = C_{\text{min}}/C_{\text{max}} = 0.795\), Fig. 11.19 yields \(\varepsilon = 0.3\) or, from Eq. 11.35 a,

\[
\varepsilon = 1 - \exp\left(-C_r^{-1}\left[1 - \exp\left(-C_r \cdot NTU\right)\right]\right) = 0.305.
\]

Hence, with

\[
q_{\text{max}} = C_{\text{min}} \left(T_{h,i} - T_{c,i}\right) = 1007 \text{W}/\text{K} (1100 \text{K}) = 1.11 \times 10^6 \text{W}
\]

\[
q = \varepsilon q_{\text{max}} = 0.305 \times 1.11 \times 10^6 \text{W} = 337,800 \text{W}
\]

\[
T_{c,o} = T_{c,i} + q/C_{\text{min}} = 300 \text{K} + (337,800 \text{W}/1007 \text{W}/\text{K}) = 635 \text{K}.
\]

Hence,

\[
\text{% fuel savings} \equiv FS = (\Delta T_c/10 \text{K})\times 1\% = (335 \text{K}/10 \text{K})\times 1\% = 33.5\%
\]

(b) Using the Heat Exchangers Toolpad of IHT to perform the parametric calculations, the following results are obtained.

\[\text{Air outlet temperature, } T_{c,o} (\text{K}) \text{ vs. } \text{Convection parameter, } UA (\text{W/K})\]

\[\text{Fuel Savings (\%)} \text{ vs. } \text{Convection parameter, } UA (\text{W/K})\]

Significant benefits are derived by increasing \(UA\), with values of \(T_{c,o} = 716 \text{ K}\) and \(FS = 41.6\%\) obtained for \(UA = 600 \text{ W}/\text{K}\). The major contributions to the total resistance are made by the inner and outer convection resistances. These contributions could be reduced by using extended surfaces on both the inner and outer surfaces.

**COMMENTS:** For part (a), properties of the flue gas should be evaluated at \((T_{h,i} + T_{h,o})/2\) and the calculations repeated. The Colburn equation yields

\[
Nu_D = 0.023 \text{Re}_D^{3/5} \text{Pr}_l^{1/3} = 20.8
\]

which is 19\% less than the result of the Sieder-Tate correlation.
**PROBLEM 11.61**

**KNOWN:** Rate of thermal energy production in combustor and transfer to load in furnace. Cold air and flue gas flowrates and specific heats in recuperator. Recuperator cold air inlet temperature.

**FIND:** Recuperator hot gas inlet and outlet temperatures and air outlet temperature for a recuperator effectiveness of $\varepsilon = 0.3$. Value of $\varepsilon$ needed to achieve a recuperator outlet temperature of 800 K.

**SCHEMATIC:**

![Diagram of recuperator system]

**ASSUMPTIONS:** (1) Negligible flowwork and potential and kinetic energy changes, (2) Constant properties, (3) Negligible effect of fuel addition on flowrate.

**PROPERTIES:** Air and gas: $c_{p,c} = c_{p,h} = 1200 \text{ J/kg} \cdot \text{K}$.

**ANALYSIS:** With $C_c = C_h = C_{\text{min}}$, the effectiveness of the recuperator, $\varepsilon = q/q_{\text{max}}$, may be expressed as

$$\varepsilon = \frac{C_c (T_{c,o} - T_{c,i})}{C_{\text{min}} (T_{h,i} - T_{c,i})} = \frac{T_{c,o} - 300 \text{ K}}{T_{h,i} - 300 \text{ K}} = 0.3$$

The unknown temperatures, $T_{c,o}$ and $T_{h,i}$, are also related through an energy balance performed on the air entering the combustor and leaving the furnace. Specifically,

$$C(T_{h,i} - T_{c,o}) = q_{\text{comb}} - q_{\text{load}} = 0.6 \times 10^6 \text{ W}$$

where $C = 1 \text{ kg/s} \times 1200 \text{ J/kg} \cdot \text{K} = 1200 \text{ W/K}$. Solving the foregoing equations, we obtain

$$T_{h,i} = 1014 \text{ K} \quad T_{c,o} = 514 \text{ K}$$

Expressing the effectiveness as

$$\varepsilon = \frac{C_h (T_{h,i} - T_{h,o})}{C_{\text{min}} (T_{h,i} - T_{c,i})} = \frac{1014 \text{ K} - T_{h,o}}{714 \text{ K}}$$

we also obtain $T_{h,o} = 800 \text{ K}$.

For a combustor air inlet temperature of $T_{c,o} = 800 \text{ K}$ and $T_{h,i} = 1014 \text{ K}$, the required effectiveness is

$$\varepsilon = \frac{T_{c,o} - T_{c,i}}{T_{h,i} - T_{c,i}} = \frac{(800 - 300) \text{ K}}{(1014 - 300) \text{ K}} = 0.70$$

**COMMENTS:** The effectiveness of the recuperator may be increased by increasing NTU and hence UA, as, for example, by increasing the number of tubes.
PROBLEM 11.62

KNOWN: Single-shell, two-tube pass heat exchanger with surface area 0.5 m\(^2\) and overall heat transfer coefficient of 2000 W/m\(^2\)\cdot K; saturated steam at 100°C condenses on one side while water at a flow rate of 0.5 kg/s enters at 15°C.

FIND: (a) Outlet temperature of the water, \(T_{c,o}\), (b) Rate of condensation of steam, \(\dot{m}_h\).

SCHEMATIC:

ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Negligible, kinetic and potential energy changes, (3) Constant properties.

PROPERTIES: Table A-6, Steam (100°C, 1 atm): \(h_{fg} = 2257 \text{ kJ/kg}\); Table A-6, Water (\(T_c = (15 + 35)\)°C/2 = 300 K): \(c_c = 4179 \text{ J/kg} \cdot \text{K}\).

ANALYSIS: (a) Using the \(\epsilon\)-NTU method of analysis, recognize that the minimum capacity fluid is the cold fluid since for the hot fluid, \(C_h \rightarrow \infty\). See Fig. 11.9a. That is,

\[
C_{\text{min}} = \dot{m}_c c_c = 0.5 \text{ kg/s} \times 4179 \text{ J/kg} \cdot \text{K} = 2090 \text{ W} / \text{K}.
\]

It follows also that,

\[
\text{NTU} = A / U / C_{\text{min}} = 0.5 \text{m}^2 \times 2000 \text{ W} / \text{m}^2 \cdot \text{K} / 2090 \text{ W} / \text{K} = 0.48.
\]

Using NTU = 0.48 and \(C_{\text{min}}/C_{\text{max}} = 0\), find from Fig. 11.16 that \(\epsilon = 0.39\). Since \(\dot{m}_c\) is the minimum fluid, from Eq. 11.22

\[
\epsilon = \left( T_{c,o} - T_{c,i} \right) / \left( T_{h,i} - T_{c,i} \right)
\]

\[
T_{c,o} = T_{c,i} + \epsilon \left( T_{h,i} - T_{c,i} \right) = 15°C + 0.39(100 - 15)°C = 48.2°C.
\]

(b) The rate of steam condensation can be expressed as

\[
\dot{m}_h = q / h_{fg}.
\]

From Eqs. 11.19 and 11.20

\[
q = \epsilon q_{\text{max}} = \epsilon C_{\text{min}} \left( T_{h,i} - T_{c,i} \right)
\]

\[
q = 0.39 \times 2090 \text{ W/K} (100 - 15) \text{ K} = 69,284 \text{ W}.
\]

Hence, the condensation rate is

\[
\dot{m}_h = 69,284 \text{ W} / 2257 \times 10^3 \text{ J/kg} = 0.031 \text{ kg/s}.
\]

COMMENTS: (1) Be sure to recognize why \(C_h \rightarrow \infty\). Note also that \(\dot{m}_c >> \dot{m}_h\).

(2) Note that \(\bar{T}_c = (T_{c,i} + T_{c,o})/2 = (15 + 48.2)°C/2 \approx 305 \text{ K}\). This compares favorably with the value of 300 K at which properties of the cold fluid were evaluated.
PROBLEM 11.63

KNOWN: Concentric tube heat exchanger with prescribed conditions.

FIND: (a) Maximum possible heat transfer, (b) Effectiveness, (c) Whether heat exchanger should be run in PF or CF to minimize size or weight; determine ratio of required areas for the two flow conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Negligible kinetic and potential energy changes, (3) Constant properties, (4) Overall heat transfer coefficient remains unchanged for PF or CF conditions.

PROPERTIES: Hot fluid (given): \( c = 2100 \text{ J/kg\cdot K} \); Cold fluid (given): \( c = 4200 \text{ J/kg\cdot K} \).

ANALYSIS: (a) The maximum possible heat transfer rate is given by Eq. 11.19.

\[
q_{\text{max}} = C_{\text{min}} \left( T_{h,i} - T_{c,o} \right).
\]

The minimum capacity fluid is the hot fluid with \( C_{\text{min}} = \dot{m}_h c_h \), giving

\[
q_{\text{max}} = \dot{m}_h c_h \left( T_{h,i} - T_{c,o} \right) = 0.125 \frac{\text{kg}}{\text{s}} \times 2100 \frac{\text{J}}{\text{kg\cdot K}} \times (210 - 40) \text{ K} = 44,625 \text{ W}.
\]

(b) The effectiveness is defined by Eq. 11.20 and the heat rate, \( q \), can be determined from an energy balance on the cold fluid.

\[
\varepsilon = q / q_{\text{max}} = \dot{m}_c c_c \left( T_{c,o} - T_{c,i} \right) / q_{\text{max}}
\]

\[
\varepsilon = 0.125 \frac{\text{kg}}{\text{s}} \times 4200 \frac{\text{J}}{\text{kg\cdot K}} \times (95 - 40) \text{ K} / 44,625 \text{ W} = 0.65.
\]

(c) Operating the heat exchanger under CF conditions will require a smaller heat transfer area than for PF conditions. The ratio of the areas is

\[
\frac{A_{\text{CF}}}{A_{\text{PF}}} = \frac{q / U \Delta T_{\text{m,CF}}}{q / U \Delta T_{\text{m,PF}}} = \frac{\Delta T_{\text{m,PF}}}{\Delta T_{\text{m,CF}}}.
\]

To calculate the LMTD, first find \( T_{h,o} \) from overall energy balances on the two fluids.

\[
T_{h,o} = T_{h,i} - \frac{\dot{m}_c c_c \left( T_{c,o} - T_{c,i} \right)}{\dot{m}_h c_h} = 210^\circ \text{C} - \frac{0.125 \times 4200}{0.125 \times 2100} (95 - 40) ^\circ \text{C} = 100 ^\circ \text{C}.
\]

Using Eq. 11.15 with \( \Delta T_1 \) and \( \Delta T_2 \) as shown below, find \( \Delta T_{\text{m}} = (\Delta T_1 - \Delta T_2) / \ell \cdot n (\Delta T_1/\Delta T_2) \).

Substituting values, find

\[
\frac{A_{\text{CF}}}{A_{\text{PF}}} = \frac{\left[ (210 - 40) - (100 - 95) \right] / \ell \cdot n (170/5)}{\left[ (210 - 95) - (100 - 40) \right] / \ell \cdot n (115/60)} = \frac{46.8^\circ \text{C}}{84.5^\circ \text{C}} = 0.55.
\]

COMMENTS: In solving part (c), it is also possible to use Figs. 11.15 and 11.16 to evaluate NTU values for corresponding \( \varepsilon \) and \( C_{\text{min}}/C_{\text{max}} \) values. With knowledge of NTU it is then possible to find \( A_{\text{CF}}/A_{\text{PF}} \).
**PROBLEM 11.64**

**KNOWN:** Concentric tube HXer with prescribed inlet fluid temperatures, fluid flow rates and overall coefficient.

**FIND:** (a) Maximum heat transfer rate, \( q_{\text{max}} \); (b) Outlet fluid temperatures when area is 0.33 \( \text{m}^2 \) with CF operation; (c) Compute and plot the effectiveness, \( \varepsilon \), and fluid outlet temperatures, \( T_{c,o} \) and \( T_{h,o} \), as a function of \( UA \) for the range 50 \( \leq \) \( UA \) \( \leq 1000 \) \( \text{W/K} \) for CF operation with all other conditions remaining the same; as \( UA \) becomes very large, find asymptotic value for \( T_{h,o} \); (d) Largest heat transfer rate which could be achieved if HXer is very long with PF operation; effectiveness for this arrangement; and (e) Compute and plot \( \varepsilon \), \( T_{c,o} \) and \( T_{h,o} \) as a function of \( UA \) for the range 50 \( \leq \) \( UA \) \( \leq 1000 \) \( \text{W/K} \) for PF operation with all other conditions remaining the same; as \( UA \) becomes very large, find asymptotic value for \( T_{c,o} \) and \( T_{h,o} \).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Negligible kinetic and potential energy changes, (3) Constant properties.

**PROPERTIES:** *Table A-6,* Water (Assume \( T_{c,o} \approx 85^\circ \text{C}, \) \( \bar{T}_c \approx 335 \) \( \text{K} \)): \( c_c = 4186 \) \( \text{J/kg} \cdot \text{K} \), (Assume \( T_{h,o} \approx 100^\circ \text{C}, \) \( \bar{T}_h = 100^\circ \text{C}, \) \( \bar{T}_h = 420 \) \( \text{K} \)): \( c_h = 4302 \) \( \text{J/kg} \cdot \text{K} \).

**ANALYSIS:** (a) With \( C_{\text{min}} = C_h \), the maximum heat transfer rate from Eq. 11.19 is

\[
q_{\text{max}} = C_{\text{min}} (T_{h,i} - T_{c,i}) = C_h (T_{h,i} - T_{c,i}) = \frac{42}{3600} \times 4302 \times \frac{200 - 35}{\text{K}} = 8281 \text{ W}.
\]

(b) Using the \( \varepsilon \)-NTU method, find \( \varepsilon \) from values of \( C_{\text{min}}, C_{\text{min}}/C_{\text{max}}, \) and NTU.

\[
C_{\text{min}} = \frac{42/3600 \text{ kg/s} \times 4302 \text{ J/kg} \cdot \text{K}}{50.19 \text{ W/K}}, \quad \text{C}_{\text{min}}/\text{C}_{\text{max}} = \frac{42 \text{ kg/h} \times 4302 \text{ J/kg} \cdot \text{K}}{84 \text{ kg/h} \times 4186 \text{ J/kg} \cdot \text{K}} = 0.514
\]

\[
\text{NTU} = \frac{180 \text{ W/m}^2 \cdot \text{K} \times 0.33 \text{ m}^2}{50.19 \text{ W/K}} = 1.184.
\]

Using Eq. 11.30 for counter flow operation, with \( C_r = C_{\text{min}}/C_{\text{max}} \), find that

\[
\varepsilon = \frac{1 - \exp[-\text{NTU} (1 - C_r)]}{1 - C_r \exp[-\text{NTU} (1 - C_r)]} = \frac{1 - \exp[-1.18 (1 - 0.514)]}{1 - 0.514 \exp[-1.18 (1 - 0.514)]} = 0.616.
\]

From the definition of effectiveness, \( \varepsilon = C_h (T_{h,i} - T_{h,o})/C_{\text{min}} (T_{h,i} - T_{c,i}) \), it follows that

\[
T_{h,o} = T_{h,i} - \varepsilon (T_{h,i} - T_{c,i}) = 200^\circ \text{C} - 0.62 (200 - 35)^\circ \text{C} = 98.4^\circ \text{C}.
\]

Equating the energy balances on both fluids, \( C_h (T_{h,i} - T_{h,o}) = C_c (T_{c,o} - T_{c,i}) \), find

\[
T_{c,o} = \frac{C_h}{C_c} (T_{h,i} - T_{h,o}) + T_{c,i} = 0.514 (200 - 98.4)^\circ \text{C} + 35^\circ \text{C} = 87.2^\circ \text{C}.
\]

Continued...
PROBLEM 11.64 (Cont.)

(c) Using the *IHT Heat Exchanger Tool, Concentric Tube, counter flow operation* and the *Properties Tool for Water*, a model was developed using the effectiveness NTU method employed in the previous analysis to compute $\varepsilon$, $T_{c,o}$ and $T_{h,o}$ as a function of UA for CF operation. The results are plotted and discussed below.

(d) For PF with same prescribed inlet conditions, the temperature distributions appear as shown above when $A \to \infty$. At the outlet, $T_{c,o} = T_{h,o}$, and from the sketch $\delta T_{h,max} + \delta T_{c,max} = (200 - 35){}^\circ C = 165{}^\circ C$. From the energy balance, find

$$C_h \delta T_{h,max} = C_c \delta T_{c,max}$$

and solving simultaneously, find

$$\delta T_{h,max} = 109.0{}^\circ C \quad T_{h,o} = T_{h,i} - \delta T_{h,max} = 200 - 109.0 = 91.0{}^\circ C.$$  

The heat rate and effectiveness are

$$q = C_h \cdot \delta T_{h,max} = 50.19 \text{ W/K} \times 109.0 \text{ K} = 5471 \text{ W}$$

$$\varepsilon = q/q_{max} = 5471 \text{ W} / 8,281 \text{ W} = 0.661.$$  

(e) Using the IHT model from part (c), but for PF operation, the effectiveness, $T_{c,o}$ and $T_{h,o}$ were computed and plotted as a function of UA.

**COMMENTS:**  
1. From the plot for CF operation as UA increases, the minimum (hot) fluid outlet temperature, $T_{h,o}$, decreases to the cold fluid temperature, $T_{c,i}$. That is when $UA \to \infty$, $T_{h,o} \to T_{c,i}$. As $UA \to \infty$, the effectiveness approaches unity as expected since a very large CF heat exchanger has a heat rate $q_{max}$ and $\varepsilon = 1$.

2. From the plot for PF operation, as UA increases, $T_{h,o}$ and $T_{c,o}$ approach an asymptotic value, 91.0{}^\circ C. Also, as $UA \to \infty$, the effectiveness increases, approaching 0.661, rather than unity as would be the case for CF operation.
PROBLEM 11.65

FIND: (a) Required length without spheres, (b) Required length with spheres, (c) Explanation for reduction in fouling and pump power associated with using spheres.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible kinetic energy, potential energy and flow work changes, (2) Negligible heat loss to surroundings, (3) Constant properties, (4) Negligible tube wall thickness.

PROPERTIES: Table A-5, Ethylene glycol (\(\bar{T}_h = 70^\circ C\)): \(c_{p,h} = 2606\) J/kg⋅K; Table A-6, Water (\(\bar{T}_c \approx 35^\circ C\)): \(c_{p,c} = 4178\) J/kg⋅K.

ANALYSIS: (a) With \(C_h = C_{\text{min}} = 1303\) W/K and \(C_c = C_{\text{max}} = 2089\) W/K, \(C_r = 0.624\). With actual and maximum possible heat rates of
\[
q = C_h \left(T_{h,i} - T_{h,o}\right) = 1303\ W/K \times (100 - 40)^\circ C = 78,180\ W
\]
\[
q_{\text{max}} = C_{\text{min}} \left(T_{h,i} - T_{c,i}\right) = 1303\ W/K \times (100 - 15)^\circ C = 110,755\ W
\]
the effectiveness is \(\varepsilon = q/q_{\text{max}} = 0.706\). From Eq. 11.30b,
\[
\text{NTU} = \frac{1}{C_r - 1} \ln \left( \frac{\varepsilon - 1}{\varepsilon C_r - 1} \right) = -2.66 \ln \left( \frac{0.294}{0.559} \right) = 1.71
\]
Hence, with \(A = \pi DL\) and NTU = \(UA/C_{\text{min}}\),
\[
L = \frac{C_{\text{min}} \text{ NTU}}{\pi D_i U} = \frac{1303\ W/K \times 1.71}{\pi (0.075m)1000\ W/m^2\cdot K} = 9.46m < \frac{\text{<}}{}
\]
(b) Since \(\dot{m}_c, \dot{m}_h, T_{h,i}, T_{h,o}\) and \(T_{c,i}\) are unchanged, \(C_r, \varepsilon\) and NTU are unchanged. Hence, with \(U = 2000\ W/m^2\cdot K\),
\[
L = 4.73m < \frac{\text{<}}{}
\]
(c) Because the spheres induce mixing of the flows, the potential for contaminant build-up on the surfaces, and hence fouling, is reduced. Although the obstruction to flow imposed by the spheres acts to increase the pressure drop, the reduction in the heat exchanger length reduces the pressure drop. The second effect may exceed that of the first, thereby reducing pump power requirements.

COMMENTS: The water outlet temperature is \(T_{c,o} = T_{c,i} + q/C_c = 15^\circ C + 78,180\ W/2089\ W/K = 52.4^\circ C\). The mean temperature (\(\bar{T}_c = 33.7^\circ C\)) is close to that used to evaluate the specific heat of water.
PROBLEM 11.66

KNOWN: Concentric tube, counter-flow heat exchanger.

FIND: Total heat transfer rate and outlet temperatures of both fluids.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Negligible kinetic and potential energy changes, (3) Constant properties.

PROPERTIES: Table A-6, Water ($T_h = 68^\circ C = 340 K$): $c_h = 4188$ J/kg$\cdot$K; Table A-6, Water ($T_c = 37^\circ C = 310 K$): $c_c = 4178$ J/kg$\cdot$K.

ANALYSIS: Using the $\varepsilon$-NTU method, begin by evaluating the capacity rates.

$$C_h = \dot{m}_h c_h = 2.5\text{kg/s} \times 4188\text{J/kg} \cdot \text{K} = 10,470\text{W/K}$$
$$C_c = \dot{m}_c c_c = 5.0\text{kg/s} \times 4178\text{J/kg} \cdot \text{K} = 20,890\text{W/K}$$

Hence, $C_{min} = C_h$ and $C_{min}/C_{max} = 0.50$

From the definition, Eq. 11.25,

$$NTU = \frac{U \cdot A}{C_{min}} = \frac{1000\text{W/m}^2 \cdot \text{K} \times 23\text{m}^2}{(10,470\text{W/K})} = 2.20.$$  

Using values of NTU and $C_{min}/C_{max}$ find from Fig. 11.15, that

$$\varepsilon \approx 0.80.$$  

From the definition of $\varepsilon$, Eq. 11.20, it follows that

$$q = \varepsilon q_{max} = \varepsilon C_{min} (T_{h,i} - T_{c,i}) = 0.80 \times 10,470\text{W/K} (100 - 20)\text{K} = 670\text{kW}.$$  

Performing energy balances on both fluids, find

$$T_{c,o} = T_{c,i} + \frac{q}{C_c} = 20^\circ C + 670\text{kW}/20,890\text{W/K} = 52.1^\circ C$$
$$T_{h,o} = T_{h,i} - \frac{q}{C_h} = 100^\circ C - 670\text{kW}/10,470\text{W/K} = 36.0^\circ C.$$  

COMMENTS: (1) Note that $T_c = (20 + 52.1)^\circ C/2 = 310\text{K}$ and $T_h = (100 + 36)^\circ C/2 = 341\text{K}$ and that these values agree well with those used to evaluate the properties.

(2) Eq. 11.30 could be used to evaluate $\varepsilon$; the result gives $\varepsilon = 0.800$.  

< Trouble reading the pdf file >
**PROBLEM 11.67**

**KNOWN:** Shell and tube heat exchanger for cooling exhaust gases with water.

**FIND:** Required surface area using $\varepsilon$-NTU method.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Negligible changes in kinetic and potential energies, (3) Constant properties, (4) Gases have properties of air.

**PROPERTIES:** Table A-6, Water, liquid ($T_c = (85 + 35)^\circ C/2 = 333 K$): $c_p = 4185 \text{ J/kg} \cdot \text{K}$.

**ANALYSIS:** Using the $\varepsilon$-NTU method, the area can be expressed as

$$A = \text{NTU} \cdot C_{\text{min}} / U$$

where NTU must be found from knowledge of $\varepsilon$ and $C_{\text{min}} / C_{\text{max}} = C_r$. The capacity rates are:

$$C_c = \dot{m}_c c_{p,c} = 2.5 \text{ kg/s} \times 4185 \text{ J/kg} \cdot \text{K} = 10,463 \text{ W/K}$$

Equating the energy balance relation for each fluid,

$$C_h = C_c \left( T_{c,o} - T_{c,i} \right) / \left( T_{h,i} - T_{h,o} \right) = 10,463 \text{ W/K} \left( 85 - 35 \right) / \left( 200 - 93 \right) = 4889 \text{ W/K}.$$  

Hence,

$$C_r = C_{\text{min}} / C_{\text{max}} = C_h / C_c = 4889 / 10,463 = 0.467.$$  

The effectiveness of the exchanger, with $q_{\text{max}} = C_{\text{min}} (T_{h,i} - T_{c,i})$ and $C_{\text{min}} = C_h$, is

$$\varepsilon = q / q_{\text{max}} = C_h \left( T_{h,i} - T_{h,o} \right) / C_h \left( T_{h,i} - T_{c,i} \right) = (200 - 93) / (200 - 35) = 0.648.$$  

Considering the HXer to be a single shell with 2,4...tube passes, Eqs. 11.31b,c are appropriate to evaluate NTU.

$$\text{NTU} = -\left( 1 + C_r^2 \right)^{-1/2} \frac{E - 1}{\ln E + 1}$$

$$E = \frac{2 / \varepsilon_1 - \left( 1 + C_r \right)}{\left( 1 + C_r^2 \right)^{1/2}}.$$  

Substituting numerical values,

$$E = \frac{2 / 0.648 - \left( 1 + 0.467 \right)}{\left( 1 + 0.467^2 \right)^{1/2}} = 1.467 \quad \text{NTU} = -\left( 1 + \left( 0.467 \right)^2 \right)^{-1/2} \frac{\ln \left( \frac{1.467 - 1}{1.467 + 1} \right)}{1.467 + 1} = 1.51.$$  

Using the appropriate numerical values in Eq. (1), the required area is

$$A = 1.51 \times 4889 \text{ W/K} / 180 \text{ W/m}^2 \cdot \text{K} = 40.9 \text{ m}^2.$$  

**COMMENTS:** Figure 11.16 could also have been used with $C_r$ and $\varepsilon$ to find NTU.
PROBLEM 11.68

KNOWN: Dimensions, fluid flow rates, and fluid temperatures for a counterflow heat exchanger used to heat blood.

FIND: (a) Outlet temperature of the blood, (b) Effect of water flowrate and inlet temperature on heat rate and blood outlet temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Negligible kinetic and potential energy changes, (3) Constant properties.

PROPERTIES: Table A.6, Water ($T_m = 55^\circ\text{C}$): $c_p = 4183 \text{ J/kg} \cdot \text{K}$.

ANALYSIS: (a) Using the $\varepsilon$ - NTU method, we first obtain $C_h = \left( \dot{m}_h c_{p,h} \right) = (0.10 \text{ kg/s} \times 4183 \text{ J/kg} \cdot \text{K}) = 418.3 \text{ W/K}$ and $C_c = \left( \dot{m}_c c_{p,c} \right) = (0.05 \text{ kg/s} \times 3500 \text{ J/kg} \cdot \text{K}) = 175 \text{ W/K} = C_{\min}$. Hence, $(C_{\min}/C_{\max}) = 0.418$ and

$$\varepsilon = \frac{U A}{C_{\min}} = \frac{\left(500 \text{ W/m}^2 \cdot \text{K}\right)\left(0.055 \text{ m}\right)(0.5 \text{ m})}{175 \text{ W/K}} = 0.247.$$

From Eq. 11.30, $\varepsilon = 0.21$. Hence, from Eq. 11.23

$$q = \varepsilon C_{\min} \left( T_{h,i} - T_{c,i} \right) = 0.21(175 \text{ W/K})(60 - 18)^\circ \text{C} = 1544 \text{ W}.$$

From Eq. 11.7,

$$T_{c,o} = T_{c,i} + \frac{q}{C_c} = 18^\circ \text{C} + \frac{1544 \text{ W}}{175 \text{ W/K}} = 26.8^\circ \text{C}$$

(b) Because the variation of $C_{\min}/C_{\max}$ with $\dot{m}_h$ does not have a significant effect on $\varepsilon$ for the prescribed NTU, $T_{c,o}$ and $q$ increase only slightly with increasing $\dot{m}_h$.

However, the water inlet temperature does have a significant effect, and accelerated heating is achieved with $T_{h,i} = 70^\circ\text{C}$.

COMMENTS: With $\dot{m}_h = 0.2$ kg/s and $T_{h,i} = 70^\circ\text{C}$, the outlet temperature of the blood is still below the desired level of $T_{c,o} \approx 37^\circ\text{C}$. This value of $T_{c,o}$ could be increased by increasing $L$ or $T_{h,i}$. 
**PROBLEM 11.69**

**KNOWN:** Inlet temperatures and flow rates of water (c) and ethylene glycol (h) in a shell-and-tube heat exchanger (one shell pass and two tube passes) of prescribed area and overall heat transfer coefficient.

**FIND:** (a) Heat transfer rate and fluid outlet temperatures and (b) Compute and plot the effectiveness, $\varepsilon$, and fluid outlet temperatures, $T_{c,o}$ and $T_{h,o}$ as a function of the flow rate of ethylene glycol, $m_h$, for the range $0.5 \leq m_h \leq 5$ kg/s.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible heat loss to surroundings, (2) Negligible kinetic and potential energy changes, (3) Constant properties, and (4) Overall coefficient remains unchanged.

**PROPERTIES:** Table A-5, Ethylene glycol ($\bar{T}_m \approx 40^\circ$C): $c_p = 2474$ J/kg·K; Table A-6, Water ($\bar{T}_m \approx 15^\circ$C): $c_p = 4186$ J/kg·K.

**ANALYSIS:** (a) Using the $\varepsilon$-NTU method we first obtain

$$C_h = \left(\bar{m}_h c_{p,h}\right) = (2\text{kg/s} \times 2474\text{J/kg} \cdot \text{K}) = 4948\text{W/K}$$

$$C_c = \left(\bar{m}_c c_{p,c}\right) = (5\text{kg/s} \times 4186\text{J/kg} \cdot \text{K}) = 20,930\text{W/K}.$$ 

Hence with $C_{\text{min}} = C_h = 4948\text{W/K} \text{ and } C_r = C_{\text{min}}/C_{\text{max}} = 0.236,$

$$\text{NTU} = \frac{UA}{C_{\text{min}}} = \left(\frac{4948\text{W/K}}{15m^2 \cdot \text{K}}\right)15m^2 = 2.43.$$ 

From Fig. 11.16, $\varepsilon = 0.81$ and from Eq. 11.23

$$q = \varepsilon C_{\text{min}} \left(T_{h,i} - T_{c,i}\right) = 0.81(4948\text{W/K})(60-10)\text{K} = 2 \times 10^5 \text{W}.$$ 

From Eqs. 11.6 and 11.7, energy balances on the fluids,

$$T_{h,o} = T_{h,i} - \frac{q}{C_h} = 60^\circ\text{C} - \frac{2 \times 10^5\text{W}}{4948\text{W/K}} = 19.6^\circ\text{C}$$

$$T_{c,o} = T_{c,i} + \frac{q}{C_c} = 10^\circ\text{C} + \frac{2 \times 10^5\text{W}}{20,930\text{W/K}} = 19.6^\circ\text{C}.$$ 

(b) Using the *IHT Heat Exchanger Tool, Shell and Tube,* and the *Properties Tool* for Water and Ethylene Glycol, $T_{c,o}, T_{h,o},$ and $\varepsilon$ as a function of $\bar{m}_h$ were computed and plotted.

At very low $C_{\text{min}}$, (low $\bar{m}_h$) note that $\varepsilon \to 1$ while $T_{h,o} \to T_{c,i}$. As $\bar{m}_h$ increases, both fluid outlet temperatures increase and the effectiveness decreases.
PROBLEM 11.70

KNOWN: Flow rate, specific heat and inlet temperature of gas in cross-flow heat exchanger. Flow rate and temperature of water which enters as saturated liquid and leaves as saturated vapor. Number of tubes, tube diameter and overall heat transfer coefficient.

FIND: Required tube length.

SCHEMATIC:

Assumptions: (1) Negligible kinetic and potential energy changes, (2) Negligible heat loss to surroundings, (3) Constant gas specific heat.

Properties: Table A-6, Saturated Water, (T = 450 K): \( h_{fg} = 2.024 \times 10^6 \text{ J/kg} \).

Analysis: Use effectiveness-NTU method

\[
\varepsilon = \frac{q}{q_{\text{max}}} = \frac{q}{C_{\text{min}} (T_{h,i} - T_{c,i})} = \frac{q}{\dot{m}_h c_{p,h} (T_{h,i} - T_{c,i})}
\]

\[
q = \dot{m}_c h_{fg} = 3 \text{ kg/s} \times 2.024 \times 10^6 \text{ J/kg} = 6.072 \times 10^6 \text{ W}
\]

\[
\varepsilon = \frac{6.072 \times 10^6 \text{ W}}{10 \text{ kg/s} \times 1120 \text{ J/kg} \cdot \text{K} (1400 - 450) \text{ K}} = 0.571\quad C_{\text{min}} / C_{\text{max}} = 0.
\]

From Fig. 11.19, find

\[
\text{NTU} = 0.8 = \frac{U_o N \pi D_o L}{C_{\text{min}}}
\]

\[
L = \frac{0.8 \times 10 \text{ kg/s} \times 1120 \text{ J/kg} \cdot \text{K}}{50 \text{ W/m}^2 \cdot \text{K} \times 500 \pi \times 0.025 \text{ m}} = 4.56 \text{ m}.
\]

Comments: (1) The gas outlet temperature is

\[
T_{h,o} = T_{h,i} - q / \dot{m}_h c_{p,h} = 1400 \text{ K} - 6.072 \times 10^6 \text{ W/10 kg/s \times 1120 J/kg \cdot K} = 857.9 \text{ K}.
\]

(2) Using the LMTD method,

\[
\Delta T_{\text{m,CF}} = \left[ (1400 - 450) - (858 - 450) \right] / \ln \left[ (1400 - 450) / (858 - 450) \right] = 641 \text{ K}.
\]

From Fig. 11.13, find \( F = 1 \), so the area and length are

\[
A_o = q / U_o F \Delta T_{\text{m,CF}} = 6.072 \times 10^6 \text{ W} / \left( 50 \text{ W/m}^2 \cdot \text{K} \times 1 \times 641 \text{ K} \right) = 189 \text{ m}^2
\]

\[
L = A / N \pi D_o = 189 \text{ m}^2 / 500 \pi (0.025 \text{ m}) = 4.82 \text{ m}.
\]
PROBLEM 11.71

KNOWN: Gas flow conditions upstream of a tube bank of prescribed geometry. Flow rate and inlet temperature of water passing through the tubes.

FIND: (a) Overall heat transfer coefficient, (b) Water and gas outlet temperatures, (c) Effect of water flow rate on heat recovery and outlet temperatures.

SCHEMATIC:

Exhaust gas

Tube bank: 10 x 10 square array of aligned tubes, D = 0.025 m,
S_T = 0.05 m, L = 4 m,
0.02 ≤ m_c,1 ≤ 0.20 kg/s

Water

2 ≤ m_c ≤ 20 kg/s

T_c,i = 300 K

m_h = 2.25 kg/s, T_h,i = 800 K, V = 5.0 m/s

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Negligible heat loss to the surroundings and kinetic and potential energy changes, (4) Negligible tube fouling and wall thermal resistance, (5) Fully developed water flow, (6) Gas properties are those of air.

PROPERTIES: Table A.6, Water (Assume T_m = 340 K): c_p = 4188 J/kg·K, μ = 420 × 10^{-6} N·s/m², k = 0.660 W/m·K, Pr = 2.66; Table A.4, Air (Assume T_m = 600 K): c_p = 1051 J/kg·K, ν = 52.7 × 10^{-6} m²/s, k = 0.047 W/m·K, Pr = 0.69.

ANALYSIS: (a) For the prescribed conditions, U = (1/h_i + 1/h_o)^{-1}. For the internal flow, with m_c,1 = 0.025 kg/s,

\[ \text{Re}_D = \frac{4m_{c,1}}{\pi D \mu} = \frac{4 \times 0.025 \text{ kg/s}}{\pi (0.025 \text{ m}) 420 \times 10^{-6} \text{ N/s/m}^2} = 3032. \]

Hence, assuming turbulent flow,

\[ \text{Nu}_D = 0.023 \text{Re}_D^{4/5} \text{Pr}^{0.4} = 0.023 (3032)^{4/5} (2.66)^{0.4} = 20.8 \]

\[ h_i = \frac{k}{D} \frac{\text{Nu}_D}{\text{Nu}_D} = \frac{0.660 \text{ W/m·K}}{0.025 \text{ m}} = 20.8 = 548. \]

For the external flow, \( V_{max} = \frac{0.05 \text{ m}}{0.05 - 0.025 \text{ m}} = 10.0 \text{ m/s}. \) Hence

\[ \text{Re}_{D,\text{max}} = \frac{V_{max} D}{\nu} = \frac{10 \text{ m/s} \times 0.025}{52.7 \times 10^{-6} \text{ m}^2/\text{s}} = 4744 \]

From the Zhukauskas correlation and Tables 7.7 and 7.8, \( \overline{\text{Nu}}_D = (0.97) 0.27 \text{Re}_{D,\text{max}}^{0.63} \text{Pr}^{0.36} (\text{Pr}/\text{Pr}_k)^{1/4}. \)

Neglecting the Prandtl number ratio,

\[ \overline{\text{Nu}}_D = (0.97) 0.27 (4744)^{0.63} (0.69)^{0.36} = 47.4 \]

\[ h_o = \frac{k}{D} \frac{\overline{\text{Nu}}_D}{\text{Nu}_D} = \frac{0.047 \text{ W/m·K}}{0.025 \text{ m}} = 47.4 = 89.1 \text{ W/m}^2\text{·K}. \]

Continued...
Hence, \( U = \left( \frac{1}{548} + \frac{1}{89.1} \right)^{-1} = 76.7 \text{ W/m}^2\cdot\text{K} \).

(b) The fluid outlet temperatures may be determined from the \( \varepsilon \)-NTU method. With \( \dot{m}_c = 2.5 \text{ kg/s} \), \( C_c = \dot{m}_c c_{p,c} = 2.5 \text{ kg/s} \times 4188 \text{ J/kg} \cdot \text{K} = 10,470 \text{ W/K} \). With \( C_h = \dot{m}_h c_{p,h} = 2.25 \text{ kg/s} \times 1051 \text{ J/kg} \cdot \text{K} = 2365 \text{ W/K} \), \( C_{min}/C_{max} = C_{mixed}/C_{unmixed} = 2365/10,470 = 0.23 \). Hence, with \( A = N \pi DL = 100 \pi \times 0.025 \text{ m} \times 4 \text{ m} = 31.4 \text{ m}^2 \),

\[
\text{NTU} = \frac{UA}{C_{min}} = \frac{76.7 \text{ W/m}^2\cdot\text{K} \left( 31.4 \text{ m}^2 \right)}{2365 \text{ W/K}} = 0.95
\]

From Fig. 11.19, \( \varepsilon \approx 0.61 \). From Eq. 11.19, \( q_{max} = C_{min}(T_{h,i} - T_{c,i}) = 2365 \text{ W/K}(800 - 300)\text{K} = 1.18 \times 10^6 \text{ W} \). Hence, \( q = \varepsilon q_{max} = 0.72 \times 10^6 \text{ W} \). From Eq. 11.6b,

\[
\left( T_{h,i} - T_{h,o} \right) = \frac{q}{C_h} = \frac{0.72 \times 10^6 \text{ W}}{2365 \text{ W/K}} = 304 \text{ K} \quad T_{h,o} = 496 \text{ K}
\]

From Eq. 11.7b, \( \left( T_{c,o} - T_{c,i} \right) = \frac{q}{C_c} = \frac{0.72 \times 10^6 \text{ W}}{10,470 \text{ W/K}} = 69 \text{ K} \quad T_{c,o} = 369 \text{ K} \)

(c) Using the appropriate Heat Exchangers, Correlations and Properties Toolpads of IHT, the following results were obtained.

With increasing \( \dot{m}_c \) (and \( \dot{m}_{c,1} \)), \( h_i \) increases, thereby increasing \( U \) and \( q \). However, because the total resistance is dominated by the gas-side condition, \( \dot{m}_c = 20 \text{ kg/s} \) only yields \( U = 83.9 \text{ W/m}^2\cdot\text{K} \), despite the fact that \( h_i = 2180 \text{ W/m}^2\cdot\text{K} \). Because the extent to which \( q \) increases with increasing \( \dot{m}_c \) is much smaller than the increase in \( \dot{m}_c \) itself, \( T_{c,o} \) decreases with increasing \( \dot{m}_c \). Hence, there is a trade-off between the amount of hot water and the temperature at which it is delivered. If, for example, the temperature must exceed 50\(^\circ\)C (\( T_{c,o} > 323 \text{ K} \)), \( \dot{m}_c \) cannot exceed 8 kg/s. To maintain an acceptable value of \( T_{c,o} \), while increasing \( \dot{m}_c \), \( \dot{m}_h \) (and \( V \)) should be increased, thereby increasing \( h_o \), and hence \( U \) and \( q \).

**COMMENTS:** If the air and water property functions of IHT are used to evaluate properties at appropriate mean values of the inlet and outlet fluid temperatures, the following, more accurate, results would be obtained for Parts (a) and (b): \( \varepsilon = 0.582 \), \( q = 0.697 \times 10^6 \text{ W} \); \( T_{c,o} = 366.6 \text{ K} \); \( T_{h,o} = 508.8 \text{ K} \); \( h_i = 523 \text{ W/m}^2\cdot\text{K} \); \( h_o = 86.5 \text{ W/m}^2\cdot\text{K} \) and \( U = 74.2 \text{ W/m}^2\cdot\text{K} \).
PROBLEM 11.72

KNOWN: Tube arrangement in steam-to-air, cross-flow heat exchanger. Flow rate \( \dot{m}_c \) and inlet temperature of air. Condensing temperature of steam.

FIND: (a) Air outlet temperature for \( \dot{m}_c = 12 \text{ kg/s} \), (b) Effect of \( \dot{m}_c \) on air outlet temperature, heat rate and condensation rate.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Negligible kinetic and potential energy changes, (3) Negligible steam side convection and tube wall conduction resistance, (4) Mean air temperature is 350 K.

PROPERTIES: Table A.4. Air (Assume \( T_c \equiv \left( T_{c,i} + T_{c,o} \right)/2 \approx 350 \text{ K, 1 atm} \): \( \rho = 0.995 \text{ kg/m}^3 \), \( c_p = 1009 \text{ J/kg K} \), \( \nu = 20.92 \times 10^{-6} \text{ m}^2/\text{s} \), \( k = 0.030 \text{ W/m K} \), \( Pr = 0.700 \); \( T_s = 400 \text{ K} \): \( Pr = 0.690 \).

ANALYSIS: (a) For a single-pass, cross-flow heat exchanger with one fluid mixed and the other unmixed, Fig. 11.19 can be used to obtain \( \varepsilon \), where \( C_{\text{min}}/C_{\text{max}} = C_{\text{mixed}}/C_{\text{unmixed}} = 0 \) and \( NTU = UA/C_{\text{min}} = U(\pi DL)/\dot{m}_c c_p \). From Eq. 11.5, \( U = \bar{h}_o \), and the Zhukauskas correlation may be used to estimate \( \bar{h}_o \).

The upstream velocity may be obtained from \( \dot{m}_c = \rho V A = \rho VN_T L S_T \). Hence,

\[
V = \frac{\dot{m}_c}{\rho N_T L S_T} = \frac{12 \text{ kg/s}}{0.995 \text{ kg/m}^3 \times 30 \times 2 \times 0.14 \text{ m}} = 1.44 \text{ m/s}.
\]

For aligned tubes,

\[
V_{\text{max}} = \frac{S_T}{S_T - D} V = \frac{0.14}{0.14 - 0.07} 1.44 \text{ m/s} = 2.88 \text{ m/s}
\]

\[
Re_{D,\text{max}} = \frac{V_{\text{max}} D}{\nu} = \frac{2.88 \text{ m/s} \times 0.07 \text{ m}}{20.92 \times 10^{-6} \text{ m}^2/\text{s}} = 9637.
\]

From Table 7.7, select values of \( C = 0.27 \) and \( m = 0.63 \). Hence,

\[
\bar{h}_o = Nu_D \frac{k}{D} = 77.1 \left( \frac{0.030 \text{ W/m K}}{0.07 \text{ m}} \right) = 33.0 \text{ W/m}^2 \cdot \text{K}.
\]

Hence,

\[
NTU = \frac{\bar{h}_o \pi DL N}{\dot{m}_c c_p} = \frac{33.0 \text{ W/m}^2 \cdot \text{K} \times \pi (0.07 \text{ m}) 2 \text{ m} (1200)}{12 \text{ kg/s} \times 1009 \text{ J/kg \cdot K}} = 1.44.
\]

From Fig. 11.19, find \( \varepsilon \approx 0.77 \) and then determine Continued...
PROBLEM 11.72 (Cont.)

\[
\varepsilon = \frac{q}{q_{\text{max}}} = \frac{\dot{m}_c c_p (T_{c,o} - T_{c,i})}{\dot{m}_c c_p (T_s - T_{c,i})} = \frac{T_{c,o} - T_{c,i}}{T_s - T_{c,i}}
\]

\[
T_{c,o} = T_{c,i} + \varepsilon (T_s - T_{c,i}) = 300 \text{K} + 0.77 (400 - 300) \text{K} = 377 \text{K} = 104^\circ \text{C}
\]

(b) With \( q = \varepsilon q_{\text{max}} = \varepsilon C_c (T_s - T_{c,i}) \) and the condensation rate given by Eqs. 10.33 and 10.26,

\[
\dot{m}_{cd} = \frac{q}{h_{fg}} = \frac{q}{h_{fg}}
\]

the foregoing model may be used with the Heat Exchangers, Correlations and Properties Toolpads of IHT to determine the effect of \( \dot{m}_c \) on \( T_{c,o} \), \( q \) and \( \dot{m}_{cd} \).

Since \( h_o \) increases with increasing \( \dot{m}_c \), \( q \) must also increase. However, since the increase in \( q \) is proportionally less than the increase in \( \dot{m}_c \), \( T_{c,o} \) decreases with increasing \( \dot{m}_c \).

The condensation rate increases proportionally with the increase in \( q \), and if the objective is to maximize the condensation rate, the largest value of \( \dot{m}_c \) should be maintained.

**COMMENTS:** If the objective is to heat the air, there is obviously a trade-off between maintaining elevated values of the flowrate and outlet temperature.
PROBLEM 11.73

KNOWN: Heat exchanger operating in parallel-flow configuration.

FIND: Expression for \( \frac{R_{lm}}{R_t} \) which doesn’t involve temperatures. Plot result.

SCHEMATIC:

[Diagram of heat exchanger with inlet and outlet temperatures labeled]

ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Negligible change in kinetic and potential energy.

ANALYSIS: (a) For the exchanger, the rate equation is

\[
q = UA \Delta T_{lm}
\]

and we can define thermal resistances as

\[
R_t = \left( T_{hi} - T_{ci} \right) / q \quad \text{or} \quad R_{lm} = (\Delta T_{lm}) / q = 1 / UA.
\]

Using the rate equation and the definition of effectiveness, find the thermal resistance based upon the inlet temperatures of the hot and cold fluids as

\[
R_t = C_{min} \left( T_{hi} - T_{ci} \right) / C_{min} \quad q = 1 / \varepsilon C_{min}.
\]

The ratio of these resistances is

\[
\frac{R_{lm}}{R_t} = \frac{1 / UA}{1 / \varepsilon C_{min}} = \frac{\varepsilon}{UA/C_{min}} = \frac{\varepsilon}{NTU}
\]

and for the parallel flow, concentric tube configuration using Eq. 11.29a,

\[
\frac{R_{lm}}{R_t} = \frac{1 - \exp\left[-NTU\left(1 + C_r\right)\right]}{NTU \left(1 + C_r\right)} = \frac{1 - \exp(-B)}{B}
\]

where \( B = NTU(1 + C_r) \). Evaluating the ratio for various values of \( B \), find

<table>

COMMENTS: (1) For \( C_{max} \to \infty, C_r \to 0 \); hence \( B \to NTU \). (2) For \( C_{max} = C_{min} \), \( B \to 2NTU \) or \( B \sim C_{min}^{-1} \). (3) For \( B \ll 1 \), \( R_{lm}/R_t \to 1 \). (4) For \( B \gg 1 \), \( R_{lm}/R_t \to B^{-1} \). (5) We conclude that care must be taken in representing heat exchangers with a thermal resistance, recognizing that the resistance will depend on flow rates for wide ranges of conditions.
PROBLEM 11.74

KNOWN: Heat exchanger condensing steam at 100°C with cooling water supplied at 15°C.

FIND: (a) Thermal resistance of the exchanger, (b) Change in thermal resistance if fouling is 0.0002 m²·K/W on each of the inner and outer tube surfaces, and (c) Plot the thermal resistance as a function of tube water inlet rate assuming all other conditions remain unchanged; comment on whether UA will remain constant if the flow rate changes.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Negligible kinetic and potential energy changes.

PROPERTIES: Table A-6, Water (T_m = 42°C=315 K): c_p = 4179 J/kg·K.

ANALYSIS: (a) For an exchanger, using the rate equation,

\[ q = UA\Delta T_{lm} = \frac{C_{\text{min}}(T_{h,i} - T_{c,i})}{R_t}, \]

the thermal resistance of the exchanger can be expressed as

\[ R_t = \frac{T_{h,i} - T_{c,i}}{UA\Delta T_{lm}} = \frac{C_{\text{min}}(T_{h,i} - T_{c,i})}{C_{\text{min}} \cdot q} = \frac{1}{C_{\text{min}}} \cdot q_{\text{max}} = \frac{1}{\varepsilon C_{\text{min}}}. \]

For the present exchanger with \( C_r = 0 \), use Eq. 11.36a with

\[ C_{\text{min}} = m_c c_p, c = 0.5 \text{ kg/s} \times 4179 \text{ J/kg·K} = 2090 \text{ W/K} \]

\[ \text{NTU} = U A / C_{\text{min}} = 2000 \text{ W/m}^2 \cdot \text{K} \times 0.5 \text{m}^2 / 2090 \text{ W/K} = 0.478 \]

\[ \varepsilon = 1 - \exp(-\text{NTU}) = 0.380. \]

Hence, the thermal resistance is

\[ R_t = \frac{1}{0.380 \times 2090 \text{ W/K}} = 1.258 \times 10^{-3} \text{ K/W}. \]

(b) With fouling present, the overall heat transfer coefficient will decrease.

\[ \frac{1}{U_0A} = \frac{1}{h_h A_h} + \frac{1}{h_c A_c} \]

\[ \frac{1}{U_f A} = \frac{1}{U_0 A} + \frac{R^*_{f,c}}{A_c} + \frac{R^*_{f,h}}{A_h} = \frac{1}{U_0 A} + 2R^*_f + \frac{2R^*_f}{A} \]

Continued …..
PROBLEM 11.74 (Cont.)

\[
\frac{1}{U_f A} = \frac{1}{2000 \text{ W} / \text{m}^2 \cdot \text{K}} + \frac{2 \times 0.0002 \text{ m}^2 \cdot \text{K} / \text{W}}{0.5 \text{ m}^2}
\]

\[U_f A = 555.6 \text{ W} / \text{K}.
\]

It follows that \( NTU = \frac{U_f A}{C_{\text{min}}} = 0.266 \) and \( \varepsilon_f = 0.233 \) giving

\[R_{t,f} = \frac{1}{\varepsilon f C_{\text{min}}} = 2.050 \times 10^{-3} \text{ K} / \text{W}
\]

and hence the increase in thermal resistance due to fouling is

\[
\left( R_{t,f} - R_t \right) / R_t = \left( 2.050 - 1.258 \right) / 1.258 = 63\%.
\]

(c) With no fouling, the thermal resistance, when all other conditions \((U_o A = 1000 \text{ W/K})\) remain unchanged, depends on \( C_{\text{min}} \) only as \( NTU = \frac{U_o A}{C_{\text{min}}} \),

\[
R_t = \frac{1}{\varepsilon C_{\text{min}}} = \frac{1}{C_{\text{min}}} \left[ 1 - \exp \left( -\frac{U_o A}{C_{\text{min}}} \right) \right]^{-1} = \frac{1}{C_{\text{min}}} \left[ 1 - \exp \left( -\frac{1000 \text{ W} / \text{K}}{C_{\text{min}}} \right) \right]^{-1}
\]

\[
\begin{array}{cccccccc}
C_{\text{min}} \text{ (W/K)} & 200 & 400 & 600 & 1000 & 1500 & 2000 & 3000 \\
R_t \text{ (K/W} \times 10^3) & 4.967 & 2.723 & 2.055 & 1.582 & 1.370 & 1.271 & 1.176
\end{array}
\]

From the plot note that \( R_t \) is a weak function of \( C_{\text{min}} \) above \( C_{\text{min}} > 1000 \text{ W/K} \), from which we conclude that using a constant \( R_t \) would be reasonable.

Concerning the variability of \( UA \) with changing \( C_{\text{min}} \): if most of the resistance is on the water side and the flow is turbulent, \( h_c \approx Re_D^{0.8} \approx u_m^{0.8} \approx \dot{m}_c^{0.8} \).

It follows that \( h_c \) will depend significantly on changes in \( C_{\text{min}} \). However, if \( h_c \) and \( h_r \) are of similar magnitude, the effect of \( C_{\text{min}} \) on \( U \) may not be significant.
**PROBLEM 11.75**

**KNOWN:** Air conditioner modeled as a reversed Carnot heat engine, with refrigerant as the working fluid, operating between indoor and outdoor temperatures of 23 and 43°C, respectively, removing 5 kW from a building. Compressor and fan motor efficiency of 80%.

**FIND:** (a) Required motor power assuming negligible thermal resistances between the refrigerant in the condenser and the outside air and between the refrigerant in the evaporator and the inside air, and (b) Required power if thermal resistances are each $3 \times 10^{-3}$ K/W.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Ideal heat exchanger with no losses, (2) Air conditioner behaves as reversed Carnot engine.

**ANALYSIS:** (a) With negligible thermal resistances, the Carnot cycle and reversed heat engine can be represented as shown above. Hence,

$$w_{\text{ideal}} = q_H - q_L = q_L \left( \frac{T_H}{T_L} - 1 \right) = 5 \text{ kW} \left[ \frac{316 \text{ K}}{296 \text{ K}} - 1 \right] = 0.3378 \text{ kW}.$$ 

Considering the fan power requirement and the efficiency of the motor,

$$w_{\text{act}} = (w_{\text{ideal}} + w_{\text{fan}})/\eta_c = (0.3378 + 0.200) \text{ kW}/0.8 = 0.672 \text{ kW}. \quad <$$

(b) Consider now thermal resistances of $R_t = 3 \times 10^{-3}$ K/W on the high temperature (condenser) and low temperature (evaporator) sides.

**Low side:** in order to remove heat from the room, $T_C < T_i$. That is

$$T_i - T_C = q_R = 5 \text{ kW} \left( 3 \times 10^{-3} \text{ K/W} \right) = 15 \text{ K}$$

$$T_C = T_i - 15 \text{ K} = 23^\circ \text{C} - 15 \text{ K} = 8^\circ \text{C}.$$ 

**High side:** in order to reject heat from the condenser to the outside air, $T_H > T_o$,

$$T_H - T_o = q_H R_t = q_c \left( \frac{T_H}{T_C} \right) R_t$$

$$T_H - (43 + 273) \text{ K} = 5 \text{ kW} \left[ \frac{T_H}{(8 + 273)} \right] 3 \times 10^{-3} \text{ K/W} \quad T_H = 333.9 \text{ K} = 61^\circ \text{C}.$$ 

The work required for this cycle is

$$w_{\text{ideal}} = q_H - q_L = q_L \left( \frac{T_H}{T_L} - 1 \right) = 5 \text{ kW} \left[ (61 + 273) \text{ K} / (8 + 273) \text{ K} - 1 \right] = 0.943 \text{ kW}$$

$$w_{\text{act}} = (w_{\text{ideal}} + w_{\text{fan}})/\eta_c = (0.943 + 0.2) \text{ kW}/0.8 = 1.43 \text{ kW}. \quad <$$

The effect of finite thermal resistances in the evaporator and condenser is to increase the power by a factor of two.
PROBLEM 11.76

KNOWN: Flow rate and pressure of saturated vapor entering a condenser. Number and diameter of condenser tubes. Water flow rate and inlet temperature. Tube outside convection coefficient.

FIND: (a) Water outlet temperature, (b) Total tube length, (c) Effect of fouling on mass condensation, (d) Effect of water flow rate and inlet temperature on condenser performance.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible heat loss to surroundings and potential and kinetic energy changes, (2) Constant properties, (3) Negligible wall conduction resistance and fouling (initially).

PROPERTIES: Water (given): \( c_p = 4178 \text{ J/kg} \cdot \text{K}, \mu = 700 \times 10^{-6} \text{ kg/s} \cdot \text{m}, k = 0.628 \text{ W/m} \cdot \text{K}, Pr = 4.6; \) Table A.6, Sat. steam (355 K): \( h_{fg} = 2.304 \times 10^6 \text{ J/kg}; \) With fouling: \( R^f = 0.0003 \text{ m}^2 \cdot \text{K/W}. \)

ANALYSIS: (a) From an energy balance, \( q_h = \dot{m}_h (i_{h,i} - i_{h,o}) = \dot{m}_h h_{fg} = q_c = \dot{m}_c c_p, \left( T_{c,o} - T_{c,i} \right), \) or

\[
T_{c,o} = T_{c,i} + \frac{\dot{m}_h c_p, p}{\dot{m}_c c_p, c} = 280 \text{ K} + \frac{1.5 \text{ kg/s} \times 2.304 \times 10^6 \text{ J/kg}}{15 \text{ kg/s} \times 4178 \text{ J/kg} \cdot \text{K}} = 335.1 \text{ K}. \]

(b) Since \( C_i = 0, \) NTU = \(-\ln(1 - \varepsilon)\), where

\[
\varepsilon = \frac{q}{q_{\text{max}}} = \frac{\dot{m}_c c_p, c \left( T_{c,o} - T_{c,i} \right)}{\dot{m}_c c_p, c \left( T_{h,i} - T_{c,i} \right)} = \frac{(335.1 - 280) \text{ K}}{(355 - 280) \text{ K}} = 0.735
\]

Hence, NTU = \(-\ln(1 - 0.735) = 1.327 = UA/C_{\text{min}}. \) The overall heat transfer coefficient is given by \( 1/U = 1/\bar{h}_i + 1/\bar{h}_o \). For the internal tube flow,

\[
\text{Re}_D = \frac{4 \dot{m}_c, i}{\pi D \mu} = \frac{4 \times 15 \text{ kg/s}/100}{\pi \left(0.01 \text{ m}\right) \times 700 \times 10^{-6} \text{ kg/s} \cdot \text{m}} = 27,284
\]

Hence, assuming fully developed flow with the Dittus-Boelter correlation,

\[
\text{Nu}_D = 0.023 \text{Re}_D^{4/5} \text{ Pr}^{0.4} = 0.023 \left(27,284\right)^{4/5} (4.6)^{0.4} = 149.8
\]

\[
\bar{h}_i = \left(k/D\right) \text{Nu}_D = \frac{0.628 \text{ W/m} \cdot \text{K}}{0.01 \text{ m}} \times 149.8 = 9408 \text{ W/m}^2 \cdot \text{K}
\]

and \( U = \left[ \left(1/9408\right) + \left(1/5000\right) \right]^{-1} \text{ W/m}^2 \cdot \text{K} = 3265 \text{ W/m}^2 \cdot \text{K}. \) Hence, the heat transfer area is

\[
A = \dot{m}_c c_p, c (\text{NTU}/U) = 15 \text{ kg/s} \left(4178 \text{ J/kg} \cdot \text{K}\right) \left(1.327/3265 \text{ W/m}^2 \cdot \text{K}\right) = 25.5 \text{ m}^2
\]

and the tube length is \( L = A/N\pi D = 25.5 \text{ m}^2/100\pi(0.01 \text{ m}) = 8.11 \text{ m}. \)

(c) With fouling, the overall heat transfer coefficient is \( 1/U_w = 1/U_{wo} + R^f. \) Hence, Continued...
PROBLEM 11.76 (Cont.)

\[
1/U_w = \left(3.063 \times 10^{-4} + 3 \times 10^{-4}\right) m^2 \cdot K/W
\]

\[
U_w = 1649 \text{ W/m}^2 \cdot \text{K.}
\]

\[
NTU = \frac{UA}{C_{\text{min}}} = \left(\frac{1649 \text{ W/} m^2 \cdot \text{K} \times 25.5 \text{ m}^2}{(15 \text{ kg/s} \times 4178 \text{ J/kg} \cdot \text{K})}\right) = 0.671
\]

From Eq. 11.36a, \( \varepsilon = 1 - \exp(-NTU) = 1 - \exp(-0.671) = 0.489. \) Hence, \( q = \varepsilon q_{\text{max}} = 0.489 \times 15 \text{ kg/s} \times 4178 \text{ J/kg} \cdot \text{K}(355 - 280)\text{K} = 2.30 \times 10^6 \text{ W}. \) Without fouling the heat rate was

\[ q = m_h h_{fg} = 1.5 \text{ kg/s} \times 2.304 \times 10^6 \text{ J/kg} = 3.46 \times 10^6 \text{ W}. \]

Hence, \( \frac{m_h,w}{m_{h,wo}} = 2.30 \times 10^6 / 3.46 \times 10^6 = 0.666. \)

The condensation rate with fouling is then \( m_{h,w} = 0.666 \times 1.5 \text{ kg/s} = 0.998 \text{ kg/s}. \)

(d) The prescribed water inlet temperature of \( T_{c,i} = 280 \text{ K} \) is already at the lower limit of available sources, and it would not be feasible to consider smaller values. In addition, with \( \bar{h}_f \) already quite large, an increase in \( m_c \) is not likely to provide a significant improvement in performance. Using the Heat Exchanger and Correlations Tools from IHT, the following results were obtained for \( 15 \leq m_c \leq 25 \text{ kg/s}. \)

Over the specified range of \( m_c \), there is approximately an 18% increase in the heat rate, and hence in the condensation rate. This increase is, in part, due to the increase in \( \bar{h}_f \) from 9408 to 14,160 W/m²·K, which increases \( U \) from 1649 to 1752 W/m²·K, as well as to a reduction in \( T_{c,o} \) from 316.6 to 306.0 K, which increases the mean driving potential for heat transfer.

COMMENTS: There is a significant reduction in performance due to fouling, which can not be restored by increasing \( m_c \). The desired performance could be achieved by oversizing the condenser, that is, by increasing the number of tubes and/or the tube length.
**PROBLEM 11.77**

**KNOWN:** Rankine cycle with saturated steam leaving the boiler at 2 MPa and a condenser pressure of 10 kPa. Net reversible work of 0.5 MW.

**FIND:** (a) Thermal efficiency of ideal Rankine cycle, (b) Required cooling water flow rate to condenser at 15°C with allowable temperature rise of 10°C, and (c) Design of a shell and tube heat exchanger (one shell and multiple tube passes) to satisfy condenser flow rate and temperature rise.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible loss from condenser to surroundings, (2) Negligible kinetic and potential energy changes in heat exchanger, (3) Ideal Rankine cycle, and (4) Negligible thermal resistance on condensate side of exchanger tubes.

**PROPERTIES:** *Steam Tables*, (Wark, 4th Edition): (1) \( p_1 = p_4 = 10 \text{ kPa} = 0.10 \text{ bar}, T_{sat} = 45.8\, ^\circ\text{C} = 319 \text{ K}, v_f = 1.0102 \times 10^{-3} \text{ m}^3/\text{kg}, h_f = 191.83 \text{ kJ/kg}; (3) \( p_2 = p_3 = 2 \text{ Mpa} = 20 \text{ bar}, h_g = 2799.5 \text{ kJ/kg}, s_g = 6.3409 \text{ kJ/kg} \cdot \text{K}; (4) s_4 = s_3 = 6.3409 \text{ kJ/kg} \cdot \text{K}, p_4 = 0.10 \text{ bar}, s_f = 0.6493 \text{ kJ/kg} \cdot \text{K}, s_g = 8.1502 \text{ kJ/kg} \cdot \text{K}, h_f = 191.83 \text{ kJ/kg-K}, h_{fg} = 2392.8 \text{ kJ/kg}; Table A-6, Water (\( T_{sat} = 293 \text{ K})): c_{p,c} = 4182 \text{ J/kg-\text{K}}, \mu = 1007 \times 10^{-6} \text{ N-s/m}^2, k = 0.603 \text{ W/m-K}, Pr = 7.0. Note: 1 bar = \( 10^5 \text{ N/m}^2 = 10^5 \text{ Pa}.

**ANALYSIS:** (a) Referring to your thermodynamics text, find that

\[
\eta = \frac{w_{net}}{Q_H} = \frac{w_t - w_p}{Q_H} = \frac{(h_3 - h_4) - v_1 (p_2 - p_1)}{h_3 - h_2}
\]

where the net work is the turbine minus the pump work. Assuming the liquid in the pump is incompressible,

\[
w_p = v_1 (p_2 - p_1) = 1.0102 \times 10^{-3} \text{ m}^3/\text{kg} \left(2 \times 10^6 - 10 \times 10^3\right) \text{N/m}^2 = 2.01 \text{kJ/kg}.
\]

To find the enthalpies at states 2, 3, and 4, consider the individual processes. For the *pump*,

\[
h_2 = h_1 + w_p = (191.83 + 2.01) \text{kJ/kg} = 193.84 \text{kJ/kg}.
\]

Since the exit state of the boiler is saturated at \( p_3 = 2 \) Mpa,

\[
h_3 = h_g = 2799.5 \text{ kJ/kg}.
\]

\[
Q_H = h_3 - h_2 = (2799.5 - 193.84) \text{kJ/kg} = 2605.7 \text{kJ/kg}.
\]

Since the process from 3 to 4 is isentropic, \( s_4 - s_3 \), hence

\[
x_4 = \left( s_4 - s_f \right) / \left( s_g - s_f \right) = (6.3409 - 0.6493) / (8.1502 - 0.6493) = 0.759
\]

\[
h_4 = h_f + x h_{fg} = [191.83 + 0.759 (2392.8)] \text{kJ/kg} = 2007.5 \text{kJ/kg}.
\]

Continued ….
PROBLEM 11.77 (Cont.)

Substituting appropriate values, the thermal efficiency is

\[ \eta = \frac{(792.0 - 2.0) \text{kJ/kg}}{2605.7 \text{ kJ/kg}} = 0.303 = 30.3\% . \]

(b) From an overall balance on the cycle, the heat rejected to the condenser is

\[ Q_c = Q_H - w_{\text{net}} = \left[ 2605.7 - (792.0 - 2.01) \right] \text{kJ/kg} = 1815.7 \text{ kJ/kg}. \]

Since the net reversible power is 0.5 MW, the required steam rate (h) is

\[ \dot{m}_h = \dot{W}_{\text{net}} / w_{\text{net}} = 0.5 \times 10^6 \text{ W} / (792.0 - 2.01) \text{kJ/kg} = 0.6329 \text{ kg/s}. \]

Hence, the heat rate to be removed by the cold water passing through the condenser is

\[ q_c = Q_c \cdot \dot{m}_h = \dot{m}_c c_{p,c} \left( T_{\text{c,out}} - T_{\text{c,in}} \right) \]

\[ 1815.7 \text{ kJ/kg} \times 0.6329 \text{ kg/s} = 1.149 \times 10^6 \text{ W} = \dot{m}_c \times 4182 \text{ J/kg} \cdot \text{K} \cdot (25 - 15) \text{ K} \]

\[ \dot{m}_c = 27.47 \text{ kg/s} \]

where \( c_{p,c} = c_{p,f} \) is evaluated at \( T_2, T_{\text{c,in}} = 15°C \) and \( T_{\text{c,out}} - T_{\text{c,in}} = 10° \text{C} \), the specified allowable rise.

(c) To design the heat exchanger, we need to evaluate \( U_A \). Considering the shell-tube configuration and since \( C_r = C_{\text{min}} / C_{\text{max}} = 0 \),

\[ \varepsilon = 1 - \exp\left( -NTU \right) = 1 - \exp\left[ - \left( \frac{U_A}{C_{\text{min}}} \right) \right] \]

\[ \varepsilon = \frac{q_c}{q_{\text{max}}} = \frac{\dot{m}_c c_{p,c} \left( T_{\text{h}} - T_{\text{c,i}} \right)}{1.149 \times 10^6 \text{ W}} = 0.326 \]

UA\(_S\) = 45,372 W / K

where \( C_{\text{min}} = \dot{m}_c c_{p,c} \). Our design process will involve the following steps: select tube diameter, \( D = 15 \text{ mm} \); set \( u_m = 2 \text{ m/s} \) in each tube and find number of tubes; perform internal flow calculation to estimate \( \dot{n}_c \) and then determine the length.

\[ \dot{m}_c = \rho A_c N u_m = \left( 1.010 \times 10^{-3} \text{ m}^3 / \text{kg} \right)^{-1} \left( \pi \left( 0.015 \text{m} \right)^2 / 4 \right) \times 2 \text{ m/s} \times N = 27.47 \text{ kg/s} \]

\[ N = 78.5 \approx 79. \]

Continued …..
PROBLEM 11.77 (Cont.)

For flow in a single tube,

\[ \text{Re}_D = \frac{4 \dot{m}_t}{\pi D \mu} = \frac{4(27.47 \text{ kg/s/79})}{\pi (0.015m)1007 \times 10^{-6} \text{ N·s/m}^2} = 29,310. \]

Assuming the flow is fully developed and using the Dittus-Boelter correlation,

\[ \text{Nu} = \frac{hD}{k} = 0.023 \text{Re}^{0.8} \text{Pr}^{0.4} = 0.023(29,310)^{0.8} (7.00)^{0.4} = 187.7 \]

\[ h = 0.603 \text{ W/m} \cdot \text{K} \times 187.7/0.015m = 7544 \text{ W/m}^2 \cdot \text{K}. \]

Hence, the tube length is

\[ U A_s = h(\pi D L) N = 45,372 \text{ W/K} \]

\[ L = 45,372 \text{ W/K} / 7544 \text{ W/m}^2 \cdot \text{K} \times (0.015m)79 = 1.6m \]

and our design has the following parameters:

\[ N = 79 \text{ tubes} \quad L = 1.6m \quad D = 15 \text{ mm}. \]

**COMMENTS:** (1) The selection of the tube diameter and water velocity values (15 mm, 2 m/s) was based upon prior experience; they seemed reasonable. We could, however, establish other requirements which would influence these choices such as allowable pressure drop and standard tube sizes.
**PROBLEM 11.78**

**KNOWN:** Rankine cycle with saturated steam leaving the boiler at 2 Mpa and a condenser pressure of 10 kPa. Heat rejected to the condenser of 2.3 MW. Condenser supplied with cooling water at rate of 70 kg/s at 15°C.

**FIND:** (a) Size of the condenser as determined by the parameter, UA, and (b) Reduction in thermal efficiency of the cycle if U decreases by 10% due to fouling assuming water flow rate and inlet temperature and the condenser steam pressure remain fixed.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible loss from condenser to surroundings, (2) Negligible kinetic and potential energy changes in exchanger, (3) Ideal Rankine cycle, (4) For fouled operating condition, \( m_{c}, T_{c,i}, \) and \( p_{4} \) remain the same.

**PROPERTIES:** Steam Tables (Wark, 4th Edition): See previous problem for calculations to obtain cycle enthalpies; \( h_{1} = 191.83 \text{ kJ/kg}, h_{f} = 2007.5 \text{ kJ/kg}.\)

**ANALYSIS:** (a) For the condenser, recognize that \( C_{\min} = C_{c}, \) and \( C_{r} = C_{\min}/C_{\max} = 0,\)

\[
\varepsilon = \frac{q_{1}}{q_{\max}} = 1 - \exp\left(-\frac{q_{1}}{C_{\min}}\right) = 1 - \exp\left(-\frac{U A}{C_{\min}}\right)
\]

\[
C_{\min} = m_{c} c_{p,c} = 70 \text{ kg/s} \times 4182 \text{ J/kg} \cdot \text{K} = 292,740 \text{ W} / \text{K}
\]

\[
q_{\max} = C_{\min}\left(T_{h} - T_{c,i}\right) = 292,740 \text{ W} / \text{K} \times 45.7 - 15 \text{ K} = 8.987 \times 10^{6} \text{ W}.
\]

\[
q = q_{h} = 2.30 \times 10^{6} \text{ W}
\]

\[
\frac{2.30 \times 10^{6} \text{ W}}{8.987 \times 10^{6} \text{ W}} = 0.256 = 1 - \exp\left(-\frac{U A}{292,740 \text{ W} / \text{K}}\right)
\]

\[UA = 86,538 \text{ W} / \text{K}.\]  

(b) In the fouled condition, U is reduced 10%, hence

\[U_{f} A = 0.9UA = 77,884 \text{ W} / \text{K}\]

and

\[
NTU_{f} = \frac{U_{f} A}{C_{\min}} = \frac{77,884 \text{ W} / \text{K}}{292,740 \text{ W} / \text{K}} = 0.266
\]

\[
\varepsilon_{f} = 1 - \exp\left(-NTU_{f}\right) = 1 - \exp\left(-0.266\right) = 0.234.
\]

Continued …..
If we operate the cycle at the same back pressure $p_4 = 10$ kPa so that $T_h = 45.7^\circ$C, the heat removal rate must decrease,

$$q_h = \varepsilon q_{\text{max}} = 0.234 \times 8.987 \times 10^6 \text{ W} = 2.103 \times 10^6 \text{ W}$$

since $q_{\text{max}} = C_{\text{min}} (T_h - T_{c,i})$ remains the same. From the previous problem, we found the heat rejected as

$$h_4 - h_1 = (2007.5 - 191.83) \text{ kJ/kg} = 1815.7 \text{ kJ/kg}$$

and hence the cycle steam rate through the fouled condenser is

$$\dot{m}_{h,f} = \frac{q_h}{h_4 - h_1} = \frac{2.103 \times 10^6 \text{ W}}{1815.7 \text{ kJ/kg}} = 1.158 \text{ kg/s}.$$  

For the unfouled condenser of part (a), the steam rate was

$$\dot{m}_h = 2.3 \text{ MW/1815.7 kJ/kg} = 1.267 \text{ kg/s}.$$  

Hence, we see that fouling reduces the steam rate by 8.5% when $U$ is decreased 10%. Since $p_4$ remains the same, the thermal efficiency remains unchanged,

$$\eta = 30.3\%$$

as calculated in the previous problem. However, the net work of the cycle will decrease 8.5%.

**COMMENTS:** Fouling of the condenser heat exchanger has no effect on the thermal efficiency of the cycle since the back pressure at the condenser is maintained constant. The effect is, however, to reduce the heat rejection rate while maintaining exchanger flow rate and inlet temperature fixed. Comparing the conditions:

PROBLEM 11.79

KNOWN: Compact heat exchanger (see Example 11.6) after extended use has prescribed fouling factors on water and gas sides.

FIND: Gas-side overall heat transfer coefficient.

SCHEMATIC:

ASSUMPTIONS: (1) Heat transfer coefficients on the inside and outside (cold- and hot-sides) are the same as for the unfouled condition, (2) Temperature effectiveness of the finned hot side surface is the same as for the unfouled condition.

ANALYSIS: The overall heat transfer coefficient follows from Eq. 11.1 as

\[
\frac{1}{U_h A_h} = \frac{1}{(\eta_o h A)^c_c} + \frac{R_{f,c}^*}{(\eta_o A)^c_c} + R_w + \frac{R_{f,h}^*}{(\eta_o h A)^h_h} + \frac{1}{(\eta_o h A)^h_h}
\]

where \( R_w \) and \( R_{f}^* \) are the wall resistance and fouling factors, respectively. Multiply both sides by \( A_h \) and recognizing that \( \eta_o,c = 1 \), obtain

\[
\frac{1}{U_h} = \frac{1}{h_c (A_c / A_h)} + \frac{R_{f,c}^*}{(A_c / A_h)} + A_h R_w + \frac{R_{f,h}^*}{\eta_o,h} + \frac{1}{\eta_o,h}.
\]

Substitute numerical values from Example 11.6 results \( (h_c, \eta_o,h, A_h R_w, A_c/A_h) \) and those from the problem statement \( (R_{f,h}^*, R_{f,c}^*, h_c) \) to find,

\[
\frac{1}{U_h} = \frac{1}{1500 \text{ W/m}^2\text{K} (0.143)} + \frac{0.0005 \text{ m}^2\text{K/W}}{(0.143)} + 3.51 \times 10^{-5} \frac{\text{ m}^2\text{K/W}}{0.91} + \frac{1}{0.91 \times 183 \text{ W/m}^2\text{K}} + 4.662 \times 10^{-3} + 6.993 \times 10^{-3} + 3.51 \times 10^{-5} + 5.495 \times 10^{-4} + 6.005 \times 10^{-3}
\]

\[
\frac{1}{U_h} = 65.4 \text{ W/m}^2\text{K}.
\]

COMMENTS: For the unfouled condition, we found \( U_h = 93.4 \text{ W/m}^2\text{K} \) from Example 11.6. Note that the thermal resistance of the tube-fin material is negligible and that fouling has a significant effect, reducing \( U_h \) by 41%.
PROBLEM 11.80

KNOWN: Compact heat exchanger with prescribed core geometry and operating parameters.

FIND: Required heat exchanger volume; number of tubes in the longitudinal and transverse directions, \( N_L \) and \( N_T \); required tube length.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Negligible KE and PE changes, (3) Single pass operation, (4) Gas properties are those of air.

PROPERTIES: Table A-6, Water (\( T_c = 325 \) K): \( \rho = 987.2 \) kg/m\(^3\), \( c_p = 4182 \) J/kg⋅K; Table A-4, Air (Assume \( T_{h,o} \approx 400 \) K, \( h_T \approx 550 \) K, 1 atm): \( c_p = 1040 \) J/kg⋅K.

ANALYSIS: To find the Hxer volume, first find \( A_h \) using the \( \varepsilon \)-NTU method. By definition,
\[
V = A_h / \alpha \quad \text{and} \quad A_h = \text{NTU} \cdot C_{\text{min}} / U_h. \tag{1.2}
\]

Find the capacity rates, \( q \), \( q_{\text{max}} \) and \( \varepsilon \):
\[
C_c = m_c c_p,c = 2 \text{ kg/s} \times 4182 \text{ J/kg} \cdot \text{K} = 8364 \text{ W/K}
\]
\[
C_h = m_h c_p,h = 1.25 \text{ kg/s} \times 1040 \text{ J/kg} \cdot \text{K} = 1300 \text{ W/K} \leftarrow C_{\text{min}}
\]

Hence,
\[
C_r = \frac{C_{\text{min}}}{C_{\text{max}}} = 0.155.
\]

It follows that
\[
\varepsilon = \frac{q}{q_{\text{max}}} = \frac{C_c (T_{c,o} - T_{c,i})}{C_{\text{min}} (T_{h,i} - T_{c,i})} = \frac{8364 \text{ W/K} (350 - 300) \text{ K}}{1300 \text{ W/K} (700 - 300) \text{ K}} = 0.804.
\]

With \( \varepsilon = 0.804 \) and \( C_r = 0.155 \), find NTU \( \approx 1.7 \) from Fig. 11.18 for a single-pass, cross flow Hxer with both fluids unmixed. Using Eqs. (2) and (1), find
\[
A_h = 1.7 \times 1300 \text{ W/K} / 9.34 \text{ W/m}^2 \cdot \text{K} = 23.7 \text{ m}^2
\]
\[
V = 23.7 \text{ m}^2 / 269 \text{ m}^2 / \text{m}^3 = 0.0880 \text{ m}^3.
\]

Continued …..
PROBLEM 11.80 (Cont.)

To determine the number of tubes in the longitudinal direction, consider the tubular arrangement in the sketch. The Hxer volume can be written as

\[ V = A_{fr} \times \ell_L \]  

(3)

where

\[ \ell_L = (N_L - 1) \ell + D_f \]  

(4)

and \( N_L \) is the number of tubes in the longitudinal direction. Combining Eqs. (3) and (4) and substituting numerical values, find

\[ N_L = \left( \frac{V}{A_{fr} - D_f} \right) / \ell + 1 \]  

(5)

where \( D_f \) is the overall diameter of the finned tube, and

\[ N_L = 1 \left( \frac{0.0880 \text{ m}^3}{0.20 \text{ m}^2 - 0.0285 \text{ m}} \right) / 0.0343 + 1 = 13.0 \approx 13. \]

To determine the number of tubes in the transverse direction, compare the overall water flow rate \( \dot{m}_c \) with that for a single tube, \( \dot{m}_t \). That is,

\[ \dot{m}_t = \rho_c A_t V_i \]  

(6)

where \( A_t \) is the tube inner cross-sectional area \( \left( \pi D_t^2 / 4 \right) \) and \( V_i \) the internal velocity. Hence,

\[ N = \frac{\dot{m}_c}{\dot{m}_t} = \frac{(2 \text{ kg/s})/987.2 \text{ kg/m}^3 \times \pi (0.0138 \text{ m})^2 \times 0.100 \text{ m/s}} = 135.4 \approx 135. \]

The total number of tubes required, \( N \), is 135; the number in the transverse direction is

\[ N_T = N / N_L = 135 / 13 = 10.4 \approx 11. \]

To determine the water tube length, recognize that the total area \( (A_h) \), less that of the finned surfaces \( (A_f) \), will be that of the water tube surface area. That is,

\[ A_h - A_f = \pi D_o \ell_T \cdot N. \]

From specification of the core geometry, we know \( A_f / A_h = 0.830 \); solve for \( \ell_T \) to obtain

\[ \ell_T = A_h \left( 1 - A_f / A_h \right) / \pi D_o \cdot N \]

(7)

\[ \ell_T = 23.7 \text{ m}^2 \left( 1 - 0.830 \right) / \pi (0.0164 \text{ m}) \times 135 = 0.58 \text{ m}. \]

COMMENTS: In summary we find that

- Total number of tubes, \( N \) (\( N_T \times N_L \)) 143
- Tubes in longitudinal direction, \( N_L \) 13
- Tubes in transverse direction, \( N_T \) 11

with a total surface area of 27.3 m\(^2\). The length of the exchanger is

- Length in longitudinal direction, \( \ell_L \) 0.44 m
- Length in transverse direction, \( \ell_T \) 0.58 m.
PROBLEM 11.81

KNOWN: Compact heat exchanger geometry, gas-side flow rate and inlet temperature, water-side convection coefficient, water flow rate, and water inlet and outlet temperatures.

SCHEMATIC:

ASSUMPTIONS: (1) Gas has properties of atmospheric air at an assumed mean temperature of 700 K, (2) Negligible fouling, (3) Negligible heat exchange with the surroundings and negligible kinetic and potential energy and flow work changes.

PROPERTIES: Table A-1, aluminum (T ≈ 300 K): k = 237 W/m-K. Table A-4, air (p = 1 atm, T = 700 K): c_p = 1075 J/kg-K, µ = 338.8 × 10^-7 N·s/m^2, Pr = 0.695. Table A-6, water (T = 330 K): c_p = 4184 J/kg-K.

ANALYSIS: For the prescribed heat exchanger core,

\[
\frac{1}{U_h} = \frac{1}{h_c \left( \frac{A_c}{A_h} \right)} + A_h R_w + \frac{1}{\eta_{o,h} h_h}
\]

where

\[
\frac{A_c}{A_h} = \frac{D_i}{D_o} \left( 1 - \frac{A_{f,h}}{A_h} \right) = \frac{8.2}{10.2} \left( 1 - 0.913 \right) = 0.070
\]

The product of A_h and the wall conduction resistance is

\[
A_h R_w = \frac{\ln \left( \frac{D_o}{D_i} \right)}{2\pi k L / A_h} = \frac{D_i \ln \left( \frac{D_o}{D_i} \right)}{2k \left( \frac{A_c}{A_h} \right)} = \frac{0.0082m \times \ln \left( \frac{10.2}{8.2} \right)}{2 \times 237 W / m \cdot K (0.070)} = 5.39 \times 10^{-4} m^2 \cdot K / W
\]

With a gas-side mass velocity of \( G = \frac{\dot{m}_h}{A_{fr}} \),

\[
Re = \frac{G D_h}{\mu} = \frac{11.7 \ kg / s \cdot m^2 \times 0.00363m}{338.8 \times 10^{-7} N \cdot s / m^2} = 1254
\]

and Fig. 11.21 yields \( j_h = 0.0096 \). Hence,

\[
h_h \approx \frac{0.0096 \ G c_p}{\Pr^{2/3}} = \frac{0.0096 \left( 11.7 \ kg / s \cdot m^2 \right) \left( 1075 \ J / kg \cdot K \right)}{(0.695)^{2/3}} = 154 \ W / m^2 \cdot K
\]

Continued …..
PROBLEM 11.81 (Cont.)

With \( r_{2c} = r_2 + t/2 = 15.8 \text{ mm} + 0.330 \text{ mm}/2 = 15.97 \text{ mm} \), \( r_{2c}/r_1 = 15.97/5.1 = 3.13 \), \( L = r_2 - r_1 = 10.7 \text{ mm} \), \( L_c = L + t/2 = 10.87 \text{ mm} = 0.0109 \text{ m} \), \( A_p = L_c t = 3.59 \times 10^{-6} \text{ m}^2 \), and \( L_c^{3/2} (h_h/kA_p)^{1/2} = 0.484 \), Fig. 3.19 yields \( \eta_f = 0.77 \). Hence,

\[
\eta_{o,h} = 1 - \frac{A_f}{A} (1 - \eta_f) = 1 - 0.913 (1 - 0.77) = 0.790
\]

\[
U_h^{-1} = \left(\frac{1500 \text{ W} / \text{m}^2 \cdot \text{K} \times 0.07}{5.39 \times 10^{-4} \text{ m}^2 \cdot \text{K} / \text{W} + \left(0.79 \times 154 \text{ W} / \text{m}^2 \cdot \text{K}\right)}\right)^{-1} = 0.0183 \text{ m}^2 \cdot \text{K} / \text{W}
\]

\[
U_h = 54.7 \text{ W} / \text{m}^2 \cdot \text{K}
\]

With \( q = C_c (T_{c,o} - T_{c,i}) = 4184 \text{ W/K} \times 80 \text{ K} = 3.35 \times 10^5 \text{ W} \), \( q_{\text{max}} = C_{\text{min}} (T_{h,i} - T_{c,i}) = 1344 \text{ W/K} \times 535 \text{ K} = 7.19 \times 10^5 \text{ W} \), \( \varepsilon = 0.466 \) and \( C_r = 0.321 \). From Figure 11.18, we then obtain \( \text{NTU} = 0.65 \).

The required gas-side surface area is then

\[
A_h = \frac{\text{NTU} \times C_{\text{min}}}{U_h} = \frac{0.65 \times 1344 \text{ W/K}}{54.7 \text{ W/m}^2 \cdot \text{K}} = 16.0 \text{ m}^2
\]

With \( \alpha = 587 \text{ m}^2 / \text{m}^3 \), the required volume is

\[
V = \frac{A_h}{\alpha} = \frac{16 \text{ m}^2}{587 \text{ m}^2 / \text{m}^3} = 0.0273 \text{ m}^3
\]

**COMMENTS:**

1. Although \( U_h \) is small and \( A_h \) larger for the continuous fins than for the circular fins of Example 11.6, the much larger value of \( \alpha \), renders the volume requirement smaller.

2. The heat exchanger length is \( L = V/A_{fr} = 0.137 \text{ m} \), and the number of tube rows is

\[
N_L = \frac{L}{S_L} + 1 = 7.23 \approx 7.
\]

3. The hypothetical fin radius \( (r_2 = 15.8 \text{ mm}) \) was estimated to be the arithmetic mean of one-half the center-to-center spacing between one tube and its six neighbors.
PROBLEM 11.82

KNOWN: Cooling coil geometry. Air flow rate and inlet and outlet temperatures. Freon pressure and convection coefficient.

FIND: Required number of tube rows.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible fouling, (2) Constant properties, (3) Negligible heat loss to surroundings.

PROPERTIES: Table A-4, Air ($ar{T}_h = 300$ K, 1 atm): $c_p = 1007$ J/kg·K, $\mu = 184.6 \times 10^{-7}$ N·s/m$^2$, $k = 0.0263$ W/m·K, $Pr = 0.707$; Table A-5, Sat. R-12 (1 atm): $T_{sat} = T_c = 243$ K, $h_{fg} = 165$ kJ/kg.

ANALYSIS: The required number of tube rows is

$$N_L = \left( \frac{L - D_f}{S_L} \right) + 1$$

where

$$L = \frac{V}{A_{fr}} \quad V = A_h / \alpha \quad A_h = NTU \left( \frac{C_{min}}{U_h} \right)$$

$$1 / U_h = \frac{1}{h_c} \left( \frac{A_c}{A_h} \right) + A_h R_w + 1 / \eta_o h h_h.$$

From Ex. 11.6, $(A_c/A_h) = 0.143$ and $A_h R_w = 3.51 \times 10^{-5}$ m$^2$·K/W. With

$$G = \frac{\dot{m}_h}{\sigma A_{fr}} = \frac{1.50 \text{ kg/s}}{0.449 \times 0.16 \text{ m}^2} = 20.9 \text{ kg/s} \cdot \text{m}^2$$

$$Re = \frac{G D_h}{\mu} = \frac{20.9 \text{ kg/s} \cdot \text{m}^2 \times 6.68 \times 10^{-3} \text{ m}}{184.6 \times 10^{-7} \text{ N} \cdot \text{s} / \text{m}^2} = 7563$$

and Fig. 11.20 gives $j_h = 0.0068$. Hence,

$$h_h = j_h \frac{G c_p}{Pr^{2/3}} = 0.0068 \frac{20.9 \text{ kg/s} \cdot \text{m}^2 \times 1007 \text{ J/kg} \cdot \text{K}}{(0.707)^{2/3}} = 180 \text{ W/m}^2 \cdot \text{K}.$$ 

With $L_c = 6.18$ mm and $A_p = 1.57 \times 10^{-6}$ m$^2$ from Ex. 11.6, $L_c^{3/2} \left( \frac{h_h}{k A_p} \right)^{1/2} = 0.338$ and, from Fig. 3.19, $\eta_f = 0.89$ for $r_2/r_1 = 1.75$. Hence, as in Ex. 11.6, $\eta_o h_h = 0.91$ and

$$1 / U_h = 1 / \left( 5000 \text{ W/m}^2 \cdot \text{K} \right) 0.143 + 3.51 \times 10^{-5} \text{ m}^2 \cdot \text{K} / \text{W} + 1 / \left( 0.91 \times 180 \text{ W/m}^2 \cdot \text{K} \right)$$

$$U_h = 133 \text{ W/m}^2 \cdot \text{K}.$$

Continued …..
PROBLEM 11.82 (Cont.)

With $C_{\min}/C_{\max} = 0$ and $C_{\min} = \dot{m}_h c_{p,h} = 1511 \text{ W/K}$,

$$\varepsilon = \frac{\dot{q}}{q_{\max}} = \frac{C_h \left( T_{h,i} - T_{h,o} \right)}{C_h \left( T_{h,i} - T_{c,i} \right)} = \frac{20 \text{ K}}{67 \text{ K}} = 0.30$$

$$\text{NTU} = -\ln(1 - \varepsilon) = 0.355$$

and

$$A_h = \text{NTU} \frac{C_{\min}}{U_h} = 0.355 \frac{1511 \text{ W/K}}{133 \text{ W/m}^2 \cdot \text{K}} = 4.03 \text{ m}^2.$$

Hence,

$$L = \frac{A_h}{\alpha A_{fr}} = \frac{4.03 \text{ m}^2}{269 \text{ m}^2 / \text{m}^3 \cdot 0.16 \text{ m}^2} = 0.0937 \text{ m}$$

and

$$N_L = \frac{L - D_f}{S_L} + 1 = \frac{0.0652}{0.0343 \text{ m}} + 1 = 2.9.$$

Hence, three or more rows must be used.

**COMMENTS:** For the prescribed operating conditions, the heat rate would be

$$\dot{q} = C_h \left( T_{h,i} - T_{h,o} \right) = 1511 \text{ W/K} (20 \text{ K}) = 30,220 \text{ W}.$$  

If R-12 enters the tubes as saturated liquid, a flow rate of at least

$$\dot{m}_c = \frac{\dot{q}}{h_{fg}} = \frac{30,220 \text{ W}}{165,000 \text{ J/kg}} = 0.183 \text{ kg/s}$$

would be needed to maintain saturated conditions in the tubes.
PROBLEM 11.83

KNOWN: Cooling coil geometry. Air flow rate and inlet temperature. Freon pressure and convection coefficient.

FIND: Air outlet temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible fouling, (2) Constant properties, (3) Negligible heat loss to surroundings.

PROPERTIES: Table A-4, Air ($\bar{T}_h = 300$ K, 1 atm): $c_p = 1007$ J/kg·K, $\mu = 184.6 \times 10^{-7}$ N·s/m$^2$, $k = 0.0263$ W/m·K, $Pr = 0.707$; Table A-5, Sat. R-12 (1 atm): $T_{sat} = T_c = 243$ K, $h_{fg} = 165$ kJ/kg.

ANALYSIS: To obtain the air outlet temperature, we must first obtain the heat rate from the $\varepsilon$-NTU method. To find $A_h$, first find the heat exchanger length,

$$L \approx (N_L - 1)S_L + D_f = 3(0.0343\text{m}) + 0.0285\text{m} = 0.131\text{m}.$$

Hence,

$$V = A_{fr}L = 0.16\text{m}^2(0.131\text{m}) = 0.021\text{m}^3$$

$$A_h = \alpha V = \left(269\text{m}^2/\text{m}^3\right)0.021\text{m}^3 = 5.65\text{m}^2.$$

The overall coefficient is

$$\frac{1}{U_h} = \frac{1}{h_c (A_c / A_h)} + A_h R_w + \frac{1}{\eta_{o,h} h_h}$$

where Ex. 11.6 yields $(A_c / A_h) = 0.143$ and $A_h R_w = 3.51 \times 10^{-5}$ m$^2$·K/W. With

$$G = \frac{m_h}{\sigma A_{fr}} = \frac{1.50 \text{ kg/s}}{0.449 \times 0.16 \text{ m}^2} = 20.9 \text{ kg/s} \cdot \text{m}^2$$

$$Re = \frac{GD_h}{\mu} = \frac{20.9 \text{ kg/s} \cdot \text{m}^2 \times 6.68 \times 10^{-3} \text{ m}}{184.6 \times 10^{-7} \text{ N} \cdot \text{s} / \text{m}^2} = 7563.$$ 

Fig. 11.20 gives $j_l = 0.0068$. Hence,

$$h_h = j_l \frac{G c_p}{Pr^{2/3}} = 0.0068 \frac{20.9 \text{ kg/s} \cdot \text{m}^2 \times 1007 \text{ J/kg} \cdot \text{K}}{(0.707)^{2/3}}$$

$$h_h = 180 \text{ W/m}^2 \cdot \text{K}.$$ 

Continued …..
PROBLEM 11.83 (Cont.)

With \( L_c = 6.18 \text{ mm} \) and \( A_p = 1.57 \times 10^{-6} \text{ m}^2 \) from Ex. 11.6, \( L_c^{3/2} \left( \frac{h_h}{kA_p} \right)^{1/2} = 0.338 \) and, from Fig. 3.19, \( \eta_f = 0.89 \) for \( r_2/r_1 = 1.75 \). Hence, as in Ex. 11.6, \( \eta_{o,h} = 0.91 \) and

\[
\frac{1}{U_h} = \frac{1}{\left( 5000 \text{ W} / \text{ m}^2 \cdot \text{ K} \right) 0.143} + 3.51 \times 10^{-5} \text{ m}^2 \cdot \text{ K} / \text{ W} + \frac{1}{0.91 \left( 180 \text{ W} / \text{ m}^2 \cdot \text{ K} \right)}
\]

\( U_h = 133 \text{ W} / \text{ m}^2 \cdot \text{ K} \).

With

\[
C_{\text{min}} = C_h = \dot{m}_h c_{p,h} = 1.5 \text{ kg/s} \left( 1007 \text{ J/kg} \cdot \text{ K} \right) = 1511\text{ W/K}
\]

\[
\text{NTU} = \frac{U_h A_h}{C_{\text{min}}} = \frac{133 \text{ W/m}^2 \cdot \text{ K} \times 5.65 \text{ m}^2}{1511 \text{ W/K}} = 0.497.
\]

With \( C_{\text{min}} / C_{\text{max}} = 0 \), Eq. 11.36a yields

\[
\varepsilon = 1 - \exp(-\text{NTU}) = 1 - \exp(-0.497) = 0.392.
\]

Hence,

\[
q = \varepsilon q_{\text{max}} = \varepsilon C_{\text{min}} \left( T_{h,i} - T_{c,i} \right) = 0.392 \left( 1511 \text{ W/K} \right) 67 \text{ K}
\]

\( q = 39,685 \text{ W} \).

The air outlet temperature is

\[
T_{h,o} = T_{h,i} - \frac{q}{C_h} = 310 \text{ K} - \frac{39,685 \text{ W}}{1511 \text{ W/K}} = 283.7 \text{ K}.
\]

COMMENTS: If R-12 enters the tubes as saturated liquid, a flow rate of at least

\[
\dot{m}_c = \frac{q}{h_{fg}} = \frac{39,685 \text{ W}}{165,000 \text{ J/kg}} = 0.241 \text{ kg/s}
\]

would be needed to maintain saturated conditions in the tubes.
**PROBLEM 11.84**

**KNOWN:** Cooling coil geometry. Gas flow rate and inlet temperature. Water pressure, flow rate and convection coefficient.

**FIND:** Required number of tube rows.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Negligible fouling, (2) Constant properties, (3) Negligible heat loss to surroundings.

**PROPERTIES:** Table A-4, Air ($\overline{T}_h = 725$ K, 1 atm): $c_p = 1081$ J/kg·K, $\mu = 346.7 \times 10^{-7}$ N·s/m², $k = 0.0536$ W/m·K, $Pr = 0.698$; Table A-6, Sat. water (2.455 bar): $T_{sat} = T_c = 400$ K, $h_{fg} = 2183$ kJ/kg.

**ANALYSIS:** The required number of tube rows is

$$N_L = \frac{L - D_f}{S_L} + 1$$

where

$$L = \frac{V}{A_{fr}} \quad V = \frac{A_h}{\alpha} \quad A_h = NTU \frac{C_{min}}{U_h}$$

$$\frac{1}{U_h} = \frac{1}{h_c (A_c / A_h)} + A_h R_W + \frac{1}{\eta_{o,h} h_h}.$$  

From Ex. 11.6, $(A_c/A_h) = 0.143$ and

$$A_h R_W = \frac{D_i \ln(D_o/D_i)}{2k(A_c/A_h)} = \frac{(0.0138m)\ln(16.4/13.8)}{2(15 \text{ W} / \text{m} \cdot \text{K})(0.143)} = 5.55 \times 10^{-4} \text{ m}^2 \cdot \text{K/W}.$$  

With

$$G = \frac{\dot{m}_h}{\sigma A_{fr}} = \frac{3.0 \text{ kg/s}}{0.449 \times 0.36 \text{ m}^2} = 18.6 \text{ kg/s} \cdot \text{m}^2$$

$$Re = \frac{GD_h}{\mu} = \frac{18.6 \text{ kg/s} \cdot \text{m}^2 \times 6.68 \times 10^{-3} \text{ m}}{346.7 \times 10^{-7} \text{ N} \cdot \text{s} / \text{m}^2} = 3576$$

and Fig. 11.20 gives $j_h = 0.009$. Hence,

$$h_h = j_h \frac{Gc_p}{\Pr^{2/3}} = 0.009 \frac{18.6 \text{ kg/s} \cdot \text{m}^2 \times 1081 \text{ J} / \text{kg} \cdot \text{K}}{(0.698)^{2/3}} = 230 \text{ W} / \text{m}^2 \cdot \text{K}.$$  

Continued …..
PROBLEM 11.84 (Cont.)

With \( \frac{r_2}{r_1} = 1.75 \), \( L_c = 6.18 \text{ mm} \) and \( A_p = 1.57 \times 10^{-6} \text{ m}^2 \) from Ex. 11.6, \( L_c^{3/2} \left( \frac{h_f}{k A_p} \right)^{1/2} = 1.52 \) and Fig. 3.19 gives \( \eta_f = 0.40 \). Hence,

\[
\eta_{o,h} = 1 - \frac{A_f}{A} (1 - \eta_f) = 1 - 0.83(1 - 0.4) = 0.50.
\]

Hence,

\[
\frac{1}{U_h} = \frac{1}{\left( 10^4 \text{ W/m}^2 \cdot \text{K} \right) 0.143} + 5.55 \times 10^{-4} \text{ m}^2 \cdot \text{K/W} + \frac{1}{0.50 \left( 230 \text{ W/m}^2 \cdot \text{K} \right)}
\]

\[U_h = 100.5 \text{ W/m}^2 \cdot \text{K}.
\]

With

\[q = \dot{m}_c h_{fg} = 0.5 \text{ kg/s} \left( 2.183 \times 10^6 \text{ J/kg} \right) = 1.092 \times 10^6 \text{ W}\]

\[C_{\text{min}} = C_h = 3.0 \text{ kg/s} (1081 \text{ J/kg} \cdot \text{K}) = 3243 \text{ W/K}\]

\[q_{\text{max}} = C_{\text{min}} \left( T_{h,i} - T_{c,i} \right) = 3243 \text{ W/K} (500 \text{ K}) = 1.622 \times 10^6 \text{ W}\]

find

\[\varepsilon = \frac{q}{q_{\text{max}}} = \frac{1.092 \times 10^6 \text{ W}}{1.622 \times 10^6 \text{ W}} = 0.674.
\]

From Eq. 11.36b

\[\text{NTU} = -\ln(1 - \varepsilon) = -\ln(1 - 0.674) = 1.121.
\]

Hence,

\[A_h = \text{NTU} \frac{C_{\text{min}}}{U_h} = 1.121 \frac{3243 \text{ W/K}}{100.5 \text{ W/m}^2 \cdot \text{K}} = 36.17 \text{ m}^2
\]

\[L = \frac{A_h}{A_{f\alpha}} = \frac{36.17 \text{ m}^2}{0.36 \text{ m}^2 (269 \text{ m}^2 / \text{m}^3)} = 0.373 \text{ m}
\]

\[N_L = \frac{L - D_f}{S_L} + 1 = \frac{373 - 28.5}{34.3} + 1 = 11.06 \approx 11.
\]

**COMMENTS:** The gas outlet temperature is

\[T_{h,o} = T_{h,i} - \frac{q}{C_{\text{min}}} = 900 \text{ K} - \frac{1.092 \times 10^6 \text{ W}}{3243 \text{ W/K}} = 564 \text{ K}.
\]

Hence \( T_h = (900 \text{ K} + 564 \text{ K})/2 = 732 \text{ K} \) is in good agreement with the assumed value.
PROBLEM 11.85

KNOWN: Cooling coil geometry. Gas flow rate and inlet temperature. Water pressure and convection coefficient.

FIND: Gas outlet temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible fouling, (2) Constant properties, (3) Negligible heat loss to surroundings.

PROPERTIES: Table A-4, Air ($T_h = 725$ K, 1 atm): $c_p = 1081$ J/kg·K, $\mu = 346.7 \times 10^{-7}$ N·s/m², $k = 0.0536$ W/m·K, $Pr = 0.698$; Table A-6, Sat. water (2.455 bar): $T_{sat} = T_c = 400$ K, $h_{fg} = 2183$ kJ/kg.

ANALYSIS: To obtain $T_{h,o}$, first obtain $q$ from the $\varepsilon$-NTU method. To determine NTU, $Ah$ must be found from knowledge of $L$.

$$L \approx (N_L - 1)S_L + D_f = 10(0.0343) + 0.0285 = 0.372m.$$  

Hence,

$$V = A_{fr}L = 0.36m^2 (0.372m) = 0.134m^3$$

$$A_h = \alpha V = \left( 269m^2/m^3 \right) 0.134m^3 = 36.05m^2.$$  

The overall coefficient is

$$\frac{1}{U_h} = \frac{1}{h_c \left( A_c / A_h \right)} + A_h R_w + \frac{1}{\eta_{o,h} h_h}.$$  

From Ex. 11.6, $(A_c / A_h) = 0.143$ and

$$A_h R_w = \frac{D_i \ln \left( D_o / D_i \right)}{2k \left( A_c / A_h \right)} = \frac{(0.0138) \ln (16.4/13.8)}{2(15 W/m K)(0.143)} = 5.55 \times 10^{-4} \text{ m}^2 \cdot \text{K/W}.$$  

With

$$G = \frac{\dot{m}_h}{\sigma A_{fr}} = \frac{3.0 \text{ kg/s}}{0.449 \times 0.36m^2} = 18.6 \text{ kg/s} \cdot \text{m}^2$$

$$Re = \frac{GD_h}{\mu} = \frac{18.6 \text{ kg/s} \cdot \text{m}^2 \times 6.68 \times 10^{-3} \text{ m}}{346.7 \times 10^{-7} \text{ N} \cdot \text{s/m}^2} = 3576$$

and Fig. 11.20 gives $j_H = 0.009$. Hence, Continued ….
**PROBLEM 11.85 (Cont.)**

\[ h_h = \frac{j_h \cdot Gc_p}{Pr^{2/3}} = 0.009 \cdot \frac{18.6 \text{ kg/s} \cdot \text{m}^2 \cdot 1081 \text{J/kg} \cdot \text{K}}{\left(0.698\right)^{2/3}} \]

\[ h_h = 230 \text{ W/m}^2 \cdot \text{K}. \]

With \( r_2/c_1 = 1.75 \), \( L_c = 6.18 \text{ mm} \) and \( A_p = 1.57 \times 10^{-6} \text{ m}^2 \) from Ex. 11.6, \( L_c^{3/2} \left( h_h / k A_p \right)^{1/2} = 1.52 \)
and Fig. 3.19 gives \( \eta_f \approx 0.40 \). Hence,

\[ \eta_{o,h} = 1 - \frac{A_f}{A} \left( 1 - \eta_f \right) = 1 - 0.83 \left( 1 - 0.4 \right) = 0.50. \]

Hence,

\[ \frac{1}{U_h} = \frac{1}{10^4 \text{ W/m}^2 \cdot \text{K}} + 5.55 \times 10^{-4} \text{ m}^2 \cdot \text{K}/\text{W} = \frac{1}{0.50 \left( 230 \text{ W}/\text{m}^2 \cdot \text{K} \right)} \]

\[ U_h = 100.5 \text{ W/m}^2 \cdot \text{K}. \]

With

\[ C_{\text{min}} = C_h = 3 \text{ kg/s} \left( 1081 \text{ J/kg} \cdot \text{K} \right) = 3243 \text{ W/K} \]

\[ NTU = \frac{U_h A_h}{C_{\text{min}}} = \frac{100.5 \text{ W/m}^2 \cdot \text{K} \left( 36.05 \text{ m}^2 \right)}{3243 \text{ W/K}} = 1.117. \]

Since \( C_{\text{min}}/C_{\text{max}} = 0 \), Eq. 11.36a gives

\[ \varepsilon = 1 - \exp(-NTU) = 1 - \exp(-1.117) = 0.673. \]

Hence,

\[ q = \varepsilon C_{\text{min}} \left( T_{h,i} - T_{c,i} \right) = 0.673 \left( 3243 \text{ W/K} \right) \left( 500 \text{ K} \right) = 1.091 \times 10^6 \text{ W} \]

and

\[ T_{h,o} = T_{h,i} - \frac{q}{C_{\text{min}}} = 900 \text{ K} - \frac{1.091 \times 10^6 \text{ W}}{3243 \text{ W/K}} = 564 \text{ K}. \]

**COMMENTS:**

(1) The assumption of \( T_h = 725 \text{ K} \) is good.

(2) If water enters the tubes as saturated liquid, a flow rate of at least

\[ \dot{m}_c = \frac{q}{h_{fg}} = \frac{1.091 \times 10^6 \text{ W}}{2.183 \times 10^6 \text{ J/kg}} = 0.50 \text{ kg/s} \]

would be need to maintain saturated conditions in the tubes.
PROBLEM 12.1

KNOWN: Rate at which radiation is intercepted by each of three surfaces (see Example 12.1).

FIND: Irradiation, G[W/m²], at each of the three surfaces.

SCHEMATIC:

ANALYSIS: The irradiation at a surface is the rate at which radiation is incident on a surface per unit area of the surface. The irradiation at surface j due to emission from surface 1 is

\[ G_j = \frac{q_{1-j}}{A_j} \]

With \( A_1 = A_2 = A_3 = A_4 = 10^{-3} \text{ m}^2 \) and the incident radiation rates \( q_{1-j} \) from the results of Example 12.1, find

\[ G_2 = \frac{12.1 \times 10^{-3} \text{ W}}{10^{-3} \text{ m}^2} = 12.1 \text{ W/m}^2 \]  

<

\[ G_3 = \frac{28.0 \times 10^{-3} \text{ W}}{10^{-3} \text{ m}^2} = 28.0 \text{ W/m}^2 \]  

<

\[ G_4 = \frac{19.8 \times 10^{-3} \text{ W}}{10^{-3} \text{ m}^2} = 19.8 \text{ W/m}^2 \]  

<

COMMENTS: The irradiation could also be computed from Eq. 12.15, which, for the present situation, takes the form

\[ G_j = I \cos \theta_j \omega_{1-j} \]

where \( I = 7000 \text{ W/m}^2 \cdot \text{sr} \) and \( \omega_{1-j} \) is the solid angle subtended by surface 1 with respect to j. For example,

\[ G_2 = I \cos \theta_2 \omega_{1-j} \]

\[ G_2 = 7000 \text{ W/m}^2 \cdot \text{sr} \times \frac{\cos 30^\circ \times 10^{-3} \text{ m}^2 \times \cos 60^\circ}{(0.5 \text{ m})^2} \]

\[ G_2 = 12.1 \text{ W/m}^2. \]

Note that, since \( A_1 \) is a diffuse radiator, the intensity I is independent of direction.
**PROBLEM 12.2**

**KNOWN:** A diffuse surface of area $A_1 = 10^{-4} \text{m}^2$ emits diffusely with total emissive power $E = 5 \times 10^4 \text{W/m}^2$.

**FIND:** (a) Rate this emission is intercepted by small surface of area $A_2 = 5 \times 10^{-4} \text{m}^2$ at a prescribed location and orientation, (b) Irradiation $G_2$ on $A_2$, and (c) Compute and plot $G_2$ as a function of the separation distance $r_2$ for the range $0.25 \leq r_2 \leq 1.0 \text{m}$ for zenith angles $\theta_2 = 0, 30$ and $60^\circ$.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Surface $A_1$ emits diffusely, (2) $A_1$ may be approximated as a differential surface area and that $A_2/r_2^2 << 1$.

**ANALYSIS:** (a) The rate at which emission from $A_1$ is intercepted by $A_2$ follows from Eq. 12.5 written on a total rather than spectral basis.

\[
q_{1\rightarrow 2} = I_{e,1}(\theta, \phi) A_1 \cos \theta_1 d\omega_{2\rightarrow 1}.
\]  

(1)

Since the surface $A_1$ is diffuse, it follows from Eq. 12.13 that

\[
I_{e,1}(\theta, \phi) = I_{e,1} = E_1/\pi.
\]  

(2)

The solid angle subtended by $A_2$ with respect to $A_1$ is

\[
d\omega_{2\rightarrow 1} = A_2 \cos \theta_2/r_2^2.
\]  

(3)

Substituting Eqs. (2) and (3) into Eq. (1) with numerical values gives

\[
q_{1\rightarrow 2} = E_1/\pi \cdot A_1 \cos \theta_1 \cdot A_2 \cos \theta_2/r_2^2 = \frac{5 \times 10^4 \text{W/m}^2}{\pi \text{sr}} \times \left(10^{-4} \text{m}^2 \times \cos 60^\circ\right) \times \left[\frac{5 \times 10^{-4} \text{m}^2 \times \cos 30^\circ}{(0.5 \text{m})^2}\right] \text{sr}
\]  

(4)

\[
q_{1\rightarrow 2} = 15.915 \text{W/m}^2\text{sr} \times \left(5 \times 10^{-5} \text{m}^2\right) \times 1.732 \times 10^{-3} \text{sr} = 1.378 \times 10^{-3} \text{W}.
\]

(b) From section 12, 2.3, the irradiation is the rate at which radiation is incident upon the surface per unit surface area,

\[
G_2 = \frac{q_{1\rightarrow 2}}{A_2} = \frac{1.378 \times 10^{-3} \text{W}}{5 \times 10^{-4} \text{m}^2} = 2.76 \text{W/m}^2.
\]

(5)

(c) Using the IHT workspace with the foregoing equations, the $G_2$ was computed as a function of the separation distance for selected zenith angles. The results are plotted below.

Continued...
For all zenith angles, $G_2$ decreases with increasing separation distance $r_2$. From Eq. (3), note that $d\omega_2$ and, hence $G_2$, vary inversely as the square of the separation distance. For any fixed separation distance, $G_2$ is a maximum when $\theta_2 = 0^\circ$ and decreases with increasing $\theta_2$, proportional to $\cos \theta_2$.

**COMMENTS:** (1) For a diffuse surface, the intensity, $I_e$, is independent of direction and related to the emissive power as $I_e = E/\pi$. Note that $\pi$ has the units of [sr] in this relation.

(2) Note that Eq. 12.5 is an important relation for determining the radiant power leaving a surface in a prescribed manner. It has been used here on a total rather than spectral basis.

(3) Returning to part (b) and referring to Figure 12.10, the irradiation on $A_2$ may be expressed as

$$G_2 = I_{i,2} \cos \theta_2 \frac{A_1 \cos \theta_1}{r_2^2}$$

Show that the result is $G_2 = 2.76 \text{ W/m}^2$. Explain how this expression follows from Eq. (12.15).
**PROBLEM 12.003**

**KNOWN:** Intensity and area of a diffuse emitter. Area and rotational frequency of a second surface, as well as its distance from and orientation relative to the diffuse emitter.

**FIND:** Energy intercepted by the second surface during a complete rotation.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) $A_1$ and $A_2$ may be approximated as differentially small surfaces, (2) $A_1$ is a diffuse emitter.

**ANALYSIS:** From Eq. 12.5, the rate at which radiation emitted by $A_1$ is intercepted by $A_2$ is

$$q_{1-2} = I_e A_1 \cos \theta_1 \omega_{2-1} = I_e A_1 \left( A_2 \cos \theta_2 / r^2 \right)$$

where $\theta_1 = 0$ and $\theta_2$ changes continuously with time. The amount of energy intercepted by both sides of $A_2$ during one rotation, $\Delta E$, may be grouped into four equivalent parcels, each corresponding to rotation over an angular domain of $0 \leq \theta_2 < \pi/2$. Hence, with $dt = d\theta_2 / \dot{\theta}_2$, the radiant energy intercepted over the period $T$ of one revolution is

$$\Delta E = \int_0^T q dt = \frac{4 I_e A_1}{\dot{\theta}_2} \left( \frac{A_2}{r^2} \right) \int_0^{\pi/2} \cos \theta_2 d\theta_2 = \frac{4 I_e A_1}{\dot{\theta}_2} \left( \frac{A_2}{r^2} \right) \sin \theta_2 \bigg|_0^{\pi/2}$$

$$\Delta E = 4 \times 100 \text{ W/m}^2 \cdot \text{sr} \times 10^{-4} \text{ m}^2 \left[ \frac{10^{-4} \text{ m}^2}{(0.50 \text{ m})^2} \right] \text{sr} = 8 \times 10^{-6} \text{ J}$$

**COMMENTS:** The maximum rate at which $A_2$ intercepts radiation corresponds to $\theta_2 = 0$ and is $q_{\text{max}} = I_e A_1 A_2 / r^2 = 4 \times 10^{-6} \text{ W}$. The period of rotation is $T = 2\pi / \dot{\theta}_2 = 3.14 \text{ s}$. 
PROBLEM 12.004

KNOWN: Furnace with prescribed aperture and emissive power.

FIND: (a) Position of gauge such that irradiation is \( G = 1000 \text{ W/m}^2 \), (b) Irradiation when gauge is tilted \( \theta_d = 20^\circ \), and (c) Compute and plot the gage irradiation, \( G \), as a function of the separation distance, \( L \), for the range \( 100 \leq L \leq 300 \text{ mm} \) and tilt angles of \( \theta_d = 0, 20, \) and \( 60^\circ \).

SCHEMATIC:

ASSUMPTIONS: (1) Furnace aperture emits diffusely, (2) \( A_d \ll L^2 \).

ANALYSIS: (a) The irradiation on the detector area is defined as the power incident on the surface per unit area of the surface. That is
\[
G = \frac{q_f \to d}{A_d} = \frac{1}{4\pi} A_f \cos \theta_f \frac{\omega_{d-f}}{L^2}.
\]
where \( q_f \to d \) is the radiant power which leaves \( A_f \) and is intercepted by \( A_d \). From Eqs. 12.2 and 12.5, \( \omega_{d-f} \) is the solid angle subtended by surface \( A_d \) with respect to \( A_f \),
\[
\omega_{d-f} = \frac{A_d \cos \theta_d}{L^2}.
\]
Noting that since the aperture emits diffusely, \( I_e = E / \pi \) (see Eq. 12.14), and hence
\[
G = \left( \frac{E}{\pi} \right) A_f \cos \theta_f \left( \frac{A_d \cos \theta_d}{L^2} \right) / A_d
\]
Solving for \( L^2 \) and substituting for the condition \( \theta_f = 0^\circ \) and \( \theta_d = 0^\circ \),
\[
L^2 = \frac{E \cos \theta_f \cos \theta_d A_f}{\pi G}.
\]

(b) When \( \theta_d = 20^\circ \), \( q_f \to d \) will be reduced by a factor of \( \cos \theta_d \) since \( \omega_{d-f} \) is reduced by a factor \( \cos \theta_d \). Hence,
\[
G = 1000 \text{ W/m}^2 \times \cos \theta_d = 1000 \text{ W/m}^2 \times \cos 20^\circ = 940 \text{ W/m}^2.
\]
(c) Using the IHT workspace with Eq. (4), \( G \) is computed and plotted as a function of \( L \) for selected \( \theta_d \). Note that \( G \) decreases inversely as \( L^2 \). As expected, \( G \) decreases with increasing \( \theta_d \) and in the limit, approaches zero as \( \theta_d \) approaches \( 90^\circ \).
PROBLEM 12.005

KNOWN: Radiation from a diffuse radiant source $A_1$ with intensity $I_1 = 1.2 \times 10^5$ W/m$^2$·sr is incident on a mirror $A_m$, which reflects radiation onto the radiation detector $A_2$.

FIND: (a) Radiant power incident on $A_m$ due to emission from the source, $A_1$, $q_{1\rightarrow m}$ (mW), (b) Intensity of radiant power leaving the perfectly reflecting, diffuse mirror $A_m$, $I_m$ (W/m$^2$·sr), and (c) Radiant power incident on the detector $A_2$ due to the reflected radiation leaving $A_m$, $q_{m\rightarrow 2}$ (µW). (d) Plot the radiant power $q_{m\rightarrow 2}$ as a function of the lateral separation distance $y_o$ for the range $0 \leq y_o \leq 0.2$ m; explain features of the resulting curve.

SCHEMATIC:

ASSUMPTIONS: (1) Surface $A_1$ emits diffusely, (2) Surface $A_m$ does not emit, but reflects perfectly and diffusely, and (3) Surface areas are much smaller than the square of their separation distances.

ANALYSIS: (a) The radiant power leaving $A_1$ that is incident on $A_m$ is

$$ q_{1\rightarrow m} = I_1 \cdot A_1 \cdot \cos \theta_1 \cdot \Delta \omega_{m-1} $$

where $\omega_{m-1}$ is the solid angle $A_m$ subtends with respect to $A_1$, Eq. 12.2,

$$ \Delta \omega_{m-1} \equiv \frac{dA_n}{r^2} = \frac{A_m \cos \theta_m}{x_0^2 + y_0^2} = \frac{2 \times 10^{-4}}{0.1^2 + 0.1^2} = 7.07 \times 10^{-3} \text{ sr} $$

with $\theta_m = 90^\circ - \theta_1$ and $\theta_1 = 45^\circ$,

$$ q_{1\rightarrow m} = 1.2 \times 10^5 \text{ W/m}^2\cdot\text{sr}\times 1 \times 10^{-4} \text{ m}^2\times \cos 45^\circ \times 7.07 \times 10^{-3} \text{ sr} = 60 \text{ mW} \quad < $$

(b) The intensity of radiation leaving $A_m$, after perfect and diffuse reflection, is

$$ I_m = \left( \frac{q_{1\rightarrow m}}{A_m} \right) / \pi = \frac{60 \times 10^{-3} \text{ W}}{\pi \times 2 \times 10^{-4}} \text{ m}^2 = 95.5 \text{ W/m}^2\cdot\text{sr} $$

(c) The radiant power leaving $A_m$ due to reflected radiation leaving $A_m$ is

$$ q_{m\rightarrow 2} = q_2 = I_m \cdot A_m \cdot \cos \theta_m \cdot \Delta \omega_{2-m} $$

where $\Delta \omega_{2-m}$ is the solid angle that $A_2$ subtends with respect to $A_m$, Eq. 12.2,

Continued …..
PROBLEM 12.005 (Cont.)

\[ \Delta \omega_{2-m} \equiv \frac{dA_m}{r^2} = \frac{A_2 \cos \theta_2}{(L_m - x_m)^2 + y_o^2} = \frac{1 \times 10^{-4} \text{ m}^2 \times \cos 45^\circ}{\left[0.1^2 + 0.1^2\right] \text{ m}^2} = 3.54 \times 10^{-3} \text{ sr} \]

with \( \theta_2 = 90^\circ - \theta_m \)

\[ q_{m\rightarrow 2} = q_2 = 95.5 \text{ W} / \text{ m}^2 \cdot \text{ sr} \times 2 \times 10^4 \text{ m}^2 \times \cos 45^\circ \times 3.54 \times 10^{-3} \text{ sr} = 47.8 \mu\text{W} \]

(d) Using the foregoing equations in the IHT workspace, \( q_2 \) is calculated and plotted as a function of \( y_o \) for the range \( 0 \leq y_o \leq 0.2 \text{ m} \).

From the relations, note that \( q_2 \) is dependent upon the geometric arrangement of the surfaces in the following manner. For small values of \( y_o \), that is, when \( \theta_1 = 0^\circ \), the \( \cos \theta_1 \) term is at a maximum, near unity. But, the solid angles \( \Delta \omega_{m-1} \) and \( \Delta \omega_{2-m} \) are very small. As \( y_o \) increases, the \( \cos \theta_1 \) term doesn’t diminish as much as the solid angles increase, causing \( q_2 \) to increase. A maximum in the power is reached as the \( \cos \theta_1 \) term decreases and the solid angles increase. The maximum radiant power occurs when \( y_o = 0.058 \text{ m} \) which corresponds to \( \theta_1 = 30^\circ \).
**PROBLEM 12.6**

**KNOWN:** Flux and intensity of direct and diffuse components, respectively, of solar irradiation.

**FIND:** Total irradiation.

**SCHEMATIC:**

![Diagram showing solar irradiation with direct and diffuse components]

**ANALYSIS:** Since the irradiation is based on the actual surface area, the contribution due to the direct solar radiation is

\[ G_{\text{dir}} = q_{\text{dir}}' \cdot \cos \theta. \]

From Eq. 12.19 the contribution due to the diffuse radiation is

\[ G_{\text{dif}} = \pi I_{\text{dif}}. \]

Hence

\[ G = G_{\text{dir}} + G_{\text{dif}} = q_{\text{dir}}' \cdot \cos \theta + \pi I_{\text{dif}} \]

or

\[ G = 1000 \text{ W/m}^2 \times 0.866 + \pi \text{ sr} \times 70 \text{ W/m}^2 \cdot \text{sr} \]

\[ G = (866 + 220) \text{ W/m}^2 \]

or

\[ G = 1086 \text{ W/m}^2. \]

**COMMENTS:** Although a diffuse approximation is often made for the non-direct component of solar radiation, the actual directional distribution deviates from this condition, providing larger intensities at angles close to the direct beam.
**PROBLEM 12.007**

**KNOWN:** Daytime solar radiation conditions with direct solar intensity \( I_{dir} = 2.10 \times 10^7 \text{ W/m}^2 \cdot \text{sr} \) within the solid angle subtended with respect to the earth, \( \Delta \omega_S = 6.74 \times 10^{-5} \text{ sr} \), and diffuse intensity \( I_{dif} = 70 \text{ W/m}^2 \cdot \text{sr} \).

**FIND:** (a) Total solar irradiation at the earth’s surface when the direct radiation is incident at 30°, and (b) Verify the prescribed value of \( \Delta \omega_S \) recognizing that the diameter of the earth is \( D_S = 1.39 \times 10^9 \text{ m} \), and the distance between the sun and the earth is \( r_{e-S} = 1.496 \times 10^{11} \text{ m} \) (1 astronomical unity).

**SCHEMATIC:**

![Schematic](image)

**ANALYSIS:** (a) The total solar irradiation is the sum of the diffuse and direct components,

\[
G_S = G_{dif} + G_{dir} = (220 + 1226) \text{ W/m}^2 = 1446 \text{ W/m}^2
\]

From Eq. 12.19 the diffuse irradiation is

\[
G_{dif} = \pi I_{dif} = \pi \times 70 \text{ W/m}^2 \cdot \text{sr} = 220 \text{ W/m}^2
\]

The direct irradiation follows from Eq. 12.15, expressed in terms of the solid angle

\[
G_{dir} = I_{dir} \cos \theta \Delta \omega_S
\]

\[
G_{dir} = 2.10 \times 10^7 \text{ W/m}^2 \cdot \text{sr} \times \cos 30^\circ \times 6.74 \times 10^{-5} \text{ sr} = 1226 \text{ W/m}^2
\]

(b) The solid angle the sun subtends with respect to the earth is calculated from Eq. 12.2,

\[
\Delta \omega_S = \frac{dA_n}{r^2} = \frac{\pi D_S^2 / 4}{r_{e-S}^2} = \frac{\pi (1.39 \times 10^9 \text{ m})^2 / 4}{(1.496 \times 10^{11} \text{ m})^2} = 6.74 \times 10^{-5} \text{ sr}
\]

where \( dA_n \) is the projected area of the sun and \( r_{e-S} \), the distance between the earth and sun. We are assuming that \( r_{e-S}^2 \gg D_S^2 \).

**COMMENTS:** Can you verify that the direct solar intensity, \( I_{dir} \), is a reasonable value, assuming that the solar disk emits as a black body at 5800 K? \( I_{h,S} = \sigma T_S^4 / \pi = \sigma (5800 \text{ K})^4 / \pi \)

\[= 2.04 \times 10^7 \text{ W/m}^2 \cdot \text{sr} \] . Because of local cloud formations, it is possible to have an appreciable diffuse component. But it is not likely to have such a high direct component as given in the problem statement.
**PROBLEM 12.8**

**KNOWN:** Directional distribution of solar radiation intensity incident at earth’s surface on an overcast day.

**FIND:** Solar irradiation at earth’s surface.

**SCHEMATIC:**

\[
I_i = I_n \cos \theta
\]

\[
I_n = 80 \text{ W/m}^2 \cdot \text{sr}
\]

**ASSUMPTIONS:** (1) Intensity is independent of azimuthal angle \( \theta \).

**ANALYSIS:** Applying Eq. 12.17 to the total intensity

\[
G = \int_0^{2\pi} \int_0^{\pi/2} I_i(\theta) \cos \theta \sin \theta \mathrm{d}\theta \mathrm{d}\phi
\]

\[
G = 2\pi I_n \int_0^{\pi/2} \cos^2 \theta \sin \theta \mathrm{d}\theta
\]

\[
G = (2\pi \text{ sr}) \times 80 \text{ W/m}^2 \cdot \text{sr} \left( -\frac{1}{3} \cos^3 \theta \right) \bigg|_0^{\pi/2}
\]

\[
G = -167.6 \text{ W/m}^2 \cdot \text{sr} \left( \cos^3 \frac{\pi}{2} - \cos^3 0 \right)
\]

\[
G = 167.6 \text{ W/m}^2.
\]
**PROBLEM 12.9**

**KNOWN:** Emissive power of a diffuse surface.

**FIND:** Fraction of emissive power that leaves surface in the directions $\pi/4 \leq \theta \leq \pi/2$ and $0 \leq \phi \leq \pi$.

**SCHEMATIC:**

![Diffuse emitting surface diagram](image)

**ASSUMPTIONS:** (1) Diffuse emitting surface.

**ANALYSIS:** According to Eq. 12.12, the total, hemispherical emissive power is

$$E = \int_0^\infty \int_0^{2\pi} \int_0^{\pi/2} I_{\lambda,e} (\lambda, \theta, \phi) \cos \theta \sin \theta \, d\theta \, d\phi \, d\lambda.$$  

For a diffuse surface $I_{\lambda,e} (\lambda, \theta, \phi)$ is independent of direction, and as given by Eq. 12.14,

$$E = \pi I_e.$$

The emissive power, which has directions prescribed by the limits on $\theta$ and $\phi$, is

$$\Delta E = \int_0^\infty I_{\lambda,e} (\lambda) \, d\lambda \times \left[ \int_0^{\pi/2} \cos \theta \sin \theta \, d\theta \right] \left[ \int_0^{\pi/4} \, d\phi \right].$$

$$\Delta E = I_e [\pi/4 \times \frac{\sin^2 \theta}{2}]_{\pi/4}^{\pi/2} = I_e \left[ \frac{\pi}{2} \left( 1 - 0.707^2 \right) \right]$$

$$\Delta E = 0.25 \pi I_e.$$

It follows that

$$\frac{\Delta E}{\pi I_e} = 0.25.$$

**COMMENTS:** The diffuse surface is an important concept in radiation heat transfer, and the directional independence of the intensity should be noted.
PROBLEM 12.10

KNOWN: Spectral distribution of $E_{\lambda}$ for a diffuse surface.

FIND: (a) Total emissive power $E$, (b) Total intensity associated with directions $\theta = 0^o$ and $\theta = 30^o$, and (c) Fraction of emissive power leaving the surface in directions $\pi/4 \leq \theta \leq \pi/2$.

SCHEMATIC:

ASSUMPTIONS: (1) Diffuse emission.

ANALYSIS: (a) From Eq. 12.11 it follows that

$$E = \int_0^\infty E_{\lambda} \, d\lambda = \int_0^5 (0) \, d\lambda + \int_5^{10} (100) \, d\lambda + \int_{10}^{15} (200) \, d\lambda + \int_{15}^{20} (100) \, d\lambda + \int_{20}^{\infty} (0) \, d\lambda$$

$$E = 100 \text{ W/m}^2 \cdot \text{um} (10 - 5) \mu m + 200 \text{ W/m}^2 \cdot \text{um} (15 - 10) \mu m + 100 \text{ W/m}^2 \cdot \text{um} (20-15) \mu m$$

$$E = 2000 \text{ W/m}^2$$

(b) For a diffuse emitter, $I_e$ is independent of $\theta$ and Eq. 12.14 gives

$$I_e = \frac{E}{\pi} = \frac{2000 \text{ W/m}^2}{\pi \text{ sr}}$$

$$I_e = 637 \text{ W/m}^2 \cdot \text{sr}$$

(c) Since the surface is diffuse, use Eqs. 12.10 and 12.14,

$$\frac{E(\pi/4 \rightarrow \pi/2)}{E} = \left[ \int_0^{\pi/4} \int_0^{\pi/2} I_e \cos \theta \sin \theta \, d\theta \, d\phi \right]$$

$$\frac{E(\pi/4 \rightarrow \pi/2)}{E} = \frac{1}{\pi} \left[ \int_0^{\pi/4} \cos \theta \sin \theta \, d\theta \right] \int_0^{2\pi} \sin^2 \theta \, d\phi$$

$$\frac{E(\pi/4 \rightarrow \pi/2)}{E} = \frac{1}{\pi} \left[ \frac{1}{2} \right] \frac{1}{2} (1^2 - 0.707^2) (2\pi - 0) = 0.50$$

COMMENTS: (1) Note how a spectral integration may be performed in parts.

(2) In performing the integration of part (c), recognize the significance of the diffuse emission assumption for which the intensity is uniform in all directions.
PROBLEM 12.11

KNOWN: Diffuse surface $\Delta A_o$, 5-mm square, with total emissive power $E_o = 4000 \text{ W/m}^2$.

FIND: (a) Rate at which radiant energy is emitted by $\Delta A_o$, $q_{emit}$; (b) Intensity $I_{o,e}$ of the radiation field emitted from the surface $\Delta A_o$; (c) Expression for $q_{emit}$ presuming knowledge of the intensity $I_{o,e}$ beginning with Eq. 12.10; (d) Rate at which radiant energy is incident on the hemispherical surface, $r = R_1 = 0.5 \text{ m}$, due to emission from $\Delta A_o$; (e) Rate at which radiant energy leaving $\Delta A_o$ is intercepted by the small area $\Delta A_2$ located in the direction $(40^\circ, \phi)$ on the hemispherical surface using Eq. 12.5; also determine the irradiation on $\Delta A_2$; (f) Repeat part (e), for the location $(0^\circ, \phi)$; are the irradiations at the two locations equal? and (g) Irradiation $G_1$ on the hemispherical surface at $r = R_1$ using Eq. 12.5.

SCHEMATIC:

ASSUMPTIONS: (1) Diffuse surface, $\Delta A_o$, (2) Medium above $\Delta A_o$ is also non-participating, (3) $R_1^2 >> \Delta A_o \cdot \Delta A_2$.

ANALYSIS: (a) The radiant power leaving $\Delta A_o$ by emission is

$$q_{emit} = E_o \cdot \Delta A_o = 4000 \text{ W/m}^2 (0.005 \text{ m} \times 0.005 \text{ m}) = 0.10 \text{ W}$$

(b) The emitted intensity is $I_{o,e}$ and is independent of direction since $\Delta A_o$ is a diffuser emitter,

$$I_{o,e} = E_o / \pi = 1273 \text{ W/m}^2 \cdot \text{sr}$$

The intensities at points $P_1$ and $P_2$ are also $I_{o,e}$ and the intensity in the directions shown in the schematic above will remain constant no matter how far the point is from the surface $\Delta A_o$ since the space is non-participating.

(c) From knowledge of $I_{o,e}$, the radiant power leaving $\Delta A_o$ from Eq. 12.10 is,

$$q_{emit} = \int \int I_{o,e} \Delta A_o \cos \theta \sin \theta \, d\theta \, d\phi = I_{o,e} \Delta A_o \int_0^{\pi/2} \int_0^{2\pi} \cos \theta \sin \theta \, d\theta \, d\phi = \pi I_{o,e} \Delta A_o = 0.10 \text{ W}$$

(d) Defining control surfaces above $\Delta A_o$ and on $A_1$, the radiant power leaving $\Delta A_o$ must pass through $A_1$. That is,

$$q_{l,inc} = E_o \cdot \Delta A_o = 0.10 \text{ W}$$

Recognize that the average irradiation on the hemisphere, $A_1$, where $A_1 = 2\pi R_1^2$, based upon the definition, Section 12.2.3,

$$\bar{G}_1 = q_{l,inc} / A_1 = E_o \Delta A_o / 2\pi R_1^2 = 63.7 \text{ mW/m}^2$$

where $q_{l,inc}$ is the radiant power incident on surface $A_1$. Continued...
(e) The radiant power leaving $\Delta A_0$ intercepted by $\Delta A_2$, where $\Delta A_2 = 4 \times 10^{-6} \text{ m}^2$, located at $(\theta = 45^\circ, \phi)$ as per the schematic, follows from Eq. 12.5,

$$q_{\Delta A_0 \rightarrow \Delta A_2} = I_{0,e} \Delta A_0 \cos \theta_0 \Delta \omega_{2-o}$$

where $\theta_0 = 45^\circ$ and the solid angle $\Delta \omega_2$ subtends with respect to $\Delta A_o$ is

$$\Delta \omega_{2-o} = \Delta A_2 \cos \theta_2 \sqrt{\frac{2}{R_1}} = 4 \times 10^{-6} \text{ m}^2 \cdot \sqrt{1/(0.5 \text{ m})^2} = 1.60 \times 10^{-5} \text{ sr}$$

where $\theta_2 = 0^\circ$, the direction normal to $\Delta A_2$,

$$q_{\Delta A_0 \rightarrow \Delta A_2} = 1273 \frac{\text{ W}}{\text{ m}^2 \cdot \text{ sr}} \times 25 \times 10^{-6} \text{ m}^2 \cos 45^\circ \times 1.60 \times 10^{-5} \text{ sr} = 3.60 \times 10^{-7} \text{ W}$$

From the definition of irradiation, Section 12.2.3,

$$G_2 = q_{\Delta A_0 \rightarrow \Delta A_2} / \Delta A_2 = 90 \text{ mW/m}^2$$

(f) With $\Delta A_2$, located at $(\theta = 0^\circ, \phi)$, where $\cos \theta_0 = 1$, $\cos \theta_2 = 1$, find

$$\Delta \omega_{2-o} = 1.60 \times 10^{-5} \text{ sr} \quad q_{\Delta A_0 \rightarrow \Delta A_2} = 5.09 \times 10^{-7} \text{ W} \quad G_2 = 127 \text{ mW/m}^2$$

Note that the irradiation on $\Delta A_2$ when it is located at $(0^\circ, \phi)$ is larger than when $\Delta A_2$ is located at $(45^\circ, \phi)$; that is, $127 \text{ mW/m}^2 > 90 \text{ W/m}^2$. Is this intuitively satisfying?

(g) Using Eq. 12.15, based upon Figure 12.10, find

$$\bar{G}_1 = \int_{\Omega} I_{1,e} \cdot dA_1 \cdot d\omega_{0-1} / A_1 = \pi I_{0,e} \Delta A_0 / \Delta A_1 = 63.7 \text{ mW/m}^2$$

where the elemental area on the hemispherical surface $A_1$ and the solid angle $\Delta A_0$ subtends with respect to $\Delta A_1$ are, respectively,

$$dA_1 = R_1^2 \sin \theta d\theta d\phi \quad d\omega_{0-1} = \Delta A_0 \cos \theta / R_1^2$$

From this calculation you found that the average irradiation on the hemisphere surface, $r = R_1$, is $\bar{G}_1 = 63.7 \text{ mW/m}^2$. From parts (e) and (f), you found irradiations, $G_2$ on $\Delta A_2$ at $(0^\circ, \phi)$ and $(45^\circ, \phi)$ as $127 \text{ mW/m}^2$ and $90 \text{ mW/m}^2$, respectively. Did you expect $\bar{G}_1$ to be less than either value for $G_2$? How do you explain this?

**COMMENTS:**

1. Note that from Parts (e) and (f) that the irradiation on $A_1$ is not uniform. Parts (d) and (g) give an average value.

2. What conclusions would you reach regarding $G_1$ if $\Delta A_o$ were a sphere?
PROBLEM 12.12

KNOWN: Hemispherical and spherical arrangements for radiant heat treatment of a thin-film material. Heater emits diffusely with intensity \( I_{e,h} = 169,000 \text{ W/m}^2\text{-sr} \) and has an area 0.0052 m\(^2\).

FIND: (a) Expressions for the irradiation on the film as a function of the zenith angle, \( \theta \), and (b) Identify arrangement which provides the more uniform irradiation, and hence better quality control for the treatment process.

SCHEMATIC:

ASSUMPTIONS: (1) Heater emits diffusely, (2) All radiation leaving the heater is absorbed by the thin film.

ANALYSIS: (a) The irradiation on any differential area, \( dA_s \), due to emission from the heater, \( A_h \), follows from its definition, Section 12.2.3,

\[
G = \frac{q_{h \rightarrow s}}{dA_s}
\]  

(1)

Where \( q_{h \rightarrow s} \) is the radiant heat rate leaving \( A_h \) and intercepted by \( dA_s \). From Eq. 12.5,

\[
q_{h \rightarrow s} = I_{e,h} \cdot dA_h \cos \theta \cdot \omega_{s-h}
\]  

(2)

where \( \omega_{s-h} \) is the solid angle \( dA_s \) subtends with respect to any point on \( A_h \). From the definition, Eq. 12.2,

\[
\omega = \frac{dA_n}{r^2}
\]  

(3)

where \( dA_n \) is normal to the viewing direction and \( r \) is the separation distance.

For the hemisphere: Referring to the schematic above, the solid angle is

\[
\omega_{s-h} = \frac{dA_s}{R^2}
\]

and the irradiation distribution on the hemispheric surface as a function of \( \theta_h \) is

\[
G = I_{e,h} A_h \cos \theta_h / R^2
\]  

(1) <

For the sphere: From the schematic, the solid angle is

\[
\omega_{s,h} = \frac{dA_s \cos \theta_s}{R_0^2} = \frac{dA_s}{4R^2 \cos \theta_h}
\]

where \( R_0 \), from the geometry of sphere cord and radii with \( \theta_s = \theta_h \), is

Continued...
PROBLEM 12.12 (Cont.)

\[ R_0 = 2R \cos \theta_h \]

and the irradiation distribution on the spherical surface as a function of \( \theta_h \) is

\[ G = I_{e,h} dA_h / 4R^2 \]  \hfill (2)

(b) The spherical shape provides more uniform irradiation as can be seen by comparing Eqs. (1) and (2). In fact, for the spherical shape, the irradiation on the thin film is uniform and therefore provides for better quality control for the treatment process. Substituting numerical values, the irradiations are:

\[ G_{\text{sph}} = 169,000 \text{W/m}^2 \cdot \text{sr} \times 0.0052 \text{m}^2 \cos \theta_h / (2m)^2 = 219.7 \cos \theta_h \text{ W/m}^2 \]  \hfill (3)

\[ G_{\text{hem}} = 169,000 \text{W/m}^2 \cdot \text{sr} \times 0.0052 \text{m}^2 / 4 (2m)^2 = 54.9 \text{ W/m}^2 \]  \hfill (4)

COMMENTS:  

(1) The radiant heat rate leaving the diffuse heater surface by emission is

\[ q_{\text{tot}} = \pi I_{e,h} A_h = 276.1 \text{ W} \]

The average irradiation on the spherical surface, \( A_{\text{sph}} = 4\pi R^2 \),

\[ \bar{G}_{\text{sph}} = q_{\text{tot}} / A_{\text{sph}} = 276.1 \text{ W/4\pi (2m)^2} = 54.9 \text{ W/m}^2 \]

while the average irradiation on the hemispherical surface, \( A_{\text{hem}} = 2\pi R^2 \) is

\[ \bar{G}_{\text{hem}} = 276.1 \text{W/2\pi (2m)^2} = 109.9 \text{ W/m}^2 \]

(2) Note from the foregoing analyses for the sphere that the result for \( \bar{G}_{\text{sph}} \) is identical to that found as Eq. (4). That follows since the irradiation is uniform.

(3) Note that \( \bar{G}_{\text{hem}} > \bar{G}_{\text{sph}} \) since the surface area of the hemisphere is half that of the sphere. Recognize that for the hemisphere thin film arrangement, the distribution of the irradiation is quite variable with a maximum at \( \theta = 0^\circ \) (top) and half the maximum value at \( \theta = 30^\circ \).
PROBLEM 12.13

KNOWN: Hot part, \( \Delta A_p \), located a distance \( x_1 \) from an origin directly beneath a motion sensor at a distance \( L_d = 1 \text{ m} \).

FIND: (a) Location \( x_1 \) at which sensor signal \( S_1 \) will be 75% that corresponding to \( x = 0 \), directly beneath the sensor, \( S_o \), and (b) Compute and plot the signal ratio, \( S/S_o \), as a function of the part position \( x_1 \) for the range \( 0.2 \leq S/S_o \leq 1 \) for \( L_d = 0.8, 1.0 \) and \( 1.2 \text{ m} \); compare the \( x \)-location for each value of \( L_d \) at which \( S/S_o = 0.75 \).

SCHEMATIC:

ASSUMPTIONS: (1) Hot part is diffuse emitter, (2) \( L_d^2 \gg \Delta A_p, \Delta A_o \).

ANALYSIS: (a) The sensor signal, \( S \), is proportional to the radiant power leaving \( \Delta A_p \) and intercepted by \( \Delta A_d \).

\[
S = q_{p \rightarrow d} = I_{p,e} \Delta A_p \cos \theta_p \Delta \omega_{d-p}
\]

when

\[
\cos \theta_p = \cos \theta_d = \frac{L_d}{R} = L_d / (L_d^2 + x_1^2)^{1/2}
\]

\[
\Delta \omega_{d-p} = \frac{\Delta A_d \cdot \cos \theta_d}{R^2} = \Delta A_d \cdot L_d / (L_d^2 + x_1^2)^{3/2}
\]

Hence,

\[
q_{p \rightarrow d} = I_{p,e} \Delta A_p \Delta A_d \frac{L_d^2}{(L_d^2 + x_1^2)^2}
\]

It follows that, with \( S_o \) occurring when \( x = 0 \) and \( L_d = 1 \text{ m} \),

\[
\frac{S}{S_o} = \frac{L_d^2 / (L_d^2 + x_1^2)^2}{L_d^2 / (L_d^2 + 0^2)^2} = \left[ \frac{L_d^2}{L_d^2 + x_1^2} \right]^2
\]

so that when \( S/S_o = 0.75 \), find,

\[ x_1 = 0.393 \text{ m} \]

(b) Using Eq. (5) in the IHT workspace, the signal ratio, \( S/S_o \), has been computed and plotted as a function of the part position \( x \) for selected \( L_d \) values.
When the part is directly under the sensor, \( x = 0 \), \( S/S_o = 1 \) for all values of \( L_d \). With increasing \( x \), \( S/S_o \) decreases most rapidly with the smallest \( L_d \). From the IHT model we found the part position \( x \) corresponding to \( S/S_o = 0.75 \) as follows.

<table>
<thead>
<tr>
<th>( S/S_o )</th>
<th>( L_d ) (m)</th>
<th>( x_1 ) (m)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.75</td>
<td>0.8</td>
<td>0.315</td>
</tr>
<tr>
<td>0.75</td>
<td>1.0</td>
<td>0.393</td>
</tr>
<tr>
<td>0.75</td>
<td>1.2</td>
<td>0.472</td>
</tr>
</tbody>
</table>

If the sensor system is set so that when \( S/S_o \) reaches 0.75 a process is initiated, the technician can use the above plot and table to determine at what position the part will begin to experience the treatment process.
PROBLEM 12.14

KNOWN: Diameter and temperature of burner. Temperature of ambient air. Burner efficiency.

FIND: (a) Radiation and convection heat rates, and wavelength corresponding to maximum spectral emission. Rate of electric energy consumption. (b) Effect of burner temperature on convection and radiation rates.

SCHEMATIC:

ASSUMPTIONS: (1) Burner emits as a blackbody, (2) Negligible irradiation of burner from surrounding, (3) Ambient air is quiescent, (4) Constant properties.

PROPERTIES: Table A-4, air (T_f = 408 K): k = 0.0344 W/m·K, ν = 27.4 × 10^{-6} m^2/s, α = 39.7 × 10^{-6} m^2/s, Pr = 0.70, β = 0.00245 K^{-1}.

ANALYSIS: (a) For emission from a black body

\[ q_{\text{rad}} = A_s E_b = \left( \pi D^2 / 4 \right) \sigma T^4 = \left( \pi \left( 0.2 \text{m} \right)^2 / 4 \right) 5.67 \times 10^{-8} \text{ W/m}^2\cdot\text{K}^4 \left( 523 \text{K} \right)^4 = 133 \text{ W} \]

With L = A_s/P = D/4 = 0.05m and Ra_L = gβ(T_s - T_∞) L^3/αν = 9.8 m/s^2 × 0.00245 K^{-1} (230 K)

\( (0.05m)^3 / (27.4 \times 39.7 \times 10^{-12} \text{ m}^4 / \text{s}^2 ) = 6.35 \times 10^5 \), Eq. (9.30) yields

\[ \bar{h} = \frac{k}{L} \text{Nu}_L = \left( \frac{k}{L} \right) 0.54 \text{Ra}_L^{1/4} = \left( \frac{0.0344 \text{ W/m} \cdot \text{K}}{0.05m} \right) 0.54 \left( 6.35 \times 10^5 \right)^{1/4} = 10.5 \text{ W/m}^2\cdot\text{K} \]

\[ q_{\text{conv}} = \bar{h} A_s \left( T_s - T_\infty \right) = 19.4 \text{ W/m}^2\cdot\text{K} \left[ \pi \left( 0.2 \text{m} \right)^2 / 4 \right] 230\text{K} = 75.7 \text{ W} \]

The electric power requirement is then

\[ P_{\text{elec}} = \frac{q_{\text{rad}} + q_{\text{conv}}}{\eta} = \frac{(133 + 75.7) \text{W}}{0.9} = 232 \text{ W} \]

The wavelength corresponding to peak emission is obtained from Wien’s law, Eq. (12.27)

\[ \lambda_{\text{max}} = \frac{2898 \mu\text{m} \cdot \text{K}}{523\text{K}} = 5.54\mu\text{m} \]

(b) As shown below, and as expected, the radiation rate increases more rapidly with temperature than the convection rate due to its stronger temperature dependence \( T_s^4 \) vs. \( T_s^{5/4} \).

Continued .....
COMMENTS: If the surroundings are treated as a large enclosure with isothermal walls at $T_{\text{sur}} = T_{\infty} = 293$ K, irradiation of the burner would be $G = \sigma T_{\text{sur}}^4 = 418$ W/m$^2$ and the corresponding heat rate would be $A_s G = 13$ W. This input is much smaller than the energy outflows due to convection and radiation and is justifiably neglected.
PROBLEM 12.15

KNOWN: Evacuated, aluminum sphere (D = 2m) serving as a radiation test chamber.

FIND: Irradiation on a small test object when the inner surface is lined with carbon black and at 600K. What effect will surface coating have?

SCHEMATIC:

ASSUMPTIONS: (1) Sphere walls are isothermal, (2) Test surface area is small compared to the enclosure surface.

ANALYSIS: It follows from the discussion of Section 13.3 that this isothermal sphere is an enclosure behaving as a blackbody. For such a condition, see Fig. 12.12(c), the irradiation on a small surface within the enclosure is equal to the blackbody emissive power at the temperature of the enclosure. That is

\[ G_1 = E_b(T_s) = \sigma T_s^4 \]

\[ G_1 = 5.67 \times 10^{-8} \text{ W/m}^2\cdot\text{K}^4 \times (600\text{K})^4 = 7348 \text{ W/m}^2. \] <

The irradiation is independent of the nature of the enclosure surface coating properties.

COMMENTS: (1) The irradiation depends only upon the enclosure surface temperature and is independent of the enclosure surface properties.

(2) Note that the test surface area must be small compared to the enclosure surface area. This allows for inter-reflections to occur such that the radiation field, within the enclosure will be uniform (diffuse) or isotropic.

(3) The irradiation level would be the same if the enclosure were not evacuated since, in general, air would be a non-participating medium.
PROBLEM 12.16

KNOWN: Isothermal enclosure of surface area, $A_s$, and small opening, $A_o$, through which 70W emerges.

FIND: (a) Temperature of the interior enclosure wall if the surface is black, (b) Temperature of the wall surface having $\varepsilon = 0.15$.

SCHEMATIC:

ASSUMPTIONS: (1) Enclosure is isothermal, (2) $A_o \ll A_s$.

ANALYSIS: A characteristic of an isothermal enclosure, according to Section 12.3, is that the radiant power emerging through a small aperture will correspond to blackbody conditions. Hence

$$q_{rad} = A_o E_b(T_s) = A_o \sigma T_s^4$$

where $q_{rad}$ is the radiant power leaving the enclosure opening. That is,

$$T_s = \left( \frac{q_{rad}}{A_o \sigma} \right)^{1/4} = \left( \frac{70 \text{W}}{0.02 \text{m}^2 \times 5.67 \times 10^{-8} \text{ W/m}^2\text{K}^4} \right)^{1/4} = 498 \text{K.}$$

Recognize that the radiated power will be independent of the emissivity of the wall surface. As long as $A_o \ll A_s$ and the enclosure is isothermal, then the radiant power will depend only upon the temperature.

COMMENTS: It is important to recognize the unique characteristics of isothermal enclosures. See Fig. 12.12 to identify them.
PROBLEM 12.17

KNOWN: Sun has equivalent blackbody temperature of 5800 K. Diameters of sun and earth as well as separation distance are prescribed.

FIND: Temperature of the earth assuming the earth is black.

SCHEMATIC:

ASSUMPTIONS: (1) Sun and earth emit as blackbodies, (2) No attenuation of solar irradiation enroute to earth, and (3) Earth atmosphere has no effect on earth energy balance.

ANALYSIS: Performing an energy balance on the earth,
\[ \dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0 \]
\[ A_{e,p} \cdot G_S = A_{e,s} \cdot E_b \left( T_e \right) \]
\[ \left( \pi D_e^2 / 4 \right) G_S = \pi D_e^2 \sigma T_e^4 \]
\[ T_e = \left( G_S / 4\sigma \right)^{1/4} \]

where \( A_{e,p} \) and \( A_{e,s} \) are the projected area and total surface area of the earth, respectively. To determine the irradiation \( G_S \) at the earth’s surface, equate the rate of emission from the sun to the rate at which this radiation passes through a spherical surface of radius \( R_{S,e} - D_e / 2 \).

\[ \dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0 \]
\[ \pi D_S^2 \sigma T_S^4 = 4\pi \left[ R_{S,e} - D_e / 2 \right]^2 G_S \]
\[ \pi \left( 1.39 \times 10^9 \text{ m} \right)^2 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (5800 \text{ K})^4 \]
\[ = 4\pi \left[ 1.5 \times 10^{11} - 1.29 \times 10^7 / 2 \right]^2 \text{ m}^2 \times G_S \]
\[ G_S = 1377.5 \text{ W/m}^2. \]

Substituting numerical values, find
\[ T_e = \left( 1377.5 \text{ W/m}^2 / 4 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \right)^{1/4} = 279 \text{ K.} \]

COMMENTS: (1) The average earth’s temperature is greater than 279 K since the effect of the atmosphere is to reduce the heat loss by radiation.

(2) Note carefully the different areas used in the earth energy balance. Emission occurs from the total spherical area, while solar irradiation is absorbed by the projected spherical area.
**PROBLEM 12.18**

**KNOWN:** Solar flux at outer edge of earth’s atmosphere, 1353 W/m$^2$.

**FIND:** (a) Emissive power of sun, (b) Surface temperature of sun, (c) Wavelength of maximum solar emission, (d) Earth equilibrium temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Sun and earth emit as blackbodies, (2) No attenuation of solar radiation enroute to earth, (3) Earth atmosphere has no effect on earth energy balance.

**ANALYSIS:** (a) Applying conservation of energy to the solar energy crossing two concentric spheres, one having the radius of the sun and the other having the radial distance from the edge of the earth’s atmosphere to the center of the sun

\[ E_s \left( \pi D_s^2 \right) = 4\pi \left( R_s - e - \frac{D_e}{2} \right)^2 q_s. \]

Hence

\[ E_s = \frac{4 \left( 1.5 \times 10^{11} \text{ m} - 0.65 \times 10^7 \text{ m} \right)^2 \times 1353 \text{ W/m}^2}{\left( 1.39 \times 10^9 \text{ m} \right)^2} = 6.302 \times 10^7 \text{ W/m}^2. \]

(b) From Eq. 12.28, the temperature of the sun is

\[ T_s = \left( \frac{E_s}{\sigma} \right)^{1/4} = \left( \frac{6.302 \times 10^7 \text{ W/m}^2}{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4} \right)^{1/4} = 5774 \text{ K.} \]

(c) From Wien’s law, Eq. 12.27, the wavelength of maximum emission is

\[ \lambda_{\text{max}} = \frac{C_3}{T} = \frac{2897.6 \mu \text{m} \cdot \text{K}}{5774 \text{ K}} = 0.50 \mu \text{m}. \]

(d) From an energy balance on the earth’s surface

\[ E_e \left( \pi D_e^2 \right) = q_s \left( \pi D_e^2 / 4 \right). \]

Hence, from Eq. 12.28,

\[ T_e = \left( \frac{q_s}{4\sigma} \right)^{1/4} = \left( \frac{1353 \text{ W/m}^2}{4 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4} \right)^{1/4} = 278 \text{ K.} \]

**COMMENTS:** The average earth temperature is higher than 278 K due to the shielding effect of the earth’s atmosphere (transparent to solar radiation but not to longer wavelength earth emission).
PROBLEM 12.19

KNOWN: Small flat plate positioned just beyond the earth’s atmosphere oriented such that its normal passes through the center of the sun. Pertinent earth-sun dimensions from Problem 12.18.

FIND: (a) Solid angle subtended by the sun about a point on the surface of the plate, (b) Incident intensity, \( I_i \), on the plate using the known value of the solar irradiation about the earth’s atmosphere, \( G_S = 1353 \text{ W/m}^2 \), and (c) Sketch of the incident intensity as a function of the zenith angle \( \theta \), where \( \theta \) is measured from the normal to the plate.

SCHEMATIC:

ASSUMPTIONS: (1) Plate oriented normal to centerline between sun and earth, (2) Height of earth’s atmosphere negligible compared to distance from the sun to the plate, (3) Dimensions of the plate are very small compared to sun-earth dimensions.

ANALYSIS: (a) The pertinent sun-earth dimensions are shown in the schematic (a) above while the position of the plate relative to the sun and the earth is shown in (b). The solid angle subtended by the sun with respect to any point on the plate follows from Eq. 12.2,

\[
\omega_{S-p} = \frac{A_s \cos \theta_p}{L_{S,p}^2} = \frac{\pi D_S^2/4 \cos \theta_p}{(R_{S,e} + D_e/2)^2} = \frac{\pi \left(1.39 \times 10^9 \text{ m}^2\right)^2/4 	imes 1}{\left(1.5 \times 10^{11} \text{ m} + 1.29 \times 10^7 \text{ m}/2\right)^2} = 6.74 \times 10^{-5} \text{ sr}\]

where \( A_s \) is the projected area of the sun (the solar disk), \( \theta_p \) is the zenith angle measured between the plate normal and the centerline between the sun and earth, and \( L_{S,p} \) is the separation distance between the plate and the sun’s center.

(b) The plate is irradiated by solar flux in the normal direction only (not diffusely). Using Eq. (12.7), the radiant power incident on the plate can be expressed as

\[
G_S \Delta A_p = I_i \cdot \Delta A_p \cos \theta_p \cdot \omega_{S-p}
\]

and the intensity \( I_i \) due to the solar irradiation \( G_S \) with \( \cos \theta_p = 1 \),

\[
I_i = G_S/\omega_{S-p} = 1353 \text{ W/m}^2/6.74 \times 10^{-5} \text{ sr} = 2.01 \times 10^7 \text{ W/m}^2 \cdot \text{sr}
\]

(c) As illustrated in the schematic to the right, the intensity \( I_i \) will be constant for the zenith angle range \( 0 \leq \theta_p \leq \theta_{p,o} \) where

\[
\theta_{p,o} = \frac{D_S/2}{L_{S,p}} = \frac{1.39 \times 10^9 \text{ m}/2}{\left(1.5 \times 10^{11} \text{ m} + 1.29 \times 10^7 \text{ m}/2\right)}
\]

\[
\theta_{p,o} = 4.633 \times 10^{-3} \text{ rad} \approx 0.27^\circ
\]

For the range \( \theta_p > \theta_{p,o} \), the intensity will be zero. Hence the \( I_i \) as a function of \( \theta_p \) will appear as shown to the right.
PROBLEM 12.20

KNOWN: Various surface temperatures.

FIND: (a) Wavelength corresponding to maximum emission for each surface, (b) Fraction of solar emission in UV, VIS and IR portions of the spectrum.

ASSUMPTIONS: (1) Spectral distribution of emission from each surface is approximately that of a blackbody, (2) The sun emits as a blackbody at 5800 K.

ANALYSIS: (a) From Wien’s law, Eq. 12.27, the wavelength of maximum emission for blackbody radiation is

\[ \lambda_{\text{max}} = \frac{C_3}{T} = \frac{2897.6 \, \mu m \cdot K}{T}. \]

For the prescribed surfaces:

<table>
<thead>
<tr>
<th>Surface</th>
<th>Sun (5800K)</th>
<th>Tungsten (2500K)</th>
<th>Hot metal (1500K)</th>
<th>Skin metal (305K)</th>
<th>Cool metal (60K)</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \lambda_{\text{max}} (\mu m) )</td>
<td>0.50</td>
<td>1.16</td>
<td>1.93</td>
<td>9.50</td>
<td>48.3</td>
</tr>
</tbody>
</table>

(b) From Fig. 12.3, the spectral regions associated with each portion of the spectrum are

<table>
<thead>
<tr>
<th>Spectrum</th>
<th>Wavelength limits, ( \mu m )</th>
</tr>
</thead>
<tbody>
<tr>
<td>UV</td>
<td>0.0 – 0.4</td>
</tr>
<tr>
<td>VIS</td>
<td>0.4 – 0.7</td>
</tr>
<tr>
<td>IR</td>
<td>0.7 - 100</td>
</tr>
</tbody>
</table>

For \( T = 5800K \) and each of the wavelength limits, from Table 12.1 find:

<table>
<thead>
<tr>
<th>( \lambda (\mu m) )</th>
<th>( 10^{-2} )</th>
<th>0.4</th>
<th>0.7</th>
<th>( 10^{2} )</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \lambda T (\mu m \cdot K) )</td>
<td>58</td>
<td>2320</td>
<td>4060</td>
<td>( 5.8 \times 10^5 )</td>
</tr>
<tr>
<td>( F_{(0\rightarrow \lambda)} )</td>
<td>0</td>
<td>0.125</td>
<td>0.491</td>
<td>1</td>
</tr>
</tbody>
</table>

Hence, the fraction of the solar emission in each portion of the spectrum is:

\[ F_{UV} = 0.125 - 0 = 0.125 \]

\[ F_{VIS} = 0.491 - 0.125 = 0.366 \]

\[ F_{IR} = 1 - 0.491 = 0.509. \]

COMMENTS: (1) Spectral concentration of surface radiation depends strongly on surface temperature.

(2) Much of the UV solar radiation is absorbed in the earth’s atmosphere.
PROBLEM 12.21

KNOWN: Visible spectral region 0.47 \( \mu \text{m} \) (blue) to 0.65 \( \mu \text{m} \) (red). Daylight and incandescent lighting corresponding to blackbody spectral distributions from the solar disk at 5800 K and a lamp bulb at 2900 K, respectively.

FIND: (a) Band emission fractions for the visible region for these two lighting sources, and (b) wavelengths corresponding to the maximum spectral intensity for each of the light sources. Comment on the results of your calculations considering the rendering of true colors under these lighting conditions.

ASSUMPTIONS: Spectral distributions of radiation from the sources approximates those of blackbodies at their respective temperatures.

ANALYSIS: (a) From Eqs. 12.30 and 12.31, the band-emission fraction in the spectral range \( \lambda_1 \) to \( \lambda_2 \) at a blackbody temperature \( T \) is

\[
F(\lambda_1 - \lambda_2, T) = F(0 \rightarrow \lambda_2, T) - F(0 \rightarrow \lambda_1, T)
\]

where the \( F(0 \rightarrow \lambda, T) \) values can be read from Table 12.1 (or, more accurately calculated using the IHT Radiation | Band Emission tool)

Daylight source (\( T = 5800 \text{ K} \))

\[
F(\lambda_1 - \lambda_2, T) = 0.4374 - 0.2113 = 0.2261
\]

where at \( \lambda_2 T = 0.65 \mu \text{m} \times 5800 \text{ K} = 3770 \mu \text{m-K} \), find \( F(0 \rightarrow \lambda T) = 0.4374 \), and at \( \lambda_1 T = 0.47 \mu \text{m} \times 5800 \text{ K} = 2726 \mu \text{m-K} \), find \( F(0 \rightarrow \lambda T) = 0.2113 \).

Incandescent source (\( T = 2900 \text{ K} \))

\[
F(\lambda_1 - \lambda_2, T) = 0.05098 - 0.00674 = 0.0442
\]

(b) The wavelengths corresponding to the peak spectral intensity of these blackbody sources can be found using Wien’s law, Eq. 12.27.

\[
\lambda_{\text{max}} = \frac{C_3}{T} = 2898 \mu \text{m} \cdot \text{K}
\]

For the daylight (d) and incandescent (i) sources, find

\[
\lambda_{\text{max}, \ d} = 2898 \mu \text{m} \cdot \text{K} / 5800 \text{ K} = 0.50 \mu \text{m}
\]

\[
\lambda_{\text{max}, \ i} = 2898 \mu \text{m} \cdot \text{K} / 2800 \text{ K} = 1.0 \mu \text{m}
\]

COMMENTS: (1) From the band-emission fraction calculation, part (a), note the substantial difference between the fractions for the daylight and incandescent sources. The fractions are a measure of the relative amount of total radiant power that is useful for lighting (visual illumination).

(2) For the daylight source, the peak of the spectral distribution is at 0.5 \( \mu \text{m} \) within the visible spectral region. In contrast, the peak for the incandescent source at 1 \( \mu \text{m} \) is considerably outside the visible region. For the daylight source, the spectral distribution is “flatter” (around the peak) than that for the incandescent source for which the spectral distribution is decreasing markedly with decreasing wavelength (on the short-wavelength side of the blackbody curve). The eye has a bell-shaped relative spectral response within the visible, and will therefore interpret colors differently under illumination by the two sources. In daylight lighting, the colors will be more “true,” whereas with incandescent lighting, the shorter wavelength colors (blue) will appear less bright than the longer wavelength colors (red).
PROBLEM 12.22

KNOWN: Lamp with prescribed filament area and temperature radiates like a blackbody at 2900 K when consuming 100 W.

FIND: (a) Efficiency of the lamp for providing visible radiation, and (b) Efficiency as a function of filament temperature for the range 1300 to 3300 K.

SCHEMATIC:

ASSUMPTIONS: (1) Filament behaves as a blackbody, (2) Glass envelope transmits all visible radiation incident upon it.

ANALYSIS: (a) We define the efficiency of the lamp as the ratio of the radiant power within the visible spectrum (0.4 - 0.7 µm) to the electrical power required to operate the lamp at the prescribed temperature.

\[ \eta = \frac{q_{vis}}{q_{elec}} \]

The radiant power for a blackbody within the visible spectrum is given as

\[ q_{vis} = F(0.4 \mu m \rightarrow 0.7 \mu m)A_s \sigma T_s^4 \left[ F(0 \rightarrow 0.7 \mu m) - F(0 \rightarrow 0.4 \mu m) \right]A_s \sigma T_s^4 \]

using Eq. 12.31 to relate the band emission factors. From Table 12.1, find

\[ \lambda_2 T_s = 0.7 \mu m \times 2900 K = 2030 \mu m \cdot K \quad F(0 \rightarrow 0.7 \mu m) = 0.0719 \]

\[ \lambda_1 T_s = 0.4 \mu m \times 2900 K = 1600 \mu m \cdot K \quad F(0 \rightarrow 0.4 \mu m) = 0.0018 \]

The efficiency is then

\[ \eta = \frac{(0.0719 - 0.0018) \times 2 \times 10^{-3} m \times 5 \times 10^{-3} m \times 5.67 \times 10^{-8} W/m^2 \cdot K^4 (2900 K)^4 100 W}{5.62 W/100 W} = 5.6\% \]

(b) Using the IHT Radiation Exchange Tool, Blackbody Emission Factor, and Eqs. (1) and (2) above, a model was developed to compute and plot \( \eta \) as a function of \( T_s \).

Continued...
PROBLEM 12.22 (Cont.)

Note that the efficiency decreases markedly with reduced filament temperature. At 2900 K, $\eta = 5.6\%$ while at 2345 K, the efficiency decreases by more than a factor of five to $\eta = 1\%$.

COMMENTS: (1) Based upon this analysis, less than 6% of the energy consumed by the lamp operating at 2900 K is converted to visible light. The transmission of the glass envelope will be less than unity, so the efficiency will be less than the calculated value.

(2) Most of the energy is absorbed by the glass envelope and then lost to the surroundings by convection and radiation. Also, a significant amount of power is conducted to the lamp base and into the lamp base socket.

(3) The IHT workspace used to generate the above plot is shown below.

```plaintext
// Radiation Exchange Tool - Blackbody Band Emission Factor:
/* The blackbody band emission factor, Figure 12.14 and Table 12.1, is */
FL1Ts = F_lambda_T(lambda1,Ts)    // Eq 12.30
// where units are lambda (micrometers, mum) and T (K)
/* The blackbody band emission factor, Figure 12.14 and Table 12.1, is */
FL2Ts = F_lambda_T(lambda2,Ts)    // Eq 12.30

// Efficiency and rate expressions:

PROBLEM 12.23

KNOWN: Solar disc behaves as a blackbody at 5800 K.

FIND: (a) Fraction of total radiation emitted by the sun that is in the visible spectral region, (b) Plot the percentage of solar emission that is at wavelengths less than \( \lambda \) as a function of \( \lambda \), and (c) Plot on the same coordinates the percentage of emission from a blackbody at 300 K that is at wavelengths less than \( \lambda \) as a function of \( \lambda \); compare the plotted results with the upper abscissa scale of Figure 12.23.

ASSUMPTIONS: (1) Visible spectral region has limits \( \lambda_1 = 0.40 \mu \text{m} \) and \( \lambda_2 = 0.70 \mu \text{m} \).

ANALYSIS: (a) Using the blackbody functions of Table 12.1, find \( F(0\rightarrow\lambda) \), the fraction of radiant flux leaving a black surface in the spectral interval 0→\( \lambda \) as a function of the product \( \lambda T \). From the tabulated values for \( F(0\rightarrow\lambda) \) with \( T = 5800 \) K,

\[
\begin{align*}
\lambda_2 &= 0.70 \mu \text{m} \quad \lambda_2 T = 4060 \mu \text{m} \cdot \text{K} \quad F(0\rightarrow\lambda_1) = 0.4914 \\
\lambda_1 &= 0.40 \mu \text{m} \quad \lambda_1 T = 2320 \mu \text{m} \cdot \text{K} \quad F(0\rightarrow\lambda_2) = 0.1245
\end{align*}
\]

Hence, for the visible spectral region, the fraction of total emitted solar flux is

\[
F(\lambda_1 \rightarrow \lambda_2) = F(0\rightarrow\lambda_2) - F(0\rightarrow\lambda_1) = 0.4914 - 0.1245 = 0.3669 \quad \text{or} \quad 37\%
\]

(b,c) Using the IHT Radiation Tool, Band Emission Factor, \( F(0\rightarrow\lambda T) \) are evaluated for the solar spectrum (\( T = 5800 \) K) and that for a blackbody temperature (\( T = 300 \) K) as a function of wavelength and are plotted below.

The left-hand curve in the plot represents the percentage of solar flux approximated as the 5800 K-blackbody spectrum in the spectral region less than \( \lambda \). The right-hand curve represents the percentage of 300 K-blackbody flux in the spectral region less than \( \lambda \). Referring to upper abscissa scale of Figure 12.23, for the solar flux, 75% of the solar flux is at wavelengths shorter than 1 \( \mu \text{m} \). For the blackbody flux (300 K), 75% of the blackbody flux is at wavelengths shorter than 20 \( \mu \text{m} \). These values are in agreement with points on the solar and 300K-blackbody curves, respectively, in the above plot.
PROBLEM 12.24

KNOWN: Thermal imagers operating in the spectral regions 3 to 5 µm and 8 to 14 µm.

FIND: (a) Band-emission factors for each of the spectral regions, 3 to 5 µm and 8 to 14 µm, for temperatures of 300 and 900 K, (b) Calculate and plot the band-emission factors for each of the spectral regions for the temperature range 300 to 1000 K; identify the maxima, and draw conclusions concerning the choice of an imager for an application; and (c) Considering imagers operating at the maximum-fraction temperatures found from the graph of part (b), determine the sensitivity (%) required of the radiation detector to provide a noise-equivalent temperature (NET) of 5°C.

ASSUMPTIONS: The sensitivity of the imager’s radiation detector within the operating spectral region is uniform.

ANALYSIS: (a) From Eqs. 12.30 and 12.31, the band-emission fraction $F(\lambda_1 \rightarrow \lambda_2, T)$ for blackbody emission in the spectral range $\lambda_1$ to $\lambda_2$ for a temperature $T$ is

$$F(\lambda_1 \rightarrow \lambda_2, T) = F(0 \rightarrow \lambda_2, T) - F(0 \rightarrow \lambda_1, T)$$

Using the IHT Radiation | Band Emission tool (or Table 12.1), evaluate $F(0-\lambda T)$ at appropriate $\lambda \cdot T$ products:

3 to 5 µm region

$F(\lambda_1 \rightarrow \lambda_2, 300 \text{ K}) = 0.1375 - 0.00017 = 0.1358$ $<$

$F(\lambda_1 \rightarrow \lambda_2, 900 \text{ K}) = 0.5640 - 0.2055 = 0.3585$ $<$

8 to 14 µm region

$F(\lambda_1 \rightarrow \lambda_2, 300 \text{ K}) = 0.5160 - 0.1403 = 0.3757$ $<$

$F(\lambda_1 \rightarrow \lambda_2, 900 \text{ K}) = 0.9511 - 0.8192 = 0.1319$ $<$

(b) Using the IHT Radiation | Band Emission tool, the band-emission fractions for each of the spectral regions is calculated and plotted below as a function of temperature.

![Band fractions for thermal imaging spectral regions](image-url)
For the 3 to 5 µm imager, the band-emission factor increases with increasing temperature. For low temperature applications, not only is the radiant power \( \sigma T^4, T \approx 300 \text{ K} \) low, but the band fraction is small. However, for high temperature applications, the imager operating conditions are more favorable with a large band-emission factor, as well as much higher radiant power \( \sigma T^4, T \rightarrow 900 \text{ K} \).

For the 8 to 14 µm imager, the band-emission factor decreases with increasing temperature. This is a more favorable instrumentation feature, since the band-emission factor (proportionally more power) becomes larger as the radiant power decreases. This imager would be preferred over the 3 to 5 µm imager at lower temperatures since the band-emission factor is 8 to 10 times higher.

Recognizing that from Wien’s law, the peaks of the blackbody curves for 300 and 900 K are approximately 10 and 3.3 µm, respectively, it follows that the imagers will receive the most radiant power when the peak target spectral distributions are close to the operating spectral region. It is good application practice to choose an imager having a spectral operating range close to the peak of the blackbody curve (or shorter than, if possible) corresponding to the target temperature.

The maxima band fractions for the 3 to 5 µm and 8 to 14 µm spectral regions correspond to temperatures of 960 and 355 K, respectively. Other application factors not considered (like smoke, water vapor, etc), the former imager is better suited with higher temperature scenes, and the latter with lower temperature scenes.

(c) Consider the 3 to 5 µm and 8 to 14 µm imagers operating at their band-emission peak temperatures, 355 and 960 K, respectively. The sensitivity \( S \) (% units) of the imager to resolve an NET of 5°C can be expressed as

\[
S(\%) = \frac{F(\lambda_1-\lambda_2, T_1) - F(\lambda_1-\lambda_2, T_2)}{F(\lambda_1-\lambda_2, T_1)} \times 100
\]

where \( T_1 = 355 \) or 960 K and \( T_2 = 360 \) or 965 K, respectively. Using this relation in the IHT workspace, find

\[
S_{3-5} = 0.035\% \quad S_{8-14} = 0.023\%
\]

That is, we require the radiation detector (with its signal-processing system) to resolve the output signal with the foregoing precision in order to indicate a 5°C change in the scene temperature.
**PROBLEM 12.25**

**KNOWN:** Tube furnace maintained at $T_f = 2000$ K used to calibrate a heat flux gage of sensitive area $5 \text{ mm}^2$ mounted coaxial with the furnace centerline, and positioned 60 mm from the opening of the furnace.

**FIND:** (a) Heat flux (kW/m$^2$) on the gage, (b) Radiant flux in the spectral region $0.4$ to $2.5$ µm, the sensitive spectral region of a solid-state (photoconductive type) heat-flux gage, and (c) Calculate and plot the heat fluxes for each of the gages as a function of the furnace temperature for the range $2000 \leq T_f \leq 3000$ K. Compare the values for the two types of gages; explain why the solid-state gage will always indicate systematically low values; does the solid-state gage performance improve, or become worse as the source temperature increases?

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Graphite tube furnace behaves as a blackbody, (3) Areas of gage and furnace opening are small relative to separation distance squared, and (4) Extension tube is cold relative to the furnace.

**ANALYSIS:** (a) The heat flux to the gage is equal to the irradiation, $G_g$, on the gage and can be expressed as (see Section 12.2.3)

$$G_g = I_f \cdot \cos \theta_g \cdot \Delta \omega_{f-g}$$

where $\Delta \omega_{f-g}$ is the solid angle that the furnace opening subtends relative to the gage. From Eq. 12.2, with $\theta_g = 0^\circ$

$$\Delta \omega_{f-g} = \frac{dA_n}{r^2} = \frac{A_f \cos \theta_g}{L^2} = \frac{\pi(0.0125 \text{ m})^2/4 \times 1}{(0.060 \text{ m})^2} = 3.409 \times 10^{-2} \text{ sr}$$

The intensity of the radiation from the furnace is

$$I_f = E_{b,f}(T_f)/\pi = \sigma T_f^4/\pi = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (2000 \text{ K})^4/\pi = 2.888 \times 10^5 \text{ W/m}^2 \cdot \text{sr}$$

Substituting numerical values,

$$G_g = 2.888 \times 10^5 \text{ W/m}^2 \cdot \text{sr} \times 1 \times 3.409 \times 10^{-2} \text{ sr} = 9.84 \text{ kW/m}^2$$

(b) The solid-state detector gage, sensitive only in the spectral region $\lambda_1 = 0.4$ µm to $\lambda_2 = 2.5$ µm, will receive the band irradiation.

$$G_{g, \lambda_1-\lambda_2} = F(\lambda_1 \rightarrow \lambda_2, T_f) \cdot G_{g,b} = \left[ F(0 \rightarrow \lambda_2, T_f) - F(0 \rightarrow \lambda_1, T_f) \right] G_{g,b}$$

Continued …..
PROBLEM 12.25 (Cont.)

where for \( \lambda_1 \ T_f = 0.4 \ \mu m \times 2000 \ K = 800 \ \mu m \cdot K \), \( F_{(0 - \lambda_1)} = 0.0000 \) and for \( \lambda_2 \cdot T_f = 2.5 \ \mu m \times 2000 \ K = 5000 \ \mu m \cdot K \), \( F_{(0 - \lambda_2)} = 0.6337 \). Hence,

\[
G_{g, \lambda_1-\lambda_2} = \left[0.6337 - 0.0000\right] \times 9.84 \ kW/m^2 = 6.24 \ kW/m^2
\]

(c) Using the foregoing equation in the IHT workspace, the heat fluxes for each of the gage types are calculated and plotted as a function of the furnace temperature.

For the black gage, the irradiation received by the gage, \( G_g \), increases as the fourth power of the furnace temperature. For the solid-state gage, the irradiation increases slightly greater than the fourth power of the furnace temperature since the band-emission factor for the spectral region, \( F_{(\lambda_1 - \lambda_2, T_f)} \), increases with increasing temperature. The solid-state gage will always indicate systematic low readings since its band-emission factor never approaches unity. However, the error will decrease with increasing temperature as a consequence of the corresponding increase in the band-emission factor.

COMMENTS: For this furnace-gage geometrical arrangement, evaluating the solid angle, \( \Delta \omega_{f-g} \), and the areas on a differential basis leads to results that are systematically high by 1%. Using the view factor concept introduced in Chapter 13 and Eq. 13.8, the results for the black and solid-state gages are 9.74 and 6.17 kW/m², respectively.
**PROBLEM 12.26**

**KNOWN:** Geometry and temperature of a ring-shaped radiator. Area of irradiated part and distance from radiator.

**FIND:** Rate at which radiant energy is incident on the part.

**SCHEMATIC:**

![Schematic of radiant heater](image)

**ASSUMPTIONS:** (1) Heater emits as a blackbody.

**ANALYSIS:** Expressing Eq. 12.5 on the basis of the total radiation, \( dq = I_e \, dA \, \cos \theta \, d\omega \), the rate at which radiation is incident on the part is

\[
q_{h-p} = \int dq = I_e \int \cos \theta d\omega \, p-h \, dA_h \approx I_e \, \cos \theta \, \omega_{p-h} \, A_h
\]

Since radiation leaving the heater in the direction of the part is oriented normal to the heater surface, \( \theta = 0 \) and \( \cos \theta = 1 \). The solid angle subtended by the part with respect to the heater is \( \omega_{p-h} = A_p \cos \theta/L^2 \), while the area of the heater is \( A_h = 2\pi r_h = 2\pi(L \sin \theta_1)W \). Hence, with \( I_e = E_b/\pi = \sigma T_h^4/\pi \),

\[
q_{h-p} = \frac{5.67 \times 10^{-8} \, W/m^2 \cdot K^4 (3000 \, K)^4}{\pi} \times 0.007 \, m^2 \left( \frac{\cos 30^\circ}{(3 \, m)^2} \right) \times 2\pi (1.5 \, m) 0.03 \, m
\]

\[
q_{h-p} = 278.4 \, W
\]

**COMMENTS:** The foregoing representation for the double integral is an excellent approximation since \( W << L \) and \( A_p << L^2 \).
**PROBLEM 12.27**

**KNOWN:** Spectral distribution of the emissive power given by Planck’s law.

**FIND:** Approximations to the Planck distribution for the extreme cases when (a) \( C_2/\lambda T >> 1 \), Wien’s law and (b) \( C_2/\lambda T << 1 \), Rayleigh-Jeans law.

**ANALYSIS:** Planck’s law provides the spectral, hemispherical emissive power of a blackbody as a function of wavelength and temperature, Eq. 12.26,

\[
E_{\lambda,b}(\lambda, T) = \frac{C_1}{\lambda^5} \left[ \exp \left( \frac{C_2}{\lambda T} \right) - 1 \right].
\]

We now consider the extreme cases of \( C_2/\lambda T >> 1 \) and \( C_2/\lambda T << 1 \).

(a) When \( C_2/\lambda T >> 1 \) (or \( \lambda T << C_2 \)), it follows \( \exp(C_2/\lambda T) >> 1 \). Hence, the \(-1\) term in the denominator of the Planck law is insignificant, giving

\[
E_{\lambda,b}(\lambda, T) \approx \frac{C_1}{\lambda^5} \left( \exp \left( -\frac{C_2}{\lambda T} \right) \right).
\]

This approximate relation is known as *Wien’s law*. The ratio of the emissive power by Wien’s law to that by the Planck law is,

\[
\frac{E_{\lambda,b,\text{Wien}}}{E_{\lambda,b,\text{Planck}}} = \frac{1/\exp(C_2/\lambda T)}{1/\left[ \exp(C_2/\lambda T) - 1 \right]}.
\]

For the condition \( \lambda T = \lambda_{\text{max}} T = 2898 \, \mu\text{m} \cdot \text{K} \), \( C_2/\lambda T = \frac{14388 \, \mu\text{m} \cdot \text{K}}{2898 \, \mu\text{m} \cdot \text{K}} = 4.966 \) and

\[
\frac{E_{\lambda,b,\text{Wien}}}{E_{\lambda,b,\text{Planck}}} \approx \frac{1/\exp(4.966)}{1/\left[ \exp(4.966) - 1 \right]} = 0.9930.
\]

That is, for \( \lambda T \leq 2898 \, \mu\text{m} \cdot \text{K} \), Wien’s law is a good approximation to the Planck distribution.

(b) If \( C_2/\lambda T << 1 \) (or \( \lambda T >> C_2 \)), the exponential term may be expressed as a series that can be approximated by the first two terms. That is,

\[
e^x = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \ldots \approx 1 + x \quad \text{when} \quad x << 1.
\]

The *Rayleigh-Jeans* approximation is then

\[
E_{\lambda,b}(\lambda, T) = \frac{C_1}{\lambda^5} \left[ 1 + (C_2/\lambda T) - 1 \right] = \frac{C_1\Gamma}{C_2 \lambda^4}.
\]

For the condition \( \lambda T = 100,000 \, \mu\text{m} \cdot \text{K} \), \( C_2/\lambda T = 0.1439 \)

\[
\frac{E_{\lambda,b,\text{R-J}}}{E_{\lambda,b,\text{Planck}}} = \frac{C_1\Gamma/C_2 \lambda^4}{C_1/\lambda^5} \left[ \exp(C_2/\lambda T) - 1 \right]^{-1} = (\lambda T/C_2) \left[ \exp(C_2/\lambda T) - 1 \right] = 1.0754.
\]

That is, for \( \lambda T \geq 100,000 \, \mu\text{m} \cdot \text{K} \), the Rayleigh-Jeans law is a good approximation (better than 10%) to the Planck distribution.

**COMMENTS:** The Wien law is used extensively in optical pyrometry for values of \( \lambda \) near 0.65 \( \mu\text{m} \) and temperatures above 700 K. The Rayleigh-Jeans law is of limited use in heat transfer but of utility for far infrared applications.
**PROBLEM 12.28**

**KNOWN:** Aperture of an isothermal furnace emits as a blackbody.

**FIND:** (a) An expression for the ratio of the fractional change in the spectral intensity to the fractional change in temperature of the furnace aperture, (b) Allowable variation in temperature of a furnace operating at 2000 K such that the spectral intensity at 0.65µm will not vary by more than 1/2%. Allowable variation for 10µm.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Furnace is isothermal and aperture radiates as a blackbody.

**ANALYSIS:** (a) The Planck spectral distribution, Eq. 12.26, is

\[ I_\lambda (\lambda, T) = \frac{C_1}{\pi \lambda^5} \left[ \exp \left( \frac{C_2}{\lambda T} \right) - 1 \right]. \]

Taking natural logarithms of both sides, find \( \ell n I_\lambda = \ell n \left[ \frac{C_1}{\pi \lambda^5} \right] - \ell n \left[ \exp \left( \frac{C_2}{\lambda T} \right) - 1 \right] \). Take the total derivative of both sides, but consider the \( \lambda \) variable as a constant.

\[
\frac{d I_\lambda}{I_\lambda} = -\frac{d \left[ \exp \left( \frac{C_2}{\lambda T} \right) - 1 \right]}{\exp \left( \frac{C_2}{\lambda T} \right) - 1} = -\frac{\exp \left( \frac{C_2}{\lambda T} \right)\left( \frac{C_2}{\lambda} \right)\left( -1/T^2 \right) dT}{\exp \left( \frac{C_2}{\lambda T} \right) - 1}.
\]

\[
\frac{d I_\lambda}{I_\lambda} = \frac{C_2}{\lambda T} \cdot \left[ \frac{\exp \left( \frac{C_2}{\lambda T} \right)}{\exp \left( \frac{C_2}{\lambda T} \right) - 1} \right] \cdot \frac{dT}{T} \quad \text{or} \quad \frac{d I_\lambda}{I_\lambda} = \frac{C_2}{\lambda T} \cdot \frac{1}{1 - \exp \left( -\frac{C_2}{\lambda T} \right)}. \]

(b) If the furnace operates at 2000 K and the desirable fractional change of the spectral intensity is 0.5% at 0.65 µm, the allowable temperature variation is

\[
\frac{dT}{T} = \frac{d I_\lambda}{I_\lambda} \cdot \left\{ C_2 \cdot \frac{1}{\lambda T \left[ 1 - \exp \left( -\frac{C_2}{\lambda T} \right) \right]} \right\}.
\]

\[
\frac{dT}{T} = 0.005/\left\{ \frac{14,388 \mu m \cdot K}{0.65 \mu m \times 2000 K} \left[ 1 - \exp \left( \frac{-14,388 \mu m \cdot K}{0.65 \mu m \times 2000 K} \right) \right] \right\} = 4.517 \times 10^{-4}.
\]

That is, the allowable fractional variation in temperature is 0.045%; at 2000 K, the allowable temperature variation is

\( \Delta T = 4.517 \times 10^{-4} \times 2000 K = 0.90 K. \)

Substituting with \( T = 2000 K \) and \( \lambda = 10 \mu m \), find that

\[ \frac{dT}{T} = 3.565 \times 10^{-3} \quad \text{and} \quad \Delta T = 3.565 \times 10^{-3} \times 2000 K = 7.1 K. \]

**COMMENTS:** Note that the power control requirements to satisfy the spectral intensity variation for 0.65 µm and 10 µm conditions are quite different. The peak of the blackbody curve for 2000 K is \( \lambda_{\text{max}} = 2898 \mu m \cdot K / 2000 K = 1.45 \mu m. \)
**PROBLEM 12.29**

**KNOWN:** Spectral emissivity, dimensions and initial temperature of a tungsten filament.

**FIND:** (a) Total hemispherical emissivity, \( \varepsilon \), when filament temperature is \( T_s = 2900 \) K; (b) Initial rate of cooling, \( dT_s/dt \), assuming the surroundings are at \( T_{sur} = 300 \) K when the current is switched off; (c) Compute and plot \( \varepsilon \) as a function of \( T_s \) for the range \( 1300 \leq T_s \leq 2900 \) K; and (d) Time required for the filament to cool from 2900 to 1300 K.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Filament temperature is uniform at any time (lumped capacitance), (2) Negligible heat loss by conduction through the support posts, (3) Surroundings large compared to the filament, (4) Spectral emissivity, density and specific heat constant over the temperature range, (5) Negligible convection.

**PROPERTIES:** Table A-1, Tungsten (2900 K); \( \rho = 19,300 \text{ kg/m}^3 \), \( c_p = 185 \text{ J/kg} \cdot \text{K} \).

**ANALYSIS:** (a) The total emissivity at \( T_s = 2900 \) K follows from Eq. 12.38 using Table 12.1 for the band emission factors,

\[
\varepsilon = \int_{0}^{\infty} \varepsilon_{\lambda} E_{\lambda b}(T_s)d\lambda = \varepsilon_1 F_{(0-2\mu m)} + \varepsilon_2 (1 - F_{0-2\mu m})
\]

\[\varepsilon = 0.45 \times 0.72 + 0.1 (1 - 0.72) = 0.352 \]

where \( F_{(0-2\mu m)} = 0.72 \) at \( \lambda T = 2 \mu m \times 2900 \text{ K} = 5800 \mu m \cdot \text{K} \).

(b) Perform an energy balance on the filament at the instant of time at which the current is switched off,

\[\dot{E}_{in} - \dot{E}_{out} = M c_p \frac{dT_s}{dt}\]

\[A_s (\alpha G_{sur} - E) = A_s (\alpha \sigma T_s^4 - \varepsilon \sigma T_s^4) = M c_p \frac{dT_s}{dt}\]

and find the change in temperature with time where \( A_s = \pi DL \), \( M = \rho \forall \), and \( \forall = (\pi D^2/4)L \),

\[\frac{dT_s}{dt} = -\frac{\pi DL \sigma (\varepsilon T_s^4 - \alpha T_s^4)}{\rho \left(\pi D^2/4\right) L c_p} = -\frac{4\sigma}{\rho c_p D} (\varepsilon T_s^4 - \alpha T_s^4)\]

\[\frac{dT_s}{dt} = -\frac{4 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (0.352 \times 2900^4 - 0.1 \times 300^4) \text{K}^4}{19,300 \text{ kg/m}^3 \times 185 \text{ J/kg} \cdot \text{K} \times 0.0008 \text{ m}} = -1977 \text{ K/s} \]

(c) Using the IHT Tool, Radiation, Band Emission Factor, and Eq. (1), a model was developed to calculate and plot \( \varepsilon \) as a function of \( T_s \). See plot below.

Continued...
(d) Using the IHT *Lumped Capacitance Model* along with the IHT workspace for part (c) to determine $\varepsilon$ as a function of $T_s$, a model was developed to predict $T_s$ as a function of cooling time. The results are shown below for the variable emissivity case ($\varepsilon$ vs. $T_s$ as per the plot below left) and the case where the emissivity is fixed at $\varepsilon(2900 \text{ K}) = 0.352$. For the variable and fixed emissivity cases, the times to reach $T_s = 1300 \text{ K}$ are

\[ t_{\text{var}} = 8.3 \text{ s} \quad t_{\text{fix}} = 5.1 \text{ s} \]

**COMMENTS:**

1. From the $\varepsilon$ vs. $T_s$ plot, note that $\varepsilon$ increases as $T_s$ increases. Could you have surmised as much by looking at the spectral emissivity distribution, $\varepsilon_{\lambda}$ vs. $\lambda$?

2. How do you explain the result that $t_{\text{var}} > t_{\text{fix}}$?
PROBLEM 12.30

KNOWN: Spectral distribution of emissivity for zirconia and tungsten filaments. Filament temperature.

FIND: (a) Total emissivity of zirconia, (b) Total emissivity of tungsten and comparative power requirement, (c) Efficiency of the two filaments.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible reflection of radiation from bulb back to filament, (2) Equivalent surface areas for the two filaments, (3) Negligible radiation emission from bulb to filament.

ANALYSIS: (a) From Eq. (12.38), the emissivity of the zirconia is

\[
e(\lambda) = \int_{0}^{\infty} \varepsilon_{\lambda} (E_{\lambda}/E_{b}) d\lambda = \varepsilon_{1} F_{(0 \rightarrow 0.4 \mu m)} + \varepsilon_{2} F_{(0.4 \rightarrow 0.7 \mu m)} + \varepsilon_{3} F_{(0.7 \mu m \rightarrow \infty)}
\]

\[
= \varepsilon_{1} F_{(0 \rightarrow 0.4 \mu m)} + \varepsilon_{2} \left(F_{(0 \rightarrow 0.7 \mu m)} - F_{(0 \rightarrow 0.4 \mu m)}\right) + \varepsilon_{3} \left(1 - F_{(0 \rightarrow 0.7 \mu m)}\right)
\]

From Table 12.1, with \( T = 3000 \) K

\[
\lambda T = 0.4 \mu m \times 3000 = 1200 \mu m \cdot K: F_{(0 \rightarrow 0.4 \mu m)} = 0.0021
\]

\[
\lambda T = 0.7 \mu m \times 3000 K = 2100 \mu m \cdot K: F_{(0 \rightarrow 0.7 \mu m)} = 0.0838
\]

\[
\varepsilon = 0.2 \times 0.0021 + 0.8 \left(0.0838 - 0.0021\right) + 0.2 \times (1 - 0.0838) = 0.249
\]

(b) For the tungsten filament,

\[
\varepsilon = \varepsilon_{1} F_{(0 \rightarrow 2 \mu m)} + \varepsilon_{2} \left(1 - F_{(0 \rightarrow 2 \mu m)}\right)
\]

With \( \lambda T = 6000 \mu m \cdot K, F(0 \rightarrow 2 \mu m) = 0.738 \)

\[
\varepsilon = 0.45 \times 0.738 + 0.1 \times (1 - 0.738) = 0.358
\]

Assuming, no reflection of radiation from the bulb back to the filament and with no losses due to natural convection, the power consumption per unit surface area of filament is \( P_{\text{elec}}^* = \varepsilon \sigma T^4 \).

Continued …..
**PROBLEM 12.30 (Cont.)**

Zirconia: \[ P_{\text{elec}}^* = 0.249 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (3000 \text{ K})^4 = 1.14 \times 10^6 \text{ W/m}^2 \]

Tungsten: \[ P_{\text{elec}}^* = 0.358 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (3000 \text{ K})^4 = 1.64 \times 10^6 \text{ W/m}^2 \]

Hence, for an equivalent surface area and temperature, the tungsten filament has the largest power consumption.

(c) Efficiency with respect to the production of visible radiation may be defined as

\[
\eta_{\text{vis}} = \frac{\int_{0.4}^{0.7} \epsilon_{\lambda} E_{\lambda,b} d\lambda}{E} = \frac{\int_{0.4}^{0.7} \epsilon_{\lambda} \left( E_{\lambda,b}/E_b \right)}{\epsilon} = \frac{\epsilon_{\text{vis}} F(0.4 \rightarrow 0.7 \mu \text{m})}{\epsilon}
\]

With \( F(0.4 \rightarrow 0.7 \mu \text{m}) = 0.0817 \) for \( T = 3000 \text{ K} \),

Zirconia: \[ \eta_{\text{vis}} = (0.8/0.249) 0.0817 = 0.263 \]

Tungsten: \[ \eta_{\text{vis}} = (0.45/0.358) 0.0817 = 0.103 \]

Hence, the zirconia filament is the more efficient.

**COMMENTS:** The production of visible radiation per unit filament surface area is \( E_{\text{vis}} = \eta_{\text{vis}} P_{\text{elec}}^* \). Hence,

Zirconia: \[ E_{\text{vis}} = 0.263 \times 1.14 \times 10^6 \text{ W/m}^2 = 3.00 \times 10^5 \text{ W/m}^2 \]

Tungsten: \[ E_{\text{vis}} = 0.103 \times 1.64 \times 10^6 \text{ W/m}^2 = 1.69 \times 10^5 \text{ W/m}^2 \]

Hence, not only is the zirconia filament more efficient, but it also produces more visible radiation with less power consumption. This problem illustrates the benefits associated with carefully considering spectral surface characteristics in radiative applications.
PROBLEM 12.31

KNOWN: Variation of spectral, hemispherical emissivity with wavelength for two materials.

FIND: Nature of the variation with temperature of the total, hemispherical emissivity.

SCHEMATIC:

ASSUMPTIONS: (1) $\varepsilon_\lambda$ is independent of temperature.

ANALYSIS: The total, hemispherical emissivity may be obtained from knowledge of the spectral, hemispherical emissivity by using Eq. 12.38

$$\varepsilon(T) = \int_0^\infty \varepsilon_\lambda(\lambda) E_{\lambda,b}(\lambda, T) d\lambda \frac{E_{\lambda,b}(\lambda, T)}{E_b(T)}$$

We also know that the spectral emissive power of a blackbody becomes more concentrated at lower wavelengths with increasing temperature (Fig. 12.13). That is, the weighting factor, $E_{\lambda,b}(\lambda,T)/E_b(T)$ increases at lower wavelengths and decreases at longer wavelengths with increasing T. Accordingly,

Material A: $\varepsilon(T)$ increases with increasing T

Material B: $\varepsilon(T)$ decreases with increasing T.

<
**PROBLEM 12.32**

**KNOWN:** Metallic surface with prescribed spectral, directional emissivity at 2000 K and 1 µm (see Example 12.6) and additional measurements of the spectral, hemispherical emissivity.

**FIND:** (a) Total hemispherical emissivity, $\varepsilon$, and the emissive power, $E$, at 2000 K.  (b) Effect of temperature on the emissivity.

**SCHEMATIC:**

![Emissivity Diagram](image)

**ANALYSIS:** (a) The total, hemispherical emissivity, $\varepsilon$, may be determined from knowledge of the spectral, hemispherical emissivity, $\varepsilon_{\lambda}$, using Eq. 12.38.

$$
\varepsilon(T) = \int_0^{\infty} \varepsilon_{\lambda}(\lambda)E_{\lambda,b}(\lambda,T)d\lambda/E_b(T) = \varepsilon_1 \int_{2\mu m}^{4\mu m} \frac{E_{\lambda,b}(\lambda,T)d\lambda}{E_b(T)} + \varepsilon_2 \int_{2\mu m}^{4\mu m} \frac{E_{\lambda,b}(\lambda,T)d\lambda}{E_b(T)}
$$

or from Eqs. 12.28 and 12.30,

$$
\varepsilon(T) = \varepsilon_1 F_{(0\rightarrow\lambda_1)} + \varepsilon_2 \left[ F_{(0\rightarrow\lambda_2)} - F_{(0\rightarrow\lambda_1)} \right]
$$

From Table 12.1,

$\lambda_1 = 2 \mu m$,  \  $T = 2000$ K : $\lambda_1 T = 4000 \mu m \cdot K$,  \  $F_{(0\rightarrow\lambda_1)} = 0.481$

$\lambda_2 = 4 \mu m$,  \  $T = 2000$ K : $\lambda_2 T = 8000 \mu m \cdot K$,  \  $F_{(0\rightarrow\lambda_2)} = 0.856$

Hence,

$$
\varepsilon(T) = 0.36 \times 0.481 + 0.20 (0.856 - 0.481) = 0.25
$$

From Eqs. 12.28 and 12.37, the total emissive power at 2000 K is

$$
E(2000 \text{ K}) = \varepsilon (2000 \text{ K}) \cdot E_b (2000 \text{ K})
$$

$$
E(2000 \text{ K}) = 0.25 \times 5.67 \times 10^{-8} \text{ W/} \text{m}^2 \cdot \text{K}^4 \times (2000 \text{ K})^4 = 2.27 \times 10^5 \text{ W/} \text{m}^2.
$$

(b) Using the *Radiation* Toolpad of IHT, the following result was generated.

![Graph](image)
At $T \approx 500$ K, most of the radiation is emitted in the far infrared region ($\lambda > 4 \, \mu\text{m}$), in which case $\varepsilon = 0$. With increasing $T$, emission is shifted to lower wavelengths, causing $\varepsilon$ to increase. As $T \to \infty$, $\varepsilon \to 0.36$.

**COMMENTS:** Note that the value of $\varepsilon_{\lambda}$ for $0 < \lambda \leq 2 \, \mu\text{m}$ cannot be read directly from the $\varepsilon_{\lambda}$ distribution provided in the problem statement. This value is calculated from knowledge of $\varepsilon_{\lambda,\theta}(\theta)$ in Example 12.6.
PROBLEM 12.33

KNOWN: Relationship for determining total, hemispherical emissivity, $\varepsilon$, by integration of the spectral emissivity distribution, $\varepsilon_\lambda$ (Eq. 12.38).

FIND: Evaluate $\varepsilon$ from $\varepsilon_\lambda$ for the following cases: (a) Ex. 12.5, use the result to benchmark your code, (b) tungsten at 2800 K, and (c) aluminum oxide at 1400 K. Use the intrinsic function INTEGRAL of IHT as your solution tool.

SCHEMATIC:

ASSUMPTIONS: (1) Surfaces are diffuse emitters.

ANALYSIS: (a) Using IHT as the solution tool, Eq. 12.38 is entered into the workspace, and a look-up table created to represent the spectral emissivity distribution. See Comment 1 for the IHT annotated code. The result is $\varepsilon = 0.558$, in agreement with the analysis of Ex. 12.5 using the band-emission factors.

(b, c) Using the same code as for the benchmarking exercise in Part (a), but with new look-up table files (*.lut) representing the spectral distributions tabulated below, the total hemispherical emissivities for the tungsten at 2800 K and aluminum oxide at 1400 K are:

$$\varepsilon_W = 0.31$$

$$\varepsilon_{\text{Al}_{2}\text{O}_3} = 0.38$$

These results compare favorably with values of 0.29 and 0.41, respectively, from Fig. 12.19. See Comment 2.

4.99 0.8
5    0.001
100  0.001 */

// Input variable
T = 1600
```

(2) For tungsten at 2800 K, the spectral limits for 98% of the blackbody spectrum are 0.51 and 8.3 µm. For aluminum at 1400 K, the spectral limits for 98% of the blackbody spectrum are 1.0 and 16.7 µm. For both cases, the foregoing tabulated spectral emissivity distributions are adequately represented for integration within the 98% limits.
PROBLEM 12.34

KNOWN: Spectral directional emissivity of a diffuse material at 2000K.

FIND: (a) Total, hemispherical emissivity, (b) Emissive power over the spectral range 0.8 to 2.5 \( \mu \)m and for directions \( 0 \leq \theta \leq \pi/6 \).

SCHEMATIC:

ASSUMPTIONS: (1) Surface is diffuse emitter.

ANALYSIS: (a) Since the surface is diffuse, \( \varepsilon_{\lambda,\theta} \) is independent of direction; from Eq. 12.36, \( \varepsilon_{\lambda,\theta} = \varepsilon_{\lambda} \). Using Eq. 12.38,

\[
\varepsilon(T) = \int_0^\infty \varepsilon_\lambda(\lambda) \varepsilon_{\lambda,b}(\lambda, T) d\lambda / E_b(T)
\]

\[
E(T) = \int_{1.5}^{2.5} \varepsilon_1 E_{\lambda,b}(\lambda,2000) d\lambda / E_b + \int_{1.5}^{\infty} \varepsilon_2 E_{\lambda,b}(\lambda,2000) d\lambda / E_b.
\]

Written now in terms of \( F(0 \rightarrow \lambda) \), with \( F(0 \rightarrow 1.5) = 0.2732 \) at \( \lambda T = 1.5 \times 2000 = 3000 \mu \)m K, (Table 12.1) find,

\( \varepsilon(2000K) = \varepsilon_1 \times F(0 \rightarrow 1.5) + \varepsilon_2 \left[ 1 - F(0 \rightarrow 1.5) \right] = 0.2 \times 0.2732 + 0.8 \times [1-0.2732] = 0.636. \) <

(b) For the prescribed spectral and geometric limits, from Eq. 12.12,

\[
\Delta E = \int_{0.8}^{2.5} \int_0^{2\pi} \int_0^{\pi/6} \varepsilon_{\lambda,\theta} I_{\lambda,b}(\lambda,T) \cos \theta \sin \theta \ d\theta \ d\phi \ d\lambda
\]

where \( I_{\lambda,c}(\lambda,\theta,\phi) = \varepsilon_{\lambda,\theta} I_{\lambda,b}(\lambda,T) \). Since the surface is diffuse, \( \varepsilon_{\lambda,\theta} = \varepsilon_{\lambda} \) and noting \( I_{\lambda,b} \) is independent of direction and equal to \( E_{\lambda,b}/\pi \), we can write

\[
\Delta E = \left\{ \int_0^{2\pi} \int_0^{\pi/6} \cos \theta \sin \theta \ d\theta \ d\phi \right\} E_b(T) \int_{0.8}^{1.5} \varepsilon_1 E_{\lambda,b}(\lambda,T) d\lambda / E_b(T) + \int_{1.5}^{2.5} \varepsilon_2 E_{\lambda,b}(\lambda,T) d\lambda / E_b(T)
\]

or in terms \( F(0 \rightarrow \lambda) \) values,

\[
\Delta E = \left\{ \int_0^{2\pi} \int_0^{\sin^2 \theta / 2} \frac{\pi / 6}{2} \right\} \frac{\sigma T^4}{\pi} \left[ \varepsilon_1 \left[ F(0 \rightarrow 1.5) - F(0 \rightarrow 0.8) \right] + \varepsilon_2 \left[ F(0 \rightarrow 2.5) - F(0 \rightarrow 1.5) \right] \right].
\]

From Table 12.1: \( \lambda T = 0.8 \times 2000 = 1600 \mu \)m K \( F(0 \rightarrow 0.8) = 0.0197 \)

\( \lambda T = 2.5 \times 2000 = 5000 \mu \)m K \( F(0 \rightarrow 2.5) = 0.6337 \)

\[
\Delta E = \left\{ 2\pi \times \frac{\sin^2 \theta / 6}{2} \right\} \frac{5.67 \times 10^{-8} \times 2000^4}{\pi} \left[ 0.2 [0.2732 - 0.0197] + 0.8 [0.6337 - 0.2732] \right]
\]

\[
\Delta E = 0.25 \times \left[ 5.67 \times 10^{-8} \times 2000^4 \right] \text{W/m}^2 \times 0.339 = 76.89 \text{ kW/m}^2 .
\]
PROBLEM 12.35

KNOWN: Directional emissivity, $\varepsilon_\theta$, of a selective surface.

FIND: Ratio of the normal emissivity, $\varepsilon_n$, to the hemispherical emissivity, $\varepsilon$.

SCHEMATIC:

ASSUMPTIONS: Surface is isotropic in $\phi$ direction.

ANALYSIS: From Eq. 12.36 written on a total, rather than spectral, basis, the hemispherical emissivity is

$$\varepsilon = 2 \int_0^{\pi/2} \varepsilon_\theta (\theta) \cos \theta \sin \theta \, d\theta.$$ 

Recognizing that the integral can be expressed in two parts, find

$$\varepsilon = 2 \left[ \int_0^{\pi/4} \varepsilon_\theta (\theta) \cos \theta \sin \theta \, d\theta + \int_{\pi/4}^{\pi/2} \varepsilon_\theta (\theta) \cos \theta \sin \theta \, d\theta \right]$$

$$\varepsilon = 2 \left[ 0.8 \int_0^{\pi/4} \cos \theta \sin \theta \, d\theta + 0.3 \int_{\pi/4}^{\pi/2} \cos \theta \sin \theta \, d\theta \right]$$

$$\varepsilon = 2 \left[ 0.8 \frac{\sin^2 \theta}{2} \left|_0^{\pi/4} \right. + 0.3 \frac{\sin^2 \theta}{2} \left|_{\pi/4}^{\pi/2} \right. \right]$$

$$\varepsilon = 2 \left[ 0.8 \frac{1}{2} (0.50 - 0) + 0.3 \times \frac{1}{2} (1 - 0.50) \right] = 0.550.$$ 

The ratio of the normal emissivity ($\varepsilon_n$) to the hemispherical emissivity is

$$\frac{\varepsilon_n}{\varepsilon} = \frac{0.8}{0.550} = 1.45.$$ 

COMMENTS: Note that Eq. 12.36 assumes the directional emissivity is independent of the $\phi$ coordinate. If this is not the case, then Eq. 12.35 is appropriate.
PROBLEM 12.35

KNOWN: Directional emissivity, $\varepsilon_\theta$, of a selective surface.

FIND: Ratio of the normal emissivity, $\varepsilon_n$, to the hemispherical emissivity, $\varepsilon$.

SCHEMATIC:

\[
\begin{array}{c}
\text{0.8} \\
\uparrow \\
\theta \\
- \pi/4 \\
\downarrow \\
\text{0.3} \\
\text{X} \\
\varepsilon_\theta
\end{array}
\]

ASSUMPTIONS: Surface is isotropic in $\phi$ direction.

ANALYSIS: From Eq. 12.36 written on a total, rather than spectral, basis, the hemispherical emissivity is

$$
\varepsilon = 2 \int_0^{\pi/2} \varepsilon_\theta(\theta) \cos \theta \sin \theta \, d\theta.
$$

Recognizing that the integral can be expressed in two parts, find

$$
\varepsilon = 2 \left[ \int_0^{\pi/4} \varepsilon_\theta(\theta) \cos \theta \sin \theta \, d\theta + \int_{\pi/4}^{\pi/2} \varepsilon_\theta(\theta) \cos \theta \sin \theta \, d\theta \right]
$$

$$
\varepsilon = 2 \left[ 0.8 \int_0^{\pi/4} \cos \theta \sin \theta \, d\theta + 0.3 \int_{\pi/4}^{\pi/2} \cos \theta \sin \theta \, d\theta \right]
$$

$$
\varepsilon = 2 \left[ 0.8 \frac{\sin^2 \theta}{2} \bigg|_0^{\pi/4} + 0.3 \frac{\sin^2 \theta}{2} \bigg|_{\pi/4}^{\pi/2} \right]
$$

$$
\varepsilon = 2 \left[ 0.8 \frac{1}{2} (0.50 - 0) + 0.3 \times \frac{1}{2} (1 - 0.50) \right] = 0.550.
$$

The ratio of the normal emissivity ($\varepsilon_n$) to the hemispherical emissivity is

$$
\frac{\varepsilon_n}{\varepsilon} = \frac{0.8}{0.550} = 1.45.
$$

COMMENTS: Note that Eq. 12.36 assumes the directional emissivity is independent of the $\phi$ coordinate. If this is not the case, then Eq. 12.35 is appropriate.
**PROBLEM 12.36**

**KNOWN:** The total directional emissivity of non-metallic materials may be approximated as
\[ \varepsilon_\theta = \varepsilon_n \cos \theta \] where \( \varepsilon_n \) is the total normal emissivity.

**FIND:** Show that for such materials, the total hemispherical emissivity, \( \varepsilon \), is \( 2/3 \) the total normal emissivity.

**SCHEMATIC:**

![Schematic diagram showing \( \varepsilon_\theta \) vs. \( \theta \) for metallic and non-metallic materials with \( \varepsilon_\theta = \varepsilon_n \cos \theta \) for non-metallic behavior and \( \varepsilon_\theta = \varepsilon_n \) for metallic behavior.]

**ANALYSIS:** From Eq. 12.36, written on a total rather than spectral basis, the hemispherical emissivity \( \varepsilon \) can be determined from the directional emissivity \( \varepsilon_\theta \) as
\[
\varepsilon = 2 \int_0^{\pi/2} \varepsilon_\theta \cos \theta \sin \theta \, d\theta
\]

With \( \varepsilon_\theta = \varepsilon_n \cos \theta \), find
\[
\varepsilon = 2 \varepsilon_n \int_0^{\pi/2} \cos^2 \theta \sin \theta \, d\theta
\]
\[
\varepsilon = \left[ -2 \varepsilon_n \frac{\cos^3 \theta}{3} \right]_0^{\pi/2} = 2/3 \varepsilon_n
\]

**COMMENTS:**
1. Refer to Fig. 12.17 illustrating on cartesian coordinates representative directional distributions of the total, directional emissivity for nonmetallic and metallic materials. In the schematic above, we've shown \( \varepsilon_\theta \) vs. \( \theta \) on a polar plot for both types of materials, in comparison with a diffuse surface.

2. See Section 12.4 for discussion on other characteristics of emissivity for materials.
PROBLEM 12.37

KNOWN: Incandescent sphere suspended in air within a darkened room exhibiting these characteristics:

\[
\begin{align*}
\text{initially:} & \quad \text{brighter around the rim} \\
\text{after some time:} & \quad \text{brighter in the center}
\end{align*}
\]

FIND: Plausible explanation for these observations.

ASSUMPTIONS: (1) The sphere is at a uniform surface temperature, \( T_s \).

ANALYSIS: Recognize that in observing the sphere by eye, emission from the central region is in a nearly normal direction. Emission from the rim region, however, has a large angle from the normal to the surface.

Note now the directional behavior, \( \varepsilon_\theta \), for conductors and non-conductors as represented in Fig. 12.17.

Assume that the sphere is fabricated from a metallic material. Then, the rim would appear brighter than the central region. This follows since \( \varepsilon_\theta \) is higher at higher angles of emission.

If the metallic sphere oxidizes with time, then the \( \varepsilon_\theta \) characteristics change. Then \( \varepsilon_\theta \) at small angles of \( \theta \) become larger than at higher angles. This would cause the sphere to appear brighter at the center portion of the sphere.

COMMENTS: Since the emissivity of non-conductors is generally larger than for metallic materials, you would also expect the oxidized sphere to appear brighter for the same surface temperature.
PROBLEM 12.38

KNOWN: Detector surface area. Area and temperature of heated surface. Radiant power measured by the detector for two orientations relative to the heated surface.

FIND: (a) Normal emissivity of heated surface, (b) Whether surface is a diffuse emitter.

SCHEMATIC:

ASSUMPTIONS: (1) Detector intercepts negligible radiation from surroundings, (2) \( A_1 \) and \( A_2 \) are differential surfaces.

ANALYSIS: The radiant power leaving the heated surface and intercepting the detector is

\[
q_{12}(\theta) = I_1(\theta)A_1 \cos \theta \omega_{2-1}
\]

\[
I_1(\theta) = \varepsilon_1(\theta)I_{b,1} = \varepsilon_1(\theta)\sigma T_1^4 / \pi \quad \omega_{2-1} = \frac{A_2 \cos \theta}{(L/\cos \theta)^2}.
\]

Hence,

\[
q_{12}(\theta) = \varepsilon_1(\theta)\frac{\sigma T_1^4}{\pi} A_1 \cos \theta \frac{A_2 \cos \theta}{(L/\cos \theta)^2}
\]

\[
\varepsilon_1(\theta) = \frac{q_{12}(\theta)\pi L^2}{\sigma T_1^4 A_1 A_2 (\cos \theta)^4}
\]

(a) For the normal condition, \( \theta = 0 \), \( \cos \theta = 1 \), and \( \varepsilon_1(\theta) \equiv \varepsilon_{1,n} \) is

\[
\varepsilon_{1,n} = \frac{1.155 \times 10^{-6} \text{ W} \pi}{5.67 \times 10^{-8} \text{ W/} \text{m}^2 \cdot \text{K}^4 (1000 \text{K})^4 5 \times 10^{-6} \text{ m}^2 \times 4 \times 10^{-6} \text{ m}^2}
\]

\[
\varepsilon_{1,n} = 0.80.
\]

(b) For the orientation with \( \theta = 60^\circ \) and \( \cos \theta = 0.5 \), so that \( \varepsilon_1(\theta = 60^\circ) \) is

\[
\varepsilon_1(60^\circ) = \frac{5.415 \times 10^{-8} \text{ W} \pi}{5.67 \times 10^{-8} \text{ W/} \text{m}^2 \cdot \text{K}^4 (1000 \text{K})^4 5 \times 10^{-6} \text{ m}^2 \times 4 \times 10^{-6} \text{ m}^2 (0.5)^4}
\]

\[
\varepsilon_1(60^\circ) = 0.60.
\]

Since \( \varepsilon_{1,n} \neq \varepsilon_1(60^\circ) \), the surface is not a diffuse emitter.

COMMENTS: Even if \( \varepsilon_1(60^\circ) \) were equal to \( \varepsilon_{1,n} \), it could not be concluded there was diffuse emission until results were obtained for a wider range of \( \theta \).
PROBLEM 12.39

KNOWN: Radiation thermometer responding to radiant power within a prescribed spectral interval and calibrated to indicate the temperature of a blackbody.

FIND: (a) Whether radiation thermometer will indicate temperature greater than, less than, or equal to $T_s$ when surface has $\varepsilon < 1$, (b) Expression for $T_s$ in terms of spectral radiance temperature and spectral emissivity, (c) Indicated temperature for prescribed conditions of $T_s$ and $\varepsilon_\lambda$.

SCHEMATIC:

ASSUMPTIONS: (1) Surface is a diffuse emitter, (2) Thermometer responds to radiant flux over interval $d\lambda$, about $\lambda$.

ANALYSIS: (a) The radiant power which reaches the radiation thermometer is

$$q_\lambda = \varepsilon_\lambda I_{\lambda,b} (\lambda, T_s) \cdot A_t \cdot \omega_t$$

where $A_t$ is the area of the surface viewed by the thermometer (referred to as the target) and $\omega_t$ the solid angle through which $A_t$ is viewed. The thermometer responds as if it were viewing a blackbody at $T_{\lambda,b}$, the spectral radiance temperature,

$$q_\lambda = I_{\lambda,b} (\lambda, T_{\lambda,b}) \cdot A_t \cdot \omega_t.$$

By equating the two relations, Eqs. (1) and (2), find

$$I_{\lambda,b} (\lambda, T_{\lambda,b}) = \varepsilon_\lambda I_{\lambda,b} (\lambda, T_s).$$

Since $\varepsilon_\lambda < 1$, it follows that $I_{\lambda,b} (\lambda, T_{\lambda,b}) < I_{\lambda,b} (\lambda, T_s)$ or that $T_{\lambda,b} < T_s$. That is, the thermometer will always indicate a temperature lower than the true or actual temperature for a surface with $\varepsilon < 1$.

(b) Using Wien’s law in Eq. (3), find

$$I_\lambda (\lambda, T) = \frac{1}{\pi} C_1 \lambda^{-5} \exp \left(-\frac{C_2}{\lambda T}\right)$$

$$\frac{1}{\pi} C_1 \lambda^{-5} \exp \left(-\frac{C_2}{\lambda T_s}\right) = \varepsilon_\lambda \cdot \frac{1}{\pi} C_1 \lambda^{-5} \exp \left(-\frac{C_2}{\lambda T}\right).$$

Canceling terms ($C_1 \lambda^{-5} / \pi$), taking natural logs of both sides of the equation and rearranging, the desired expression is

$$\frac{1}{T_s} = \frac{1}{T_\lambda} + \frac{\lambda}{C_2} \ln \varepsilon_\lambda. \quad (4)$$

(c) For $T_s = 1000K$ and $\varepsilon = 0.9$, from Eq. (4), the indicated temperature is

$$\frac{1}{T_\lambda} = \frac{1}{T_s} - \frac{\lambda}{C_2} \ln \varepsilon_\lambda = \frac{1}{1000K} - \frac{0.65 \mu m}{14.388 \mu m \cdot K} \ln (0.9) \quad T_\lambda = 995.3K.$$ 

That is, the thermometer indicates 5K less than the true temperature.
PROBLEM 12.40

KNOWN: Spectral distribution of emission from a blackbody. Uncertainty in measurement of intensity.

FIND: Corresponding uncertainties in using the intensity measurement to determine (a) the surface temperature or (b) the emissivity.

ASSUMPTIONS: Diffuse surface behavior.

ANALYSIS: From Eq. 12.25, the spectral intensity associated with emission may be expressed as

\[ I_{\lambda,e} = \varepsilon_{\lambda} I_{\lambda,b} = \frac{\varepsilon_{\lambda} C_1 / \pi}{\lambda^5 \left[ \exp \left( \frac{C_2}{\lambda T} \right) - 1 \right]} \]

(a) To determine the effect of temperature on intensity, we evaluate the derivative,

\[ \frac{\partial I_{\lambda,e}}{\partial T} = -\frac{(\varepsilon_{\lambda} C_1 / \pi) \lambda^5 \exp \left( \frac{C_2}{\lambda T} \right) \left(-C_2 / \lambda T^2\right)}{\left\{ \lambda^5 \left[ \exp \left( \frac{C_2}{\lambda T} \right) - 1 \right] \right\}^2} \]

\[ \frac{\partial I_{\lambda,e}}{\partial T} = \frac{\left(C_2 / \lambda T^2\right) \exp \left( \frac{C_2}{\lambda T} \right)}{\exp \left( \frac{C_2}{\lambda T} \right) - 1} I_{\lambda,e} \]

Hence,

\[ \frac{dT}{T} = \frac{1 - \exp \left(-\frac{C_2}{\lambda T}\right)}{(C_2 / \lambda T)} \frac{dI_{\lambda,e}}{I_{\lambda,e}} \]

With \( \left(\frac{dI_{\lambda,e}}{I_{\lambda,e}}\right) = 0.1, \ C_2 = 1.439 \times 10^4 \mu m \cdot K \) and \( \lambda = 10 \mu m, \)

\[ \frac{dT}{T} = \left[1 - \exp \left(-1439 K / T\right) \right] \times 0.1 \]

\[ T = 500 K: \frac{dT}{T} = 0.033 \rightarrow 3.3\% \ \text{uncertainty} \]

\[ T = 1000 K: \frac{dT}{T} = 0.053 \rightarrow 5.5\% \ \text{uncertainty} \]

(b) To determine the effect of the emissivity on intensity, we evaluate

\[ \frac{\partial I_{\lambda,e}}{\partial \varepsilon_{\lambda}} = I_{\lambda,b} = \frac{I_{\lambda,e}}{\varepsilon_{\lambda}} \]

Hence,

\[ \frac{d\varepsilon_{\lambda}}{\varepsilon_{\lambda}} = \frac{dI_{\lambda,e}}{I_{\lambda,e}} = 0.10 \rightarrow 10\% \ \text{uncertainty} \]

COMMENTS: The uncertainty in the temperature is less than that of the intensity, but increases with increasing temperature (and wavelength). In the limit as \( C_2 / \lambda T \rightarrow 0, \exp (- C_2 / \lambda T) \rightarrow 1 - C_2 / \lambda T \) and \( dT / T \rightarrow d I_{\lambda,e} / I_{\lambda,e}. \) The uncertainty in temperature then corresponds to that of the intensity measurement. The same is true for the uncertainty in the emissivity, irrespective of the value of T or \( \lambda. \)
PROBLEM 12.41

KNOWN: Temperature, thickness and spectral emissivity of steel strip emerging from a hot roller. Temperature dependence of total, hemispherical emissivity.

FIND: (a) Initial total, hemispherical emissivity, (b) Initial cooling rate, (c) Time to cool to prescribed final temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible conduction (in longitudinal direction), convection and radiation from surroundings, (2) Negligible transverse temperature gradients.

PROPERTIES: Steel (given): \( \rho = 7900 \text{ kg/m}^3 \), \( c = 640 \text{ J/kg}\cdot\text{K} \), \( \varepsilon = 1200\varepsilon_i/T \) (K).

ANALYSIS: (a) The initial total hemispherical emissivity is

\[
\varepsilon_i = \int_0^{\infty} \varepsilon_\lambda \left[ E_\lambda b(1200)/E_b(1200) \right] d\lambda
\]

and integrating by parts using values from Table 12.1, find

\[
\lambda T = 1200 \mu \text{m} \cdot \text{K} \Rightarrow F(0-1 \mu \text{m}) = 0.002; \lambda T = 7200 \mu \text{m} \cdot \text{K} \Rightarrow F(0-6 \mu \text{m}) = 0.819
\]

\[
\varepsilon_i = 0.6 \times 0.002 + 0.4(0.819 - 0.002) + 0.25(1 - 0.819) = 0.373.
\]

(b) From an energy balance on a unit surface area of strip (top and bottom),

\[
-E_{\text{out}} = \frac{dE_{\text{st}}}{dt} = -2\varepsilon \sigma T^4 = d(\rho \delta c T)/dt
\]

\[
\frac{dT}{dt} = \frac{-2\varepsilon_i \sigma T^4}{\rho \delta c} = \frac{-2(0.373)5.67 \times 10^{-8} \text{W/m}^2 \cdot \text{K}^4 (1200 \text{K})^4}{7900 \text{ kg/m}^3 (0.003 \text{ m}) (640 \text{ J/kg} \cdot \text{K})} = -5.78 \text{ K/s}.
\]

(c) From the energy balance,

\[
\frac{dT}{dt} = \frac{-2\varepsilon_i (1200/T) \sigma T^4}{\rho \delta c}, \quad \int T_i \frac{dT}{T^3} = \frac{-2400\varepsilon_i \sigma}{\rho \delta c} \int_0^t dt, \quad t = \frac{\rho \delta c}{4800\varepsilon_i \sigma} \left( \frac{1}{T_f^2} - \frac{1}{T_i^2} \right)
\]

\[
t = \frac{7900 \text{ kg/m}^3 (0.003 \text{ m}) 640 \text{ J/kg} \cdot \text{K}}{4800 \text{ K} \times 0.373 \times 5.67 \times 10^{-8} \text{W/m}^2 \cdot \text{K}^4} \left( \frac{1}{600^2} - \frac{1}{1200^2} \right) \text{K}^{-2} = 311 \text{s}.
\]

COMMENTS: Initially, from Eq. 1.9, \( h = \varepsilon_i \sigma T_i^3 = 36.6 \text{ W/m}^2 \cdot \text{K} \). Assuming a plate width of \( W = 1 \text{m} \), the Rayleigh number may be evaluated from \( Ra_L = g\beta(T_i - T_\infty) (W/2)^3/\nu \alpha \). Assuming \( T_\infty = 300 \text{ K} \) and evaluating properties at \( T_i = 750 \text{ K} \), \( Ra_L = 2.4 \times 10^8 \). From Eq. 9.31, \( Nu_L = 93 \), giving \( \bar{h} = 10 \text{ W/m}^2 \cdot \text{K} \). Hence heat loss by radiation exceeds that associated with free convection. To check the validity of neglecting transverse temperature gradients, compute \( Bi = h(\delta/2)/k \). With \( h = 36.6 \text{ W/m}^2 \cdot \text{K} \) and \( k = 28 \text{ W/m} \cdot \text{K} \), \( Bi = 0.002 << 1 \). Hence the assumption is valid.
**PROBLEM 12.42**

**KNOWN:** Large body of nonluminous gas at 1200 K has emission bands between 2.5 – 3.5 \( \mu m \) and between 5 – 8 \( \mu m \) with effective emissivities of 0.8 and 0.6, respectively.

**FIND:** Emissive power of the gas.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Gas radiates only in specified bands, (2) Emitted radiation is diffuse.

**ANALYSIS:** The emissive power of the gas is

\[
E_g = \varepsilon E_b\left(T_g\right) = \int_0^\infty \varepsilon_\lambda E_{\lambda,b}\left(T_g\right) d\lambda
\]

\[
E_g = \int_{2.5}^{3.5} \varepsilon_{\lambda,1} E_{\lambda,b}\left(T_g\right) d\lambda + \int_{5}^{8} \varepsilon_{\lambda,2} E_{\lambda,b}\left(T_g\right) d\lambda
\]

\[
E_g = \left[\varepsilon_1 F_{(2.5-3.5 \mu m)} + \varepsilon_2 F_{(5-8 \mu m)}\right] \sigma T_g^4.
\]

Using the blackbody function \( F_{(0-\lambda T)} \) from Table 12.1 with \( T_g = 1200 \) K,

<table>
<thead>
<tr>
<th>( \lambda T (\mu m \cdot K) )</th>
<th>2.5 ( \times ) 1200</th>
<th>3.5 ( \times ) 1200</th>
<th>5 ( \times ) 1200</th>
<th>8 ( \times ) 1200</th>
</tr>
</thead>
<tbody>
<tr>
<td>( F_{(0-\lambda T)} )</td>
<td>0.273</td>
<td>0.516</td>
<td>0.738</td>
<td>0.905</td>
</tr>
</tbody>
</table>

so that

\[
F_{(2.5-3.5 \mu m)} = F_{(0-3.5 \mu m)} - F_{(0-2.5 \mu m)} = 0.516 - 0.273 = 0.243
\]

\[
F_{(5-8 \mu m)} = F_{(0-8 \mu m)} - F_{(0-5 \mu m)} = 0.905 - 0.738 = 0.167.
\]

Hence the emissive power is

\[
E_g = [0.8 \times 0.243 + 0.6 \times 0.167] \times 10^{-8} \text{ W} / \text{m}^2 \cdot \text{K}^4 (1200 \text{ K})^4
\]

\[
E_g = 0.295 \times 117,573 \text{ W} / \text{m}^2 = 34,684 \text{ W} / \text{m}^2.
\]

**COMMENTS:** Note that the effective emissivity for the gas is 0.295. This seems surprising since emission occurs only at the discrete bands. Since \( \lambda_{\text{max}} = 2.4 \mu m \), all of the spectral emissive power is at wavelengths beyond the peak of blackbody radiation at 1200 K.
PROBLEM 12.43

KNOWN: An opaque surface with prescribed spectral, hemispherical reflectivity distribution is subjected to a prescribed spectral irradiation.

FIND: (a) The spectral, hemispherical absorptivity, (b) Total irradiation, (c) The absorbed radiant flux, and (d) Total, hemispherical absorptivity.

SCHEMATIC:

ASSUMPTIONS: (1) Surface is opaque.

ANALYSIS: (a) The spectral, hemispherical absorptivity, $\alpha_\lambda$, for an opaque surface is given by Eq. 12.58,

$$\alpha_\lambda = 1 - \rho_\lambda$$

which is shown as a dashed line on the $\rho_\lambda$ distribution axes.

(b) The total irradiation, $G$, follows from Eq. 12.16 which can be integrated by parts,

$$G = \int_{0}^{\infty} G_\lambda d\lambda = \int_{0}^{5 \mu m} G \chi_1 \lambda d\lambda + \int_{5 \mu m}^{10 \mu m} G \chi_2 \lambda d\lambda + \int_{10 \mu m}^{20 \mu m} G \chi_3 \lambda d\lambda$$

$$G = \frac{1}{2} \times 600 \frac{W}{m^2 \cdot \mu m} (5 - 0) \mu m + 600 \frac{W}{m^2 \cdot \mu m} (10 - 5) \mu m + \frac{1}{2} \times 600 \frac{W}{m^2 \cdot \mu m} (20 - 10) \mu m$$

$$G = 7500 \text{ W/m}^2.$$

(c) The absorbed irradiation follows from Eqs. 12.45 and 12.46 with the form

$$G_{abs} = \int_{0}^{\infty} \alpha_\lambda G_\lambda d\lambda = \alpha_1 \int_{0}^{5 \mu m} G_\lambda d\lambda + G_{\lambda_2} \int_{5 \mu m}^{10 \mu m} \alpha_\lambda d\lambda + \alpha_3 \int_{10 \mu m}^{20 \mu m} G_\lambda d\lambda.$$ 

Noting that $\alpha_1 = 1.0$ for $\lambda = 0 \rightarrow 5 \mu m$, $G_{\lambda_2} = 600 \text{ W/m}^2 \cdot \mu m$ for $\lambda = 5 \rightarrow 10 \mu m$ and $\alpha_3 = 0$ for $\lambda > 10 \mu m$, find that

$$G_{abs} = 1.0 \left(0.5 \times 600 \frac{W}{m^2 \cdot \mu m}\right) (5 - 0) \mu m + 600 \frac{W}{m^2 \cdot \mu m} (0.5 \times 0.5) (10 - 5) \mu m + 0$$

$$G_{abs} = 2250 \text{ W/m}^2.$$

(d) The total, hemispherical absorptivity is defined as the fraction of the total irradiation that is absorbed. From Eq. 12.45,

$$\alpha = \frac{G_{abs}}{G} = \frac{2250 \text{ W/m}^2}{7500 \text{ W/m}^2} = 0.30.$$

COMMENTS: Recognize that the total, hemispherical absorptivity, $\alpha = 0.3$, is for the given spectral irradiation. For a different $G_\lambda$, one would then expect a different value for $\alpha$. 

PROBLEM 12.44

KNOWN: Temperature and spectral emissivity of small object suspended in large furnace of prescribed temperature and total emissivity.

FIND: (a) Total surface emissivity and absorptivity, (b) Reflected radiative flux and net radiative flux to surface, (c) Spectral emissive power at $\lambda = 2 \, \mu m$, (d) Wavelength $\lambda_{1/2}$ for which one-half of total emissive power is in spectral region $\lambda \geq \lambda_{1/2}$.

SCHEMATIC:

ASSUMPTIONS: (1) Surface is opaque and diffuse, (2) Walls of furnace are much larger than object.

ANALYSIS: (a) The emissivity of the object may be obtained from Eq. 12.38, which is expressed as

$$\varepsilon(T_s) = \int_0^\infty \varepsilon_\lambda(\lambda) E_{\lambda,b}(\lambda, T_s) d\lambda$$

where, with $\lambda_1 T_s = 400 \, \mu m \cdot K$ and $\lambda_2 T_s = 1200 \, \mu m \cdot K$, $F(0\rightarrow1\mu m) = 0$ and $F(0\rightarrow3\mu m) = 0.002$. Hence,

$$\varepsilon(T_s) = 0.7(0.002) + 0.5(0.998) = 0.500$$

(b) The reflected radiative flux is

$$G_{ref} = \rho G = (1-\alpha) E_b(T_f) = 0.399 \times 5.67 \times 10^{-8} \, W/\text{m}^2\cdotK^4 (2000 \, K)^4 = 3.620 \times 10^5 \, W/\text{m}^2$$

(c) At $\lambda = 2 \, \mu m$, $\lambda T_s = 800 \, K$ and, from Table 12.1, $I_{\lambda,b}(\lambda, T)/\sigma T^5 = 0.991 \times 10^{-7} \, (\mu m \cdot K \cdot sr)^{-1}$. Hence,
PROBLEM 12.44 (Cont.)

\[ I_{\lambda,b} = 0.991 \times 10^{-7} \times 5.67 \times 10^{-8} \frac{W/m^2 \cdot K^4}{\mu m \cdot K \cdot sr} \times (400 K)^5 = 0.0575 \frac{W}{m^2 \cdot \mu m \cdot sr} \]

Hence, with \( E_{\lambda} = \varepsilon_{\lambda} E_{\lambda,b} = \varepsilon_{\lambda} \pi I_{\lambda,b} \),

\[ E_{\lambda} = 0.7 (\pi sr) 0.0575 W/m^2 \cdot \mu m \cdot sr = 0.126 W/m^2 \cdot \mu m \]

(d) From Table 12.1, \( F_{(0-\lambda)} = 0.5 \) corresponds to \( \lambda T_s \approx 4100 \mu m \cdot K \), in which case,

\[ \lambda_{1/2} \approx 4100 \mu m \cdot K/400 K \approx 10.3 \mu m \]

COMMENTS: Because of the significant difference between \( T_f \) and \( T_s \), \( \alpha \neq \varepsilon \). With increasing \( T_s \rightarrow T_f \), \( \varepsilon \) would increase and approach a value of 0.601.
**PROBLEM 12.45**

**KNOWN:** Small flat plate maintained at 400 K coated with white paint having spectral absorptivity distribution (Figure 12.23) approximated as a stairstep function. Enclosure surface maintained at 3000 K with prescribed spectral emissivity distribution.

**FIND:** (a) Total emissivity of the enclosure surface, $\varepsilon_{es}$, and (b) Total emissivity, $\varepsilon$, and absorptivity, $\alpha$, of the surface.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Coated plate with white paint is diffuse and opaque, so that $\alpha_{\lambda} = \varepsilon_{\lambda}$, (2) Plate is small compared to the enclosure surface, and (3) Enclosure surface is isothermal, diffuse and opaque.

**ANALYSIS:** (a) The total emissivity of the enclosure surface at $T_{es} = 3000$ K follows from Eq. 12.38 which can be expressed in terms of the bond emission factor, $F_{0,\lambda T}$, Eq. 12.30,

$$\varepsilon_{es} = \varepsilon_1 F_{0,\lambda T_{es}} + \varepsilon_2 \left[ 1 - F_{0,\lambda T_{es}} \right]$$

where, from Table 12.1, with $\lambda_1 T_{es} = 2 \mu m \times 3000$ K = 6000 $\mu m\cdot K$, $F_{0,\lambda T} = 0.738$. 

(b) The total emissivity of the coated plate at $T = 400$ K can be expressed as

$$\varepsilon = \alpha_1 F_{0,\lambda T_s} + \alpha_2 \left[ F_{0,\lambda T_{es}} - F_{0,\lambda T_s} \right] + \alpha_3 \left[ 1 - F_{0,\lambda T_{es}} \right]$$

$$\varepsilon = 0.75 \times 0 + 0.15 \left[ 0.002134 - 0.000 \right] + 0.96 \left[ 1 - 0.002134 \right] = 0.958$$

where, from Table 12.1, the band emission factors are: for $\lambda_1 T_s = 0.4 \times 400 = 160 \mu m\cdot K$, find $F_{0,\lambda T_s} = 0.000$; for $\lambda_2 T_{es} = 3.0 \times 400 = 1200 \mu m\cdot K$, find $F_{0,\lambda T_{es}} = 0.002134$. The total absorptivity for the irradiation due to the enclosure surface at $T_{es} = 3000$ K is

$$\alpha = \alpha_1 F_{0,\lambda T_{es}} + \alpha_2 \left[ F_{0,\lambda T_{es}} - F_{0,\lambda T_s} \right] + \alpha_3 \left[ 1 - F_{0,\lambda T_{es}} \right]$$

$$\alpha = 0.75 \times 0.002134 + 0.15 \left[ 0.8900 - 0.002134 \right] + 0.96 \left[ 1 - 0.8900 \right] = 0.240$$

where, from Table 12.1, the band emission factors are: for $\lambda_1 T_{es} = 0.4 \times 3000 = 1200 \mu m\cdot K$, find $F_{0,\lambda T_{es}} = 0.002134$; for $\lambda_2 T_{es} = 3.0 \times 3000 = 9000 \mu m\cdot K$, find $F_{0,\lambda T_{es}} = 0.8900$.

**COMMENTS:** (1) In evaluating the total emissivity and absorptivity, remember that $\varepsilon = \varepsilon(\varepsilon_{\lambda}, T_s)$ and $\alpha = \alpha(\alpha_{\lambda}, G_{\lambda})$ where $T_s$ is the temperature of the surface and $G_{\lambda}$ is the spectral irradiation, which if the surroundings are large and isothermal, $G_{\lambda} = E_{b,\lambda}(T_{sur})$. Hence, $\alpha = \alpha(\alpha_{\lambda}, T_{sur})$. For the opaque, diffuse surface, $\alpha_{\lambda} = \varepsilon_{\lambda}$.

(2) Note that the coated plate (white paint) has an absorptivity for the 3000 K-enclosure surface irradiation of $\alpha = 0.240$. You would expect it to be a low value since the coating appears visually “white”.

(3) The emissivity of the coated plate is quite high, $\varepsilon = 0.958$. Would you have expected this of a “white paint”? Most paints are oxide systems (high absorptivity at long wavelengths) with pigmentation (controls the “color” and hence absorptivity in the visible and near infrared regions).
PROBLEM 12.46

KNOWN: Area, temperature, irradiation and spectral absorptivity of a surface.

FIND: Absorbed irradiation, emissive power, radiosity and net radiation transfer from the surface.

SCHEMATIC:

ASSUMPTIONS: (1) Opaque, diffuse surface behavior, (2) Spectral distribution of solar radiation corresponds to emission from a blackbody at 5800 K.

ANALYSIS: The absorptivity to solar irradiation is
\[
\alpha_S = \frac{\int_0^\infty \alpha_\lambda \, G_\lambda \, d\lambda}{G} = \frac{\int_0^\infty \alpha_\lambda \, E_\lambda b \, (5800 \text{ K}) \, d\lambda}{E_b} = \alpha_1 F(0.5 \rightarrow 1 \text{ \mu m}) + \alpha_2 F(2 \rightarrow \infty).
\]

From Table 12.1,
\[
\begin{align*}
\lambda T &= 2900 \text{ \mu m-K:} & F(0 \rightarrow 0.5 \text{ \mu m}) &= 0.250 \\
\lambda T &= 5800 \text{ \mu m-K:} & F(0 \rightarrow 1 \text{ \mu m}) &= 0.720 \\
\lambda T &= 11,600 \text{ \mu m-K:} & F(0 \rightarrow 2 \text{ \mu m}) &= 0.941
\end{align*}
\]

\[
\alpha_S = 0.8(0.720 - 0.250) + 0.9(1 - 0.941) = 0.429.
\]

Hence,
\[
G_{\text{abs}} = \alpha_S G_S = 0.429 \left(1200 \text{ W/m}^2\right) = 515 \text{ W/m}^2.
\]

The emissivity is
\[
\varepsilon = \int_0^\infty \varepsilon_\lambda E_\lambda b \, (400 \text{ K}) \, d\lambda / E_b = \varepsilon_1 F(0.5 \rightarrow 1 \text{ \mu m}) + \varepsilon_2 F(2 \rightarrow \infty).
\]

From Table 12.1,
\[
\begin{align*}
\lambda T &= 200 \text{ \mu m-K:} & F(0 \rightarrow 0.5 \text{ \mu m}) &= 0 \\
\lambda T &= 400 \text{ \mu m-K:} & F(0 \rightarrow 1 \text{ \mu m}) &= 0 \\
\lambda T &= 800 \text{ \mu m-K} & F(0 \rightarrow 2 \text{ \mu m}) &= 0
\end{align*}
\]

Hence, \( \varepsilon = \varepsilon_2 = 0.9, \)
\[
E = \varepsilon_2 T_S^4 = 0.9 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot K^4 (400 \text{ K})^4 = 1306 \text{ W/m}^2.
\]

The radiosity is
\[
J = E + \rho_S G_S = E + (1 - \alpha_S) G_S = [1306 + 0.571 \times 1200] \text{ W/m}^2 = 1991 \text{ W/m}^2.
\]

The net radiation transfer from the surface is
\[
q_{\text{net}} = (E - \alpha_S G_S) A_S = (1306 - 515) \text{ W/m}^2 \times 4 \text{ m}^2 = 3164 \text{ W}.
\]

COMMENTS: Unless 3164 W are supplied to the surface by other means (for example, by convection), the surface temperature will decrease with time.
PROBLEM 12.47

KNOWN: Temperature and spectral emissivity of a receiving surface. Direction and spectral distribution of incident flux. Distance and aperture of surface radiation detector.

FIND: Radiant power received by the detector.

SCHEMATIC:

ASSUMPTIONS: (1) Target surface is diffuse, (2) $A_d/L^2 \ll 1$.

ANALYSIS: The radiant power received by the detector depends on emission and reflection from the target.

$$q_d = \frac{\varepsilon \sigma T_s^4 + \rho G}{\pi} A_s \frac{A_d}{L^2}$$

$$\varepsilon = \int_0^\infty \frac{\varepsilon \lambda E_{\lambda b} (700 \text{ K}) d\lambda}{E_b (700 \text{ K})} = \varepsilon_1 F(3 \rightarrow 10 \mu m) + \varepsilon_2 F(10 \rightarrow \infty).$$

From Table 12.1, $\lambda T = 2100 \mu \text{m-K}$: $F(0 \rightarrow 3 \mu \text{m}) = 0.0838$

$\lambda T = 7000 \mu \text{m-K}$: $F(0 \rightarrow 10 \mu \text{m}) = 0.8081$.

The emissivity can be expected as

$$\varepsilon = 0.5 \left(0.8081 - 0.0838\right) + 0.9 \left(1 - 0.8081\right) = 0.535.$$ 

Also,

$$\rho = \int_0^\infty \frac{\rho \lambda G \varepsilon \lambda d\lambda}{G} = \int_0^\infty (1 - \varepsilon \lambda) \frac{q'' \lambda d\lambda}{q''} = 1 \times F(0 \rightarrow 3 \mu \text{m}) + 0.5 \times F(3 \rightarrow 6 \mu \text{m}) = 1 \times 0.4 + 0.5 \times 0.6 = 0.70.$$ 

Hence, with $G = q'' \cos \theta_i = 866 \text{ W/m}^2$,

$$q_d = \frac{0.535 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot K^4 (700 \text{ K})^4 + 0.7 \times 866 \times 10^{-4} \text{ W/m}^2}{10^{-4} \text{ m}^2 \cdot (1 \text{ m})^2}$$

$$q_d = 2.51 \times 10^{-6} \text{ W}.$$ 

COMMENTS: A total radiation detector cannot discriminate between emitted and reflected radiation from a surface.
PROBLEM 12.48

KNOWN: Small disk positioned at center of an isothermal, hemispherical enclosure with a small aperture.

FIND: Radiant power [\(\mu W\)] leaving the aperture.

SCHEMATIC:

ASSUMPTIONS: (1) Disk is diffuse-gray, (2) Enclosure is isothermal and has area much larger than disk, (3) Aperture area is very small compared to enclosure area, (4) Areas of disk and aperture are small compared to radius squared of the enclosure.

ANALYSIS: The radiant power leaving the aperture is due to radiation leaving the disk and to irradiation on the aperture from the enclosure. That is,

\[
q_{ap} = q_{1\rightarrow 2} + G_2 \cdot A_2.
\]  

(1)

The radiation leaving the disk can be written in terms of the radiosity of the disk. For the diffuse disk,

\[
q_{1\rightarrow 2} = \frac{1}{\pi} J_1 \cdot A_1 \cos \theta_1 \cdot \omega_{2\rightarrow 1}
\]  

(2)

and with \(\varepsilon = \alpha\) for the gray behavior, the radiosity is

\[
J_1 = \varepsilon_1 E_b(T_1) + \rho G_1 = \varepsilon_1 \sigma T_1^4 + (1-\varepsilon_1)\sigma T_3^4
\]  

(3)

where the irradiation \(G_1\) is the emissive power of the black enclosure, \(E_b(T_3); G_1 = G_2 = E_b(T_3)\).

The solid angle \(\omega_{2\rightarrow 1}\) follows from Eq. 12.2,

\[
\omega_{2\rightarrow 1} = \frac{A_2}{R^2}.
\]  

(4)

Combining Eqs. (2), (3) and (4) into Eq. (1) with \(G_2 = \sigma T_3^4\), the radiant power is

\[
q_{ap} = \frac{1}{\pi} \sigma \left[ \varepsilon_1 T_1^4 + (1-\varepsilon_1)T_3^4 \right] A_1 \cos \theta_1 \cdot \frac{A_2}{R^2} + A_2 \sigma T_3^4
\]

\[
q_{ap} = \frac{1}{\pi} \times 5.67 \times 10^{-8} \frac{W}{m^2 \cdot K^4} \left[ 0.7(900K)^4 + (1-0.7)(300K)^4 \right] \frac{\pi}{4} (0.005m)^2 \cos 45^\circ \times
\]

\[
\frac{\pi}{4} \left( \frac{0.002m}{0.100m} \right)^2 + \frac{\pi}{4} \left( \frac{0.002m}{0.002m} \right)^2 \times 5.67 \times 10^{-8} \frac{W}{m^2 \cdot K^4} (300K)^4
\]

\[
q_{ap} = (36.2 + 0.19 +1443) \mu W = 1479 \mu W.
\]

COMMENTS: Note the relative magnitudes of the three radiation components. Also, recognize that the emissivity of the enclosure \(\varepsilon_3\) doesn’t enter into the analysis. Why?
PROBLEM 12.49

KNOWN: Spectral, hemispherical absorptivity of an opaque surface.

FIND: (a) Solar absorptivity, (b) Total, hemispherical emissivity for $T_s = 340K$.

SCHEMATIC:

ASSUMPTIONS: (1) Surface is opaque, (2) $\varepsilon_\lambda = \alpha_\lambda$, (3) Solar spectrum has $G_\lambda = G_{\lambda,S}$ proportional to $E_{\lambda,b}(\lambda, 5800K)$.

ANALYSIS: (a) The solar absorptivity follows from Eq. 12.47.

\[
\alpha_S = \int_0^\infty \alpha_\lambda(\lambda) E_{\lambda,b}(\lambda,5800K) \, d\lambda / \int_0^\infty E_{\lambda,b}(\lambda,5800K) \, d\lambda.
\]

The integral can be written in three parts using $F(0 \rightarrow \lambda)$ terms.

\[
\alpha_S = \alpha_1 F(0 \rightarrow 0.3) + \alpha_2 \left[ F(0 \rightarrow 1.5) - F(0 \rightarrow 0.3) \right] + \alpha_3 \left[ 1 - F(0 \rightarrow 1.5) \right].
\]

From Table 12.1,

\[
\lambda T = 0.3 \times 5800 = 1740 \, \mu m \cdot K \quad F(0 \rightarrow 0.3 \mu m) = 0.0335
\]

\[
\lambda T = 1.5 \times 5800 = 8700 \, \mu m \cdot K \quad F(0 \rightarrow 1.5 \mu m) = 0.8805.
\]

Hence,

\[
\alpha_S = 0 \times 0.0335 + 0.9 \left[ 0.8805 - 0.0335 \right] + 0.1 \left[ 1 - 0.8805 \right] = 0.774.
\]

(b) The total, hemispherical emissivity for the surface at 340K will be

\[
\varepsilon = \int_0^\infty \varepsilon_\lambda(\lambda) E_{\lambda,b}(\lambda,340K) \, d\lambda / E_b(340K).
\]

If $\varepsilon_\lambda = \alpha_\lambda$, then using the $\alpha_\lambda$ distribution above, the integral can be written in terms of $F(0 \rightarrow \lambda)$ values. It is readily recognized that since

\[
F(0 \rightarrow 1.5 \mu m, 340K) = 0.000 \quad \text{at} \quad \lambda T = 1.5 \times 340 = 510 \, \mu m \cdot K
\]

there is negligible spectral emissive power below 1.5 $\mu$m. It follows then that

\[
\varepsilon = \varepsilon_\lambda = \alpha_\lambda = 0.1
\]

COMMENTS: The assumption $\varepsilon_\lambda = \alpha_\lambda$ can be satisfied if this surface were irradiated diffusely or if the surface itself were diffuse. Note that for this surface under the specified conditions of solar irradiation and surface temperature $\alpha_S \neq \varepsilon$. Such a surface is referred to as a spectrally selective surface.
PROBLEM 12.50

KNOWN: Spectral distribution of the absorptivity and irradiation of a surface at 1000 K.

FIND: (a) Total, hemispherical absorptivity, (b) Total, hemispherical emissivity, (c) Net radiant flux to the surface.

SCHEMATIC:

ASSUMPTIONS: (1) $\alpha_{\lambda} = \varepsilon_{\lambda}$.

ANALYSIS: (a) From Eq. 12.46,

$$\alpha = \frac{\int_0^{\infty} \alpha_{\lambda} G_{\lambda} \, d\lambda}{\int_0^{\infty} G_{\lambda} \, d\lambda} = \frac{\int_0^{2 \mu m} \alpha_{\lambda} G_{\lambda} \, d\lambda + \int_0^{4 \mu m} \alpha_{\lambda} G_{\lambda} \, d\lambda + \int_0^{6 \mu m} \alpha_{\lambda} G_{\lambda} \, d\lambda}{\int_0^{2 \mu m} G_{\lambda} \, d\lambda + \int_0^{4 \mu m} G_{\lambda} \, d\lambda + \int_0^{6 \mu m} G_{\lambda} \, d\lambda}$$

$$\alpha = \frac{0 \times \frac{1}{2}(2-0)(5000) + 0.6 \times (4-2)(5000) + 0.6 \times \frac{1}{2}(6-4)(5000)}{1 \times (2-0)(5000) + (4-2)(5000) + 1 \times (6-4)(5000)} = \frac{9000}{20,000} = 0.45.$$  

(b) From Eq. 12.38,

$$\varepsilon = \frac{\int_0^{\infty} \varepsilon_{\lambda} E_{\lambda, b} \, d\lambda}{E_b} = \frac{\int_0^{2 \mu m} \varepsilon_{\lambda} E_{\lambda, b} \, d\lambda + \int_0^{\infty} \varepsilon_{\lambda} E_{\lambda, b} \, d\lambda}{E_b} = \frac{0.6 \int_0^{2 \mu m} E_{\lambda, b} \, d\lambda}{E_b} + 0.6 \int_0^{\infty} E_{\lambda, b} \, d\lambda$$

$$\varepsilon = 0.6 F(2 \mu m \rightarrow \infty) = 0.6 \left[1 - F(0 \rightarrow 2 \mu m) \right].$$

From Table 12.1, with $\lambda T = 2 \mu m \times 1000K = 2000 \mu m \cdot K$, find $F(0 \rightarrow 2 \mu m) = 0.0667$. Hence,

$$\varepsilon = 0.6 \left[1 - 0.0667 \right] = 0.56.$$  

(c) The net radiant heat flux to the surface is

$$q_{\text{rad,net}} = \alpha G - E = \alpha G - \varepsilon \sigma T^4$$

$$q_{\text{rad,net}} = 0.45 \left( 20,000 \text{W/m}^2 \right) - 0.56 \times 5.67 \times 10^{-8} \text{W/m}^2 \cdot \text{K}^4 \times (1000 \text{K})^4$$

$$q_{\text{rad,net}} = \left( 9000 - 31,751 \right) \text{W/m}^2 = -22,751 \text{W/m}^2.$$
PROBLEM 12.51

KNOWN: Spectral distribution of surface absorptivity and irradiation. Surface temperature.

FIND: (a) Total absorptivity, (b) Emissive power, (c) Nature of surface temperature change.

SCHEMATIC:

ASSUMPTIONS: (1) Opaque, diffuse surface behavior, (2) Convection effects are negligible.

ANALYSIS: (a) From Eqs. 12.45 and 12.46, the absorptivity is defined as

$$\alpha = \frac{G_{abs}}{G} = \int_0^\infty \alpha_\lambda \cdot G_\lambda \cdot d\lambda / \int_0^\infty G_\lambda \cdot d\lambda.$$  

The absorbed irradiation is,

$$G_{abs} = 0.4 \left( 5000 \text{W/m}^2 \cdot \mu\text{m} \times 2 \mu\text{m} \right) / 2 + 0.8 \times 5000 \text{W/m}^2 \cdot \mu\text{m} \times (5 - 2) \mu\text{m} + 0 = 14,000 \text{ W/m}^2.$$  

The irradiation is,

$$G = \left( 2 \mu\text{m} \times 5000 \text{ W/m}^2 \cdot \mu\text{m} \right) / 2 + (10 - 2) \mu\text{m} \times 5000 \text{ W/m}^2 \cdot \mu\text{m} = 45,000 \text{ W/m}^2.$$  

Hence, $\alpha = 14,000 \text{ W/m}^2 / 45,000 \text{ W/m}^2 = 0.311.$

(b) From Eq. 12.38, the emissivity is

$$\varepsilon = \int_0^\infty \varepsilon_\lambda \cdot E_{\lambda,b} \cdot d\lambda / E_b = 0.4 \int_0^2 E_{\lambda,b} \cdot d\lambda / E_b + 0.8 \int_2^5 E_{\lambda,b} \cdot d\lambda / E_b.$$  

From Table 12.1, $\lambda T = 2 \mu\text{m} \times 1250\text{K} = 2500\text{K},$ $F_{(0-2)} = 0.162,$ $\lambda T = 5 \mu\text{m} \times 1250\text{K} = 6250\text{K},$ $F_{(0-5)} = 0.757.$  

Hence, $\varepsilon = 0.4 \times 0.162 + 0.8 \times (0.757 - 0.162) = 0.54.$

$$E = \varepsilon E_b = \varepsilon \sigma \cdot T^4 = 0.54 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \cdot (1250\text{K})^4 = 74,751 \text{ W/m}^2.$$  

(c) From an energy balance on the surface, the net heat flux to the surface is

$$q_{net} = \alpha \cdot G - E = (14,000 - 74,751) \text{ W/m}^2 = -60,751 \text{ W/m}^2.$$  

Hence the temperature of the surface is decreasing.

COMMENTS: Note that $\alpha \neq \varepsilon.$ Hence the surface is not gray for the prescribed conditions.
PROBLEM 12.52

FIND: Bulb temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Uniform glass temperature, $T_s$, and uniform irradiation of inner surface, (3) Surface of glass is diffuse, (4) Negligible absorption of radiation by filament due to emission from inner surface of bulb, (5) Net radiation transfer from outer surface of bulb is due to exchange with large surroundings, (6) Bulb temperature is sufficiently low to provide negligible emission at $\lambda < 2\mu m$, (7) Ambient air is quiescent.

PROPERTIES: Table A-4, air (assume $T_f = 323 K$): $\nu = 1.82 \times 10^{-5}$ m$^2$/s, $\alpha = 2.59 \times 10^{-5}$ m$^2$/s, $k = 0.028$ W/m$\cdot$K, $\beta = 0.0031$ K$^{-1}$, Pr = 0.704.

ANALYSIS: From an energy balance on the glass bulb,

$$q_{\text{rad},i} = q_{\text{rad},o} + q_{\text{conv}} = \varepsilon_b \sigma \left(T_s^4 - T_{\text{sur}}^4\right) + \overline{h}(T_s - T_{\infty})$$  \hspace{1cm} (1)

where $\varepsilon_b = \varepsilon_{\lambda > 2\mu m} = \alpha_{\lambda > 2\mu m} = 1$ and $\overline{h}$ is obtained from Eq. (9.35)

$$\overline{Nu_D} = 2 + \frac{0.589 \, Ra_D^{1/4}}{\left[1 + \left(0.469/Pr\right)^{9/16}\right]^{4/9}} = \frac{\overline{h}D}{k}$$  \hspace{1cm} (2)

with $Ra_D = g\beta (T_s - T_{\infty})D^3/\nu\alpha$. Radiation absorption at the inner surface of the bulb may be expressed as

$$q_{\text{rad},i}^* = \alpha G = \alpha \left(P_{\text{elec}} / \pi D^2\right)$$  \hspace{1cm} (3)

where, from Eq. (12.46),

$$\alpha = \alpha_1 \int_0^{0.4} (G_\lambda/G) d\lambda + \alpha_2 \int_{0.4}^{2.0} (G_\lambda/G) d\lambda + \alpha_3 \int_2^{\infty} (G_\lambda/G) d\lambda$$

Continued .....
PROBLEM 12.52 (Cont.)

The irradiation is due to emission from the filament, in which case \((G_\lambda/G) \sim (E_\lambda/E) f = (\epsilon_{f,\lambda}/E_{b})\). Hence,

\[
\alpha = (\alpha_1 / \epsilon_f) \int_0^{0.4} \epsilon_{f,\lambda} (E_{\lambda,b}/E_b) d\lambda + (\alpha_2 / \epsilon_f) \int_{0.4}^{2.0} \epsilon_{f,\lambda} (E_{\lambda,b}/E_b) d\lambda + (\alpha_3 / \epsilon_f) \int_{2}^{\infty} \epsilon_{f,\lambda} (E_{\lambda,b}/E_b) d\lambda \tag{4}
\]

where, from the spectral distribution of Problem 12.25, \(\epsilon_{f,\lambda} \equiv \epsilon_1 = 0.45\) for \(\lambda < 2\mu m\) and \(\epsilon_{f,\lambda} \equiv \epsilon_2 = 0.10\) for \(\lambda > 2\mu m\). From Eq. (12.38)

\[
\epsilon_f = \int_0^\infty \epsilon_{f,\lambda} (E_{\lambda,b}/E_b) d\lambda = \epsilon_1 F_{(0\rightarrow 2\mu m)} + \epsilon_2 (1 - F_{(0\rightarrow 2\mu m)})
\]

With \(\lambda T_f = 2\mu m \times 3000\) K = 6000 \(\mu m \cdot K\), \(F_{(0\rightarrow 2\mu m)} = 0.738\) from Table 12.1. Hence,

\[
\epsilon_f = 0.45 \times 0.738 + 0.1 (1 - 0.738) = 0.358
\]

Equation (4) may now be expressed as

\[
\alpha = (\alpha_1 / \epsilon_f) \epsilon_1 F_{(0\rightarrow 0.4\mu m)} + (\alpha_2 / \epsilon_f) \epsilon_1 (F_{(0\rightarrow 2\mu m)} - F_{(0\rightarrow 0.4\mu m)}) + (\alpha_3 / \epsilon_f) \epsilon_2 (1 - F_{(0\rightarrow 2\mu m)})
\]

where, with \(\lambda T = 0.4\mu m \times 3000\) K = 1200 \(\mu m \cdot K\), \(F_{(0\rightarrow 0.4\mu m)} = 0.0021\). Hence,

\[
\alpha = (1 / 0.358) 0.45 \times 0.0021 + (0.1 / 0.358) 0.45 \times (0.738 - 0.0021) + (1 / 0.358) 0.1 (1 - 0.738) = 0.168
\]

Substituting Eqs. (2) and (3) into Eq. (1), as well as values of \(\epsilon_b = 1\) and \(\alpha = 0.168\), an iterative solution yields

\[
T_s = 348.1\ K
\]

COMMENTS: For the prescribed conditions, \(q^{*}_{\text{rad,i}} = 713\) W/m\(^2\), \(q^{*}_{\text{rad,o}} = 385.5\) W/m\(^2\) and \(q^{*}_{\text{conv}} = 327.5\) W/m\(^2\).
PROBLEM 12.53

KNOWN: Spectral emissivity of an opaque, diffuse surface.

FIND: (a) Total, hemispherical emissivity of the surface when maintained at 1000 K, (b) Total, hemispherical absorptivity when irradiated by large surroundings of emissivity 0.8 and temperature 1500 K, (c) Radiosity when maintained at 1000 K and irradiated as prescribed in part (b), (d) Net radiation flux into surface for conditions of part (c), and (e) Compute and plot each of the parameters of parts (a)-(c) as a function of the surface temperature $T_s$ for the range $750 < T_s \leq 2000$ K.

SCHEMATIC:

ASSUMPTIONS: (1) Surface is opaque, diffuse, and (2) Surroundings are large compared to the surface.

ANALYSIS: (a) When the surface is maintained at 1000 K, the total, hemispherical emissivity is evaluated from Eq. 12.38 written as

$$\varepsilon = \int_0^{\lambda_1} \varepsilon_{\lambda,1} E_{\lambda,b}(T) \, d\lambda/E_b(T) + \int_{\lambda_1}^{\infty} \varepsilon_{\lambda,2} E_{\lambda,b}(T) \, d\lambda/E_b(T)$$

where for $\lambda T = 6 \mu m \times 1000 K = 6000 \mu m \cdot K$, from Table 12.1, find $F_{0-\lambda T} = 0.738$. Hence,

$$\varepsilon = 0.8 \times 0.738 + 0.3(1 - 0.738) = 0.669.$$  

(b) When the surface is irradiated by large surroundings at $T_{\text{sur}} = 1500$ K, $G = E_b(T_{\text{sur}})$.

From Eq. 12.46,

$$\alpha = \int_0^{\lambda} \alpha_{\lambda} G_{\lambda} \, d\lambda/\int_0^{\lambda} G_{\lambda} \, d\lambda = \int_0^{\lambda_1} \varepsilon_{\lambda,1} E_{\lambda,b}(T_{\text{sur}}) \, d\lambda/E_b(T_{\text{sur}})$$

$$\alpha = \varepsilon_{\lambda,1} F(0-\lambda T_{\text{sur}}) + \varepsilon_{\lambda,2}(1 - F(0-\lambda T_{\text{sur}}))$$

where for $\lambda T_{\text{sur}} = 6 \mu m \times 1500 K = 9000 \mu m \cdot K$, from Table 12.1, find $F(0-\lambda T) = 0.890$. Hence,

$$\alpha = 0.8 \times 0.890 + 0.3(1 - 0.890) = 0.745.$$  

Note that $\alpha = \varepsilon_{\lambda}$ for all conditions and the emissivity of the surroundings is irrelevant.

(c) The radiosity for the surface maintained at 1000 K and irradiated as in part (b) is

$$J = \varepsilon E_b(T) + \rho G = \varepsilon E_b(T) + (1 - \alpha)E_b(T_{\text{sur}})$$

$$J = 0.669 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (1000 \text{ K})^4 + (1 - 0.745) 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (1500 \text{ K})^4$$

$$J = (37,932 + 73,196) \text{ W/m}^2 = 111,128 \text{ W/m}^2.$$  

Continued...
(d) The net radiation flux into the surface with $G = \sigma T_{\text{sur}}^4$ is

$$q''_{\text{rad,in}} = \alpha G - \varepsilon E_b(T) = G - J$$

$$q''_{\text{rad,in}} = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K} (1500 \text{ K})^4 - 111,128 \text{ W/m}^2$$

$$q''_{\text{rad,in}} = 175,915 \text{ W/m}^2.$$

(e) The foregoing equations were entered into the IHT workspace along with the IHT Radiation Tool, Band Emission Factor, to evaluate $F_{(0-\lambda T)}$ values and the respective parameters for parts (a)-(d) were computed and are plotted below.

Note that the absorptivity, $\alpha = \alpha(\alpha_\lambda, T_{\text{sur}})$, remains constant as $T_s$ changes since it is a function of $\alpha_\lambda$ (or $\varepsilon_\lambda$) and $T_{\text{sur}}$ only. The emissivity $\varepsilon = \varepsilon(\varepsilon_\lambda, T_s)$ is a function of $T_s$ and increases as $T_s$ increases. Could you have surmised as much by looking at the spectral emissivity distribution? At what condition is $\varepsilon = \alpha$?

The radiosity, $J_1$ increases with increasing $T_s$ since $E_0(T)$ increases markedly with temperature; the reflected irradiation, $(1 - \alpha)E_0(T_{\text{sur}})$ decreases only slightly as $T_s$ increases compared to $E_0(T)$. Since $G$ is independent of $T_s$, it follows that the variation of $q''_{\text{rad,in}}$ will be due to the radiosity change; note the sign difference.

**COMMENTS:** We didn’t use the emissivity of the surroundings ($\varepsilon = 0.8$) to determine the irradiation onto the surface. Why?
**PROBLEM 12.54**

**KNOWN:** Furnace wall temperature and aperture diameter. Distance of detector from aperture and orientation of detector relative to aperture.

**FIND:** (a) Rate at which radiation from the furnace is intercepted by the detector, (b) Effect of aperture window of prescribed spectral transmissivity on the radiation interception rate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Radiation emerging from aperture has characteristics of emission from a blackbody, (2) Cover material is diffuse, (3) Aperture and detector surface may be approximated as infinitesimally small.

**ANALYSIS:** (a) From Eq. 12.5, the heat rate leaving the furnace aperture and intercepted by the detector is

\[ q = I_e A_a \cos \theta_1 \omega_{s-a}. \]

From Eqs. 12.14 and 12.28

\[ I_e = \frac{E_b(T_f)}{\pi} = \frac{\sigma T_f^4}{\pi} = \frac{5.67 \times 10^{-8} (1500)^4}{\pi} = 9.14 \times 10^4 \text{ W/m}^2 \cdot \text{sr}. \]

From Eq. 12.2,

\[ \omega_{s-a} = \frac{A_p}{r^2} = \frac{A_s \cdot \cos \theta_2}{r^2} = \frac{10^{-5} \text{ m}^2 \times \cos 45^\circ}{(1 \text{ m})^2} = 0.707 \times 10^{-5} \text{ sr}. \]

Hence

\[ q = 9.14 \times 10^4 \text{ W/m}^2 \cdot \text{sr} \left( \pi (0.02 \text{ m})^2/4 \right) \cos 30^\circ \times 0.707 \times 10^{-5} \text{ sr} = 1.76 \times 10^{-4} \text{ W}. \]

(b) With the window, the heat rate is

\[ q = \tau (I_e A_a \cos \theta_1 \omega_{s-a}) \]

where \( \tau \) is the transmissivity of the window to radiation emitted by the furnace wall. From Eq. 12.55,

\[ \tau = \frac{\int_0^{\infty} \tau_\lambda G_\lambda \ d\lambda}{\int_0^{\infty} G_\lambda \ d\lambda} = \frac{\int_0^{\infty} \tau_\lambda E_{\lambda,b}(T_f) \ d\lambda}{\int_0^{\infty} E_{\lambda,b} \ d\lambda} = 0.8 \int_0^{\infty} \left( \frac{E_{\lambda,b}}{E_b} \right) \ d\lambda = 0.8 F_0(0 \rightarrow 2 \mu m). \]

With \( \lambda T = 2 \mu m \times 1500K = 3000 \mu m \cdot K \), Table 12.1 gives \( F_0(0 \rightarrow 2 \mu m) = 0.273 \). Hence, with \( \tau = 0.273 \times 0.8 = 0.218 \), find

\[ q = 0.218 \times 1.76 \times 10^{-4} \text{ W} = 0.384 \times 10^{-4} \text{ W}. \]
**PROBLEM 12.55**

**KNOWN:** Thermocouple is irradiated by a blackbody furnace at $1500 \text{ K}$ with $25 \text{ mm}^2$ aperture. Optical fiber of prescribed spectral transmissivity in sight path.

**FIND:** (a) Distance $L$ from the furnace detector should be positioned such that its irradiation is $G = 50 \text{ W/m}^2$ and, (b) Compute and plot irradiation, $G$, vs separation distance $L$ for the range $100 \leq L \leq 400 \text{ mm}$ for blackbody furnace temperatures of $T_f = 1000$, $1500$ and $2000 \text{ K}$.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Furnace aperture emits diffusely, (2) $A_d \ll L^2$.

**ANALYSIS:** (a) The irradiation on the detector due to emission from the furnace which passes through the filter is defined as

$$G_d = \frac{q_f \rightarrow d}{A_d} = \frac{50 \text{ W/m}^2}{L}$$  \hspace{1cm} (1)

where the power leaving the furnace and intercepted at the detector is

$$q_f \rightarrow d = \left[ I_f \cdot A_f \cos \theta_f \cdot \omega_{d-f} \right] \tau_{\text{filter}} = \left[ \frac{\sigma T^4}{\pi} \cdot A_f \cos \theta_f \cdot \frac{A_d}{L^2} \right] \tau_{\text{filter}}.$$  \hspace{1cm} (2)

The transmittance of the filter is

$$\tau_{\text{filter}} = \tau_{\lambda 1} F_0 - \lambda_T + \tau_{\lambda 2} (1 - F_0 - \lambda_T) = 0.4036 + 0.8(1 - 0.4036) = 0.477$$  \hspace{1cm} (3)

where $F_0 - \lambda_T = 0.4036$ with $\lambda_T = 2.4 \times 1500 = 3600 \mu\text{m-K}$ from Table 12.1. Combining Eqs. (1) and (2) and substituting numerical values,

$$G_d = \left( \frac{1}{\pi} \right) 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (1500 \text{K})^4 (25 \times 10^{-6} \text{ m}^2 \times 1)(A_d / L^2) \times 0.477 / A_d = 50 \text{ W/m}^2$$

find

$$L = 147 \text{ mm}.$$  \hspace{1cm} <

(b) Using the foregoing equations in the IHT workspace along with the **IHT Radiation Tool, Band Emission Factor**, $G$ was computed and plotted as a function of $L$ for selected blackbody temperatures.

![Graph of irradiation vs separation distance](image-url)

Continued...
PROBLEM 12.55 (Cont.)

The irradiation decreases with increasing separation distance $x$ as the inverse square of the distance. At any fixed separation distance, the irradiation increases as $T_f$ increases. In what manner will $G$ depend upon $T_f$? Is $G \sim T_f^4$? Why not?

COMMENTS: The IHT workspace used to generate the above plot is shown below.

```plaintext
// Irradiation, Eq (2):
G = qfd / Ad

PROBLEM 12.56

KNOWN: Spectral transmissivity of a plain and tinted glass.

FIND: (a) Solar energy transmitted by each glass, (b) Visible radiant energy transmitted by each with solar irradiation.

SCHEMATIC:

ASSUMPTIONS: (1) Spectral distribution of solar irradiation is proportional to spectral emissive power of a blackbody at 5800K.

ANALYSIS: To compare the energy transmitted by the glasses, it is sufficient to calculate the transmissivity of each glass for the prescribed spectral range when the irradiation distribution is that of the solar spectrum. From Eq. 12.55,

\[
\tau_S = \int_0^\infty \tau_\lambda \cdot G_\lambda,SD\lambda / \int_0^\infty G_\lambda,Sd\lambda = \int_0^\infty \tau_\lambda \cdot E_{\lambda,b}(\lambda,5800K) d\lambda / E_b(5800K).
\]

Recognizing that \( \tau_\lambda \) will be constant for the range \( \lambda_1 \to \lambda_2 \), using Eq. 12.31, find

\[
\tau_S = \tau_\lambda \cdot F(\lambda_1 \to \lambda_2) = \tau_\lambda \left[ F(0 \to \lambda_2) - F(0 \to \lambda_1) \right].
\]

(a) For the two glasses, the solar transmissivity, using Table 12.1 for \( F \), is then

**Plain glass:**
\[
\lambda_2 = 2.5 \text{ \( \mu \)m} \quad \lambda_1 = 0.3 \text{ \( \mu \)m}
\]
\[
\tau_S = 0.9 \left[ 0.966 - 0.033 \right] = 0.839.
\]

**Tinted glass:**
\[
\lambda_2 = 1.5 \text{ \( \mu \)m} \quad \lambda_1 = 0.5 \text{ \( \mu \)m}
\]
\[
\tau_S = 0.9 \left[ 0.886 - 0.250 \right] = 0.568.
\]

(b) The limits of the visible spectrum are \( \lambda_1 = 0.4 \) and \( \lambda_2 = 0.7 \text{ \( \mu \)m} \). For the tinted glass, \( \lambda_1 = 0.5 \text{ \( \mu \)m} \) rather than \( 0.4 \text{ \( \mu \)m} \). From Table 12.1,

**Plain glass:**
\[
\lambda_2 = 0.7 \text{ \( \mu \)m} \quad \lambda_1 = 0.4 \text{ \( \mu \)m}
\]
\[
\tau_{vis} = 0.9 \left[ 0.491 - 0.125 \right] = 0.329
\]

**Tinted glass:**
\[
\tau_{vis} = 0.9 \left[ 0.491 - 0.250 \right] = 0.217
\]

COMMENTS: For solar energy, the transmissivities are 0.839 for the plain glass vs. 0.568 for the plain and tinted glasses. Within the visible region, \( \tau_{vis} \) is 0.329 vs. 0.217. Tinting reduces solar flux by 32% and visible solar flux by 34%.
PROBLEM 12.57

KNOWN: Spectral transmissivity and reflectivity of light bulb coating. Dimensions, temperature and spectral emissivity of a tungsten filament.

FIND: (a) Advantages of the coating, (b) Filament electric power requirement for different coating spectral reflectivities.

SCHEMATIC:

ASSUMPTIONS: (1) All of the radiation reflected from the inner surface of bulb is absorbed by the filament.

ANALYSIS: (a) For $\lambda_c = 0.7 \, \mu m$, the coating has two important advantages: (i) It transmits all of the visible radiation emitted by the filament, thereby maximizing the lighting efficiency. (ii) It returns all of the infrared radiation to the filament, thereby reducing the electric power requirement and conserving energy. (b) The power requirement is simply the amount of radiation transmitted by the bulb, or

$$P_{elec} = A_f E_{(0 \rightarrow \lambda_c)} = \pi \left( DL + D^2 / 2 \right) \int_0^{\lambda_c} \varepsilon_\lambda E_{\lambda.b} d\lambda$$

From the spectral distribution of Problem 12.25, $\varepsilon_\lambda = 0.45$ for both values of $\lambda_c$. Hence,

$$P_{elec} = \left\{ \pi \left[ 0.0008 \times 0.02 + (0.0008)^2 / 2 \right] m^2 \right\} 0.45 E_b \int_0^{\lambda_c} \left( E_{\lambda.b} / E_b \right) d\lambda$$

$$P_{elec} = 5.13 \times 10^{-5} m^2 \times 0.45 \times 5.67 \times 10^{-8} W / m^2 \cdot K^4 (3000 \, K)^4 F_{(0 \rightarrow \lambda_c)}$$

$$P_{elec} = 106 \, W \cdot F_{(0 \rightarrow \lambda_c)}$$

For $\lambda_c = 0.7 \mu m$, $\lambda_c T = 2100 \, \mu m \cdot K$ and from Table 12.1, $F_{(0 \rightarrow \lambda_c)} = 0.0838$. Hence,

$$\lambda_c = 0.7 \mu m : P_{elec} = 106 \, W \times 0.0838 = 8.88 \, W$$

For $\lambda_c = 2 \mu m$, $\lambda_c T = 6000 \, \mu m \cdot K$ and $F_{(0 \rightarrow \lambda_c)} = 0.738$. Hence,

$$\lambda_c = 2.0 \mu m : P_{elec} = 106 \, W \times 0.738 = 78.2 \, W$$

COMMENTS: Clearly, significant energy conservation could be realized with a reflective coating and $\lambda_c = 0.7 \mu m$. Although a coating with the prescribed spectral characteristics is highly idealized and does not exist, there are coatings that may be used to reflect a portion of the infrared radiation from the filament and to thereby provide some energy savings.
PROBLEM 12.58

KNOWN: Spectral transmissivity of low iron glass (see Fig. 12.24).

FIND: Interpretation of the greenhouse effect.

SCHEMATIC:

```
Greenhouse
interior, T=27°C
```

Low-iron glass

ANALYSIS: The glass affects the net radiation transfer to the contents of the greenhouse. Since most of the solar radiation is in the spectral region $\lambda < 3 \, \mu m$, the glass will transmit a large fraction of this radiation. However, the contents of the greenhouse, being at a comparatively low temperature, emit most of their radiation in the medium to far infrared. This radiation is not transmitted by the glass. Hence the glass allows short wavelength solar radiation to enter the greenhouse, but does not permit long wavelength radiation to leave.
**PROBLEM 12.59**

**KNOWN:** Spectrally selective, diffuse surface exposed to solar irradiation.

**FIND:** (a) Spectral transmissivity, \( \tau_\lambda \), (b) Transmissivity, \( \tau_S \), reflectivity, \( \rho_S \), and absorptivity, \( \alpha_S \), for solar irradiation, (c) Emissivity, \( \varepsilon \), when surface is at \( T_s = 350K \), (d) Net heat flux by radiation to the surface.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Surface is diffuse, (2) Spectral distribution of solar irradiation is proportional to \( E_{\lambda,b}(\lambda, 5800K) \).

**ANALYSIS:**

(a) Conservation of radiant energy requires, according to Eq. 12.56, that
\[ \rho_\lambda + \alpha_\lambda + \tau_\lambda = 1 \]
Hence, the spectral transmissivity appears as shown above (dashed line). Note that the surface is opaque for \( \lambda > 1.38 \mu m \).

(b) The transmissivity to solar irradiation, \( G_S \), follows from Eq. 12.55,
\[ \tau_S = \int_0^{1.38} E_{\lambda,b}(\lambda, 5800K) d\lambda / E_b(5800K) = 0.7 \times 8.56 = 0.599 \]
where \( \lambda_1 T_S = 1.38 \times 5800 = 8000 \mu m K \) and from Table 12.1, \( F(0-\lambda_1) = 0.856 \). From Eqs. 12.52 and 12.57,
\[ \rho_S = \int_0^\infty \rho_\lambda G_{\lambda,b}(\lambda) d\lambda / G_S = \rho_{\lambda,1}F(0-\lambda_1) = 0.1 \times 0.856 = 0.086 \]
\[ \alpha_S = 1 - \rho_S - \tau_S = 1 - 0.086 - 0.599 = 0.315 \].

(c) For the surface at \( T_s = 350K \), the emissivity can be determined from Eq. 12.38. Since the surface is diffuse, according to Eq. 12.65, \( \alpha_\lambda = \varepsilon_\lambda \), the expression has the form
\[ \varepsilon = \int_0^\infty \varepsilon_\lambda E_{\lambda,b}(T_s) d\lambda / E_b(T_s) = \int_0^\infty \alpha_\lambda E_{\lambda,b}(350K) d\lambda / E_b(350K) \]
\[ \varepsilon = \alpha_{\lambda,1}F(0-1.38\mu m) + \alpha_{\lambda,2} \left[ 1 - F(0-1.38\mu m) \right] = \alpha_{\lambda,2} = 1 \]
where from Table 12.1 with \( \lambda_1 T_S = 1.38 \times 350 = 483 \mu m K \), \( F(0-\lambda) \approx 0 \).

(d) The net heat flux by radiation to the surface is determined by a radiation balance
\[ q_{rad} = G_S - \rho_S G_S - \tau_S G_S - E \]
\[ q_{rad} = \alpha_S G_S - E \]
\[ q_{rad} = 0.315 \times 750 \ W / m^2 - 1.0 \times 5.67 \times 10^{-8} \ W / m^2 \cdot K^4 \times (350K)^4 = -615 \ W / m^2 \].
PROBLEM 12.60

KNOWN: Large furnace with diffuse, opaque walls \((T_f, \varepsilon_f)\) and a small diffuse, spectrally selective object \((T_o, \tau_\lambda, \rho_\lambda)\).

FIND: For points on the furnace wall and the object, find \(\varepsilon, \alpha, E, G\) and \(J\).

SCHEMATIC:

ASSUMPTIONS: (1) Furnace walls are isothermal, diffuse, and gray, (2) Object is isothermal and diffuse.

ANALYSIS: Consider first the furnace wall (A). Since the wall material is diffuse and gray, it follows that
\[
\varepsilon_A = \varepsilon_f = \alpha_A = 0.85.
\]
The emissive power is
\[
E_A = \varepsilon_A E_b(T_f) = \varepsilon_A \sigma T_f^4 = 0.85 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (300 \text{ K})^4 = 3.904 \times 10^6 \text{ W/m}^2.
\]
Since the furnace is an isothermal enclosure, blackbody conditions exist such that
\[
G_A = J_A = E_b(T_f) = \sigma T_f^4 = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (300 \text{ K})^4 = 4.593 \times 10^6 \text{ W/m}^2.
\]
Considering now the semitransparent, diffuse, spectrally selective object at \(T_o = 300 \text{ K}\). From the radiation balance requirement, find
\[
\alpha_\lambda = 1 - \rho_\lambda - \tau_\lambda \quad \text{or} \quad \alpha_1 = 1 - 0.6 - 0.3 = 0.1 \quad \text{and} \quad \alpha_2 = 1 - 0.7 - 0.0 = 0.3
\]
\[
\alpha_B = \int_0^{\infty} \alpha_\lambda G_\lambda \, d\lambda / G = F_0 - \lambda T \cdot \alpha_1 + (1 - F_0 - \lambda T) \cdot \alpha_2 = 0.970 \times 0.1 + (1 - 0.970) \times 0.3 = 0.106
\]
where \(F_0 - \lambda T = 0.970\) at \(\lambda T = 5 \mu\text{m} \times 300 \text{ K} = 15,000 \mu\text{m} \cdot \text{K}\) since \(G = E_b(T_f)\). Since the object is diffuse, \(\varepsilon_\lambda = \alpha_\lambda\), hence
\[
\varepsilon_B = \int_0^{\infty} \varepsilon_\lambda E_{\lambda,b}(T_o) \, d\lambda / E_{b,o} = F_0 - \lambda T \alpha_1 + (1 - F_0 - \lambda T) \cdot \alpha_2 = 0.0138 \times 0.1 + (1 - 0.0138) \times 0.3 = 0.297
\]
where \(F_0 - \lambda T = 0.0138\) at \(\lambda T = 5 \mu\text{m} \times 300 \text{ K} = 1500 \mu\text{mK}\). The emissive power is
\[
E_B = \varepsilon_B E_{b,B}(T_o) = 0.297 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (300 \text{ K})^4 = 136.5 \text{ W/m}^2.
\]
The irradiation is that due to the large furnace for which blackbody conditions exist,
\[
G_B = G_A = \sigma T_f^4 = 4.593 \times 10^6 \text{ W/m}^2.
\]
The radiosity leaving point B is due to emission and reflected irradiation,
\[
J_B = E_B + \rho_B G_B = 136.5 \text{ W/m}^2 + 0.3 \times 4.593 \times 10^6 \text{ W/m}^2 = 1.378 \times 10^6 \text{ W/m}^2.
\]
If we include transmitted irradiation, \(J_B = E_B + (\rho_B + \tau_B) G_B = E_B + (1 - \alpha_B) G_B = 4.106 \times 10^6 \text{ W/m}^2\).

In the first calculation, note how we set \(\rho_B \approx \rho_\lambda (\lambda < 5 \mu\text{m})\).
PROBLEM 12.61

KNOWN: Spectral characteristics of four diffuse surfaces exposed to solar radiation.

FIND: Surfaces which may be assumed to be gray.

SCHEMATIC:

ASSUMPTIONS: (1) Diffuse surface behavior.

ANALYSIS: A gray surface is one for which $\alpha_\lambda$ and $\varepsilon_\lambda$ are constant over the spectral regions of the irradiation and the surface emission.

For $\lambda = 3 \, \mu m$ and $T = 5800K$, $\lambda T = 17,400 \, \mu m \cdot K$ and from Table 12.1, find $F_{(0 \rightarrow \lambda)} = 0.984$. Hence, 98.4% of the solar radiation is in the spectral region below 3 $\mu m$.

For $\lambda = 6 \, \mu m$ and $T = 300K$, $\lambda T = 1800 \, \mu m \cdot K$ and from Table 12.1, find $F_{(0 \rightarrow \lambda)} = 0.039$. Hence, 96.1% of the surface emission is in the spectral region above 6 $\mu m$.

Hence: Surface A is gray: $\alpha_S \approx \varepsilon = 0.8$

Surface B is not gray: $\alpha_S \approx 0.8, \varepsilon = 0.3$

Surface C is not gray: $\alpha_S \approx 0.3, \varepsilon = 0.7$

Surface D is gray: $\alpha_S \approx \varepsilon = 0.3$. 

<
**PROBLEM 12.62**

**KNOWN:** A gray, but directionally selective, material with \( \alpha(\theta, \phi) = 0.5(1 - \cos\phi) \).

**FIND:** (a) Hemispherical absorptivity when irradiated with collimated solar flux in the direction \((\theta = 45^\circ \text{ and } \phi = 0^\circ)\) and (b) Hemispherical emissivity of the material.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Gray surface behavior.

**ANALYSIS:**

(a) The surface has the directional absorptivity given as

\[
\alpha(\theta, \phi) = \alpha_{\lambda, \phi} = 0.5[1 - \cos\phi].
\]

When irradiated in the direction \(\theta = 45^\circ\) and \(\phi = 0^\circ\), the directional absorptivity for this condition is

\[
\alpha(45^\circ, 0^\circ) = 0.5[1 - \cos(0^\circ)] = 0.
\]

That is, the surface is completely reflecting (or transmitting) for irradiation in this direction.

(b) From Kirchhoff's law,

\[
\alpha_{\theta, \phi} = \varepsilon_{\theta, \phi}
\]

so that

\[
\varepsilon_{\theta, \phi} = \alpha_{\theta, \phi} = 0.5(1 - \cos\phi).
\]

Using Eq. 12.35 find

\[
\varepsilon = \frac{\int_{0}^{2\pi} \int_{0}^{\pi/2} \varepsilon_{\theta, \phi, \lambda} \cos\theta \sin\theta \cos\phi \sin\phi \, d\phi \, d\theta}{\int_{0}^{2\pi} \int_{0}^{\pi/2} \cos\theta \sin\theta \cos\phi \sin\phi \, d\phi}
\]

\[
\varepsilon = \frac{\int_{0}^{2\pi} 0.5(1 - \cos\phi) \, d\phi}{\int_{0}^{2\pi} \, d\phi} = \frac{0.5(\phi - \sin\phi)}{2\pi} \bigg|_{0}^{2\pi} = 0.5.
\]

<
**PROBLEM 12.63**

**KNOWN:** Area and temperature of an opaque surface. Rate of incident radiation, absorbed radiation and heat transfer by convection.

**FIND:** Surface irradiation, emissive power, radiosity, absorptivity, reflectivity and emissivity.

**SCHEMATIC:**

- \( G_A = 1300 \text{ W} \)
- \( E = 300 \text{ W} \)
- \( A_s = 3 \text{ m}^2 \)
- \( T_s = 500 \text{ K} \)
- \( G_{abs} A_s = 1000 \text{ W} \)

**ASSUMPTIONS:** (1) Steady-state, (2) Adiabatic sides and bottom.

**ANALYSIS:** The irradiation, emissive power and radiosity are

\[
G = \frac{1300 \text{ W}}{3 \text{ m}^2} = 433 \text{ W/ m}^2
\]

\[
E = G_{abs} - q_{conv} = (1000 - 300) \text{ W/ m}^2 = 233 \text{ W/ m}^2
\]

\[
J = E + G_{ref} = E + (G - G_{abs}) = \left[ 233 + (433 - 333) \right] \text{ W/ m}^2 = 333 \text{ W/ m}^2
\]

The absorptivity, reflectivity and emissivity are

\[
\alpha = \frac{G_{abs}}{G} = \frac{333 \text{ W/ m}^2}{433 \text{ W/ m}^2} = 0.769
\]

\[
\rho = 1 - \alpha = 0.231
\]

\[
\varepsilon = \frac{E}{E_b} = \frac{E}{\sigma T_s^4} = \frac{233 \text{ W/ m}^2}{5.67 \times 10^{-8} \text{ W/ m}^2 \text{ K}^4 (500 \text{ K})^4} = 0.066
\]

**COMMENTS:** The expression for E follows from a surface energy balance for which the absorbed irradiation is balanced by emission and convection.
PROBLEM 12.64

KNOWN: Isothermal enclosure at a uniform temperature provides a known irradiation on two small surfaces whose absorption rates have been measured.

FIND: (a) Net heat transfer rates and temperatures of the two surfaces, (b) Absorptivity of the surfaces, (c) Emissive power of the surfaces, (d) Emissivity of the surfaces.

SCHEMATIC:

ASSUMPTIONS: (1) Enclosure is at a uniform temperature and large compared to surfaces A and B, (2) Surfaces A and B have been in the enclosure a long time, (3) Irradiation to both surfaces is the same.

ANALYSIS: (a) Since the surfaces A and B have been within the enclosure a long time, thermal equilibrium conditions exist. That is,

\[ q_{A,\text{net}} = q_{B,\text{net}} = 0. \]

Furthermore, the surface temperatures are the same as the enclosure, \( T_{s,A} = T_{s,B} = T_{\text{enc}} \). Since the enclosure is at a uniform temperature, it follows that blackbody radiation exists within the enclosure (see Fig. 12.12) and

\[ T_{\text{enc}} = \left( \frac{G}{\sigma} \right)^{1/4} = \left( \frac{6300 \text{ W/m}^2}{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4} \right)^{1/4} = 577.4 \text{ K}. \]

(b) From Eq. 12.45, the absorptivity is \( \alpha_{G} = \frac{G_{\text{abs}}}{G} \),

\[ \alpha_A = \frac{5600 \text{ W/m}^2}{6300 \text{ W/m}^2} = 0.89 \quad \alpha_B = \frac{630 \text{ W/m}^2}{6300 \text{ W/m}^2} = 0.10. \]

(c) Since the surfaces experience zero net heat transfer, the energy balance is \( G_{\text{abs}} = E \). That is, the absorbed irradiation is equal to the emissive power,

\[ E_A = 5600 \text{ W/m}^2 \quad E_B = 630 \text{ W/m}^2. \]

(d) The emissive power, \( E(T) \), is written as

\[ E = \varepsilon E_b(T) = \varepsilon \sigma T^4 \quad \text{or} \quad \varepsilon = E / \sigma T^4. \]

Since the temperature of the surfaces and the emissive powers are known,

\[ \varepsilon_A = \frac{5600 \text{ W/m}^2}{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (577.4 \text{ K})^4} = 0.89 \quad \varepsilon_B = 0.10. \]

COMMENTS: Note for this equilibrium condition, \( \varepsilon = \alpha \).
**PROBLEM 12.65**

**KNOWN:** Opaque, horizontal plate, well insulated on backside, is subjected to a prescribed irradiation. Also known are the reflected irradiation, emissive power, plate temperature and convection coefficient for known air temperature.

**FIND:** (a) Emissivity, absorptivity and radiosity and (b) Net heat transfer per unit area of the plate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Plate is insulated on backside, (2) Plate is opaque.

**ANALYSIS:**

(a) The total, hemispherical emissivity of the plate according to Eq. 12.37 is
\[
\varepsilon = \frac{E}{E_b(T_s)} = \frac{E}{\sigma T_s^4} = \frac{1200 \text{ W/m}^2}{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (227 + 273)^4 \text{ K}^4} = 0.34.
\]

The total, hemispherical absorptivity is related to the reflectivity by Eq. 12.57 for an opaque surface. That is, \( \alpha = 1 - \rho \). By definition, the reflectivity is the fraction of irradiation reflected, Eq. 12.51, such that
\[
\alpha = \frac{500 \text{ W/m}^2}{1200 \text{ W/m}^2} = 0.20 = 0.80.
\]

The radiosity, \( J \), is defined as the radiant flux leaving the surface by emission and reflection per unit area of the surface (see Section 12.24).
\[
J = \rho G + \varepsilon E_b = \frac{G_{\text{ref}}}{G} + E = 500 \text{ W/m}^2 / (2500 \text{ W/m}^2) = 1 - 0.20 = 0.80.
\]

(b) The net heat transfer is determined from an energy balance,
\[
q_{\text{net}} = q_{\text{in}} - q_{\text{out}} = G - G_{\text{ref}} - E - q_{\text{conv}}
\]
\[
q_{\text{net}} = (2500 - 500 - 1200) \text{ W/m}^2 - 15 \text{ W/m}^2 \cdot (227 - 127) \text{ K} = -700 \text{ W/m}^2.
\]

An alternate approach to the energy balance using the radiosity,
\[
q_{\text{net}}^* = G - J - q_{\text{conv}}
\]
\[
q_{\text{net}}^* = (2500 - 1700 - 1500) \text{ W/m}^2 = -700 \text{ W/m}^2.
\]

**COMMENTS:** (1) Since the net heat rate per unit area is negative, energy must be added to the plate in order to maintain it at \( T_s = 227^\circ \text{C} \). (2) Note that \( \alpha \neq \varepsilon \). Hence, the plate is not a gray body. (3) Note the use of radiosity in performing energy balances. That is, considering only the radiation processes, \( q_{\text{net}}^* = G - J \).
PROBLEM 12.66

KNOWN: Horizontal, opaque surface at steady-state temperature of 77°C is exposed to a convection process; emissive power, irradiation and reflectivity are prescribed.

FIND: (a) Absorptivity of the surface, (b) Net radiation heat transfer rate for the surface; indicate direction, (c) Total heat transfer rate for the surface; indicate direction.

SCHEMATIC:

\[ T_\alpha = 27°C \quad h = 28 W/m^2 \cdot K \quad G = 1380 W/m^2 \quad E = 628 W/m^2 \quad T_s = 77°C, \rho = 0.4 \]

ASSUMPTIONS: (1) Surface is opaque, (2) Effect of surroundings included in the specified irradiation, (3) Steady-state conditions.

ANALYSIS: (a) From the definition of the thermal radiative properties and a radiation balance for an opaque surface on a total wavelength basis, according to Eq. 12.59,

\[ \alpha = 1 - \rho = 1 - 0.4 = 0.6. \]

(b) The net radiation heat transfer rate to the surface follows from a surface energy balance considering only radiation processes. From the schematic,

\[ q^{\text{net, rad}} = (E_{\text{in}}^\sigma - E_{\text{out}}^\sigma)_{\text{rad}} \]

\[ q^{\text{net, rad}} = G - \rho G - E = (1380 - 0.4 \times 1380 - 628) W/m^2 = 200 W/m^2. \]

Since \( q^{\text{net, rad}} \) is positive, the net radiation heat transfer rate is to the surface.

(c) Performing a surface energy balance considering all heat transfer processes, the local heat transfer rate is

\[ q^{\text{tot}} = (E_{\text{in}}^\sigma - E_{\text{out}}^\sigma) \]

\[ q^{\text{tot}} = q^{\text{net, rad}} - q^{\text{conv}} \]

\[ q^{\text{tot}} = 200 W/m^2 - 28 W/m^2 \cdot K (77 - 27) K = -1200 W/m^2. \]

The total heat flux is shown as a negative value indicating the heat flux is from the surface.

COMMENTS: (1) Note that the surface radiation balance could also be expresses as

\[ q^{\text{net, rad}} = G - J \quad \text{or} \quad \alpha G - E. \]

Note the use of radiosity to express the radiation flux leaving the surface.

(2) From knowledge of the surface emissive power and \( T_s \), find the emissivity as

\[ \varepsilon \equiv E/\sigma T_s^4 = 628 W/m^2 / \left( 5.67 \times 10^{-8} W/m^2 \cdot K^4 \right) (77 + 273)^4 K^4 = 0.74. \]

Since \( \varepsilon \neq \alpha \), we know the surface is not gray.
**PROBLEM 12.67**

**KNOWN:** Temperature and spectral characteristics of a diffuse surface at \( T_s = 500 \) K situated in a large enclosure with uniform temperature, \( T_{sur} = 1500 \) K.

**FIND:** (a) Sketch of spectral distribution of \( E_\lambda \) and \( E_{\lambda,b} \) for the surface, (b) Net heat flux to the surface, \( q_{\text{rad,in}}^{\prime\prime} \) (c) Compute and plot \( q_{\text{rad,in}}^{\prime\prime} \) as a function of \( T_s \) for the range \( 500 \leq T_s \leq 1000 \) K; also plot the heat flux for a diffuse, gray surface with total emissivities of 0.4 and 0.8; and (d) Compute and plot \( \varepsilon \) and \( \alpha \) as a function of the surface temperature for the range \( 500 \leq T_s \leq 1000 \) K.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Surface is diffuse, (2) Convective effects are negligible, (3) Surface irradiation corresponds to blackbody emission at 1500 K.

**ANALYSIS:** (a) From Wien’s law, Eq. 12.27, \( \lambda_{\text{max}} T = 2897.6 \) \( \mu \)m·K. Hence, for blackbody emission from the surface at \( T_s = 500 \) K,

\[
\lambda_{\text{max}} = \frac{2897.6 \mu \text{m} \cdot \text{K}}{500 \text{ K}} = 5.80 \mu \text{m}.
\]

(b) From an energy balance on the surface, the net heat flux to the surface is

\[
q_{\text{rad,in}}^{\prime\prime} = \alpha G - E = \alpha E_b (1500 \text{ K}) - \varepsilon E_b (500 \text{ K}).
\]

From Eq. 12.46,

\[
\alpha = 0.4 \int_0^4 \frac{E_{\lambda,b}(1500)}{E_b} d\lambda + 0.8 \int_4^\infty \frac{E_{\lambda,b}(1500)}{E_b} d\lambda = 0.4 F_{(0-4)} - 0.8 [1 - F_{(0-4)}].
\]

From Table 12.1 with \( \lambda T = 4 \mu \text{m} \times 1500 \text{ K} = 6000 \mu \text{m} \cdot \text{K}, F_{(0-4)} = 0.738, find

\[
\alpha = 0.4 \times 0.738 + 0.8 (1 - 0.738) = 0.505.
\]

From Eq. 12.38

\[
\varepsilon = 0.4 \int_0^4 \frac{E_{\lambda,b}(500)}{E_b} d\lambda + 0.8 \int_4^\infty \frac{E_{\lambda,b}(500)}{E_b} d\lambda = 0.4 F_{(0-4)} + 0.8 [1 - F_{(0-4)}].
\]

From Table 12.1 with \( \lambda T = 4 \mu \text{m} \times 500 \text{ K} = 2000 \mu \text{m} \cdot \text{K}, F_{(0-4)} = 0.0667, find

\[
\varepsilon = 0.4 \times 0.0667 + 0.8 (1 - 0.0667) = 0.773.
\]

Hence, the net heat flux to the surface is

\[
q_{\text{rad,in}}^{\prime\prime} = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 [0.505 \times (1500 \text{ K})^4 - 0.773 \times (500 \text{ K})^4] = 1.422 \times 10^5 \text{ W/m}^2.
\]

Continued...
PROBLEM 12.67 (Cont.)

(c) Using the foregoing equations in the IHT workspace along with the *IHT Radiation Tool, Band Emission Factor*, $q_{\text{rad,in}}^{''}$ was computed and plotted as a function of $T_s$.

![Graph showing net radiation heat rate vs. surface temperature]

The net radiation heat rate, $q_{\text{rad,in}}^{''}$ decreases with increasing surface temperature since $E$ increases with $T_s$ and the absorbed irradiation remains constant according to Eq. (1). The heat flux is largest for the gray surface with $\varepsilon = 0.4$ and the smallest for the gray surface with $\varepsilon = 0.8$. As expected, the heat flux for the selective surface is between the limits of the two gray surfaces.

(d) Using the IHT model of part (c), the emissivity and absorptivity of the surface are computed and plotted below.

![Graph showing emissivity and absorptivity vs. surface temperature]

The absorptivity, $\alpha = \alpha(\alpha_\lambda, T_{\text{sur}})$, remains constant as $T_s$ changes since it is a function of $\alpha_\lambda$ (or $\varepsilon_\lambda$) and $T_{\text{sur}}$ only. The emissivity, $\varepsilon = \varepsilon(\varepsilon_\lambda, T_s)$ is a function of $T_s$ and decreases as $T_s$ increases. Could you have surmised as much by looking at the spectral emissivity distribution? Under what condition would you expect $\alpha = \varepsilon$?
PROBLEM 12.68

KNOWN: Opaque, diffuse surface with prescribed spectral reflectivity and at a temperature of 750K is subjected to a prescribed spectral irradiation, \( G_\lambda \).

FIND: (a) Total absorptivity, \( \alpha \), (b) Total emissivity, \( \epsilon \), (c) Net radiative heat flux to the surface.

SCHEMATIC:

ASSUMPTIONS: (1) Opaque and diffuse surface, (2) Backside insulated.

ANALYSIS: (a) The total absorptivity is determined from Eq. 12.46 and 12.56,

\[
\alpha_\lambda = 1 - \rho_\lambda \quad \text{and} \quad \alpha = \int_0^\infty \alpha_\lambda G_\lambda \, d\lambda / G.
\]

Evaluating by separate integrals over various wavelength intervals.

\[
\alpha = \frac{\left(1 - \rho_{\lambda,1}\right) \int_1^3 G_\lambda \, d\lambda + \left(1 - \rho_{\lambda,2}\right) \int_3^6 G_\lambda \, d\lambda + \left(1 - \rho_{\lambda,2}\right) \int_6^8 G_\lambda \, d\lambda}{\int_1^3 G_\lambda \, d\lambda + \int_3^6 G_\lambda \, d\lambda + \int_6^8 G_\lambda \, d\lambda} = \frac{G_{\text{abs}}}{G}
\]

\( G_{\text{abs}} = (1-0.6) \left[ 0.5 \times 500 \text{W/m}^2 \cdot \mu m (3-1) \mu m \right] + (1-0.2) \left[ 500 \text{W/m}^2 \cdot \mu m (6-3) \mu m \right] + (1-0.2) \left[ 0.5 \times 500 \text{W/m}^2 \cdot \mu m (8-6) \mu m \right]
\]

\[
G = 0.5 \times 500 \text{W/m}^2 \cdot \mu m (3-1) \mu m + 500 \text{W/m}^2 \cdot \mu m (6-3) \mu m + 0.5 \times 500 \text{W/m}^2 \cdot \mu m (8-6) \mu m
\]

\[
\alpha = \frac{[200+1200+400] \text{W/m}^2}{[500+1500+500] \text{W/m}^2} = 1800 \text{W/m}^2 / 2500 \text{W/m}^2 = 0.720.
\]

(b) The total emissivity of the surface is determined from Eq. 12.38 and 12.65,

\[
\epsilon_\lambda = \alpha_\lambda \quad \text{and, hence} \quad \epsilon_\lambda = 1 - \rho_\lambda.
\]

The total emissivity can then be expressed as

\[
\epsilon = \int_0^\infty \epsilon_\lambda \, E_{\lambda,b} (\lambda, T_s) \, d\lambda / E_b (T_s) = \int_0^\infty (1 - \rho_\lambda) \, E_{\lambda,b} (\lambda, T_s) \, d\lambda / E_b (T_s)
\]

\[
\epsilon = \left(1 - \rho_{\lambda,1}\right) \int_0^3 E_{\lambda,b} (\lambda, T_s) \, d\lambda / E_b (T_s) + \left(1 - \rho_{\lambda,2}\right) \int_3^6 E_{\lambda,b} (\lambda, T_s) \, d\lambda / E_b (T_s)
\]

\[
\epsilon = \left(1 - \rho_{\lambda,1}\right) F_{(0-3) \mu m} + \left(1 - \rho_{\lambda,2}\right) [1 - F_{(0-3) \mu m}]
\]

\[
\epsilon = (1-0.6) \times 0.111 + (1-0.2)[1-0.111] = 0.756
\]

where Table 12.1 is used to find \( F_{(0-\lambda)} = 0.111 \) for \( \lambda_1 T_s = 3 \times 750 = 2250 \mu mK.\)

(c) The net radiative heat flux to the surface is

\[
q_{\text{rad}} = \alpha G - \epsilon E_b (T_s) = \alpha G - \epsilon \sigma T_s^4
\]

\[
q_{\text{rad}} = 0.720 \times 2500 \text{W/m}^2 - 0.756 \times 5.67 \times 10^{-8} \text{W/m}^2 \cdot K \cdot 750K^4 = -11,763 \text{W/m}^2.
\]
PROBLEM 12.69

KNOWN: Opaque, gray surface at 27°C with prescribed irradiation, reflected flux and convection process.

FIND: Net heat flux from the surface.

SCHEMATIC:

ASSUMPTIONS: (1) Surface is opaque and gray, (2) Surface is diffuse, (3) Effects of surroundings are included in specified irradiation.

ANALYSIS: From an energy balance on the surface, the net heat flux from the surface is

\[
q_{\text{net}} = \dot{E}_{\text{out}} - \dot{E}_{\text{in}}
\]

\[
q_{\text{net}} = q_{\text{conv}} + E + G_{\text{ref}} - G = h(T_s - T_\infty) + \epsilon \sigma T_s^4 + G_{\text{ref}} - G.
\]  \hspace{1cm} (1)

To determine \( \epsilon \), from Eq. 12.59 and Kirchoff’s law for a diffuse-gray surface, Eq. 12.62,

\[
\epsilon \alpha = 1 - \rho = 1 - \left( \frac{G_{\text{ref}}}{G} \right) = 1 - \left( \frac{800}{1000} \right) = 1 - 0.8 = 0.2
\]  \hspace{1cm} (2)

where from Eq. 12.51, \( \rho = G_{\text{ref}}/G \). The net heat flux from the surface, Eq. (1), is

\[
q_{\text{net}} = 15 \text{ W/m}^2 \cdot \text{K} \left( 27 - 17 \right) \text{K} + 0.2 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left( 27 + 273 \right)^4 \text{ K}^4
\]

\[
+ 800 \text{ W/m}^2 - 1000 \text{ W/m}^2
\]

\[
q_{\text{net}} = (150 + 91.9 + 800 - 1000) \text{ W/m}^2 = 42 \text{ W/m}^2.
\]

COMMENTS: (1) For this situation, the radiosity is

\[
J = G_{\text{ref}} + E = (800 + 91.9) \text{ W/m}^2 = 892 \text{ W/m}^2.
\]

The energy balance can be written involving the radiosity (radiation leaving the surface) and the irradiation (radiation to the surface).

\[
q_{\text{net}} = J - G + q_{\text{conv}} = (892 - 1000 + 150) \text{ W/m}^2 = 42 \text{ W/m}^2.
\]

(2) Note the need to assume the surface is diffuse, gray and opaque in order that Eq. (2) is applicable.
PROBLEM 12.70

KNOWN: Diffuse glass at \( T_g = 750 \) K with prescribed spectral radiative properties being heated in a large oven having walls with emissivity of 0.75 and 1800 K.

FIND: (a) Total transmissivity \( r \), total reflectivity \( \rho \), and total emissivity \( \varepsilon \) of the glass; Net radiative heat flux to the glass, (b) \( q_{\text{rad,in}} \); and (c) Compute and plot \( q_{\text{rad,in}} \) as a function of glass temperatures for the range \( 500 \leq T_g \leq 800 \) K for oven wall temperatures of \( T_w = 1500, 1800 \) and 2000 K.

SCHEMATIC:

ASSUMPTIONS: (1) Glass is of uniform temperature, (2) Glass is diffuse, (3) Furnace walls large compared to the glass; \( \varepsilon_w \) plays no role, (4) Negligible convection.

ANALYSIS: (a) From knowledge of the spectral transmittance, \( \tau_\lambda \), and spectral reflectivity, \( \rho_\lambda \), the following radiation properties are evaluated:

Total transmissivity, \( r \): For the irradiation from the furnace walls, \( G_\lambda = E_\lambda (\lambda, T_w) \). Hence

\[
\tau = \int_0^\infty \tau_\lambda E_\lambda(\lambda, T_w) d\lambda / \sigma T_w^4 = \tau_\lambda T F(0-\lambda T) = 0.9 \times 0.25 = 0.225 .
\]

where \( \lambda T = 1.6 \mu m \times 1800 \) K = 2880 \( \mu m \cdot K \approx 2898 \mu m \cdot K \) giving \( F(0-\lambda T) \approx 0.25 \).

Total reflectivity, \( \rho \): With \( G_\lambda = E_{\lambda,b}(\lambda, T_w) \), \( T_w = 1800 \) K, and \( F_{0-\lambda T} = 0.25 \),

\[
\rho = \rho_\lambda T F(0-\lambda T) + \rho_{\lambda 2} \left(1 - F(0-\lambda T)\right) = 0.05 \times 0.25 + 0.5(1 - 0.25) = 0.388
\]

Total absorptivity, \( \alpha \): To perform the energy balance later, we’ll need \( \alpha \). Employ the conservation expression,

\[
\alpha = 1 - \rho - \tau = 1 - 0.388 - 0.225 = 0.387 .
\]

Emissivity, \( \varepsilon \): Based upon surface temperature \( T_g = 750 \) K, for

\[
\lambda T = 1.6 \mu m \times 750 K = 1200 \mu m \cdot K, \quad F_{0-\lambda T} \approx 0.002 .
\]

Hence for \( \lambda > 1.6 \mu m \), \( \varepsilon \approx \varepsilon_\lambda \approx 0.5 \).

(b) Performing an energy balance on the glass, the net radiative heat flux by radiation into the glass is,

Continued...
PROBLEM 12.70 (Cont.)

\[ q_{\text{net}, \text{in}} = E_{\text{in}}' - E_{\text{out}}' \]

\[ q_{\text{net}, \text{in}}' = 2 \left( \alpha G - \varepsilon E_b \left( T_g \right) \right) \]

where \( G = \sigma T_w^4 \)

\[ q_{\text{net}, \text{in}}' = 2 \left[ 0.387\sigma (1800\text{K})^4 - 0.5\sigma (750\text{K})^4 \right] \]

\[ q_{\text{net}, \text{in}}' = 442.8 \text{ kW/m}^2. \]

(b) Using the foregoing equations in the IHT Workspace along with the IHT Radiation Tool, Band Emission Factor, the net radiative heat flux, \( q_{\text{rad}, \text{in}}' \), was computed and plotted as a function of \( T_g \) for selected wall temperatures \( T_w \).

As the glass temperature increases, the rate of emission increases so we’d expect the net radiative heat rate into the glass to decrease. Note that the decrease is not very significant. The effect of increased wall temperature is to increase the irradiation and, hence the absorbed irradiation to the surface and the net radiative flux increase.
PROBLEM 12.71

KNOWN: Temperature, absorptivity, transmissivity, radiosity and convection conditions for a semitransparent plate.

FIND: Plate irradiation and total hemispherical emissivity.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform surface conditions.

ANALYSIS: From an energy balance on the plate

\[ \dot{E}_{in} = \dot{E}_{out} \]

\[ 2G = 2q_{conv} + 2J. \]

Solving for the irradiation and substituting numerical values,

\[ G = 40 \text{ W/m}^2 \cdot \text{K} (350 - 300) \text{ K} + 5000 \text{ W/m}^2 = 7000 \text{ W/m}^2. \] <

From the definition of J,

\[ J = E + \rho G + \tau G = E + (1 - \alpha)G. \]

Solving for the emissivity and substituting numerical values,

\[ \varepsilon = \frac{J - (1 - \alpha)G}{\sigma T^4} = \frac{5000 \text{ W/m}^2 - 0.6(7000 \text{ W/m}^2)}{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (350 \text{ K})^4} = 0.94. \] <

Hence,

\[ \alpha \neq \varepsilon \]

and the surface is not gray for the prescribed conditions.

COMMENTS: The emissivity may also be determined by expressing the plate energy balance as

\[ 2\alpha G = 2q_{conv} + 2E. \]

Hence

\[ \varepsilon \sigma T^4 = \alpha G - h(T - T_\infty) \]

\[ = \frac{0.4(7000 \text{ W/m}^2) - 40 \text{ W/m}^2 \cdot \text{K} (50 \text{ K})}{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (350 \text{ K})^4} = 0.94. \]
PROBLEM 12.72

KNOWN: Material with prescribed radiative properties covering the peep hole of a furnace and exposed to surroundings on the outer surface.

FIND: Steady-state temperature of the cover, \( T_s \); heat loss from furnace.

SCHEMATIC:

ASSUMPTIONS: (1) Cover is isothermal, no gradient, (2) Surroundings of the outer surface are large compared to cover, (3) Cover is insulated from its mount on furnace wall, (4) Negligible convection on interior surface.

PROPERTIES: Cover material (given): For irradiation from the furnace interior: \( \tau_f = 0.8, \rho_f = 0; \) For room temperature emission: \( \tau = 0, \epsilon = 0.8. \)

ANALYSIS: Perform an energy balance identifying the modes of heat transfer,

\[
\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0\quad \alpha_f G_f + \alpha_{\text{sur}} G_{\text{sur}} - 2\epsilon E_b(T_s) - h(T_s - T_\infty) = 0. \tag{1}
\]

Recognize that

\[
G_f = \sigma T_f^4 \quad \quad G_{\text{sur}} = \sigma T_{\text{sur}}^4. \tag{2,3}
\]

From Eq. 12.57, it follows that

\[
\alpha_f = 1 - \tau_f - \rho_f = 1 - 0.8 - 0.0 = 0.2. \tag{4}
\]

Since the irradiation \( G_{\text{sur}} \) will have nearly the same spectral distribution as the emissive power of the cover, \( E_b(T_s) \), and since \( G_{\text{sur}} \) is diffuse irradiation,

\[
\alpha_{\text{sur}} = \epsilon = 0.8. \tag{5}
\]

This reasoning follows from Eqs. 12.65 and 12.66. Substituting Eqs. (2-5) into Eq. (1) and using numerical values,

\[
0.2 \times 5.67 \times 10^{-8} \times (450 + 273)^4 \times \frac{\text{W}}{\text{m}^2} + 0.8 \times 5.67 \times 10^{-8} \times 300^4 \times \frac{\text{W}}{\text{m}^2} - 2 \times 0.8 \times 5.67 \times 10^{-8} \times T_s^4 \times \frac{\text{W}}{\text{m}^2} - 50 \times \frac{\text{W}}{\text{m}^2} \cdot \text{K} \times (T_s - 300) \times \text{K} = 0 <
\]

9.072 \times 10^{-8} T_s^4 + 50 T_s = 18,466 \quad \text{or} \quad T_s = 344\text{K}.

The heat loss from the furnace (see energy balance schematic) is

\[
q_f,\text{loss} = A_s \left[ \alpha_f G_f + \tau_f G_f - \epsilon E_b(T_s) \right] = \frac{\pi D^2}{4} \left[ (\alpha_f + \tau_f) G_f - \epsilon E_b(T_s) \right]
\]

\[
q_f,\text{loss} = \pi \times (0.050\text{m})^2 / 4 \times (0.8 + 0.2) \times (723\text{K})^4
\]

\[
-0.8 \times (344\text{K})^4 \times 5.67 \times 10^{-8} \times \text{W/m}^2 \cdot \text{K}^4 = 29.2\text{ W}. <
\]
**PROBLEM 12.73**

**KNOWN:** Window with prescribed $\tau_\lambda$ and $\rho_\lambda$ mounted on cooled vacuum chamber passing radiation from a solar simulator.

**FIND:** (a) Solar transmissivity of the window material, (b) State-state temperature reached by window with simulator operating, (c) Net radiation heat transfer to chamber.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Diffuse behavior of window material, (3) Chamber and room surroundings large compared to window, (4) Solar simulator flux has spectral distribution of 5800K blackbody, (5) Window insulated from its mount, (6) Window is isothermal at $T_w$.

**ANALYSIS:** (a) Using Eq. 12.55 and recognizing that $G_\lambda S \sim E_{\lambda, b} (\lambda, 5800 K)$,

$$\tau_S = \tau_1 \int_{0.38}^{1.9} \frac{E_{\lambda, b} (\lambda, 5800 K)}{E_b (5800 K)} d\lambda = \tau_1 \left[ F_1 (0\rightarrow 1.9 \mu m) - F_1 (0\rightarrow 0.38 \mu m) \right].$$

From Table 12.1 at $\lambda T = 1.9 \times 5800 = 11,020 \mu m \cdot K$, $F_1 (0\rightarrow \lambda) = 0.932$; at $\lambda T = 0.38 \times 5800 \mu m \cdot K = 2,204 \mu m \cdot K$, $F_1 (0\rightarrow \lambda) = 0.101$; hence

$$\tau_S = 0.90 \times \left[ 0.932 - 0.101 \right] = 0.748.$$  

Recognizing that later we’ll need $\alpha_S$, use Eq. 12.52 to find $\rho_S$

$$\rho_S = \rho_1 F_1 (0\rightarrow 0.38 \mu m) + \rho_2 \left[ F_1 (0\rightarrow 1.9 \mu m) - F_1 (0\rightarrow 0.38 \mu m) \right] + \rho_3 \left[ 1 - F_1 (0\rightarrow 1.9 \mu m) \right]$$

$$\rho_S = 0.15 \times 0.101 + 0.05 \left[ 0.932 - 0.101 \right] + 0.15 \left[ 1 - 0.932 \right] = 0.067$$

$$\alpha_S = 1 - \rho_S - \tau_S = 1 - 0.067 - 0.748 = 0.185.$$  

(b) Perform an energy balance on the window.

$$\alpha_S G_S - q_{w\rightarrow c}^w - q_{w\rightarrow sur}^w - q_{conv}^w = 0$$

$$\alpha_S G_S - \varepsilon \sigma \left( T_{w}^4 - T_{c}^4 \right) - \varepsilon \sigma \left( T_{w}^4 - T_{sur}^4 \right) + h (T_w - T_\infty) = 0.$$  

Recognize that $\rho_\lambda (\lambda > 1.9) = 0.15$ and that $\varepsilon = 1 - 0.15 = 0.85$ since $T_w$ will be near 300K.

Substituting numerical values, find by trial and error,

$$0.185 \times 3000 \text{ W} / \text{m}^2 - 0.85 \times \sigma \left[ 2T_{w}^4 - 298^4 - 77^4 \right] k^4 - 28 \text{ W} / \text{m}^2 \cdot \text{K} (T_w - 298) \text{ K} = 0$$

$$T_w = 302.6 \text{ K} = 29.6^\circ \text{C}.$$  

(c) The net radiation transfer per unit area of the window to the vacuum chamber, excluding the transmitted simulated solar flux is

$$q_{w\rightarrow c}^w = \varepsilon \sigma \left( T_{w}^4 - T_{c}^4 \right) = 0.85 \times 5.67 \times 10^{-8} \text{ W} / \text{m}^2 \cdot \text{K}^4 \left[ 302.6^4 - 77^4 \right] k^4 = 402 \text{ W} / \text{m}^2.$$  

PROBLEM 12.74

KNOWN: Reading and emissivity of a thermocouple (TC) located in a large duct to measure gas stream temperature. Duct wall temperature and emissivity; convection coefficient.

FIND: (a) Gas temperature, \( T_\infty \), (b) Effect of convection coefficient on measurement error.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible heat loss from TC sensing junction to support, (3) Duct wall much larger than TC, (4) TC surface is diffuse-gray.

ANALYSIS: (a) Performing an energy balance on the thermocouple, it follows that

\[
q'_{w-s} - q'_{\text{conv}} = 0
\]

where radiation exchange between the duct wall and the TC is given by Eq. 1.7. Hence,

\[
e_s \sigma (T_W^4 - T_S^4) - h (T_S - T_\infty) = 0
\]

Solving for \( T_\infty \) with \( T_s = 180^\circ \text{C} \),

\[
T_\infty = T_s - \frac{e_s \sigma}{h} (T_W^4 - T_S^4)
\]

\[
T_\infty = (180 + 273) K - \frac{0.6 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4}{125 \text{ W/m}^2 \cdot \text{K}} (450^4 - 180^4)
\]

\[
T_\infty = 453 K - 62.9 K = 390 K = 117^\circ \text{C}.
\]

(b) Using the IHT First Law model for an Isothermal Solid Sphere to solve the foregoing energy balance for \( T_s \), with \( T_\infty = 125^\circ \text{C} \), the measurement error, defined as \( \Delta T = T_s - T_\infty \), was determined and is plotted as a function of \( h \).

The measurement error is enormous (\( \Delta T \approx 270^\circ \text{C} \)) for \( h = 10 \text{ W/m}^2 \cdot \text{K} \), but decreases with increasing \( h \). However, even for \( h = 1000 \text{ W/m}^2 \cdot \text{K} \), the error (\( \Delta T \approx 8^\circ \text{C} \)) is not negligible. Such errors must always be considered when measuring a gas temperature in surroundings whose temperature differs significantly from that of the gas.

PROBLEM 12.74 (Cont.)

COMMENTS: (1) Because the duct wall surface area is much larger than that of the thermocouple, its emissivity is not a factor. (2) For such a situation, a shield about the thermocouple would reduce the influence of the hot duct wall on the indicated TC temperature. A low emissivity thermocouple coating would also help.
KNOWN: Diameter and emissivity of a horizontal thermocouple (TC) sheath located in a large room. Air and wall temperatures.

FIND: (a) Temperature indicated by the TC, (b) Effect of emissivity on measurement error.

SCHEMATIC:

ASSUMPTIONS: (1) Room walls approximate isothermal, large surroundings, (2) Room air is quiescent, (3) TC approximates horizontal cylinder, (4) No conduction losses, (5) TC surface is opaque, diffuse and gray.

PROPERTIES: Table A-4, Air (assume $T_s = 25^\circ C$, $T_f = (T_s + T_\infty)/2 \approx 296$ K, 1 atm):

\[ \nu = 15.53 \times 10^{-6} \text{ m}^2/\text{s}, \ k = 0.026 \text{ W/m} \cdot \text{K}, \ \alpha = 22.0 \times 10^{-6} \text{ m}^2/\text{s}, \ Pr = 0.708, \ \beta = 1/T_f. \]

ANALYSIS: (a) Perform an energy balance on the thermocouple considering convection and radiation processes. On a unit area basis, with $q_{\text{conv}}^* = \overline{h}(T_s - T_\infty)$,

\[ E_{\text{in}} - E_{\text{out}} = 0 \]

\[ \alpha G - \varepsilon E_b(T_s) - \overline{h}(T_s - T_\infty) = 0. \quad (1) \]

Since the surroundings are isothermal and large compared to the thermocouple, $G = E_b(T_{\text{sur}})$. For the gray-diffuse surface, $\alpha = \varepsilon$. Using the Stefan-Boltzman law, $E_b = \sigma T^4$, Eq. (1) becomes

\[ \varepsilon \sigma (T_{\text{sur}}^4 - T_s^4) - \overline{h}(T_s - T_\infty) = 0. \quad (2) \]

Using the Churchill-Chu correlation for a horizontal cylinder, estimate $\overline{h}$ due to free convection.

\[ \overline{Nu_D} = \frac{\overline{h}D}{k} = \left\lfloor \frac{0.60 + \frac{0.387 \text{Ra}_D^{1/6}}{1 + (0.559/\text{Pr})^{9/16}}^{8/27}}{2} \right\rfloor, \quad \text{Ra}_D = \frac{g \beta A T D^3}{\nu \alpha}. \quad (3,4) \]

To evaluate $\text{Ra}_D$ and $\overline{Nu_D}$, assume $T_s = 25^\circ C$, giving

\[ \text{Ra}_D = \frac{9.8 \text{ m/s}^2 (1/296 \text{ K})(25 - 20) \text{ K}(0.004 \text{ m})^3}{15.53 \times 10^{-6} \text{ m}^2/\text{s} \times 22.0 \times 10^{-6} \text{ m}^2/\text{s}} = 31.0 \]

\[ \overline{h} = \frac{0.026 \text{ W/m} \cdot \text{K}}{0.004 \text{ m}} \left\lfloor \frac{0.60 + \frac{0.387(31.0)^{1/6}}{1 + (0.559/0.708)^{9/16}}^{8/27}}{2} \right\rfloor = 8.89 \text{ W/m}^2 \cdot \text{K}. \quad (5) \]

With $\varepsilon = 0.4$, the energy balance, Eq. (2), becomes

\[ 0.4 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 [(30 + 273)^4 - T_s^4] \text{K}^4 - 8.89 \text{ W/m}^2 \cdot \text{K} \cdot [T_s - (20 + 273)] \text{K} = 0 \quad (6) \]

where all temperatures are in kelvin units. By trial-and-error, find

\[ T_s \approx 22.2^\circ C \]

Continued...
(b) The thermocouple measurement error is defined as $\Delta T = T_s - T_\infty$ and is a consequence of radiation exchange with the surroundings. Using the IHT First Law Model for an Isothermal Solid Cylinder with the appropriate Correlations and Properties Toolpads to solve the foregoing energy balance for $T_s$, the measurement error was determined as a function of the emissivity.

The measurement error decreases with decreasing $\varepsilon$, and hence a reduction in net radiation transfer from the surroundings. However, even for $\varepsilon = 0.1$, the error ($\Delta T \approx 1^\circ\text{C}$) is not negligible.
PROBLEM 12.76

KNOWN: Temperature sensor imbedded in a diffuse, gray tube of emissivity 0.8 positioned within a room with walls and ambient air at 30 and 20 °C, respectively. Convection coefficient is 5 W/m² K.

FIND: (a) Temperature of sensor for prescribed conditions, (b) Effect of surface emissivity and using a fan to induce air flow over the tube.

SCHEMATIC:

ASSUMPTIONS: (1) Room walls (surroundings) much larger than tube, (2) Tube is diffuse, gray surface, (3) No losses from tube by conduction, (4) Steady-state conditions, (5) Sensor measures temperature of tube surface.

ANALYSIS: (a) Performing an energy balance on the tube, \( \dot{E}_{in} - \dot{E}_{out} = 0 \). Hence, \( q_{rad}^* - q_{conv}^* = 0 \), or \( \varepsilon t \sigma (T_w^4 - T_t^4) - h(T_t - T_w) = 0 \). With \( h = 5 \text{ W/m}² \text{ K} \) and \( \varepsilon_t = 0.8 \), the energy balance becomes

\[
0.8 \times 5.67 \times 10^{-8} \text{ W/m}² \text{ K}^4 \left( (30 + 273)^4 - T_t^4 \right) K^4 = 5 \text{ W/m}² \text{ K} \left[ T_t - (20 + 273) \right] K
\]

which yields \( T_t = 298 \text{ K} = 25^\circ \text{C} \).

(b) Using the IHT First Law Model, the following results were determined.

The sensor temperature exceeds the air temperature due to radiation absorption, which must be balanced by convection heat transfer. Hence, the excess temperature \( T_t - T_\infty \), may be reduced by increasing \( h \) or by decreasing \( \alpha_t \), which equals \( \varepsilon_t \) for a diffuse-gray surface, and hence the absorbed radiation.

COMMENTS: A fan will increase the air velocity over the sensor and thereby increase the convection heat transfer coefficient. Hence, the sensor will indicate a temperature closer to \( T_\infty \).
**PROBLEM 12.77**

**KNOWN:** Diffuse-gray sphere is placed in large oven with known wall temperature and experiences convection process.

**FIND:** (a) Net heat transfer rate to the sphere when its temperature is 300 K, (b) Steady-state temperature of the sphere, (c) Time required for the sphere, initially at 300 K, to come within 20 K of the steady-state temperature, and (d) Elapsed time of part (c) as a function of the convection coefficient for $10 \leq h \leq 25 \text{ W/m}^2\cdot\text{K}$ for emissivities 0.2, 0.4 and 0.8.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Sphere surface is diffuse-gray, (2) Sphere area is much smaller than the oven wall area, (3) Sphere surface is isothermal.

**PROPERTIES:** Sphere (Given) : $\alpha = 7.25 \times 10^{-5} \text{ m}^2/\text{s}$, $k = 185 \text{ W/m}\cdot\text{K}$.

**ANALYSIS:** (a) From an energy balance on the sphere find

$$q_{\text{net}} = q_{\text{in}} - q_{\text{out}}$$

$$q_{\text{net}} = \alpha G A_s + q_{\text{conv}} - E A_s$$

$$q_{\text{net}} = \alpha \sigma T_0^4 A_s + h A_s (T_{\infty} - T_s) - \varepsilon \sigma T_s^4 A_s. \quad (1)$$

Note that the irradiation to the sphere is the emissive power of a blackbody at the temperature of the oven walls. This follows since the oven walls are isothermal and have a much larger area than the sphere area. Substituting numerical values, noting that $\alpha = \varepsilon$ since the surface is diffuse-gray and that $A_s = \pi D^2$, find

$$q_{\text{net}} = \left[ 0.8 \times 5.67 \times 10^{-8} \text{ W/m}^2\cdot\text{K} \cdot 4 \times (600\text{K})^4 + 15 \text{ W/m}^2\cdot\text{K} \times (400 - 300) \text{ K} - 0.8 \times 5.67 \times 10^{-8} \text{ W/m}^2\cdot\text{K} \times 4 \times (300\text{K})^4 \right] \pi (30 \times 10^{-3} \text{ m})^2$$

$$q_{\text{net}} = [16.6 + 4.2 - 1.0] \text{ W} = 19.8 \text{ W}. \quad (1)$$

(b) For steady-state conditions, $q_{\text{net}}$ in the energy balance of Eq. (1) will be zero,

$$0 = \alpha \sigma T_0^4 A_s + h A_s (T_{\infty} - T_{ss}) - \varepsilon \sigma T_{ss}^4 A_s \quad (2)$$

Substitute numerical values and find the steady-state temperature as

$$T_{ss} = 538.2 \text{ K}$$

Continued...
PROBLEM 12.77 (Cont.)

(c) Using the *IHT Lumped Capacitance Model* considering convection and radiation processes, the temperature-time history of the sphere, initially at $T_s(0) = T_i = 300 \text{ K}$, can be determined. The elapsed time required to reach

$$T_s(t_o) = (538.2 - 20) \text{ K} = 518.2 \text{ K}$$

was found as

$$t_o = 855 \text{s} = 14.3 \text{ min}$$

(d) Using the IHT model of part (c), the elapsed time for the sphere to reach within 20 K of its steady-state temperature, $t_f$, as a function of the convection coefficient for selected emissivities is plotted below.

For a fixed convection coefficient, $t_f$ increases with decreasing $\varepsilon$ since the radiant heat transfer into the sphere decreases with decreasing emissivity. For a given emissivity, the $t_f$ decreases with increasing $h$ since the convection heat rate increases with increasing $h$. However, the effect is much more significant with lower values of emissivity.

**COMMENTS:**
(1) Why is $t_f$ more strongly dependent on $h$ for a lower sphere emissivity? Hint: Compare the relative heat rates by convection and radiation processes.

(2) The steady-state temperature, $T_{ss}$, as a function of the convection coefficient for selected emissivities calculated using (2) is plotted below. Are these results consistent with the above plot of $t_f$ vs $h$?
**PROBLEM 12.78**

**KNOWN:** Thermograph with spectral response in 9 to 12 µm region views a target of area 200mm² with solid angle 0.001 sr in a normal direction.

**FIND:** (a) For a black surface at 60°C, the emissive power in 9 – 12 µm spectral band, (b) Radiant power (W), received by thermograph when viewing black target at 60°C, (c) Radiant power (W) received by thermograph when viewing a gray, diffuse target having ε = 0.7 and considering the surroundings at T_{sur} = 23°C.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Wall is diffuse, (2) Surroundings are black with T_{sur} = 23°C.

**ANALYSIS:**

(a) Emissive power in spectral range 9 to 12 µm for a 60°C black surface is

\[
E_t = E_b \left( 9 - 12 \mu m \right) = E_b \left[ F(0 \rightarrow 12 \mu m) - F(0 - 9 \mu m) \right]
\]

where \( E_b (T_s) = \sigma T_s^4 \). From Table 12.1:

\[
\begin{align*}
\lambda_2 T_s &= 12 \times (60 + 273) \approx 4000 \mu m \ K, & F(0 - 12 \mu m) &= 0.491 \\
\lambda_1 T_s &= 9 \times (60 + 273) \approx 3000 \mu m \ K, & F(0 - 9 \mu m) &= 0.273.
\end{align*}
\]

Hence

\[
E_t = 5.667 \times 10^{-8} \ W/m^2 \cdot K^4 \times (60 + 273)^4 K^4 [0.491 - 0.273] = 144.9 \ W/m^2.
\]

(b) The radiant power, \( q_b \) (W), received by the thermograph from a black target is determined as

\[
q_b = \frac{E_t}{\pi} \cdot A_s \cos \theta \cdot \omega
\]

where \( E_t \) = emissive power in 9 – 12 µm spectral region, part (a) result
\( A_s \) = target area viewed by thermograph, 200mm² \((2 \times 10^{-4} \ m^2)\)
\( \omega \) = solid angle thermograph aperture subtends when viewed from the target, 0.001 sr
\( \theta \) = angle between target area normal and view direction, 0°.

Hence,

\[
q_b = \frac{144.9 \ W/m^2}{\pi \ sr} \times \left( 2 \times 10^{-4} \ m^2 \right) \times \cos 0^\circ \times 0.001 \ sr = 9.23 \mu W.
\]

Continued ….
(c) When the target is a gray, diffuse emitter, $\varepsilon = 0.7$, the thermograph will receive emitted power from the target and reflected irradiation resulting from the surroundings at $T_{\text{sur}} = 23^\circ \text{C}$. Schematically:

The power is expressed as

$$ q = q_e + q_r = \varepsilon q_b + I_r \cdot A_s \cos \theta_1 \cdot \omega \left[ F_{(0 \rightarrow 12 \mu m)} - F_{(0 \rightarrow 9 \mu m)} \right] $$

where

$q_b =$ radiant power from black surface, part (b) result
$F_{(0 - \lambda)} =$ band emission fraction for $T_{\text{sur}} = 23^\circ \text{C}$; using Table 12.1
$\lambda_2 T_{\text{sur}} = 12 \times (23 + 273) = 3552 \ \mu\text{m} \cdot \text{K}$; $F_{(0 - \lambda_2)} = 0.394$
$\lambda_4 T_{\text{sur}} = 9 \times (23 + 273) = 2664 \ \mu\text{m} \cdot \text{K}$; $F_{(0 - \lambda_4)} = 0.197$
$I_r =$ reflected intensity, which because of diffuse nature of surface
$I_r = \rho \frac{G}{\pi} = (1 - \varepsilon) \frac{E_b(T_{\text{sur}})}{\pi}$.

Hence

$$ q = 0.7 \times 9.23 \mu \text{W} + (1 - 0.7) \frac{5.667 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (273 + 23)^4 \text{ K}}{\pi \text{ sr}} \times \left[ 2 \times 10^{-4} \text{ m}^2 \right] \times \cos 0^\circ \times 0.001 \text{ sr} \times [0.394 - 0.197] $$

$$ q = 6.46 \mu \text{W} + 1.64 \mu \text{W} = 8.10 \mu \text{W}. \quad \downarrow $$

COMMENTS: (1) Comparing the results of parts (a) and (b), note that the power to the thermograph is slightly less for the gray surface with $\varepsilon = 0.7$. From part (b) see that the effect of the irradiation is substantial; that is, $1.64/8.10 \approx 20\%$ of the power received by the thermograph is due to reflected irradiation. Ignoring such effects leads to misinterpretation of temperature measurements using thermography.

(2) Many thermography devices have a spectral response in the 3 to 5 $\mu \text{m}$ wavelength region as well as 9 – 12 $\mu \text{m}$.
PROBLEM 12.79

KNOWN: Radiation thermometer (RT) viewing a steel billet being heated in a furnace.

FIND: Temperature of the billet when the RT indicates 1160K.

SCHEMATIC:

ASSUMPTIONS: (1) Billet is diffuse-gray, (2) Billet is small object in large enclosure, (3) Furnace behaves as isothermal, large enclosure, (4) RT is a radiometer sensitive to total (rather than a prescribed spectral band) radiation and is calibrated to correctly indicate the temperature of a black body, (5) RT receives radiant power originating from the target area on the billet.

ANALYSIS: The radiant power reaching the radiation thermometer (RT) is proportional to the radiosity of the billet. For the diffuse-gray billet within the large enclosure (furnace), the radiosity is

\[ J = \varepsilon E_b(T) + \rho G = \varepsilon E_b(T) + (1-\varepsilon)E_b(T_w) \]

\[ J = \varepsilon \sigma T^4 + (1-\varepsilon)\sigma T_w^4 \]  \hspace{1cm} (1)

where \( \alpha = \varepsilon, \ G = E_b(T_w) \) and \( E_b = \sigma T^4 \). When viewing the billet, the RT indicates \( T_a = 1100K \), referred to as the apparent temperature of the billet. That is, the RT indicates the billet is a blackbody at \( T_a \) for which the radiosity will be

\[ E_b(T_a) = J = \sigma T_a^4. \]  \hspace{1cm} (2)

Recognizing that \( J_a = J \), set Eqs. (1) and (2) equal to one another and solve for \( T \), the billet true temperature.

\[ T = \left[ \frac{1}{\varepsilon} \frac{T_a^4}{T_w^4} \frac{1-\varepsilon}{\varepsilon} \right]^{1/4}. \]

Substituting numerical values, find

\[ T = \left[ \frac{1}{0.8} (1160K)^4 - \frac{1-0.8}{0.8} (1500K)^4 \right]^{1/4} = 999K. \]

COMMENTS: (1) The effect of the reflected wall irradiation from the billet is to cause the RT to indicate a temperature higher than the true temperature.

(2) What temperature would the RT indicate when viewing the furnace wall assuming the wall emissivity were 0.85?

(3) What temperature would the RT indicate if the RT were sensitive to spectral radiation at 0.65 \( \mu \)m instead of total radiation? Hint: in Eqs. (1) and (2) replace the emissive power terms with spectral intensity. Answer: 1365K.
PROBLEM 12.80

KNOWN: Irradiation and temperature of a small surface.

FIND: Rate at which radiation is received by a detector due to emission and reflection from the surface.

SCHEMATIC:

ASSUMPTIONS: (1) Opaque, diffuse-gray surface behavior, (2) \( A_s \) and \( A_d \) may be approximated as differential areas.

ANALYSIS: Radiation intercepted by the detector is due to emission and reflection from the surface, and from the definition of the intensity, it may be expressed as

\[
q_{s-d} = I_{e+r} A_s \cos \theta \Delta \omega.
\]

The solid angle intercepted by \( A_d \) with respect to a point on \( A_s \) is

\[
\Delta \omega = \frac{A_d}{r^2} = 10^{-6} \text{ sr}.
\]

Since the surface is diffuse it follows from Eq. 12.24 that

\[
I_{e+r} = \frac{J}{\pi}
\]

where, since the surface is opaque and gray (\( \varepsilon = \alpha = 1 - \rho \)),

\[
J = E + \rho G = \varepsilon E_b + (1 - \varepsilon) G.
\]

Substituting for \( E_b \) from Eq. 12.28

\[
J = \varepsilon \sigma T_s^4 + (1 - \varepsilon) G = 0.7 \times 5.67 \times 10^{-8} \frac{W}{m^2 \cdot K^4} (500 K)^4 + 0.3 \times 1500 \frac{W}{m^2}
\]

or

\[
J = (2481 + 450) W/m^2 = 2931 W/m^2.
\]

Hence

\[
I_{e+r} = \frac{2931 W/m^2}{\pi \text{ sr}} = 933 W/m^2 \cdot \text{sr}
\]

and

\[
q_{s-d} = 933 W/m^2 \cdot \text{sr} \left(10^{-4} m^2 \cdot 0.866 \right) 10^{-6} \text{sr} = 8.08 \times 10^{-8} W.
\]
**PROBLEM 12.81**

**KNOWN:** Small, diffuse, gray block with \( \varepsilon = 0.92 \) at 35°C is located within a large oven whose walls are at 175°C with \( \varepsilon = 0.85 \).

**FIND:** Radiant power reaching detector when viewing (a) a deep hole in the block and (b) an area on the block’s surface.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Block is isothermal, diffuse, gray and small compared to the enclosure, (2) Oven is isothermal enclosure.

**ANALYSIS:** (a) The small, deep hole in the isothermal block approximates a blackbody at \( T_s \). The radiant power to the detector can be determined from Eq. 12.54 written in the form:

\[
q = I_e \cdot A_t \cdot \omega_t = \frac{\sigma T_s^4}{\pi} \cdot A_t \cdot \omega_t
\]

\[
q = \frac{1}{\pi \text{ sr}} \left[ 5.67 \times 10^{-8} \times (35 + 273)^4 \right] \frac{W}{m^2} \times \frac{\pi \left(3 \times 10^{-3}\right)^2}{4} m^2 \times 0.001 \text{ sr} = 1.15 \mu W
\]

where \( A_t = \pi D_t^2 / 4 \). Note that the hole diameter must be greater than 3mm diameter.

(b) When the detector views an area on the surface of the block, the radiant power reaching the detector will be due to emission and reflected irradiation originating from the enclosure walls. In terms of the radiosity, Section 12.24, we can write using Eq. 12.24,

\[
q = I_{e+r} \cdot A_t \cdot \omega_t = \frac{J}{\pi} \cdot A_t \cdot \omega_t.
\]

Since the surface is diffuse and gray, the radiosity can be expressed as

\[
J = \varepsilon \cdot E_b (T_s) + \rho \cdot G = \varepsilon \cdot E_b (T_s) + (1 - \varepsilon) \cdot E_b (T_{\text{sur}})
\]

recognizing that \( \rho = 1 - \varepsilon \) and \( G = E_b (T_{\text{sur}}) \). The radiant power is

\[
q = \frac{1}{\pi} \left[ \varepsilon \cdot E_b (T_s) + (1 - \varepsilon) \cdot E_b (T_{\text{sur}}) \right] \cdot A_t \cdot \omega_t
\]

\[
q = \frac{1}{\pi \text{ sr}} \left[ 0.92 \times 5.67 \times 10^{-8} \times (35 + 273)^4 + (1 - 0.92) \times 5.67 \times 10^{-8} \times (175 + 273)^4 \right] W/m^2 \times \frac{\pi \left(3 \times 10^{-3}\right)^2}{4} m^2 \times 0.001 \text{ sr} = 1.47 \mu W.
\]

**COMMENTS:** The effect of reflected irradiation when \( \varepsilon < 1 \) is important for objects in enclosures. The practical application is one of measuring temperature by radiation from objects within furnaces.
**PROBLEM 12.82**

**KNOWN:** Diffuse, gray opaque disk (1) coaxial with a ring-shaped disk (2), both with prescribed temperatures and emissivities. Cooled detector disk (3), also coaxially positioned at a prescribed location.

**FIND:** Rate at which radiation is incident on the detector due to emission and reflection from A\(_1\).

**SCHEMATIC:**

- A\(_2\), \(T_2 = 1000 \text{ K}\), \(r_i = 500 \text{ mm}\)
- \(D_1 = 10 \text{ mm}\), \(r_1 = 0.3\)
- \(D_3 = 10 \text{ mm}\)
- \(L_A = 1 \text{ m}\)
- \(L_B = 1 \text{ m}\)
- \(\Delta r = 10 \text{ mm}\)

**ASSUMPTIONS:** (1) A\(_1\) is diffuse-gray, (2) A\(_2\) is black, (3) A\(_1\) and A\(_3\) << \(R^2\), the distance of separation, (4) \(\Delta r << r_i\) such that A\(_2\) \approx 2 \pi r_i \Delta r, and (5) Backside of A\(_2\) is insulated.

**ANALYSIS:** The radiant power leaving A\(_1\) intercepted by A\(_3\) is of the form

\[
q_{1\to3} = \left(\frac{J_1}{\pi}\right) A_1 \cos \theta_1 \cdot \omega_{3-1}
\]

where for this configuration of A\(_1\) and A\(_3\),

\[
\theta_1 = 0^\circ, \quad \omega_{3-1} = A_3 \cos \theta_3 / (L_A + L_B)^2
\]

Hence,

\[
q_{1\to3} = \left(\frac{J_1}{\pi}\right) A_1 \cdot A_3 / (L_A + L_B)^2
\]

The irradiation on A\(_1\) due to emission from A\(_2\), \(G_1\), is

\[
G_1 = q_{2\to1} / A_1 = \left(\frac{I_2 \cdot A_2 \cos \theta_2'}{\omega_{1-2}}\right) / A_1
\]

where

\[
\omega_{1-2} = A_1 \cos \theta_1' / R^2
\]

is constant over the surface A\(_2\). From geometry,

\[
\theta_1' = \theta_2' = \tan^{-1}\left[\left(\frac{r_i + \Delta r}{2}\right) / L_A\right] = \tan^{-1}\left[\left(0.500 + 0.005\right) / 1.000\right] = 26.8^\circ
\]

\[
R = L_A / \cos \theta_1' = 1 \text{ m} / \cos 26.8^\circ = 1.12 \text{ m}.
\]

Hence,

\[
G_1 = \left(\frac{\sigma T_2^4}{\pi}\right) A_2 \cos 26.8^\circ \cdot \left[A_1 \cos 26.8^\circ / (1.12 \text{ m})^2\right] / A_1 = 360.2 \text{ W} / \text{m}^2
\]

using A\(_2\) = \(2 \pi r_i \Delta r = 3.142 \times 10^{-2} \text{ m}^2\) and

\[
J_1 = (1 - 0.3) \times 360.2 \text{ W} / \text{m}^2 + 0.3 \times 5.67 \times 10^{-8} \text{ W} / \text{m}^2 \cdot \text{K}^4 \cdot (400 \text{ K})^4 = 687.7 \text{ W} / \text{m}^2.
\]

Hence the radiant power is

\[
q_{1\to3} = \left(687.7 \text{ W} / \text{m}^2 / \pi\right) \left[\pi (0.010 \text{ m})^2 / 4\right]^2 / (1 \text{ m} + 1 \text{ m})^2 = 337.6 \times 10^{-9} \text{ W}.
\]
**PROBLEM 12.83**

**KNOWN:** Area and emissivity of opaque sample in hemispherical enclosure. Area and position of detector which views sample through an aperture. Sample and enclosure temperatures.

**FIND:** (a) Detector irradiation, (b) Spectral distribution and maximum intensities.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Diffuse-gray surfaces, (2) Hemispherical enclosure forms a blackbody cavity about the sample, $A_h >> A_s$, (3) Detector field of view is limited to sample surface.

**ANALYSIS:** (a) The irradiation can be evaluated as $G_d = q_{s-d}/A_d$ and $q_{s-d} = I_{s(e+r)} A_s \omega_{s-d}$. Evaluating parameters: $\omega_{s-d} \approx A_d/L_d^2 = 2 \text{ mm}^2/(300 \text{ mm})^2 = 2.22 \times 10^{-5} \text{ sr}$, find

$$I_{s(e)} = \frac{E_s}{\pi} = \frac{\epsilon_s \sigma T_s^4}{\pi} = \frac{0.1 \left(5.67 \times 10^{-8} \text{ W/m}^2\text{K}^4\right)(400 \text{ K})^4}{\pi \text{ sr}} = 46.2 \text{ W/m}^2\text{sr}$$

$$I_{s(r)} = \frac{\rho_s G_s}{\pi} = \frac{(1-\epsilon_s) \sigma T_h^4}{\pi \text{ sr}} = \frac{0.9 \left(5.67 \times 10^{-8} \text{ W/m}^2\text{K}^4\right)(273 \text{ K})^4}{\pi \text{ sr}} = 90.2 \text{ W/m}^2\text{sr}$$

$$q_{s-d} = (46.2 + 90.2) \text{ W/m}^2\text{sr} \left(5 \times 10^{-6} \text{ m}^2 \times 2.22 \times 10^{-5} \text{ sr}\right) = 1.51 \times 10^{-8} \text{ W}$$

$$G_d = 1.51 \times 10^{-8} \text{ W} / 2 \times 10^{-6} \text{ m}^2 = 7.57 \times 10^{-3} \text{ W/m}^2.$$

(b) Since $\lambda_{\text{max}} T = 2898 \mu\text{mK}$, it follows that $\lambda_{\text{max}(e)} = 2898 \mu\text{mK}/400 \text{K} = 7.25 \mu\text{m}$ and $\lambda_{\text{max}(r)} = 2898 \mu\text{mK}/273 \text{K} = 10.62 \mu\text{m}$.

**COMMENTS:** Although $T_h$ is substantially smaller than $T_s$, the high sample reflectivity renders the reflected component of $J_s$ comparable to the emitted component.
PROBLEM 12.84

KNOWN: Sample at $T_s = 700$ K with ring-shaped cold shield viewed normally by a radiation detector.

FIND: (a) Shield temperature, $T_{sh}$, required so that its emitted radiation is 1% of the total radiant power received by the detector, and (b) Compute and plot $T_{sh}$ as a function of the sample emissivity for the range $0.05 \leq \varepsilon \leq 0.35$ subject to the parametric constraint that the radiation emitted from the cold shield is 0.05, 1 or 1.5% of the total radiation received by the detector.

SCHEMATIC:

ASSUMPTIONS: (1) Sample is diffuse and gray, (2) Cold shield is black, and (3) $A_d, D^2_s, D^2_t << L^2_t$.

ANALYSIS: (a) The radiant power intercepted by the detector from within the target area is
$$q_d = q_{s \rightarrow d} + q_{sh \rightarrow d}$$

The contribution from the sample is
$$q_{s \rightarrow d} = I_{s,e} A_s \cos \theta_s \Delta \omega_{d-s} \quad \theta_s = 0^\circ$$
$$I_{s,e} = \varepsilon_s E_b / \pi = \varepsilon_s \sigma T^4_s / \pi$$
$$\Delta \omega_{d-s} = A_d \cos \theta_d = A_d / L^2_t \quad \theta_d = 0^\circ$$
$$q_{s \rightarrow d} = \varepsilon_s \sigma T^4_s A_s A_d / \pi L^2_t$$ (1)

The contribution from the ring-shaped cold shield is
$$q_{sh \rightarrow d} = I_{sh,e} A_{sh} \cos \theta_{sh} \Delta \omega_{d-sh}$$
$$I_{sh,e} = E_b / \pi = \sigma T^4_{sh} / \pi$$

and, from the geometry of the shield-detector,
$$A_{sh} = \pi / 4 \left(D^2_t - D^2_s \right)$$
$$\cos \theta_{sh} = L_t \sqrt{\left(\frac{D}{2}\right)^2 - \frac{L^2_t}{4}}^{1/2}$$

Continued...
PROBLEM 12.84 (Cont.)

where \( \bar{D} = (D_s + D_t)/2 \)

\[
\Delta \omega_{d-sh} = \frac{A_d \cos \theta_d}{R^2} \quad \cos \theta_d = \cos \theta_{sh}
\]

where \( R = \left[ L_t^2 + \bar{D}^2 \right]^{1/2} \)

\[
q_{sh \rightarrow d} = \frac{\sigma T_{sh}^4 A_{sh}}{\pi} \left[ \frac{L_t}{\left( (D_s + D_t)/4 \right)^2 + L_t^2} \right]^{1/2} \left( \frac{A_d}{((D_s + D_t)/4)^2 + L_t^2} \right)^2
\]

(2)

The requirement that the emitted radiation from the cold shield is 1\% of the total radiation intercepted by the detector is expressed as

\[
\frac{q_{sh-d}}{q_{tot}} = \frac{q_{sh-d}}{q_{sh-d} + q_{s-d}} = 0.01
\]

(3)

By evaluating Eq. (3) using Eqs. (1) and (3), find

\[
T_{sh} = 134 \text{ K}
\]

(b) Using the foregoing equations in the IHT workspace, the required shield temperature for \( q_{sh-d}/q_{tot} = 0.5, 1 \text{ or } 1.5 \% \) was computed and plotted as a function of the sample emissivity.

![Graph showing shield temperature as a function of sample emissivity](image)

As the shield emission-to-total radiant power ratio decreases (from 1.5 to 0.5\%) , the required shield temperature decreases. The required shield temperature increases with increasing sample emissivity for a fixed ratio.
PROBLEM 12.84

KNOWN: Sample at $T_s = 700$ K with ring-shaped cold shield viewed normally by a radiation detector.

FIND: (a) Shield temperature, $T_{sh}$, required so that its emitted radiation is 1% of the total radiant power received by the detector, and (b) Compute and plot $T_{sh}$ as a function of the sample emissivity for the range $0.05 \leq \varepsilon \leq 0.35$ subject to the parametric constraint that the radiation emitted from the cold shield is 0.05, 1 or 1.5% of the total radiation received by the detector.

SCHEMATIC:

ASSUMPTIONS: (1) Sample is diffuse and gray, (2) Cold shield is black, and (3) $A_d, D_{s}^2, D_{t}^2 << L_{t}^2$.

ANALYSIS: (a) The radiant power intercepted by the detector from within the target area is

$q_d = q_{s \rightarrow d} + q_{sh \rightarrow d}$

The contribution from the sample is

$q_{s \rightarrow d} = I_{s,e} A_s \cos \theta_s \Delta \omega_{d-s} \quad \theta_s = 0^\circ$

$I_{s,e} = \varepsilon_s E_b / \pi = \varepsilon_s \sigma T_s^4 / \pi$

$\Delta \omega_{d-s} = \frac{A_d \cos \theta_d}{L_t^2} = \frac{A_d}{L_t^2} \quad \theta_d = 0^\circ$

$q_{s \rightarrow d} = \varepsilon_s \sigma T_s^4 A_s A_d / \pi L_t^2 \quad (1)$

The contribution from the ring-shaped cold shield is

$q_{sh \rightarrow d} = I_{sh,e} A_{sh} \cos \theta_{sh} \Delta \omega_{d-sh}$

$I_{sh,e} = E_b / \pi = \sigma T_{sh}^4 / \pi$

and, from the geometry of the shield -detector,

$A_{sh} = \frac{\pi}{4} \left( D_t^2 - D_s^2 \right)$

$\cos \theta_{sh} = L_t \sqrt{ \left( \frac{D}{2} \right)^2 - L_t^2 }^{1/2}$

Continued...
PROBLEM 12.84 (Cont.)

where \( D = (D_s + D_t)/2 \)

\[
\Delta \omega_{d-sh} = \frac{A_d \cos \theta_d}{R^2} \cos \theta_d = \cos \theta_{sh}

\frac{q_{sh-d}}{q_{tot}} = 0.01
\]

By evaluating Eq. (3) using Eqs. (1) and (3), find

\[
T_{sh} = 134 \text{ K}
\]

(b) Using the foregoing equations in the IHT workspace, the required shield temperature for \( q_{sh-d}/q_{tot} = 0.5, 1 \) or 1.5% was computed and plotted as a function of the sample emissivity.

![Graph showing shield temperature vs. sample emissivity](image)

As the shield emission-to-total radiant power ratio decreases (from 1.5 to 0.5%), the required shield temperature decreases. The required shield temperature increases with increasing sample emissivity for a fixed ratio.
KNOWN: Infrared scanner (radiometer) with a 3- to 5-micrometer spectral bandpass views a metal plate maintained at $T_s = 327^\circ C$ having four diffuse, gray coatings of different emissivities. Surroundings at $T_{\text{sur}} = 87^\circ C$.

FIND: (a) Expression for the scanner output signal, $S_o$, in terms of the responsivity, $R$ ($\mu V \cdot m^2/W$), the black coating ($\varepsilon_o = 1$) emissive power and appropriate band emission fractions; assuming $R = 1 \mu V \cdot m^2/W$, evaluate $S_o(V)$; (b) Expression for the output signal, $S_c$, in terms of the responsivity $R$, the blackbody emissive power of the coating, the blackbody emissive power of the surroundings, the coating emissivity, $\varepsilon_c$, and appropriate band emission fractions; (c) Scanner signals, $S_c$ ($\mu V$), when viewing with emissivities of 0.8, 0.5 and 0.2 assuming $R = 1 \mu V \cdot m^2/W$; and (d) Apparent temperatures which the scanner will indicate based upon the signals found in part (c) for each of the three coatings.

SCHEMATIC:

ASSUMPTIONS: (1) Plate has uniform temperature, (2) Surroundings are isothermal and large compared to the plate, and (3) Coatings are diffuse and gray so that $\varepsilon = \alpha$ and $\rho = 1 - \varepsilon$.

ANALYSIS: (a) When viewing the black coating ($\varepsilon_o = 1$), the scanner output signal can be expressed as

$$S_o = R F(\lambda_1 - \lambda_2, T_s) E_b(T_s)$$

(1)

where $R$ is the responsivity ($\mu V \cdot m^2/W$), $E_b(T_s)$ is the blackbody emissive power at $T_s$, and $F(\lambda_1 - \lambda_2, T_s)$ is the fraction of the spectral band between $\lambda_1$ and $\lambda_2$ in the spectrum for a blackbody at $T_s$,

$$F(\lambda_1 - \lambda_2, T_s) = F(0 - \lambda_2, T_s) - F(0 - \lambda_1, T_s)$$

(2)

where the band fractions Eq. 12.38 are evaluated using Table 12.1 with $\lambda_1 T_s = 3 \mu m \ (327 + 273)K = 1800 \mu m \cdot K$ and $\lambda_2 T_s = 5 \mu m \ (327 + 273) = 3000 \mu m \cdot K$. Substituting numerical values with $R = 1 \mu V \cdot m^2/W$, find

$$S_o = 1 \mu V \cdot m^2/W \left[0.2732 - 0.0393\right] 5.67 \times 10^{-8} W/m^2 \cdot K^4 (600K)^4$$

$$S_o = 1718 \mu V$$

(b) When viewing one of the coatings ($\varepsilon_c < \varepsilon_o = 1$), the scanner output signal as illustrated in the schematic above will be affected by the emission and reflected irradiation from the surroundings,

$$S_c = R \left\{ F(\lambda_1 - \lambda_2, T_s) \varepsilon_c E_b(T_s) + F(\lambda_1 - \lambda_2, T_{\text{sur}}) \rho_c G_c \right\}$$

(3)

where the reflected irradiation parameters are Continued...
PROBLEM 12.85 (Cont.)

\[ \rho_c = 1 - \varepsilon_c \quad G_c = \sigma T_{\text{sur}}^4 \] (4,5)

and the related band fractions are

\[ F(\lambda_1 - \lambda_2, T_{\text{sur}}) - F(0 - \lambda_1, T_{\text{sur}}) \]

(6)

Combining Eqs. (2-6) above, the scanner output signal when viewing a coating is

\[ S_c = R \left[ \left( F(0 - \lambda_2 T_s) - F(0 - \lambda_1 T_s) \right) \varepsilon_c \sigma T_s^4 + \left( F(0 - \lambda_2 T_{\text{sur}}) - F(0 - \lambda_1 T_{\text{sur}}) \right) \right] \left( 1 - \varepsilon_c \right) \sigma T_{\text{sur}}^4 \] (7)

(c) Substituting numerical values into Eq. (7), find

\[ S_c = 1 \mu V \cdot m^2/W \left\{ [0.2732 - 0.0393] \varepsilon_c \sigma (600K)^4 + [0.0393 - 0.0010] \left( 1 - \varepsilon_c \right) \sigma (360K)^4 \right\} \]

where for \( \lambda_2 T_{\text{sur}} = 5 \mu m \times 360 K = 1800 \mu m \cdot K, F(0 - \lambda_1 T_{\text{sur}}) = 0.0393 \) and \( \lambda_1 T_{\text{sur}} = 3 \mu m \times 360 K = 1080 \mu m \cdot K, \]

(8)

(d) The scanner calibrated against a black surface (\( \varepsilon_1 = 1 \)) interprets the radiation reaching the detector by emission and reflected radiation from a coating target (\( \varepsilon_c < \varepsilon_o \)) as that from a blackbody at an apparent temperature \( T_a \). That is,

\[ S_c = R F(\lambda_1 - \lambda_2, T_a) E_b (T_a) = R \left[ F(0 - \lambda_2 T_a) - F(0 - \lambda_1 T_a) \right] \sigma T_a^4 \]

For each of the coatings in part (c), solving Eq. (8) using the IHT workspace with the Radiation Tool, Band Emission Factor, the following results were obtained,

\[ \begin{array}{cccc}
\varepsilon_c & S_c (\mu V) & T_a (K) & T_a - T_s (K) \\
0.8 & 1382 & 579.3 & -20.7 \\
0.5 & 878 & 539.2 & -60.8 \\
0.2 & 373 & 476.7 & -123.3 \\
\end{array} \]

COMMENTS: (1) From part (c) results for \( S_c \), note that the contribution of the reflected irradiation becomes relatively more significant with lower values of \( \varepsilon_c \).

(2) From part (d) results for the apparent temperature, note that the error, \( (T - T_a) \), becomes larger with decreasing \( \varepsilon_c \). By rewriting Eq. (8) to include the emissivity of the coating,

\[ S'_c = R \left[ F(0 - \lambda_2 T_a) - F(0 - \lambda_1 T_a) \right] \varepsilon_c \sigma T_a^4 \]

The apparent temperature \( T'_a \) will be influenced only by the reflected irradiation. The results correcting only for the emissivity, \( \varepsilon_c \), are

\[ \begin{array}{ccc}
\varepsilon_c & T'_a (K) & T'_a - T_s (K) \\
0.8 & 600.5 & +0.5 \\
0.5 & 602.2 & +2.2 \\
0.2 & 608.5 & +8.5 \\
\end{array} \]
PROBLEM 12.86

KNOWN: Billet at $T = 500$ K which is diffuse, gray with emissivity $\varepsilon_t = 0.9$ heated within a large furnace having isothermal walls at $T_f = 750$ K with diffuse, gray surface of emissivity $\varepsilon_f = 0.8$. Radiation detector with sensitive area $A_d = 5.0 \times 10^{-4}$ m$^2$ positioned normal to and at a distance $R = 0.5$ m from the billet. Detector receives radiation from a billet target area $A_t = 3.0 \times 10^{-6}$ m$^2$.

FIND: (a) Symbolic expressions and numerical values for the following radiation parameters associated with the target surface (t): irradiation on the target, $G_t$; intensity of the reflected irradiation leaving the target, $I_{t,ref}$; emissive power of the target, $E_t$; intensity of the emitted radiation leaving the target, $I_{t,emit}$; and radiosity of the target $J_t$; and (b) Expression and numerical value for the radiation which leaves the target in the spectral region $\lambda \geq 4 \ \mu m$ and is intercepted by the radiation detector, $q_{t \rightarrow d}$; write the expression in terms of the target reflected and emitted intensities $I_{t,ref}$ and $I_{t,emit}$, respectively, as well as other geometric and radiation parameters.

SCHEMATIC:

ASSUMPTIONS: (1) Furnace wall is isothermal and large compared to the billet, (2) Billet surface is diffuse gray, and (3) $A_t, A_d \ll R^2$.

ANALYSIS: (a) Expressions and numerical values for radiation parameters associated with the target are:

Irradiation, $G_t$: due to blackbody emission from the furnace walls which are isothermal and large relative to the billet target,

$$G_t = E_b (T_f) = \sigma T_f^4 = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (750 \text{ K})^4 = 17,940 \text{ W/m}^2$$

Intensity of reflected irradiation, $I_{t,ref}$: since the billet is diffuse, $I = G_t / \pi$ from Eq. 12.19, and diffuse-gray, $\rho_t = 1 - \varepsilon_t$,

$$I_{t,ref} = \rho_t \frac{G_t}{\pi} = (1 - \varepsilon_t) \frac{G_t}{\pi}$$

$$I_{t,ref} = (1 - 0.9) \times 19,740 \text{ W/m}^2 / \pi = 571 \text{ W/m}^2 \cdot \text{sr}$$

Emissive power, $E_t$: from the Stefan-Boltzmann law, Eq. 12.28, and the definition of the total emissivity, Eq. 12.37,

$$E_t = \varepsilon_t E_b (T_t) = \varepsilon_t \sigma T_t^4$$

$$E_t = 0.9 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (500 \text{ K})^4 = 3189 \text{ W/m}^2$$

Continued...
PROBLEM 12.86 (Cont.)

*Intensity of emitted radiation, $I_{t, emit}$:* since the billet is diffuse, $I_e = E/\pi$ from Eq. 12.14,

$$I_{t, emit} = E/\pi = 3189 \text{ W/m}^2/\pi = 1015 \text{ W/m}^2 \cdot \text{sr}$$

*Radiosity, $J_t$:* the radiosity accounts for the emitted radiation and reflected portion of the irradiation; for the diffuse surface, from Eq. 12.24,

$$J_t = \pi \left( I_{t, ref} + I_{t, emit} \right)$$

$$J_t = 571 + 1015 \text{ W/m}^2 \cdot \text{sr} = 4983 \text{ W/m}^2$$

(b) The radiant power in the spectral region $\lambda \geq 4 \mu\text{m}$ leaving the target which is intercepted by the detector follows from Eq. 12.5,

$$q_{t \rightarrow d} = \left[ F_{\text{ref}} I_{t, ref} + F_{\text{emit}} I_{t, emit} \right] A_t \cos \theta_t \omega_{d-t}$$

The F factors account for the fraction of the total spectral region for $\lambda \geq 4 \mu\text{m},$

$$F_{\text{ref}} = 1 - F(0 - \lambda T_t) = 1 - 0.2732 = 0.727$$

$$F_{\text{emit}} = 1 - F(0 - \lambda T_t) = 1 - 0.06673 = 0.933$$

where from Eq. 12.30 and Table 12.1, for $\lambda T_t = 4 \mu\text{m} \times 750 \text{ K} = 3000 \mu\text{m} \cdot \text{K}$, $F(0 - \lambda T_t) = 0.2732$ and for $\lambda T_t = 4 \mu\text{m} \times 500 \text{ K} = 2000 \mu\text{m} \cdot \text{K}$, $F(0 - \lambda T_t) = 0.06673$. Since the radiation detector is normal to the billet, $\cos \theta_t = 1$. The solid angle subtended by the detector area with respect to the target area is

$$\omega_{d-t} = \frac{A_d \cos \theta_d}{R^2} = \frac{5 \times 10^{-4} \text{ m}^2 \times 1}{(0.5 \text{ m})^2} = 2.00 \times 10^{-3} \text{ sr}$$

Hence, the radiant power is

$$q_{t \rightarrow d} = (0.727 \times 571 + 0.933 \times 1015) \text{ W/m}^2 \cdot \text{sr} \times 3.0 \times 10^{-6} \text{ m}^2 \times 1 \times 2.00 \times 10^{-3} \text{ sr}$$

$$q_{t \rightarrow d} = (2.491 + 5.682) \times 10^{-6} \text{ W} = 8.17 \mu\text{W}$$

**COMMENTS:**

(1) Why doesn’t the emissivity of the furnace walls, $\varepsilon$, affect the target irradiation?

(2) Note the importance of the diffuse, gray assumption for the billet target surface. In what ways was the assumption used in the analysis?

(3) From the calculation of the radiant power to the detector, $q_{t \rightarrow d}$, note that the contribution of the reflected irradiation is nearly a third of the total.
KNOWN: Painted plate located inside a large enclosure being heated by an infrared lamp bank.

FIND: (a) Lamp irradiation required to maintain plate at $T_s = 140^\circ C$ for the prescribed convection and enclosure irradiation conditions, (b) Compute and plot the lamp irradiation, $G_{\text{lamp}}$, required as a function of the plate temperature, $T_s$, for the range $100 \leq T_s \leq 300 ^\circ C$ and for convection coefficients of $h = 15$, 20 and 30 W/m$^2$·K, and (c) Compute and plot the air stream temperature, $T_\infty$, required to maintain the plate at $140^\circ C$ as a function of the convection coefficient $h$ for the range $10 \leq h \leq 30$ W/m$^2$·K with a lamp irradiation $G_{\text{lamp}} = 3000$ W/m$^2$.

SCHEMATIC:

\[ T_\infty = 27 ^\circ C \]
\[ h = 20 \text{ W/m}^2\cdot\text{K} \]

ASSUMPTIONS: (1) Steady-state conditions, (2) No losses on backside of plate.

ANALYSIS: (a) Perform an energy balance on the plate, per unit area,

\[
\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0
\]

\[
\alpha_{\text{wall}} \cdot G_{\text{wall}} + \alpha_{\text{lamp}} G_{\text{lamp}} - q_{\text{conv}} - E_s = 0
\]

where the emissive power of the surface and convective fluxes are

\[
E_s = \varepsilon_s E_b(T_s) = \varepsilon_s \cdot \sigma T_s^4 \quad q_{\text{conv}} = h(T_s - T_\infty)
\]

Substituting values, find the lamp irradiation

\[
0.7 \times 450 \text{ W/m}^2 + 0.6 \times G_{\text{lamp}} - 20 \text{ W/m}^2 \cdot \text{K} (413 - 300 \text{ K})
\]

\[
-0.8 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (413 \text{ K})^4 = 0
\]

\[
G_{\text{lamp}} = 5441 \text{ W/m}^2
\]

(b) Using the foregoing equations in the IHT workspace, the irradiation, $G_{\text{lamp}}$, required to maintain the plate temperature in the range $100 \leq T_s \leq 300 ^\circ C$ for selected convection coefficients was computed. The results are plotted below.
As expected, to maintain the plate at higher temperatures, the lamp irradiation must be increased. At any plate operating temperature condition, the lamp irradiation must be increased if the convection coefficient increases. With forced convection (say, \( h \geq 20 \text{ W/m}^2\cdot\text{K} \)) of the airstream at 27°C, excessive irradiation levels are required to maintain the plate above the cure temperature of 140°C.

(c) Using the IHT model developed for part (b), the airstream temperature, \( T_\infty \), required to maintain the plate at \( T_s = 140^\circ\text{C} \) as a function of the convection coefficient with \( G_{\text{lamp}} = 3000 \text{ W/m}^2\cdot\text{K} \) was computed and the results are plotted below.

As the convection coefficient increases, for example by increasing the airstream velocity over the plate, the required air temperature must increase. Give a physical explanation for why this is so.

COMMENTS: (1) For a spectrally selective surface, we should expect the absorptivity to depend upon the spectral distribution of the source and \( \alpha \neq \varepsilon \).

(2) Note the new terms used in this problem; use your Glossary, Section 12.9 to reinforce their meaning.
**PROBLEM 12.88**

**KNOWN:** Small sample of reflectivity, $\rho_\lambda$, and diameter, $D$, is irradiated with an isothermal enclosure at $T_f$.

**FIND:** (a) Absorptivity, $\alpha$, of the sample with prescribed $\rho_\lambda$, (b) Emissivity, $\varepsilon$, of the sample, (c) Heat removed by coolant to the sample, (d) Explanation of why system provides a measure of $\rho_\lambda$.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Sample is diffuse and opaque, (2) Furnace is an isothermal enclosure with area much larger than the sample, (3) Aperture of furnace is small.

**ANALYSIS:**

(a) The absorptivity, $\alpha$, follows from Eq. 12.42, where the irradiation on the sample is $G = E_b(T_f)$ and $\alpha_\lambda = 1 - \rho_\lambda$.

$$\alpha_\lambda G_\lambda d\lambda / G = \int_0^\infty \alpha_\lambda G_\lambda d\lambda / E_b(1000K)$$

$$\alpha_\lambda = \left(1 - \rho_\lambda, 1\right) F_{0-\lambda_1} + \left(1 - \rho_\lambda, 2\right) \left[1 - F_{0-\lambda_1}\right].$$

Using Table 12.1 for $\lambda_1 T_f = 4 \times 1000 = 4000 \mu m \cdot K$, $F_{(0-\lambda)} = 0.491$ giving

$$\alpha = \left(1 - 0.2\right) \times 0.491 + \left(1 - 0.8\right) \times 0 \times 0.491 = 0.49. \quad <$$

(b) The emissivity, $\varepsilon$, follows from Eq. 12.37 with $\varepsilon_\lambda = \alpha_\lambda = 1 - \rho_\lambda$ since the sample is diffuse.

$$\varepsilon = \frac{E(T_s)}{E_b(T_s)} = \int_0^\infty \varepsilon_\lambda E_{\lambda, b}(\lambda, 300K) d\lambda / E_b(300K)$$

$$\varepsilon = \left(1 - \rho_\lambda, 1\right) F_{(0-\lambda_1)} + \left(1 - \rho_\lambda, 2\right) \left[1 - F_{(0-\lambda_1)}\right].$$

Using Table 12.1 for $\lambda_1 T_s = 4 \times 300 = 1200 \mu m \cdot K$, $F_{(0-\lambda)} = 0.002$ giving

$$\varepsilon = \left(1 - 0.2\right) \times 0.002 + \left(1 - 0.8\right) \times \left(1 - 0.002\right) = 0.20. \quad <$$

(c) Performing an energy balance on the sample, the heat removal rate by the cooling water is

$$q_{cool} = A_s \left[ \alpha G + q_{conv, b} - \varepsilon E_b(T_s) \right]$$

where

$$G = E_b(T_f) = E_b(1000K)$$

$$q_{conv, b} = h(T_f - T_s) A_s = \pi D^2 / 4$$

$$q_{cool} = \left(\pi / 4\right) \left(0.03m\right)^2 \left[0.49 \times 5.67 \times 10^{-8} W/m^2 \cdot K^4 \times (1000K)^4\right] + 10 W/m^2 \cdot K \left((1000 - 300)K \right) \left(-0.2 \times 5.67 \times 10^{-8} W/m^2 \cdot K^4 \times (300K)^4\right] = 24.4 W. \quad <$$

(d) Assume that reflection makes the dominant contribution to the radiosity of the sample. When viewing in the direction A, the spectral radiant power is proportional to $\rho_\lambda G_\lambda$. In direction B, the spectral radiant power is proportional to $E_{\lambda, b}(T_f)$. Noting that $G_\lambda = E_{\lambda, b}(T_f)$, the ratio gives $\rho_\lambda$. 

PROBLEM 12.89

KNOWN: Small, opaque surface initially at 1200 K with prescribed $\alpha_\lambda$ distribution placed in a large enclosure at 2400 K.

FIND: (a) Total, hemispherical absorptivity of the sample surface, (b) Total, hemispherical emissivity, (c) $\alpha$ and $\varepsilon$ after long time has elapsed, (d) Variation of sample temperature with time.

SCHEMATIC:

ASSUMPTIONS: (1) Surface is diffusely radiated, (2) Enclosure is much larger than surface and at a uniform temperature.

PROPERTIES: Table A.1, Tungsten ($T = 1800$ K): $\rho = 19,300$ kg/m$^3$, $c_p = 163$ J/kg·K, $k = 102$ W/m·K.

ANALYSIS: (a) The total, hemispherical absorptivity follows from Eq. 12.46, where $G_\lambda = E_{\lambda,b}(T_{\text{sur}})$. That is, the irradiation corresponds to the spectral emissive power of a blackbody at the enclosure temperature and is independent of the enclosure emissivity.

$$\alpha = \int_0^\infty \alpha_\lambda G_\lambda \, d\lambda = \int_0^\infty \alpha_\lambda E_{\lambda,b}(\lambda, T_{\text{sur}}) \, d\lambda / E_{b}(T_{\text{sur}})$$

$$\alpha = \alpha_1 \int_0^{2\mu m} E_{\lambda,b}(\lambda, T_{\text{sur}}) \, d\lambda / \sigma T_{\text{sur}}^4 + \alpha_2 \int_{2\mu m}^\infty E_{\lambda,b}(\lambda, T_{\text{sur}}) \, d\lambda / \sigma T_{\text{sur}}^4$$

$$\alpha = \alpha_1 F_{(0\rightarrow2\mu m)} + \alpha_2 \left[1 - F_{(0\rightarrow2\mu m)}\right] = 0.1 \times 0.6076 + 0.8[1 - 0.6076] = 0.375$$

where at $\lambda T = 2 \times 2400 = 4800$ $\mu$m·K, $F_{(0\rightarrow2\mu m)} = 0.6076$ from Table 12.1.

(b) The total, hemispherical emissivity follows from Eq. 12.38,

$$\varepsilon = \int_0^\infty \varepsilon_\lambda E_{\lambda,b}(\lambda, T_s) \, d\lambda / \int_0^\infty E_{\lambda,b}(\lambda, T_s) \, d\lambda .$$

Since the surface is diffuse, $\varepsilon_\lambda = \alpha_\lambda$ and the integral can be expressed as

$$\varepsilon = \alpha_1 \int_0^{2\mu m} E_{\lambda,b}(\lambda, T_s) \, d\lambda / \sigma T_s^4 + \alpha_2 \int_{2\mu m}^\infty E_{\lambda,b}(\lambda, T_s) \, d\lambda / \sigma T_s^4$$

$$\varepsilon = \alpha_1 F_{(0\rightarrow2\mu m)} + \alpha_2 \left[1 - F_{(0\rightarrow2\mu m)}\right] = 0.1 \times 0.1403 + 0.8[1 - 0.1403] = 0.702$$

where at $\lambda T = 2 \times 1200 = 2400$ $\mu$m·K, find $F_{(0\rightarrow2\mu m)} = 0.1403$ from Table 12.1.

(c) After a long period of time, the surface will be at the temperature of the enclosure. This condition of thermal equilibrium is described by Kirchhoff’s law, for which

$$\varepsilon = \alpha = 0.375.$$
(d) Using the IHT *Lumped Capacitance* Model, the energy balance relation is of the form

\[ \rho c_p \frac{dT}{dt} = A_s [\alpha G - \varepsilon(T)E_b(T)] \]

where \( T = T_s \), \( \forall = \pi D^3/6 \), \( A_s = \pi D^2 \) and \( G = \sigma T_{\text{sur}}^4 \). Integrating over time in increments of \( \Delta t = 0.5 \) seconds and using the *Radiation* Toolpad to determine \( \varepsilon(t) \), the following results are obtained.

The temperature of the specimen increases rapidly with time and achieves a value of 2399 K within \( t \approx 47 \) seconds. The emissivity decreases with increasing time, approaching the absorptivity as \( T \) approaches \( T_{\text{sur}} \).

**COMMENTS:**

(1) Recognize that \( \alpha \) always depends upon the spectral irradiation distribution, which, in this case, corresponds to emission from a blackbody at the temperature of the enclosure.

(2) With \( h_r = \varepsilon\sigma(T + T_{\text{sur}})(T^2 + T_{\text{sur}}^2) = 0.375\sigma T_{\text{sur}}^3 = 1176 \text{ W/m}^2 \cdot \text{K} \), \( \text{Bi} = h_r (r_0/3)/k = (1176 \text{ W/m}^2 \cdot \text{K}) \times 10^{-3} \text{ m/102 W/m} \cdot \text{K} = 0.0192 \ll 1 \), use of the lumped capacitance model is justified.
**PROBLEM 12.90**

**KNOWN:** Vertical plate of height $L = 2$ m suspended in quiescent air. Exposed surface with diffuse coating of prescribed spectral absorptivity distribution subjected to simulated solar irradiation, $G_{s,\lambda}$. Plate steady-state temperature $T_s = 400$ K.

**FIND:** (a) Plate emissivity, $\varepsilon$, plate absorptivity, $\alpha$, plate irradiation, $G$, and using an appropriate correlation, the free convection coefficient, $\overline{h}$, and (b) Plate steady-state temperature if the irradiation found in part (a) were doubled.

**SCHEMATIC:**

![Schematic diagram]

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Ambient air is extensive, quiescent, (3) Spectral distribution of the simulated solar irradiation, $G_{s,\lambda}$, proportional to that of a blackbody at 5800 K, (4) Coating is opaque, diffuse, and (5) Plate is perfectly insulated on the edges and the back side, and (6) Plate is isothermal.

**PROPERTIES:** Table A.4, Air ($T_f = 350$ K, 1 atm): $\nu = 20.92 \times 10^{-6}$ m$^2$/s, $k = 0.030$ W/m·K, $\alpha = 29.90 \times 10^{-6}$ m$^2$/s, $Pr = 0.700$.

**ANALYSIS:** (a) Perform an energy balance on the plate as shown in the schematic on a per unit plate width basis,

$$\dot{E}_{in} - \dot{E}_{out} = 0$$

$$\left[ \alpha G - \varepsilon \sigma T_s^4 - \overline{h} (T_s - T_\infty) \right] L = 0 \quad (1)$$

where $\alpha$ and $\varepsilon$ are determined from knowledge of $\alpha_\lambda$ and $\overline{h}$ is estimated from an appropriate correlation.

*Plate total emissivity*: From Eq. 12.38 written in terms of the band emission factor, $F_{(0-\lambda T)}$, Eq. 12.30,

$$\varepsilon = \alpha_1 F_{(0-\lambda T_s)} + \alpha_2 \left[ 1 - F_{(0-\lambda T_s)} \right]$$

$$\varepsilon = 0.9 \times 0 + 0.1 [1 - 0] = 0.1$$

where, from Table 12.1, with $\lambda, T_s = 1 \mu m \times 400$ K = 400 $\mu m$·K, $F(0-\lambda T) = 0.000$.

*Plate absorptivity*: With the spectral distribution of simulated solar irradiation proportional to $E_b (T_s = 5800$ K),

Continued...
PROBLEM 12.90 (Cont.)

\[
\alpha = \alpha_1 F(0 - \lambda_1 T_s) + \alpha_2 \left[ 1 - F(0 - \lambda_1 T_s) \right]
\]

\[
\alpha = 0.9 \times 0.7202 + 0.1 \left[ 1 - 0.7202 \right] = 0.676
\]

where, from Table 12.1, with \( \lambda_1 T_s = 5800 \mu \text{m} \cdot \text{K}, F(0 - \lambda_1 T) = 0.7202. 

Estimating the free convection coefficient, \( \overline{h} \): Using the Churchill-Chu correlation Eq. (9.26) with properties evaluated at \( T_f = (T_s + T_{\infty})/2 = 350 \text{ K} \),

\[
Ra_L = \frac{g \beta (T_s - T_{\infty}) L^3}{\nu \alpha}
\]

\[
Ra_L = \frac{9.8 \text{ m}^2 \text{s}^{-2} \left( 1/350 \text{ K} \right) \times 100 \text{ K} \left( 2 \text{ m} \right)^3}{20.92 \times 10^{-6} \text{ m}^2 \text{s}^{-1} \times 29.90 \times 10^{-6} \text{ m}^2 \text{s}^{-1}} = 3.581 \times 10^{10}
\]

\[
\overline{Nu}_L = \left\{ 0.825 + \frac{0.387 Ra_L^{1/6}}{1 + (0.492/Pr)^{9/16}} \right\}^2
\]

\[
\overline{Nu}_L = \left\{ 0.825 + \frac{0.387 Ra_L^{1/6}}{1 + (0.492/0.700)^{9/16}} \right\}^2 = 377.6
\]

\[
\overline{h}_L = \overline{Nu}_L k/L = 377.6 \times 0.030 \text{ W} \cdot \text{m}^{-1} \cdot \text{K} / 2 \text{ m} = 5.66 \text{ W} / \text{m}^2 \cdot \text{K}
\]

Irradiation on the Plate: Substituting numerical values into Eq. (1), find \( G \).

\[
0.676G - 0.1 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K} = 0
\]

\[
G = 1052 \text{ W/m}^2
\]

(b) If the irradiation were doubled, \( G = 2104 \text{ W/m}^2 \), the plate temperature \( T_s \) will increase, of course, requiring re-evaluation of \( \varepsilon \) and \( \overline{h} \). Since \( \alpha \) depends upon the irradiation distribution, and not the plate temperature, \( \alpha \) will remain the same. As a first approximation, assume \( \varepsilon = 0.1 \) and \( \overline{h} = 5.66 \text{ W/m}^2 \cdot \text{K} \) and with \( G = 2104 \text{ W/m}^2 \), use Eq. (1) to find

\[
T_s \approx 492 \text{ K}
\]

With \( T_f = (T_s + T_{\infty})/2 = (492 + 300)K/2 = 400 \text{ K} \), use the correlation to reevaluate \( \overline{h} \). For \( T_s = 492 \text{ K} \), \( \varepsilon = 0.1 \) is yet a good assumption. We used IHT with the foregoing equations in part (a) and found these results.

\[
T_s = 477 \text{ K} \quad T_f = 388.5 \quad \overline{h} = 6.38 \text{ W/m}^2 \cdot \text{K} \quad \varepsilon = 0.1
\]
PROBLEM 12.91

KNOWN: Diameter and initial temperature of copper rod. Wall and gas temperature.

FIND: (a) Expression for initial rate of change of rod temperature, (b) Initial rate for prescribed conditions, (c) Transient response of rod temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Applicability of lumped capacitance approximation, (2) Furnace approximates a blackbody cavity, (3) Thin film is diffuse and has negligible thermal resistance, (4) Properties of nitrogen approximate those of air (Part c).

PROPERTIES: Table A.1, copper (T = 300 K): \( c_p = 385 \text{ J/kg} \cdot \text{K}, \rho = 8933 \text{ kg/m}^3, k = 401 \text{ W/m} \cdot \text{K} \). Table A.4, nitrogen (p = 1 atm, T_i = 900 K): \( \nu = 100.3 \times 10^{-6} \text{ m}^2/\text{s}, \alpha = 139 \times 10^{-6} \text{ m}^2/\text{s}, k = 0.0597 \text{ W/m} \cdot \text{K}, Pr = 0.721 \).

ANALYSIS: (a) Applying conservation of energy at an instant of time to a control surface about the cylinder, \( \dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \dot{E}_{\text{st}} \), where energy inflow is due to natural convection and radiation from the furnace wall and energy outflow is due to emission. Hence, for a unit cylinder length,

\[
q_{\text{conv}} + q_{\text{rad,net}} = \frac{\rho \pi D^2}{4} c_p \frac{dT}{dt}
\]

where

\[
q_{\text{conv}} = \overline{h}(\pi D)(T_{\infty} - T)
\]

\[
q_{\text{rad,net}} = \pi D(\alpha G - \varepsilon E_b) = \pi D[\alpha E_b(T_w) - \varepsilon E_b(T)]
\]

Hence, at \( t = 0 \) (T = T_i),

\[
dT/dt = \left(4/\rho c_p D\right)[\overline{h}(T_{\infty} - T_i) + \alpha E_b(T_w) - \varepsilon E_b(T_i)]
\]

(b) With \( Ra_D = \frac{g \beta (T_{\infty} - T_i) D^3}{\alpha \nu} = \frac{9.8 \text{ m/s}^2 (1/900 \text{ K})(1200 \text{ K})(0.01 \text{ m})^3}{100.3 \times 139 \times 10^{-12} \text{ m}^4/\text{s}^2} = 937 \), Eq. (9.34) yields

\[
\overline{Nu}_D = \left\{0.60 + \frac{0.387Ra_D^{1/6}}{1 + (0.559/Pr)^{9/16}}\right\}^2 = 2.58
\]

\[
\overline{h} = k \frac{\overline{Nu}_D}{D} = \left(\frac{0.0597 \text{ W/m} \cdot \text{K}}{0.01 \text{ m}}\right) 2.58 = 15.4 \text{ W/m}^2 \cdot \text{K}
\]

With \( T = T_i = 300 \text{ K}, \lambda T = 600 \mu\text{m} \cdot \text{K} \) yields \( F_{(0 \rightarrow \lambda)} = 0 \), in which case \( \varepsilon = \varepsilon_1 F_{(0 \rightarrow \lambda)} + \varepsilon_2 \left[1 - F_{(0 \rightarrow \lambda)}\right] = 0.4 \).

With \( T = T_w = 1500 \text{ K}, \lambda T = 3000 \text{ K} \) yields \( F_{(0 \rightarrow \lambda)} = 0.273 \). Hence, with \( \alpha_{\lambda} = \varepsilon_{\lambda}, \alpha = \varepsilon_1 F_{(0 \rightarrow \lambda)} + \varepsilon_2 [1 - F_{(0 \rightarrow \lambda)}] = 0.9(0.273) + 0.4(1 - 0.273) = 0.537 \). It follows that

Continued...
\[
\frac{dT}{dt} = \frac{4}{8933 \text{ kg/m}^3} \left(385 \text{ J/kg} \cdot \text{K} \right) 0.01 \text{ m} \left[ \frac{15 \text{ W}}{m^2 \cdot \text{K}} (1500 - 300) \text{ K} \right] \\
+ 0.537 \times 5.67 \times 10^{-4} \frac{\text{ W}}{m^2 \cdot \text{K}^4} (1500 \text{ K})^4 - 0.4 \times 5.67 \times 10^{-8} \frac{\text{ W}}{m^2 \cdot \text{K}^4} (300 \text{ K})^4 \\
\]
\[
dT/dt = 1.163 \times 10^{-4} \text{ m}^2 \cdot \text{K/J} \left[ 18,480 + 154,140 - 180 \right] \text{W/m}^2 = 20 \text{ K/s}
\]

Defining a pseudo radiation coefficient as \( h_r = (\alpha G - \varepsilon E_b)(T_w - T_i) = (153,960 \text{ W/m}^2)/1200 \text{ K} = 128.3 \text{ W/m}^2\cdot\text{K} \), \( Bi = (h + h_r)(D/4)/k = 143.7 \text{ W/m}^2\cdot\text{K} \ (0.0025 \text{ m})/401 \text{ W/m} \cdot \text{K} = 0.0009 \). Hence, the lumped capacitance approximation is appropriate.

(c) Using the IHT Lumped Capacitance Model with the Correlations, Radiation and Properties (copper and air) Toolpads, the transient response of the rod was computed for \( 300 \leq T < 1200 \text{ K} \), where the upper limit was determined by the temperature range of the copper property table.

The rate of change of the rod temperature, \( dT/dt \), decreases with increasing temperature, in accordance with a reduction in the convective and net radiative heating rates. Note, however, that even at \( T = 1200 \text{ K} \), \( \alpha G \), which is fixed, is large relative to \( q_{conv}^\varepsilon \) and \( \varepsilon E_b \) and \( dT/dt \) is still significant.
PROBLEM 12.92

KNOWN: Temperatures of furnace wall and top and bottom surfaces of a planar sample. Dimensions and emissivity of sample.

FIND: (a) Sample thermal conductivity, (b) Validity of assuming uniform bottom surface temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in sample, (3) Constant k, (4) Diffuse-gray surface, (5) Irradiation equal to blackbody emission at 1400K.

PROPERTIES: Table A-6, Water coolant (300K): $c_p = 4179 \text{ J/kg} \cdot \text{K}$

ANALYSIS: (a) From energy balance at top surface,

$$\alpha G - E = q''_{\text{cond}} = k_s \left( T_s - T_c \right) / L$$

where $E = \varepsilon_s \sigma T_s^4$, $G = \sigma T_w^4$, $\alpha = \varepsilon_s$ giving

$$\varepsilon_s \sigma T_w^4 - \varepsilon_s \sigma T_s^4 = k_s \left( T_s - T_c \right) / L.$$

Solving for the thermal conductivity and substituting numerical values, find

$$k_s = \frac{\varepsilon_s L \sigma}{T_s - T_c} \left( T_w^4 - T_s^4 \right)$$

$$k_s = \frac{0.85 \times 0.015 \times 5.67 \times 10^{-8}}{(1000 - 300) \text{ K}} \left[ (1400^4) - (1000^4) \right] \text{ W} / \text{ m} \cdot \text{ K}$$

$$k_s = 2.93 \text{ W} / \text{ m} \cdot \text{ K}.$$

(b) Non-uniformity of bottom surface temperature depends on coolant temperature rise. From the energy balance

$$q = \dot{m}_c c_p \Delta T_c = (\alpha G - E) W^2$$

$$\Delta T_c = 0.85 \times 5.67 \times 10^{-8} \text{ W} / \text{ m}^2 \cdot \text{ K}^4 \left[ 1400^4 - 1000^4 \right] \text{ K}^4 (0.10 \text{ m})^2 / 0.1 \text{ kg/s} \times 4179 \text{ J/kg} \cdot \text{ K}$$

$$\Delta T_c = 3.3 \text{ K}.$$

The variation in $T_c$ (~3K) is small compared to $(T_s - T_c) \approx 700 \text{ K}$. Hence it is not large enough to introduce significant error in the k determination.
**PROBLEM 12.93**

**KNOWN:** Thicknesses and thermal conductivities of a ceramic/metal composite. Emissivity of ceramic surface. Temperatures of vacuum chamber wall and substrate lower surface. Receiving area of radiation detector, distance of detector from sample, and sample surface area viewed by detector.

**FIND:** (a) Ceramic top surface temperature and heat flux, (b) Rate at which radiation emitted by the ceramic is intercepted by detector, (c) Effect of an interfacial (ceramic/substrate) contact resistance on sample top and bottom surface temperatures.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional, steady-state conduction in sample, (2) Constant properties, (3) Chamber forms a blackbody enclosure at $T_w$, (4) Ceramic surface is diffuse/gray, (5) Negligible interface contact resistance for part (a).

**PROPERTIES:** Ceramic: $k_c = 60$ W/m-K, $\varepsilon_c = 0.8$. Substrate: $k_s = 25$ W/m-K.

**ANALYSIS:** (a) From an energy balance at the exposed ceramic surface, $q_{cond} = q_{rad}$, or

$$\frac{T_1 - T_2}{(L_s/k_s) + (L_c/k_c)} = \varepsilon_c \sigma \left( T_2^4 - T_w^4 \right)$$

$$\frac{1500 \text{K} - T_2}{0.008 \text{m}} + \frac{0.005 \text{m}}{25 \text{W/m K}} = 0.8 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left( T_2^4 - 90^4 \right) \text{K}^4$$

$$3.72 \times 10^6 - 2479 T_2 = 4.54 \times 10^{-8} T_2^4 - 2.98$$

$$4.54 \times 10^{-8} T_2^4 + 2479 T_2 = 3.72 \times 10^6$$

Solving, we obtain

$$T_2 = 1425 \text{ K}$$

$$q_h^* = \frac{T_1 - T_2}{(L_s/k_s) + (L_c/k_c)} = \frac{(1500 - 1425) \text{K}}{4.033 \times 10^{-4} \text{ m}^2 \cdot \text{K/W}} = 1.87 \times 10^5 \text{ W/m}^2$$

(b) Since the ceramic surface is diffuse, the total intensity of radiation emitted in all directions is $I_e = \varepsilon_c E_b(T_s)/\pi$. Hence, the rate at which emitted radiation is intercepted by the detector is

$$q_{c(\text{em})-d} = I_e \Delta A_c \left( A_d / L_{s-d}^2 \right)$$

$$q_{c(\text{em})-d} = \frac{0.8 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left( 1425 \text{K} \right)^4}{\pi \text{sr}} \times 10^{-4} \text{ m}^2 \times 10^{-5} \text{ sr} = 5.95 \times 10^{-5} \text{ W}$$

Continued...
(c) With the development of an interfacial thermal contact resistance and fixed values of \( q''_h \) and \( T_w \), (i) \( T_2 \) remains the same (its value is determined by the requirement that \( q''_h = \varepsilon_c \sigma \left( T_2^4 - T_w^4 \right) \)), while (ii) \( T_1 \) increases (its value is determined by the requirement that \( q''_h = \left( T_1 - T_2 \right) / R''_{tot} \), where \( R''_{tot} = [(L_s/k_s) + R''_{t,c} + (L_c/k_c)] \); if \( q''_h \) and \( T_2 \) are fixed, \( T_1 \) must increase with increasing \( R''_{tot} \).

**COMMENTS:** The detector will also see radiation which is reflected from the ceramic. The corresponding radiation rate is \( q_{c(reflection)-d} = \rho_c G_c A_c A_d / L_s^2 - d = 0.2 \sigma (90 \text{ K})^4 \times 10^{-4} \text{ m}^2 \times (10^{-5} \text{ sr}) = 7.44 \times 10^{-10} \text{ W} \). Hence, reflection is negligible.
PROBLEM 12.94

KNOWN: Wafer heated by ion beam source within large process-gas chamber with walls at uniform temperature; radiometer views a $5 \times 5$ mm target on the wafer. Black panel mounted in place of wafer in a pre-production test of the equipment.

FIND: (a) Radiant power ($\mu$W) received by the radiometer when the black panel temperature is $T_{bp} = 800$ K and (b) Temperature of the wafer, $T_w$, when the ion beam source is adjusted so that the radiant power received by the radiometer is the same as that of part (a)

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Chamber represents large, isothermal surroundings, (3) Wafer is opaque, diffuse-gray, and (4) Target area $<<$ square of distance between target and radiometer objective.

ANALYSIS: (a) The radiant power leaving the black-panel target and reaching the radiometer as illustrated in the schematic below is

$$ q_{bp-rad} = \left[ E_{b,bp}(T_{bp}) / \pi \right] A_t \cos \theta_t \cdot \Delta \omega_{rad-t} $$

where $\theta_t = 0^\circ$ and the solid angle the radiometer subtends with respect to the target follows from Eq. 12.2,

$$ \Delta \omega_{rad-t} = \frac{dA_n}{r^2} = \frac{\left( \pi D_0^2 / 4 \right)}{r^2} = \frac{\pi(0.025 \text{ m})^2 / 4}{(0.500 \text{ m})^2} = 1.964 \times 10^{-3} \text{ sr} $$

With $E_{b,bp} = \sigma_{4b}^4$, find

$$ q_{bp-rad} = \left[ 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4(800 \text{ K})^4 / \pi \text{ sr} \right] \times (0.005 \text{ m})^2 \times \cos 30^\circ \times 1.964 \times 10^{-3} \text{ sr} $$

$$ q_{bp-rad} = 314 \mu\text{W} $$

Continued …..
PROBLEM 12.94 (Cont.)

(b) With the wafer mounted, the ion beam source is adjusted until the radiometer receives the same radiant power as with part (a) for the black panel. The power reaching the radiometer is expressed in terms of the wafer radiosity,

\[ q_{w-rad} = \left[ \frac{I_w}{\pi} \right] A_t \cos \theta_t \cdot \Delta \omega_{rad-t} \]  

(2)

Since \( q_{w-rad} = q_{bp-rad} \) (see Eq. (1)), recognize that

\[ J_w = E_{b, bp} \left( T_{bp} \right) \]  

(3)

where the radiosity is

\[ J_w = \varepsilon_w E_{b, w} (T_w) + \rho_w G_w = \varepsilon_w E_{b, w} (T_w) + (1 - \varepsilon_w) E_b (T_{ch}) \]  

(4)

and \( G_w \) is equal to the blackbody emissive power at \( T_{ch} \). Using Eqs. (3) and (4) and substituting numerical values, find

\[ \sigma T_{bp}^4 = \varepsilon_w \sigma T_w^4 + (1 - \varepsilon_w) \sigma T_{ch}^4 \]

\[ (800 \text{ K})^4 = 0.7 T_w^4 + 0.3(400 \text{ K})^4 \]

\[ T_w = 871 \text{ K} < \]

COMMENTS: (1) Explain why \( T_w \) is higher than 800 K, the temperature of the black panel, when the radiometer receives the same radiant power for both situations.

(2) If the chamber walls were cold relative to the wafer, say near liquid nitrogen temperature, \( T_{ch} = 80 \text{ K} \), and the test repeated with the same indicated radiometer power, is the wafer temperature higher or lower than 871 K?

(3) If the chamber walls were maintained at 800 K, and the test repeated with the same indicated radiometer power, what is the wafer temperature?
PROBLEM 12.95

KNOWN: Spectrally selective workpiece placed in an oven with walls at $T_\infty = 1000$ K experiencing convection with air at $T_\infty = 600$ K.

FIND: (a) Steady-state temperature, $T_s$, by performing an energy balance on the workpiece; show control surface identifying all relevant processes; (b) Compute and plot $T_s$ as a function of the convection coefficient $h$, for the range $10 \leq h \leq 120$ W/m$^2$K; on the same plot, show the behavior for diffuse surfaces of emissivity 0.2 and 0.8.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Convection coefficient constant, independent of temperature, (3) Workpiece is diffusely irradiated by oven wall which is large isothermal surroundings, (4) Spectral emissivity independent of workpiece temperature.

ANALYSIS: (a) Performing an energy balance on the workpiece,

\[
\dot{E}_{in} - \dot{E}_{out} = \alpha E_b(T_f) - \varepsilon E_b(T_s) - q_{conv} = 0 \quad \text{and} \quad G = E_b(T_f),
\]

\[
\alpha E_b(T_f) - \varepsilon E_b(T_s) - h(T_s - T_\infty) = 0
\]

where the total absorptivity is, with $\alpha = \varepsilon_\lambda$,

\[
\alpha = F_{0\rightarrow5\mu m,1000K} \cdot \varepsilon_1 + \left(1 - F_{0\rightarrow5\mu m,1000K}\right) \varepsilon_2 = 0.6337 \times 0.2 + (1 - 0.6337) \times 0.8 = 0.419
\]

using Table 12.1 with $\lambda T = 5 \times 1000 = 5000$ $\mu$m-K for which $F_{0\rightarrow\lambda T} = 0.6337$. The total emissivity is,

\[
\varepsilon = F_{0\rightarrow5\mu m,T_s} \varepsilon_1 + \left(1 - F_{0\rightarrow5\mu m,T_s}\right) \varepsilon_2
\]

which requires knowing $T_s$. Hence, an iterative solution is required, beginning by assuming a value of $T_s$ to find $\varepsilon$ using Eq. (3), and then using that value in Eq. (2) to find $T_s$. The result is,

\[
T_s = 800 \text{ K}
\]

for which $\varepsilon = 0.512$.

(b) Using the IHT workspace with the foregoing equations and the Radiation Exchange Tool, Band Emission Factor, a model was developed to calculate $T_s$ as a function of the convection coefficient. Additionally, $T_s$ was plotted for the cases when the workpiece is diffuse, gray with $\varepsilon = 0.2$ and 0.8

Continued...
For the workpiece with the selective surface ($\varepsilon_{\lambda}$ as shown in the schematic), the temperature decreases with increasing convection coefficient. For the gray surface, $\varepsilon = 0.2$ or $0.8$, the temperature is lower and higher, respectively, than that of the workpiece. Recall from part (c), at $h = 60 \text{ W/m}^2\text{K}$, $\varepsilon = 0.512$ and $\alpha = 0.419$, so that it is understandable why the curve for the workpiece is between that for the two gray surfaces.

**COMMENTS:**
1. For the conditions in part (b), make a sketch of the workpiece emissivity and the absorptivity as a function of its temperature.
2. The IHT workspace model used to generate the plot is shown below. Note how we used this model to also calculate $T_s$ vs $h$ for the gray surfaces by adjusting $\lambda_1$.

```plaintext
// Energy Balance:
alpha * Gf - eps * Ebs - h * (Ts - Tinf) = 0
Gf = Ebf // Irradiation from furnace, W/m^2
Ebf = sigma * Tf^4 // Blackbody emissive power, W/m^2; furnace wall
Ebs = sigma * Ts^4 // Blackbody emissive power, W/m^2; workpiece
sigma = 5.67e-8 // Stefan-Boltzmann constant, W/m^2.K^4

// Radiation Tool - Band Emission Factor, Total emissivity and absorptivity
eps = FL1Ts * eps1 + (1 - FL1Ts) * eps2
// The blackbody band emission factor, Figure 12.14 and Table 12.1, is */
FL1Ts = F_lambda_T(lambda1,Ts) // Eq 12.30
// where units are lambda (micrometers, mum) and T (K)
alpha = FL1Tf * eps1 + (1 - FL1Tf) * eps2
FL1Tf = F_lambda_T(lambda1,Tf) // Eq 12.30

// Assigned Variables:
Ts > 0 // Workpiece temperature, K; assures positive value for Ts
Tf = 1000 // Furnace wall temperature, K
Tinf = 600 // Air temperature, K
h = 60 // Convection coefficient, W/m^2.K
eps1 = 0.2 // Spectral emissivity, 0 <= epsL <= 5 micrometers
eps2 = 0.8 // Spectral emissivity, 5 <= epsL <= infinity
//lambda1 = 5 // Wavelength, micrometers; spectrally selective workpiece
//lambda1 = 1e6 // Wavelength; gray surface for which eps = 0.2
lambda1 = 0.5 // Wavelength; gray surface for which eps = 0.8
```
**PROBLEM 12.96**

**KNOWN:** Laser-materials-processing apparatus. Spectrally selective sample heated to the operating temperature $T_s = 2000$ K by laser irradiation ($0.5 \mu m$), $G_{\text{laser}}$, experiences convection with an inert gas and radiation exchange with the enclosure.

**FIND:** (a) Total emissivity of the sample, $\varepsilon$; (b) Total absorptivity of the sample, $\alpha$, for irradiation from the enclosure; (c) Laser irradiation required to maintain the sample at $T_s = 2000$ K by performing an energy balance on the sample; (d) Sketch of the sample emissivity during the cool-down process when the laser and inert gas flow are deactivated; identify key features including the emissivity for the final condition ($t \to \infty$); and (e) Time-to-cool the sample from the operating condition at $T_s (0) = 2000$ K to a safe-to-touch temperature of $T_s (t) = 40^\circ$C; use the lumped capacitance method and include the effects of convection with inert gas ($T_\infty = 300$ K, $h = 50$ W/m$^2$·K) as well as radiation exchange $T_{\text{enc}} = T_\infty$.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Enclosure is isothermal and large compared to the sample, (2) Sample is opaque and diffuse, but spectrally selective, so that $\varepsilon_\lambda = \alpha_\lambda$, (3) Sample is isothermal.

**PROPERTIES:** Sample (Given) $\rho = 3900$ kg/m$^3$, $c_p = 760$ J/kg K, $k = 45$ W/m-K.

**ANALYSIS:** (a) The total emissivity of the sample, $\varepsilon$, at $T_s = 2000$ K follows from Eq. 12.38 which can be expressed in terms of the band emission factor, $F_{(0-\lambda, T)}$ Eq. 12.30,

$$\varepsilon = \varepsilon_1 F_{(0-\lambda_1, T_s)} + \varepsilon_2 \left[1 - F_{(0-\lambda_1, T_s)}\right]$$

$$\varepsilon = 0.8 \times 0.7378 + 0.2 \left[1 - 0.7378\right] = 0.643$$

where from Table 12.1, with $\lambda_1 T_s = 3 \mu m \times 2000$ K = 6000 $\mu$m·K, $F_{(0-\lambda_1, T)} = 0.7378$.

(b) The total absorptivity of the sample, $\alpha$, for irradiation from the enclosure at $T_{\text{enc}} = 300$ K, is

$$\alpha = \varepsilon_1 F_{(0-\lambda_1, T_{\text{enc}})} + \varepsilon_2 \left[1 - F_{(0-\lambda_1, T_{\text{enc}})}\right]$$

$$\alpha = 0.8 \times 0 + 0.2 \left[1 - 0\right] = 0.200$$

where, from Table 12.1, with $\lambda_1 T_{\text{enc}} = 3 \mu m \times 300$ K = 900 $\mu$m·K, $F_{(0-\lambda_1, T)} = 0$.

Continued...
(c) The energy balance on the sample, on a per unit area basis, as shown in the schematic at the right is

\[ \dot{E}_{in} - \dot{E}_{out} = 0 \]
\[ + \alpha_{las} G_{laser} + 2\alpha G - 2\varepsilon E_b (T_s) - q_{cv}^* = 0 \]
\[ \alpha_{las} G_{laser} + 2\alpha \sigma T_{enc}^4 - 2\varepsilon T_s^4 - 2h (T_s - T_{\infty}) = 0 \]

Recognizing that \( \alpha_{las}(0.5 \mu m) = 0.8 \), and substituting numerical values find,

\[ 0.8 \times G_{laser} + 2 \times 0.200 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (300 \text{ K})^4 \]
\[ -2 \times 0.643 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (2000 \text{ K})^4 - 2 \times 50 \text{ W/m}^2 \cdot \text{K} (2000 - 500) \text{ K} = 0 \]
\[ 0.8 \times G_{laser} = \left[ -184.6 + 1.167 \times 10^6 + 1.500 \times 10^5 \right] \text{ W/m}^2 \]
\[ G_{laser} = 1646 \text{ kW/m}^2 \]

(d) During the cool-down process, the total emissivity \( \varepsilon \) will decrease as the temperature decreases, \( T_s(t) \). In the limit, \( t \rightarrow \infty \), the sample will reach that of the enclosure, \( T_s(\infty) = T_{enc} \) for which \( \varepsilon = \alpha = 0.200 \).

(e) Using the \textit{IHT Lumped Capacitance Model} considering radiation exchange (\( T_{enc} = 300 \text{ K} \)) and convection (\( T_{\infty} = 300 \text{ K}, h = 50 \text{ W/m}^2 \cdot \text{K} \)) and evaluating the emissivity using Eq. (1) with the \textit{Radiation Tool, Band Emission Factors}, the temperature-time history was determined and the time-to-cool to \( T(t) = 40^\circ \text{C} \) was found as

\[ t = 119 \text{ s} \]

\textbf{COMMENTS:} (1) From the IHT model used for part (e), the emissivity as a function of cooling time and sample temperature were computed and are plotted below. Compare these results to your sketch of part (c).
PROBLEM 12.96 (Cont.)

(2) The IHT workspace model to perform the lumped capacitance analysis with variable emissivity is shown below.

```
// Lumped Capacitance Model - convection and emission/irradiation radiation processes:
/* Conservation of energy requirement on the control volume, CV. */
Edotin - Edotout = Edotst
Edotin = As * ( + Gabs)
Edotout = As * ( + q"cv + E )
Edotst = rho * vol * cp * Der(T,t)
T_C = T - 273
// Absorbed irradiation from large surroundings on CS
Gabs = alpha * G
G = sigma * T^4
sigma = 5.67e-8 // Stefan-Boltzmann constant, W/m^2·K^4
// Emissive power of CS
E = eps * Eb
Eb = sigma * T^4 // Stefan-Boltzmann constant, W/m^2·K^4
// Absorbed irradiation from large surroundings on CS
G = alpha * G
G = sigma * T^4
sigma = 5.67e-8 // Stefan-Boltzmann constant, W/m^2·K^4
// Convection heat flux for control surface CS
q"cv = h * ( T - Tinf )
// The independent variables for this system and their assigned numerical values are */
As = 2 * 1 // surface area, m^2; unit area, top and bottom surfaces
vol = 1 * w // vol, m^3
w = 0.001 // sample thickness, m
rho = 3900 // density, kg/m^3
cp = 760 // specific heat, J/kg·K
// Convection heat flux, CS
h = 50 // convection coefficient, W/m^2·K
Tinf = 300 // fluid temperature, K
// Emission, CS
//eps = 0.5 // emissivity; value used to test the model initially
// Irradiation from large surroundings, CS
alpha = 0.200 // absorptivity; from Part (b); remains constant during cool-down
Tsur = 300 // surroundings temperature, K

// Radiation Tool - Band emission factor:
eps = eps1 * FL1T + eps2 * ( 1 - FL1T )
// The blackbody band emission factor, Figure 12.14 and Table 12.1, is */
FL1T = F_lambda_T(lambda1,T) // Eq 12.30
// where units are lambda (micrometers, mum) and T (K)
lambda1 = 3 // wavelength, mum
eps1 = 0.8 // spectral emissivity; for lambda < lambda1
eps2 = 0.2 // spectral emissivity; for lambda > lambda1
```
**PROBLEM 12.97**

**KNOWN:** Cross flow of air over a cylinder placed within a large furnace.

**FIND:** (a) Steady-state temperature of the cylinder when it is diffuse and gray with \( \varepsilon = 0.5 \), (b) Steady-state temperature when surface has spectral properties shown below, (c) Steady-state temperature of the diffuse, gray cylinder if air flow is parallel to the cylindrical axis, (d) Effect of air velocity on cylinder temperature for conditions of part (a).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Cylinder is isothermal, (2) Furnace walls are isothermal and very large in area compared to the cylinder, (3) Steady-state conditions.

**PROPERTIES:** Table A.4. Air \( (T_f \approx 600 \text{ K}) \): \( \nu = 52.69 \times 10^{-6} \text{ m}^2/\text{s} \), \( k = 46.9 \times 10^{-3} \text{ W/m-K} \), \( \text{Pr} = 0.685 \).

**ANALYSIS:**

(a) When the cylinder surface is gray and diffuse with \( \varepsilon = 0.5 \), the energy balance is of the form, 

\[
\dot{q}_{\text{rad}} - \dot{q}_{\text{conv}} = 0.
\]

Hence, 

\[
\varepsilon \sigma (T_s^4 - T_{\infty}^4) - \bar{h}(T_s - T_{\infty}) = 0.
\]

The heat transfer coefficient, \( \bar{h} \), can be estimated from the Churchill-Bernstein correlation,

\[
\frac{\text{Nu}_D}{D} = \left( \frac{h D}{k} \right) = 0.3 + \frac{0.62 \text{Re}_D^{1/2} \text{Pr}^{1/3}}{\left[ 1 + (0.4/\text{Pr})^{2/3} \right]^{1/4}} \left[ 1 + \left( \frac{\text{Re}_D}{282,000} \right)^{5/8} \right]^{4/5}
\]

where \( \text{Re}_D = V D / \nu = 3 \text{ m/s} \times 30 \times 10^{-3} \text{ m} / 52.69 \times 10^{-6} \text{ m}^2/\text{s} = 1710 \). Hence, 

\[
\text{Nu}_D = 20.8
\]

\[
\bar{h} = 20.8 \times 46.9 \times 10^{-3} \text{ W/m-K} / 30 \times 10^{-3} \text{ m} = 32.5 \text{ W/m}^2 \cdot \text{K}.
\]

Using this value of \( \bar{h} \) in the energy balance expression, we obtain

\[
0.5 \times 5.67 \times 10^{-8} (1000^4 - T_s^4) \text{ W/m}^2 - 32.5 \text{ W/m}^2 \cdot \text{K}(T_s - 400) \text{ K} = 0
\]

which yields \( T_s \approx 839 \text{ K} \).

(b) When the cylinder has the spectrally selective behavior, the energy balance is written as

\[
\alpha G - \varepsilon E_b(T_s) - \dot{q}_{\text{conv}} = 0
\]

where \( G = E_b(T_{\text{sur}}) \). With \( \alpha = \int_0^\infty \alpha_\lambda G_\lambda \, d\lambda / G \),

\[
\alpha = 0.1 \times F_{0 \rightarrow 3} + 0.5 \times (1 - F_{0 \rightarrow 3}) = 0.1 \times 0.273 + 0.5 \times (1 - 0.273) = 0.391
\]

where, using Table 12.1 with \( \lambda T = 3 \times 1000 = 3000 \mu\text{m-K} \), \( F_{0 \rightarrow 3} = 0.273 \). Assuming \( T_s \) is such that emission in the spectral region \( \lambda < 3 \mu\text{m} \) is negligible, the energy balance becomes

Continued...
PROBLEM 12.97 (Cont.)

0.391 \times 5.67 \times 10^{-8} \times 1000^4 \text{ W/m}^2 - 0.5 \times 5.67 \times 10^{-8} \times T_s^4 \text{ W/m}^2 - 32.5 \text{ W/m}^2 \cdot K(T_s - 400) K = 0

which yields $T_s \approx 770$ K.

Note that, for $\lambda T = 3 \times 770 = 2310$ $\mu$m$\cdot$K, $F(0\rightarrow\lambda) = 0.11$; hence the assumption of $\varepsilon = 0.5$ is acceptable. Note also that the value of $\bar{h}$ based upon $T_f = 600$ K is also acceptable.

(c) When the cylinder is diffuse-gray with air flow in the longitudinal direction, the characteristic length for convection is different. Assume conditions can be modeled as flow over a flat plate of $L = 150$ mm. With

$$Re_L = \frac{V L}{v} = 3 \text{ m/s} \times 150 \times 10^{-3} \text{ m} / 52.69 \times 10^{-6} \text{ m}^2 / \text{s} = 8540$$

$$\overline{Nu}_L = (\bar{h} L / k) = 0.664 \text{Re}_L^{1/2} \text{Pr}^{1/3} \bar{h} = 0.664(8540)^{1/2}0.685^{1/3} = 54.1$$

$$\bar{h} = 54.1 \times 0.0469 \text{ W/m} \cdot \text{K} / 0.150 \text{ m} = 16.9 \text{ W/m}^2 \cdot \text{K}.$$  

The energy balance now becomes

$$0.5 \times 5.667 \times 10^{-8} \text{ W/m}^2 \cdot K^4 (1000^4 - T_s^4) K^4 - 16.9 \text{ W/m}^2 \cdot K(T_s - 400) K = 0$$

which yields $T_s \approx 850$ K.

(b) Using the IHT First Law Model with the Correlations and Properties Toolpads, the effect of velocity may be determined and the results are as follows:

Since the convection coefficient increases with increasing $V$ (from 18.5 to 90.6 W/m$^2$·K for $1 \leq V \leq 20$ m/s), the cylinder temperature decreases, since a smaller value of $(T_s - T_{\infty})$ is needed to dissipate the absorbed irradiation by convection.

COMMENTS: The cylinder temperature exceeds the air temperature due to absorption of the incident radiation. The cylinder temperature would approach $T_s$ as $\bar{h} \to \infty$ and/or $\alpha \to 0$. If $\alpha \to 0$ and $\bar{h}$ has a small to moderate value, would $T_s$ be larger than, equal to, or less than $T_{\infty}$? Why?
PROBLEM 12.98

KNOWN: Instrumentation pod, initially at 87°C, on a conveyor system passes through a large vacuum brazing furnace. Inner surface of pod surrounded by a mass of phase-change material (PCM). Outer surface with special diffuse, opaque coating of \( \varepsilon_\lambda \). Electronics in pod dissipate 50 W.

FIND: How long before all the PCM changes to the liquid state?

SCHEMATIC:

ASSUMPTIONS: (1) Surface area of furnace walls much larger than that of pod, (2) No convection, (3) No heat transfer to pod from conveyor, (4) Pod coating is diffuse, opaque, (5) Initially pod internal temperature is uniform at \( T_{pcm} = 87°C \) and remains so during time interval \( \Delta t_m \), (6) Surface area provided is that exposed to walls.

PROPERTIES: Phase-change material, PCM (given): Fusion temperature, \( T_f = 87°C \), \( h_{fg} = 25 \) kJ/kg.

ANALYSIS: Perform an energy balance on the pod for an interval of time \( \Delta t_m \) which corresponds to the time for which the PCM changes from solid to liquid state,

\[
E_{in} - E_{out} + E_{gen} = \Delta E
\]

\[
\left[ (\alpha G - \varepsilon E_b) A_s + P_e \right] \Delta t_m = M h_{fg}
\]

where \( P_e \) is the electrical power dissipation rate, \( M \) is the mass of PCM, and \( h_{fg} \) is the heat of fusion of PCM.

Irradiation:
\( G = \sigma T_w = 5.67 \times 10^{-8} \text{ W/m}^2\cdot\text{K}^4 (1200 \text{ K})^4 = 117,573 \text{ W/m}^2 \)

Emissive power:
\( E_b = \sigma T_m^4 = \sigma (87 + 273)^4 = 952 \text{ W/m}^2 \)

Emissivity:
\( \varepsilon = \varepsilon_1 F_{0,\lambda T} + \varepsilon_2 (1 - F_{0,\lambda T}) \)
\( \varepsilon = 0.05 \times 0.0393 + 0.9 \times (1 - 0.0393) \)
\( \varepsilon = 0.867 \)

Absorptivity:
\( \alpha = \alpha_1 F_{0,\lambda T} + \alpha_2 (1 - F_{0,\lambda T}) \)
\( \alpha = 0.005 \times 0.7378 + 0.9 \times (1 - 0.7378) \)
\( \alpha = 0.273 \)

Substituting numerical values into the energy balance, find,
\[
\left[ (0.273 \times 117,573 - 0.867 \times 952) \text{ W/m}^2 \times 0.040 \text{ m}^2 + 50 \text{ W} \right] \Delta t_m = 1.6 \text{ kg} \times 25 \times 10^3 \text{ J/kg}
\]
\( \Delta t_m = 30.7 \text{ s} = 0.51 \text{ min.} \)
PROBLEM 12.99

KNOWN: Niobium sphere, levitated in surroundings at 300 K and initially at 300 K, is suddenly irradiated with a laser \((10 \text{ W/m}^2)\) and heated to its melting temperature.

FIND: (a) Time required to reach the melting temperature, (b) Power required from the RF heater causing uniform volumetric generation to maintain the sphere at the melting temperature, and (c) Whether the spacewise isothermal sphere assumption is realistic for these conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Niobium sphere is spacewise isothermal and diffuse-gray, (2) Initially sphere is at uniform temperature \(T_i\), (3) Constant properties, (4) Sphere is small compared to the uniform temperature surroundings.

PROPERTIES: Table A-1, Niobium \((\bar{T} = (300 + 2741)K/2 = 1520 \text{ K})\): \(T_{mp} = 2741 \text{ K}\), \(\rho = 8570 \text{ kg/m}^3\), \(c_p = 324 \text{ J/kg} \cdot \text{K}\), \(k = 72.1 \text{ W/m} \cdot \text{K}\).

ANALYSIS: (a) Following the methodology of Section 5.3 for general lumped capacitance analysis, the time required to reach the melting point \(T_{mp}\) may be determined from an energy balance on the sphere,

\[
\dot{E}_{in} - \dot{E}_{out} = \dot{E}_{st} \quad q_o' \cdot A_c - \varepsilon \sigma A_s \left( T^4 - T_{sur}^4 \right) = M c_p \left( \frac{dT}{dt} \right)
\]

where \(A_c = \pi D^2/4\), \(A_s = \pi D^2\), and \(M = \rho V = \rho (\pi D^3/6)\). Hence,

\[
q_o' \left( \pi D^2/4 \right) - \varepsilon \sigma \left( \pi D^2 \right) \left( T^4 - T_{sur}^4 \right) = \rho \left( \pi D^3/6 \right) c_p \left( \frac{dT}{dt} \right).
\]

Regrouping, setting the limits of integration, and integrating, find

\[
\left[ \frac{q_o'}{4 \varepsilon \sigma} + T_{sur}^4 \right] T^4 = \frac{\rho D c dT}{6 \varepsilon \sigma} dt \quad b \int_0^t dt = \int_{T_i}^{T_{mp}} \frac{dT}{a^4 - T^4}
\]

where

\[
a^4 = \frac{q_o'}{4 \varepsilon \sigma} + T_{sur}^4 = \frac{10 \text{ W}/\text{mm}^2 \left(10^3 \text{ m/m}^2 \right)^2}{4 \times 0.6 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}} + (300 \text{ K})^4 \quad a = 2928 \text{ K}
\]

\[
b = \frac{6 \varepsilon \sigma}{\rho D c_p} = \frac{6 \times 0.6 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4}{8570 \text{ kg/m}^3 \times 0.003 \text{ m} \times 324 \text{ J/kg} \cdot \text{K}} = 2.4504 \times 10^{-11} \text{ K}^{-1} \cdot \text{s}^{-1}
\]

which from Eq. 5.18, has the solution

\[
t = \frac{1}{4 ba^3} \left\{ \ln \left[ \frac{a + T_{mp}}{a - T_{mp}} \right] - \ln \left[ \frac{a + T_i}{a - T_i} \right] + 2 \left[ \tan^{-1} \left( \frac{T_{mp}}{a} \right) - \tan^{-1} \left( \frac{T_i}{a} \right) \right] \right\}
\]

Continued …..
PROBLEM 12.99 (Cont.)

\[
t = \frac{1}{4 \left(2.4504 \times 10^{-11} K^{-1} \cdot s^{-1}\right)(2928 K)^3} \left\{ \ln \left[ \frac{2928 + 2741}{2928 - 2741} \right] - \ln \left[ \frac{2928 + 300}{2928 - 300} \right] \right\} \\
+ 2 \left[ \tan^{-1} \left( \frac{2741}{2928} \right) - \tan^{-1} \left( \frac{300}{2928} \right) \right]
\]

\[
t = 0.40604 \left( 3.4117 - 0.2056 + 2 \left[ 0.7524 - 0.1021 \right] \right) = 1.83 \text{s.}
\]

(b) The power required of the RF heater to induce a uniform volumetric generation to sustain steady-state operation at the melting point follows from an energy balance on the sphere,

\[
\dot{E}_{\text{in}} - \dot{E}_{\text{out}} + \dot{E}_{\text{gen}} = 0 \quad -\varepsilon\sigma A_s (T_{\text{mp}} - T_{\text{sur}}) = -\dot{E}_{\text{gen}}
\]

\[
\dot{E}_{\text{gen}} = \dot{q}V = 0.6 \times 5.67 \times 10^{-8} W / m^2 \cdot K^4 \left( \pi \times 0.0032^2 \right) m^2 \left( 2741^4 - 300^4 \right) K^4 = 54.3 W.
\]

(c) The lumped capacitance method is appropriate when

\[
\text{Bi} = \frac{h_r L_C}{k} = \frac{h_r (D/6)}{k} < 0.1
\]

where \( h_r \) is the linearized radiation coefficient, which has the largest value when \( T = T_{\text{mp}} = 2741 K, \)

\[
h_r = \varepsilon\sigma \left( T + T_{\text{sur}} \right) \left( T^2 + T_{\text{sur}}^2 \right)
\]

\[
h_r = 0.6 \times 5.67 \times 10^{-8} W / m^2 \cdot K^4 (2741 + 300) \left( 2741^2 + 300^2 \right) K^3 = 787 W / m^2 \cdot K.
\]

Hence, since

\[
\text{Bi} = 787 W / m^2 \cdot K (0.003 m/3) / 72.1 W / m \cdot K = 1.09 \times 10^{-2}
\]

we conclude that the transient analysis using the lumped capacitance method is satisfactory.

**COMMENTS:**

(1) Note that at steady-state conditions with internal generation, the difference in temperature between the center and surface, is

\[
T_o = T_s = \frac{\dot{q} (D/2)^2}{6k}
\]

and with \( V = \pi D^3/6 \), from the part (b) results,

\[
\dot{q} = \dot{E}_{\text{gen}} / V = 54.3 W / (\pi \times 0.003^3 / 6) m^3 = 3.841 \times 10^9 W / m^3.
\]

Find using an approximate value for the thermal conductivity in the liquid state,

\[
\Delta T = T_o - T_s = \frac{3.841 \times 10^9 W / m^3 (0.03 m/2)^2}{6 \times 80 W / m \cdot K} = 18 K.
\]

We conclude that the sphere is very nearly isothermal even under these conditions.

(2) The relation for \( \Delta T \) in the previous comment follows from solving the heat diffusion equation written for the one-dimensional (spherical) radial coordinate system. See the deviation in Section 3.4.2 for the cylindrical case (Eq. 3.53).
PROBLEM 12.100

KNOWN: Spherical niobium droplet levitated in a vacuum chamber with cool walls. Niobium surface is diffuse with prescribed spectral emissivity distribution. Melting temperature, \( T_{\text{mp}} = 2741 \text{ K} \).

FIND: Requirements for maintaining the drop at its melting temperature by two methods of heating: (a) Uniform internal generation rate, \( \dot{q} \) (W/m\(^3\)), using a radio frequency (RF) field, and (b) Irradiation, \( G_{\text{laser}} \) (W/mm\(^2\)), using a laser beam operating at 0.632 \( \mu \text{m} \); and (c) Time for the drop to cool to 400 K if the heating method were terminated.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions during the heating processes, (2) Chamber is isothermal and large relative to the drop, (3) Niobium surface is diffuse but spectral selective, (4) \( \dot{q} \) is uniform, (5) Laser beam diameter is larger than the droplet, (6) Drop is spacewise isothermal during the cool down.

PROPERTIES: Table A.1, Niobium (\( \bar{T} = (2741 + 400)\text{K}/2 = 1600 \text{ K} \)): \( \rho = 8570 \text{ kg/m}^3 \), \( c_p = 336 \text{ J/kg} \cdot \text{K} \), \( k = 75.6 \text{ W/m} \cdot \text{K} \).

ANALYSIS: (a) For the RF field-method of heating, perform an energy balance on the drop considering volumetric generation, irradiation and emission,

\[
\dot{E}_{\text{in}} - \dot{E}_{\text{out}} + \dot{E}_g = 0
\]

\[
\left[ \alpha G - \varepsilon E_b (T_s) \right] A_s + \dot{q} \varepsilon \gamma = 0
\]  

(1)

where \( A_s = \pi D^2 \) and \( V = \pi D^3/6 \). The irradiation and blackbody emissive power are,

\[
G = \sigma T_w^4
\]

\[
E_b = \sigma T_s^4
\]  

(2,3)

The absorptivity and emissivity are evaluated using Eqs. 12.46 and 12.48, respectively, with the band emission fractions, Eq. 12.30, and

\[
\alpha = \alpha (\alpha_{\lambda}, T_w) = \varepsilon_1 F\left(0 - \lambda_1 T_w\right) + \varepsilon_2 \left[1 - F\left(0 - \lambda_1 T_w\right)\right]
\]

(4)

\[
\alpha = 0.4 \times 0.000 + 0.2 (1 - 0.000) = 0.2
\]

where, from Table 12.1, with \( \lambda_1 T_w = 1 \mu\text{m} \times 300 \text{K} = 300 \mu\text{m} \cdot \text{K} \), \( F(0 - \lambda T) = 0.000 \).

\[
\varepsilon = \varepsilon (\varepsilon_{\lambda}, T_s) = \varepsilon_1 F\left(0 - \lambda_1 T_s\right) + \varepsilon_2 \left[1 - F\left(0 - \lambda_1 T_s\right)\right]
\]

(5)

\[
\varepsilon = 0.4 \times 0.2147 + 0.2 (1 - 0.2147) = 0.243
\]

with \( \lambda_1 T_s = 1 \mu\text{m} \times 2741 \text{K} = 2741 \mu\text{m} \cdot \text{K} \), \( F(0 - \lambda T) = 0.2147 \). Substituting numerical values with \( T_s = T_{\text{mp}} = 2741 \text{ K} \) and \( T_w = 300 \text{ K} \), find

Continued...
PROBLEM 12.100 (Cont.)

\[
\begin{bmatrix}
0.2 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (300 \text{ K})^4 - 0.243 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (2741 \text{ K})^4
\end{bmatrix}
\]

\[\pi (0.003 \text{ m})^2 + q \pi (0.003 \text{ m})^3 / 6 = 0\]

\[q = [-91.85 + 777.724] \text{ W/m}^2 (6/0.003 \text{ m}) = 1.556 \times 10^9 \text{ W/m}^3\]

(b) For the laser-beam heating method, performing an energy balance on the drop considering absorbed laser irradiation, irradiation from the enclosure walls and emission,

\[\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0\]

\[\left[ \alpha G - \varepsilon E_b (T_s) \right] A_s + \alpha_{\text{las}} G_{\text{laser}} A_p = 0 \tag{6}\]

where \(A_p\) represents the projected area of the droplet,

\[A_p = \pi D^2 / 4\] \tag{7}

**Laser irradiation at 10.6 \mu m.** Recognize that for the laser irradiation, \(G_{\text{laser}}\) (10.6 \mu m), the spectral absorptivity is

\[\alpha_{\text{las}} (10.6 \mu m) = 0.2\]

Substituting numerical values onto the energy balance, Eq. (6), find

\[\left[ 0.2 \times \sigma \times (300 \text{ K})^4 - 0.243 \times \sigma \times (2741 \text{ K})^4 \right] \pi (0.003 \text{ m})^2 + 0.2 \times G_{\text{laser}} \times \pi (0.003 \text{ m})^2 / 4 = 0\]

\[G_{\text{laser}} (10.6 \mu m) = 1.56 \times 10^7 \text{ W/m}^2 = 15.6 \text{ W/mm}^2\]

**Laser irradiation at 0.632 \mu m.** For laser irradiation at 0.632 \mu m, the spectral absorptivity is

\[\alpha_{\text{las}} (0.632 \mu m) = 0.4\]

Substituting numerical values into the energy balance, find

\[G_{\text{laser}} (0.632 \mu m) = 7.76 \times 10^6 \text{ W/m}^2 = 7.8 \text{ W/mm}^2\]

(c) With the method of heating terminated, the drop experiences only radiation exchange and begins cooling. Using the *IHT Lumped Capacitance Model* with irradiation and emission processes and the *Radiation Tool, Band Emission Factor* for estimating the emissivity as a function of drop temperature, Eq. (5), the time-to-cool to 400 K from an initial temperature, \(T_s(0) = T_m = 2741 \text{ K}\) was found as

\[T_s(t) = 400 \text{ K} \quad t = 772 \text{ s} = 12.9 \text{ min}\]

**COMMENTS:**

1. Why doesn’t the emissivity of the chamber wall, \(\varepsilon_w\), affect the irradiation onto the drop?

2. The validity of the lumped capacitance method can be determined by evaluating the Biot number,
where we estimated an average radiation coefficient as
\[
\overline{h}_{\text{rad}} = 4\varepsilon\sigma T^3 = 4 \times 0.2 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (1600 \text{ K})^3 = 185 \text{ W/m}^2 \cdot \text{K}
\]

following the estimation method described in Problem 1.20. Since \( \text{Bi} \ll 0.1 \), the lumped capacitance method was appropriate.

(3) In the IHT model of part (c), the emissivity was calculated as a function of \( T_s(t) \) varying from 0.243 at \( T_s = T_{mp} \) to 0.200 at \( T_s = 300 \text{ K} \). If we had done an analysis assuming the drop were diffuse, gray with \( \alpha = \varepsilon = 0.2 \), the time-to-cool would be \( t = 773 \text{ s} \). How do you explain that this simpler approach predicts a time-to-cool that is in good agreement with the result of part (c)?

(4) A copy of the IHT workspace with the model of part (c) is shown below.
**PROBLEM 12.101**

**KNOWN:** Temperatures of furnace and surroundings separated by ceramic plate. Maximum allowable temperature and spectral absorptivity of plate.

**FIND:** (a) Minimum value of air-side convection coefficient, \( h_o \), (b) Effect of \( h_o \) on plate temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Diffuse surface, (2) Negligible temperature gradients in plate, (3) Negligible inside convection, (4) Furnace and surroundings act as blackbodies.

**ANALYSIS:** (a) From a surface energy balance on the plate, \( \alpha_w G_w + \alpha_{sur} G_{sur} = 2 \varepsilon \sigma T_{sur}^4 + h_o (T_s - T_{\infty}) \). Hence,

\[
h_o = \frac{\alpha_w \sigma T_w^4 + \alpha_{sur} \sigma T_{sur}^4 - 2 \varepsilon \sigma T_s^4}{(T_s - T_{\infty})}
\]

Evaluating the absorptivities and emissivity,

\[
\alpha_w = \int_0^\infty \alpha_\lambda G_\lambda \, d\lambda / G = \int_0^\infty \alpha_\lambda E_\lambda b (T_w) / E_b (T_w) \, d\lambda = 0.3 F_{(0-3 \mu m)} + 0.8 \left[ 1 - F_{(0-3 \mu m)} \right]
\]

With \( \lambda T_w = 3 \mu m \times 2400 K = 7200 \mu m \cdot K \), Table 12.1 \( \rightarrow F_{(0-3 \mu m)} = 0.819 \). Hence,

\[
\alpha_w = 0.3 \times 0.819 + 0.8(1 - 0.819) = 0.391
\]

Since \( T_{sur} = 300 K \), irradiation from the surroundings is at wavelengths well above 3 \( \mu m \). Hence,

\[
\alpha_{sur} = \int_0^\infty \alpha_\lambda E_\lambda b (T_{sur}) / E_b (T_{sur}) \, d\lambda = 0.800.
\]

The emissivity is \( \varepsilon = \int_0^\infty \varepsilon_\lambda E_\lambda b (T_{sur}) / E_b (T_{sur}) \, d\lambda = 0.3 F_{(0-3 \mu m)} + 0.8 \left[ 1 - F_{(0-3 \mu m)} \right] \). With \( \lambda T_s = 5400 \mu m \cdot K \), Table 12.1 \( \rightarrow F_{(0-3 \mu m)} = 0.680 \). Hence, \( \varepsilon = 0.3 \times 0.68 + 0.8(1 - 0.68) = 0.460 \).

For the maximum allowable value of \( T_s = 1800 K \), it follows that

\[
h_o = \frac{0.391 \times 5.67 \times 10^{-8} (2400)^4 + 0.8 \times 5.67 \times 10^{-8} (300)^4 - 2 \times 0.46 \times 5.67 \times 10^{-8} (1800)^4}{(1800 - 300)}
\]

\[
h_o = \frac{7.335 \times 10^5 + 3.674 \times 10^2 - 5.476 \times 10^5}{1500} = 126 \text{ W/m}^2 \cdot \text{K}.
\]

(b) Using the IHT First Law Model with the Radiation Toolpad, parametric calculations were performed to determine the effect of \( h_o \).

Continued...
With increasing $h_o$, and hence enhanced convection heat transfer at the outer surface, the plate temperature is reduced.

**COMMENTS:** (1) The surface is not gray. (2) The required value of $h_o \geq 126 \text{ W/m}^2\cdot\text{K}$ is well within the range of air cooling.
**PROBLEM 12.102**

**KNOWN:** Spectral radiative properties of thin coating applied to long circular copper rods of prescribed diameter and initial temperature. Wall and atmosphere conditions of furnace in which rods are inserted.

**FIND:** (a) Emissivity and absorptivity of the coated rods when their temperature is \( T_s = 300 \) K, (b) Initial rate of change of their temperature, \( dT_s/dt \), (c) Emissivity and absorptivity when they reach steady-state temperature, and (d) Time required for the rods, initially at \( T_s = 300 \) K, to reach 1000 K.

**SCHEMATIC:**

ASSUMPTIONS: (1) Rod temperature is uniform, (2) Nitrogen is quiescent, (3) Constant properties, (4) Diffuse, opaque surface coating, (5) Furnace walls form a blackbody cavity about the cylinders, \( G = E_b(T_f) \), (6) Negligible end effects.

**PROPERTIES:** *Table A.1*, Copper (300 K): \( \rho = 8933 \text{ kg/m}^3 \), \( c_p = 385 \text{ J/kg} \cdot \text{K} \), \( k = 401 \text{ W/m} \cdot \text{K} \); *Table A.4*, Nitrogen \( (T_f = 800 \text{ K}, 1 \text{ atm}) \): \( \nu = 82.9 \times 10^{-6} \text{ m}^2/\text{s} \), \( k = 0.0548 \text{ W/m} \cdot \text{K} \), \( \alpha = 116 \times 10^{-6} \text{ m}^2/\text{s} \), \( Pr = 0.715 \), \( \beta = (T_f)^{-1} = 1.25 \times 10^{-3} \text{ K}^{-1} \).

**ANALYSIS:** (a) The total emissivity of the copper rod, \( \varepsilon \), at \( T_s = 300 \) K follows from Eq. 12.38 which can be expressed in terms of the band emission factor, \( F(0 - \lambda T) \), Eq. 12.30,

\[
\varepsilon = \varepsilon_1 F(0 - \lambda_1 T_s) + \varepsilon_2 [1 - F(0 - \lambda_1 T_s)]
\]

where, from Table 12.1, with \( \lambda_1 T_s = 4 \mu\text{m} \times 300 \text{ K} = 1200 \mu\text{m} \cdot \text{K} \), \( F(0 - \lambda T) = 0.0021 \). The total absorptivity, \( \alpha \), for irradiation for the furnace walls at \( T_f = 1300 \text{ K} \), is

\[
\alpha = \varepsilon_1 F(0 - \lambda_1 T_f) + \varepsilon_2 [1 - F(0 - \lambda_1 T_f)]
\]

where, from Table 12.1, with \( \lambda_1 T_f = 4 \mu\text{m} \times 1300 \text{ K} = 5200 \mu\text{m} \cdot \text{K} \), \( F(0 - \lambda T) = 0.6590 \).

(b) From an energy balance on a control volume about the rod,

\[
\dot{E}_{st} = \rho c_p \left( \pi D^2/4 \right) L \left( dT_s/dt \right) = \dot{E}_{in} - \dot{E}_{out} = \pi DL \left[ \alpha G + \hbar (T_\infty - T_s) - E \right]
\]

\[
dT_s/dt = 4 \left[ \alpha G + \hbar (T_\infty - T_s) - \varepsilon \sigma T_s^4 \right]/\rho c_p D.
\]

With

\[
Ra_D = \frac{g \beta (T_\infty - T_s) D^3}{v \alpha} = \frac{9.8 \text{ m}^2/\text{s} \left( 1.25 \times 10^{-3} \text{ K}^{-1} \right) 1000 \text{ K} (0.01 \text{ m})^3}{82.9 \times 10^{-6} \text{ m}^2/\text{s} \times 116 \times 10^{-6} \text{ m}^2/\text{s}} = 1274
\]

Eq. 9.34 gives Continued...
PROBLEM 12.102 (Cont.)

\[
\overline{h} = \frac{0.0548}{0.01} \left[ 0.60 + \frac{0.387 (1274)^{1/6}}{1 + (0.559/0.715)^{9/16}} \right]^{8/27} = 15.1 \text{ W/m}^2 \text{ K} \tag{5}
\]

With values of \(\varepsilon\) and \(\alpha\) from part (a), the rate of temperature change with time is

\[
dT_s/dt = 4 \left[ 0.53 \times 5.67 \times 10^{-8} \text{ W/m}^2 \text{ K}^4 \times (1300 \text{ K})^4 + 15.1 \text{ W/m}^2 \text{ K} \times 1000 \text{ K} - 0.8 \times 5.67 \times 10^{-8} \text{ W/m}^2 \text{ K} \times (300 \text{ K})^4 \right] \frac{8933 \text{ kg/m}^3 \times 385 \text{ J/kg K}}{0.01 \text{ m} \times 401 \text{ W/m} \cdot \text{K}}
\]

\[
dT_s/dt = 1.16 \times 10^{-4} \left[ 85,829 + 15,100 - 3767 \right] \text{ K/s} = 11.7 \text{ K/s}.
\]

(c) Under steady-state conditions, \(T_s = T_\infty = T_f = 1300 \text{ K}\). For this situation, \(\varepsilon = \alpha\), hence

\[
\varepsilon = \alpha = 0.536
\]

(d) The time required for the rods, initially at \(T_s(0) = 300 \text{ K}\), to reach 1000 K can be determined using the lumped capacitance method. Using the IHT Lumped Capacitance Model, considering convection, irradiation and emission processes; the Correlations Tool, Free Convection, Horizontal Cylinder, Radiation Tool, Band Emission Fractions; and a user-generated Lookup Table Function for the nitrogen thermophysical properties, find

\[
T_s(t_o) = 1000 \text{ K} \quad t_o = 81.8 \text{ s}
\]

**COMMENTS:**

1. To determine the validity of the lumped capacitance method to this heating process, evaluate the approximate Biot number, \(\text{Bi} = \overline{h}D/k = 15 \text{ W/m}^2 \cdot \text{K} \times 0.010 \text{ m}/401 \text{ W/m} \cdot \text{K} = 0.0004\). Since \(\text{Bi} < 0.1\), the method is appropriate.

2. The IHT workspace with the model used for part (c) is shown below.

```plaintext
// Lumped Capacitance Model - irradiation, emission, convection

**PROBLEM 12.103**

**KNOWN:** Large combination convection-radiation oven heating a cylindrical product of a prescribed spectral emissivity.

**FIND:** (a) Initial heat transfer rate to the product when first placed in oven at 300 K, (b) Steady-state temperature of the product, (c) Time to achieve a temperature within 50°C of the steady-state temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Cylinder is opaque-diffuse, (2) Oven walls are very large compared to the product, (3) Cylinder end effects are negligible, (4) $\varepsilon_\lambda$ is dependent of temperature.

**PROPERTIES:** Table A-4, Air ($T_f = 525$ K, 1 atm): $\nu = 42.2 \times 10^{-6}$ m$^2$/s, $k = 0.0423$ W/m·K, $Pr = 0.684$; (T$_f$ = 850 K (assumed), 1 atm): $\nu = 93.8 \times 10^{-6}$ m$^2$/s, $k = 0.0596$ W/m·K, $Pr = 0.716$.

**ANALYSIS:**

(a) The net heat rate to the product is $q_{net} = A_s (q_{conv} + \alpha G - \varepsilon E_b)$, or

$$q_{net} = \pi DL \left[ h(T_\infty - T) + \alpha G - \varepsilon \sigma T^4 \right]$$  

(1)

Evaluating properties at $T_f = 525$ K, $Re_D = \frac{VD}{\nu} = 5 \text{ m/s} \times 0.025 \text{ m} / 42.2 \times 10^{-6} \text{ m}^2/\text{s} = 2960$, and the Churchill-Bernstein correlation yields

$$\frac{Nu_D}{k} = 0.3 + \frac{0.62 Re_D^{1/2} Pr^{1/3}}{[1 + (0.4/Pr)^{2/3}]} \left[ 1 + \left( \frac{Re_D}{282,000} \right)^{5/8} \right]^{4/5} = 27.5$$

Hence,

$$h = \frac{0.0423 \text{ W/m·K}}{0.025 \text{ m}} \times 27.5 = 46.5 \text{ W/m}^2 \cdot \text{K}$$

The total, hemispherical emissivity of the diffuse, spectrally selective surface follows from Eq. 12.38, $\varepsilon = \int_0^\infty \varepsilon_\lambda (\lambda, T_s) \frac{\varepsilon T_s^4}{\sigma} d\lambda = \varepsilon_1 (\lambda - 4 \mu m) + \varepsilon_2 (1 - \lambda (4 \mu m))$, where $\lambda_T = 4 \mu m \times 300$ K = 1200 $\mu$m·K and $F_0 (\lambda_T) = 0.002$ (Table 12.1). Hence, $\varepsilon = 0.8 \times 0.002 + 0.2 (1 - 0.002) = 0.201$.

The absorptivity is for irradiation from the oven walls which, because they are large and isothermal, behave as a black surface at 1000 K. From Eq. 12.46, with $G_\lambda = E_\lambda, b_0 (\lambda, 1000 \text{ K})$ and $\alpha_\lambda = \varepsilon_\lambda$,

$$\alpha = \varepsilon_1 F_0 (\lambda - 4 \mu m) + \varepsilon_2 (1 - F_0 (\lambda - 4 \mu m)) = 0.8 \times 0.481 + 0.2 (1 - 0.481) = 0.489$$

where, for $\lambda_T = 4 \times 1000 = 4000 \mu$m·K from Table 12.1, $F_0 (\lambda_T) = 0.481$. From Eq. (1) the net initial heat rate is

$$q_{net} = \pi \times 0.025 \text{ m} \times 0.2 \text{ m} \left[ 46.5 \text{ W/m}^2 \cdot \text{K}(750 - 300) \text{ K} + 0.489 \sigma (1000)^4 \text{ K}^4 - 0.201 \sigma (300 \text{ K})^4 \right]$$

Continued...
(b) For the steady-state condition, the net heat rate will be zero, and the energy balance yields,

\[ 0 = \bar{h} (T_\infty - T) + \alpha G - \varepsilon \sigma T^4 \]

(Eq. 2)

Evaluating properties at an assumed film temperature of \( T_f = 850 \, \text{K} \), \( \text{Re}_D = \frac{V_D}{\nu} = 5 \, \text{m/s} \times \frac{0.025 \, \text{m}}{93.8 \times 10^{-6} \, \text{m}^2/\text{s}} = 1333 \), and the Churchill-Bernstein correlation yields \( \text{Nu}_D = 18.6 \). Hence, \( \bar{h} = 18.6 \) \((0.0596 \, \text{W/m} \cdot \text{K})/0.025 \, \text{m} = 44.3 \, \text{W/m}^2 \cdot \text{K} \). Since irradiation from the oven walls is fixed, the absorptivity is unchanged, in which case \( \alpha = 0.489 \). However, the emissivity depends on the product temperature. Assuming \( T = 950 \, \text{K} \), we obtain

\[ \varepsilon = \varepsilon_1 F_1(0 \rightarrow 4 \mu \text{m}) + \varepsilon_2 (1 - F_1(0 \rightarrow 4 \mu \text{m})) = 0.8 \times 0.443 + 0.2(1 - 0.443) = 0.466 \]

where for \( \lambda T = 4 \times 950 = 3800 \, \mu \text{m} \cdot \text{K} \), \( F_0 \rightarrow \lambda T = 0.443 \), from Table 12.1. Substituting values into Eq. (2) with \( \sigma = 5.67 \times 10^{-8} \, \text{W/m}^2 \cdot \text{K}^4 \),

\[ 0 = 44.3 \, (750 - T) + 0.489 \, \sigma \, (1000 \, \text{K})^4 - 0.466 \, \sigma \, T^4. \]

A trial-and-error solution yields \( T = 930 \, \text{K} \).

(c) Using the IHT Lumped Capacitance Model with the Correlations, Properties (for copper and air) and Radiation Toolpads, the transient response of the cylinder was computed and the time to reach \( T = 880 \, \text{K} \) is

\[ t = 537 \, \text{s}. \]

**COMMENTS:** Note that \( \bar{h} \) is relatively insensitive to \( T \), while \( \varepsilon \) is not. At \( T = 930 \, \text{K} \), \( \varepsilon = 0.456 \).
PROBLEM 12.104

KNOWN: Workpiece, initially at 25°C, to be annealed at a temperature above 725°C for a period of 5 minutes and then cooled; furnace wall temperature and convection conditions; cooling surroundings and convection conditions.

FIND: (a) Emissivity and absorptivity of the workpiece at 25°C when it is placed in the furnace, (b) Net heat rate per unit area into the workpiece for this initial condition; change in temperature with time, dT/dt, for the workpiece; (c) Calculate and plot the emissivity of the workpiece as a function of temperature for the range 25 to 750°C using the Radiation Band Emission tool in IHT, (d) The time required for the workpiece to reach 725°C assuming the applicability of the lumped-capacitance method using the DER(T,t) function in IHT to represent the temperature-time derivative in your energy balance; (e) Calculate the time for the workpiece to cool from 750°C to a safe-to-touch temperature of 40°C if the cool surroundings and cooling air temperature are 25°C and the convection coefficient is 100 W/m²·K; and (f) Assuming that the workpiece temperature increases from 725 to 750°C during the five-minute annealing period, sketch (don’t plot) the temperature history of the workpiece from the start of heating to the end of cooling; identify key features of the process; determine the total time requirement; and justify the lumped-capacitance method of analysis.

SCHEMATIC:

Assumptions: (1) Workpiece is opaque and diffuse, (2) Spectral emissivity is independent of temperature, and (3) Furnace and cooling environment are large isothermal surroundings.

Analysis: (a) Using Eqs. 12.38 and 12.46, ε and α can be determined using band-emission factors, Eq. 12.30 and 12.31.

Emissivity, workpiece at 25°C

ε = ε₁λ₁ · F(0−λT) + ε₂λ₂ · [1 − F(0−λT)]

ε = 0.3 × 1.6 × 10⁻⁵ + 0.8 × (1 − 1.6 × 10⁻⁵) = 0.8

where F(0−λT) is determined from Table 12.1 with λT = 2.5 μm × 298 K = 745 μm·K.

Absorptivity, furnace temperature Tf = 750°C

α = ε₁λ₁ · F(0−λ, Tf) + ε₂λ₂ · [1 − F(0−λ, Tf)]

α = 0.3 × 0.174 + 0.8 × (1 − 0.174) = 0.713

where F(0 − λT) is determined with λT = 2.5 μm × 1023 K = 2557.5 μm·K.

(b) For the initial condition, T(0) = Ti, the energy balance shown schematically below is written in terms of the net heat rate in,
PROBLEM 12.104 (Cont.)

\[
\dot{E}_\text{in}'' - \dot{E}_\text{out}'' = \dot{E}_\text{st}'' \\
q''_{\text{net, in}} = \dot{E}_\text{in}'' - \dot{E}_\text{out}''
\]

where \( G = E_b(T_f) \). Substituting numerical values,

\[
q''_{\text{net, in}} = \left[ h(T_\infty - T_i) - \varepsilon \sigma T_i^4 + \alpha \sigma T_i^4 \right]
\]

\[
q''_{\text{net, in}} = 2 \left[ 100 \text{ W/m}^2 \cdot \text{K} (750 - 25) \text{K} - 0.8 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (298 \text{ K})^4 + 0.713 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (1023 \text{ K})^4 \right]
\]

\[
q''_{\text{net, in}} = 2 \times 116.4 \text{ kW/m}^2 = 233 \text{ kW/m}^2
\]

Considering the energy storage term,

\[
\dot{E}_\text{st}'' = \rho c L \frac{dT}{dt} = q''_{\text{net, in}}
\]

\[
\frac{dT}{dt} = q''_{\text{net, in}} = \frac{233 \text{ kW/m}^2}{2700 \text{ kg/m}^3 \times 885 \text{ J/kg} \times 0.010 \text{ m}} = 9.75 \text{ K/s}
\]

(c) With the relation for \( \varepsilon \) of Part (a) in the IHT workspace, and using the Radiation Band Emission tool, \( \varepsilon \) as a function of workpiece temperature is calculated and plotted below.

Continued ….
PROBLEM 12.104 (Cont.)

As expected, $\varepsilon$ decreases with increasing $T$, and when $T = T_f = 750^\circ C$, $\varepsilon = \alpha = 0.713$. Why is that so?

(d) The energy balance of Part (b), using the lumped capacitance method with the \textit{IHT DER} ($T,t$) function, has the form,

$$2 \left[ h(T_\infty - T) - \varepsilon \sigma T^4 + \alpha \sigma T_f^4 \right] = \rho c L \text{ DER} (T,t)$$

where $\varepsilon = \varepsilon(T)$ from Part (c). From a plot of $T$ vs. $t$ (not shown) in the \textit{IHT} workspace, find

$$T(t_a) = 725^\circ C \quad \text{when} \quad t_a = 186 \text{ s}$$

(e) The time to cool the workpiece from $750^\circ C$ to the safe-to-touch temperature of $40^\circ C$ can be determined using the \textit{IHT} code from Part (d). The cooling conditions are $T_\infty = 25^\circ C$ and $h = 100$ W/m$^2$·K with $T_{sur} = 25^\circ C$. The emissivity is still evaluated using the relation of Part (c), but the absorptivity, which depends upon the surrounding temperature, is $\alpha = 0.80$. From the results in the \textit{IHT} workspace, find

$$T(t_c) = 40^\circ C \quad \text{when} \quad t_c = 413 \text{ s}$$

(f) Assuming the workpiece temperature increases from $725^\circ C$ to $750^\circ C$ during a five-minute annealing period, the temperature history is as shown below.

![Temperature History Diagram]

The workpiece heats from $25^\circ C$ to $725^\circ C$ in $t_a = 186$ s, anneals for a 5-minute period during which the temperature reaches $750^\circ C$, followed by the cool-down process which takes $413$ s. The total required time is

$$t = t_a + 5 \times 60 \text{ s} + t_c = (186 + 300 + 413)\text{s} = 899 \text{ s} = 15 \text{ min}$$

Continued ….
The Biot number based upon convection only is

\[ Bi = \frac{h_{CV}(L/2)}{k} = \frac{100 \text{ W/m}^2 \cdot \text{K} \times 0.005 \text{ m}}{165 \text{ W/m} \cdot \text{K}} = 0.003 << 0.1 \]

so the lumped-capacitance method of analysis is appropriate.

**COMMENTS:** The *IHT* code to obtain the heating time, including emissivity as a function of the workpiece temperature, Part (b), is shown below, complete except for the input variables.

```c
/* Analysis. The radiative properties and net heat flux in are calculated when the workpiece is just inserted into the furnace. The workpiece experiences emission, absorbed irradiation and convection processes. See Help | Solver | Intrinsic Functions for information on DER(T, t). */

/* Results - conditions at \( t = 186 \) s, Ts C - 725 C */

PROBLEM 12.105

KNOWN: For the semiconductor silicon, the spectral distribution of absorptivity, \( \alpha_\lambda \), at selected temperatures. High-intensity, tungsten halogen lamps having spectral distribution approximating that of a blackbody at 2800 K.

FIND: (a) 1%-limits of the spectral band that includes 98% of the blackbody radiation corresponding to the spectral distribution of the lamps; spectral region for which you need to know the spectral absorptivity; (b) Sketch the variation of the total absorptivity as a function of silicon temperature; explain key features; (c) Calculate the total absorptivity at 400, 600 and 900°C for the lamp irradiation; explain results and the temperature dependence; (d) Calculate the total emissivity of the wafer at 600 and 900°C; explain results and the temperature dependence; and (e) Irradiation on the upper surface required to maintain the wafer at 600°C in a vacuum chamber with walls at 20°C. Use the Look-up Table and Integral Functions of IHT to perform the necessary integrations.

SCHEMATIC:

ASSUMPTIONS: (1) Silicon is a diffuse emitter, (2) Chamber is large, isothermal surroundings for the wafer, (3) Wafer is isothermal.

ANALYSIS: (a) From Eqs. 12.30 and 12.31, using Table 12.1 for the band emission factors, \( F(0 \rightarrow \lambda T) \), equal to 0.01 and 0.99 are:

\[
F(0 \rightarrow \lambda 1 \cdot T) = 0.01 \text{ at } \lambda 1 \cdot T = 1437 \mu m \cdot K
\]

\[
F(0 \rightarrow \lambda 2 \cdot T) = 0.99 \text{ at } \lambda 2 \cdot T = 23,324 \mu m \cdot K
\]

So that we have \( \lambda 1 \) and \( \lambda 2 \) limits for several temperatures, the following values are tabulated.

<table>
<thead>
<tr>
<th>T(°C)</th>

<td>19.9</td>
</tr>
</tbody>
</table>

For the 2800 K blackbody lamp irradiation, we need to know the spectral absorptivity over the spectral range 0.51 to 8.33 \( \mu m \) in order to include 98% of the radiation.

(b) The spectral absorptivity is calculated from Eq. 12.46 in which the spectral distribution of the lamp irradiation \( G_\lambda \) is proportional to the blackbody spectral emissive power \( E_{\lambda,b}(\lambda, T) \) at the temperature of lamps, \( T_\ell \) 2800 K.

\[
\alpha_\ell = \frac{\int_0^\infty \alpha_\lambda G_\lambda d\lambda}{\int_0^\infty G_\lambda d\lambda} = \frac{\int_0^\infty \alpha_\lambda E_{\lambda,b}(\lambda, 2800 K)}{\sigma T_\ell^4}
\]

Continued …..
PROBLEM 12.105 (Cont.)

For 2800 K, the peak of the blackbody curve is at 1 µm; the limits of integration for 98% coverage are 0.5 to 8.3 µm according to part (a) results. Note that αλ increases at all wavelengths with temperature, until around 900°C where the behavior is gray. Hence, we’d expect the total absorptivity of the wafer for lamp irradiation to appear as shown in the graph below.

At 900°C, since the wafer is gray, we expect \( \alpha_{\ell} = \alpha_{\lambda} \approx 0.68 \). Near room temperature, since \( \alpha_{\lambda} = 0 \) beyond the band edge, \( \alpha_{\ell} \) is dependent upon \( \alpha_{\lambda} \) in the spectral region below and slightly beyond the peak. From the blackbody tables, the band emission fraction to the short-wavelength side of the peak is 0.25. Hence, estimate \( \alpha_{\ell} = 0.68 \times 0.25 = 0.17 \) at these low temperatures. The increase of \( \alpha_{\ell} \) with temperature is at first moderate, since the longer wavelength region is less significant than is the shorter region. As temperature increases, the \( \alpha_{\lambda} \) closer to the peak begin to change more noticeably, explaining the greater dependence of \( \alpha_{\ell} \) on temperature.

(c) The integration of part (b) can be performed numerically using the IHT INTEGRAL function and specifying the spectral absorptivity in a Lookup Table file (*.lut). The code is shown in the Comments (1) and the results are:

\[
\begin{array}{ccc}
T_w (°C) & 400 & 600 & 900 \\
\alpha_{\ell} & 0.30 & 0.59 & 0.68 \\
\end{array}
\]

(d) The total emissivity can be calculated from Eq. 12.38, recognizing that \( \varepsilon_{\lambda} = \alpha_{\lambda} \) and that for silicon temperatures of 600 and 900°C, the 1% limits for the spectral integration are 1.65 - 26.7 µm and 1.23 - 19.9 µm, respectively. The integration is performed in the same manner as described in part (c); see Comments (2).

\[
\begin{array}{cc}
T (°C) & 600 & 900 \\
\varepsilon & 0.66 & 0.68 \\
\end{array}
\]

(e) From an energy balance on the silicon wafer with irradiation on the upper surface as shown in the schematic below, calculate the irradiation required to maintain the wafer at 600°C.

\[
\hat{E}_{in}'' - \hat{E}_{out}'' = 0 \quad \alpha_{\ell} G_{\ell} - 2\varepsilon E_b (T_w) - \alpha_{\text{sur}} E_b (T_{\text{sur}}) = 0
\]

Recognize that \( \alpha_{\text{sur}} \) corresponds to the spectral distribution of \( E_{\lambda,b} (T_{\text{sur}}) \); that is, upon \( \alpha_{\lambda} \) for long wavelengths (\( \lambda_{\text{max}} = 10 \) µm). We assume \( \alpha_{\text{sur}} = 0.1 \), and with \( T_{\text{sur}} = 20^°C \), find

\[
0.59 \ G_{\ell} - 2\sigma \left[ 0.66(600 + 273)^4 K^4 - 0.1(20 + 273)^4 K^4 \right] = 0
\]

Continued .....
PROBLEM 12.105 (Cont.)

\[ G_\ell = 73.5 \text{ kW/m}^2 \]

where \( E_b(T) = \sigma T^4 \) and \( \sigma = 5.67 \times 10^{-8} \text{ W/m}^2\cdot\text{K}^4 \).

\[ \epsilon E_b(T_w) \quad \alpha_{\text{sur}} E_b(T_{\text{sur}}) \quad \alpha_\ell G_\ell \quad T_w = 600^\circ\text{C} \]

\[ \epsilon E_b(T_w) \quad \alpha_{\text{sur}} E_b(T_{\text{sur}}) \]

COMMENTS: (1) The \textit{IHT} code to obtain the total absorptivity for the lamp irradiation, \( \alpha_\ell \) for a wafer temperature of 400°C is shown below. Similar look-up tables were written for the spectral absorptivity for 600 and 800°C.

/* Results; integration for total absorptivity of lamp irradiation

(2) The \textit{IHT} code to obtain the total emissivity for a wafer temperature of 600°C has the same organization as for obtaining the total absorptivity. We perform the integration, however, with the blackbody spectral emissivity evaluated at the wafer temperature (rather than the lamp temperature). The same look-up file for the spectral absorptivity created in the part (c) code can be used.
**PROBLEM 12.106**

**KNOWN:** Solar irradiation of 1100 W/m² incident on a flat roof surface of prescribed solar absorptivity and emissivity; air temperature and convection heat transfer coefficient.

**FIND:** (a) Roof surface temperature, (b) Effect of absorptivity, emissivity and convection coefficient on temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Back-side of plate is perfectly insulated, (3) Negligible irradiation to plate by atmospheric (sky) emission.

**ANALYSIS:** (a) Performing a surface energy balance on the exposed side of the plate,

\[ \alpha S G_S - \varepsilon_{\text{conv}} - \varepsilon E_b(T_s) = 0 \quad \alpha S G_S - \overline{h}(T_s - T_{\infty}) - \varepsilon\sigma T_s^4 = 0 \]

Substituting numerical values and using absolute temperatures,

\[ 0.6 \times 1100 \frac{W}{m^2} - 25 \frac{W}{m^2 \cdot K} (T_s - 300)K - 0.2(5.67 \times 10^{-8} \frac{W}{m^2 \cdot K^4})T_s^4 = 0 \]

Regrouping, \( 8160 = 25T_s + 1.1340 \times 10^{-8} T_s^4 \), and performing a trial-and-error solution,

\[ T_s = 321.5 \text{K} = 48.5^\circ \text{C} . \]

(b) Using the IHT *First Law* Model for a plane wall, the following results were obtained.

---

Irrespective of the value of \( \overline{h} \), \( T \) decreases with increasing \( \varepsilon \) (due to increased emission) and decreasing \( \alpha_S \) (due to reduced absorption of solar energy). For moderate to large \( \alpha_S \) and/or small \( \varepsilon \) (net radiation transfer to the surface) \( T \) decreases with increasing \( \overline{h} \) due to enhanced cooling by convection. However, for small \( \alpha_S \) and large \( \varepsilon \), emission exceeds absorption, dictating convection heat transfer to the surface and hence \( T < T_{\infty} \). With increasing \( \overline{h} \), \( T \to T_{\infty} \), irrespective of the values of \( \alpha_S \) and \( \varepsilon \).

**COMMENTS:** To minimize the roof temperature, the value of \( \varepsilon/\alpha_S \) should be maximized.
PROBLEM 12.107

KNOWN: Cavity with window whose outer surface experiences convection and radiation.

FIND: Temperature of the window and power required to maintain cavity at prescribed temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Cavity behaves as a blackbody, (3) Solar spectral distribution is that of a blackbody at 5800K, (4) Window is isothermal, (5) Negligible convection on lower surface of window.

PROPERTIES: Window material: 0.2 ≤ λ ≤ 4 µm, τ_λ = 0.9, ρ_λ = 0, hence α_λ = 1 - τ_λ = 0.1; 4 µm < λ, τ_λ = 0, α = ε = 0.95, diffuse-gray, opaque

ANALYSIS: To determine the window temperature, perform an energy balance on the window,

\[ \dot{E}_{in} - \dot{E}_{out} = 0 \]

\[ [\alpha_{\text{sur}} G_{\text{sur}} + \alpha_S G_S - \varepsilon E_b - q_{\text{conv}}]_{\text{upper}} + [\alpha_C G_C - \varepsilon E_b (T)]_{\text{lower}} = 0. \quad (1) \]

Calculate the absorptivities for various irradiation conditions using Eq. 12.46,

\[ \alpha = \int_0^\infty \alpha_\lambda G_\lambda d\lambda / \int_0^\infty G_\lambda d\lambda \quad (2) \]

where \( G(\lambda) \) is the spectral distribution of the irradiation.

Surroundings, \( \alpha_{\text{sur}} \): \( G_{\text{sur}} = E_b (T_{\text{sur}}) = \sigma T_{\text{sur}}^4 \)

\[ \alpha_{\text{sur}} = 0.1 \left[ F(0\to4\mu m) - F(0\to0.2\mu m) \right] + 0.95 \left[ 1 - F(0\to4\mu m) \right] \]

where from Table 12.1, with \( T = T_{\text{sur}} = (25 + 273)K = 298K \),

\[ \lambda T = 0.2\mu m \times 298K = 59.6\mu m \cdot K, \quad F(0\to\lambda T) = 0.000 \]

\[ \lambda T = 4\mu m \times 298K = 1192\mu m \cdot K, \quad F(0\to\lambda T) = 0.002 \]

\[ \alpha_{\text{sur}} = 0.1[0.002-0.000] + 0.95[1-0.002] = 0.948. \quad (3) \]

Solar, \( \alpha_S \): \( G_S \sim E_b (5800K) \)

\[ \alpha_S = 0.1 \left[ F(0\to4\mu m) - F(0\to0.2\mu m) \right] + 0.95 \left[ 1 - F(0\to4\mu m) \right] \]

where from Table 12.1, with \( T = 5800K \),

\[ \lambda T = 0.2\mu m \times 5800K = 1160\mu m \cdot K, \quad F(0\to\lambda T) = 0.002 \]

\[ \lambda T = 4\mu m \times 5800K = 23,200\mu m \cdot K, \quad F(0\to\lambda T) = 0.990 \]

\[ \alpha_S = 0.1[0.990-0.002] + 0.95[1-0.990] = 0.108. \quad (4) \]

Continued …..
PROBLEM 12.107 (Cont.)

Cavity, $\alpha_C$:

$$
\alpha_C = 0.1 \left[ F(0\rightarrow4\mu m) - F(0\rightarrow0.2\mu m) \right] + 0.95 \left[ 1 - F(0\rightarrow4\mu m) \right]
$$

where from Table 12.1 with $T_c = 250^\circ C = 523K$,

$$
\lambda T = 0.2\mu m \times 523K = 104.6\mu m \cdot K, \quad F(0\rightarrow\lambda T) = 0.000
$$

$$
\lambda T = 4\mu m \times 523K = 2092\mu m \cdot K \quad F(0\rightarrow\lambda T) = 0.082
$$

$$
\alpha_C = 0.1[0.082 - 0.000] + 0.95[1 - 0.082] = 0.880.
$$

To determine the emissivity of the window, we need to know its temperature. However, we know that $T$ will be less than $T_c$ and the long wavelength behavior will dominate. That is,

$$
\varepsilon \approx \varepsilon_{\lambda} (\lambda > 4\mu m) = 0.95.
$$

With these radiative properties now known, the energy equation, Eq. (1) can now be evaluated using $q_{conv} = h(T - T_{\infty})$ with all temperatures in kelvin units.

$$
0.948 \times \sigma (298K)^4 + 0.108 \times 800W/m^2 - 0.95 \times \sigma T^4 - 10W/m^2 \cdot K (T - 298K)
$$

$$
+ 0.880 \sigma (523K)^4 - 0.95 \times \sigma T^4 = 0
$$

$$
1.077 \times 10^{-7} T^4 + 10 T - 7223 = 0.
$$

Using a trial-and-error approach, find the window temperature as $T = 413K = 139^\circ C$.

To determine the power required to maintain the cavity at $T_c = 250^\circ C$, perform an energy balance on the cavity.

$$
\dot{E}_{in} - \dot{E}_{out} = 0
$$

$$
q_p + A_c [\rho E_b(T_c) + \tau_S G_s + \varepsilon E_b(T) - E_b(T_c)] = 0.
$$

For simplicity, we have assumed the window opaque to irradiation from the surroundings. It follows that

$$
\tau_S = 1 - \rho S - \alpha_S = 1 - 0.108 = 0.892
$$

$$
\rho = 1 - \alpha = 1 - \varepsilon = 1 - 0.95 = 0.05.
$$

Hence, the power required to maintain the cavity, when $A_C = (\pi/4)D^2$, is

$$
q_p = A_c \left[ \sigma T_c^4 - \rho \sigma T_c^4 - \tau_S G_s - \varepsilon \sigma T^4 \right]
$$

$$
q_p = \frac{\pi}{4} (0.050m)^2 \left[ \sigma (523K)^4 - 0.05 \sigma (523K)^4 - 0.892 \times 800W/m^2 - 0.95 \sigma (412K)^4 \right]
$$

$$
q_p = 3.47W.
$$

**COMMENTS:** Note that the assumed value of $\varepsilon = 0.95$ is not fully satisfied. With $T = 412K$, we would expect $\varepsilon = 0.929$. Hence, an iteration may be appropriate.
KNOWN: Features of an evacuated tube solar collector.

FIND: Ideal surface spectral characteristics.

SCHEMATIC:

ANALYSIS: The outer tube should be transparent to the incident solar radiation, which is concentrated in the spectral region $\lambda \leq 3\mu m$, but it should be opaque and highly reflective to radiation emitted by the outer surface of the inner tube, which is concentrated in the spectral region above $3\mu m$. Accordingly, ideal spectral characteristics for the outer tube are

Note that large $\rho_\lambda$ is desirable for the outer, as well as the inner, surface of the outer tube. If the surface is diffuse, a large value of $\rho_\lambda$ yields a small value of $\varepsilon_\lambda = \alpha_\lambda = 1 - \rho_\lambda$. Hence losses due to emission from the outer surface to the surroundings would be negligible.

The opaque outer surface of the inner tube should absorb all of the incident solar radiation ($\lambda \leq 3\mu m$) and emit little or no radiation, which would be in the spectral region $\lambda > 3\mu m$. Accordingly, assuming diffuse surface behavior, ideal spectral characteristics are:
PROBLEM 12.109

KNOWN: Plate exposed to solar flux with prescribed solar absorptivity and emissivity; convection and surrounding conditions also prescribed.

FIND: Steady-state temperature of the plate.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Plate is small compared to surroundings, (3) Backside of plate is perfectly insulated, (4) Diffuse behavior.

ANALYSIS: Perform a surface energy balance on the top surface of the plate.

\[ \dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0 \]

\[ \alpha_S G_S + \alpha G_{\text{sur}} - q_{\text{conv}} - \varepsilon E_b(T_s) = 0 \]

Note that the effect of the surroundings is to provide an irradiation, \( G_{\text{sur}} \), on the plate; since the spectral distribution of \( G_{\text{sur}} \) and \( E_b(T_s) \) are nearly the same, according to Kirchoff’s law, \( \alpha = \varepsilon \). Recognizing that \( G_{\text{sur}} = \sigma T_{\text{sur}}^4 \) and using Newton’s law of cooling, the energy balance is

\[ \alpha_S G_S + \varepsilon \sigma T_{\text{sur}}^4 - \bar{h}(T_s - T_\infty) - \varepsilon \sigma T_s^4 = 0. \]

Substituting numerical values,

\[ 0.9 \times 900 \text{ W/m}^2 + 0.1 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K} \times (17 + 273)^4 \text{ K}^4 - 20 \text{ W/m}^2 \cdot \text{K} (T_s - 290) \text{ K} - 0.1 \left( 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \right) T_s^4 = 0 \]

\[ 6650 \text{ W/m}^2 = 20 T_s + 5.67 \times 10^{-9} T_s^4. \]

From a trial-and-error solution, find

\[ T_s = 329.2 \text{ K}. \]

COMMENTS: (1) When performing an analysis with both convection and radiation processes present, all temperatures must be expressed in absolute units (K).

(2) Note also that the terms \( \alpha G_{\text{sur}} - \varepsilon E_b(T_s) \) could be expressed as a radiation exchange term, written as

\[ q_{\text{rad}} = q / A = \varepsilon \sigma \left( T_{\text{sur}}^4 - T_s^4 \right). \]

The conditions for application of this relation were met and are namely: surroundings much larger than surface, diffuse surface, and spectral distributions of irradiation and emission are similar (or the surface is gray).
PROBLEM 12.110

KNOWN: Directional distribution of $\alpha_\theta$ for a horizontal, opaque, gray surface exposed to direct and diffuse irradiation.

FIND: (a) Absorptivity to direct radiation at 45° and to diffuse radiation, and (b) Equilibrium temperature for specified direct and diffuse irradiation components.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Opaque, gray surface behavior, (3) Negligible convection at top surface and perfectly insulated back surface.

ANALYSIS: (a) From knowledge of $\alpha_\theta(\theta)$ – see graph above – it is evident that the absorptivity of the surface to the direct radiation (45°) is

$\alpha_{\text{dir}} = \alpha_\theta(45^\circ) = 0.8.$

The absorptivity to the diffuse radiation is the hemispherical absorptivity given by Eq. 12.44. Dropping the $\lambda$ subscript,

$$\alpha_{\text{dir}} = 2 \left[ \int_0^{\pi/2} \alpha_\theta(\theta) \cos \theta \sin \theta \, d\theta \right]$$

(b) Performing a surface energy balance,

$$\dot{E}_\text{in} - \dot{E}_\text{out} = 0$$

$$\alpha_{\text{dir}} G_{\text{dir}} + \alpha_{\text{dir}} G_{\text{dif}} - \varepsilon \sigma T_s^4 = 0.$$ (2)

The total, hemispherical emissivity may be obtained from Eq. 12.36 where again the subscript may be deleted. Since this equation is of precisely the same form as Eq. 12.44 – see Eq. (1) above – and since $\alpha_\theta = \varepsilon_\theta$, it follows that

$$\varepsilon = \alpha_{\text{dif}} = 0.625$$

and from Eq. (2), find

$$T_s^4 = \frac{(0.8 \times 600 + 0.625 \times 100) \text{W/m}^2}{0.625 \times 5.67 \times 10^{-8} \text{W/m}^2 \cdot \text{K}^4} = 1.53 \times 10^{10} \text{K}^4, \quad T_s = 352 \text{ K}.$$ (3)

COMMENTS: In assuming gray surface behavior, spectral effects are not present, and total and spectral properties are identical. However, the surface is not diffuse and hence hemispherical and directional properties differ.
**PROBLEM 12.111**

**KNOWN:** Plate temperature and spectral and directional dependence of its absorptivity. Direction and magnitude of solar flux.

**FIND:** (a) Expression for total absorptivity, (b) Expression for total emissivity, (c) Net radiant flux, (d) Effect of cut-off wavelength associated with directional dependence of the absorptivity.

**SCHEMATIC:**

![Schematic Diagram](image)

**ASSUMPTIONS:** (1) Diffuse component of solar flux is negligible, (2) Spectral distribution of solar radiation may be approximated as that from a blackbody at 5800 K, (3) Properties are independent of azimuthal angle $\phi$.

**ANALYSIS:** (a) For $\lambda < \lambda_c$ and $\theta = 45^\circ$, $\alpha_\lambda = \alpha_1 \cos \theta = 0.707 \alpha_1$. From Eq. (12.47) the total absorptivity is then

$$\alpha_S = 0.707 \alpha_1 \left[ \int_0^{\lambda_c} \frac{E_{\lambda,b} \left( \lambda, 5800 \text{ K} \right) \text{d}\lambda}{E_b} \right] + \alpha_2 \left[ \int_{\lambda_c}^{\infty} \frac{E_{\lambda,b} \left( \lambda, 5800 \text{ K} \right) \text{d}\lambda}{E_b} \right] = 0.707 \alpha_1 F_{(0\rightarrow\lambda_c)} + \alpha_2 \left[ 1 - F_{(0\rightarrow\lambda_c)} \right]$$

For the prescribed value of $\lambda_c$, $\lambda_c T = 11,600 \mu$m·K and, from Table 12.1, $F_{(0\rightarrow\lambda_c)} = 0.941$. Hence, $\alpha_S = 0.707 \times 0.93 \times 0.941 + 0.25 (1 - 0.941) = 0.619 + 0.015 = 0.634$ <

(b) With $\varepsilon_{\lambda,\theta} = \varepsilon_{\lambda,0}$, Eq (12.36) may be used to obtain $\varepsilon_{\lambda}$ for $\lambda < \lambda_c$.

$$\varepsilon_{\lambda} (\lambda, T) = 2\alpha_1 \int_0^{\pi/2} \cos^2 \theta \sin \theta \text{d}\theta = -2\alpha_1 \frac{\cos^3 \theta}{3} \bigg|_0^{\pi/2} = \frac{2}{3} \alpha_1$$

From Eq. (12.38),

$$\varepsilon = 0.667 \alpha_1 \left[ \int_0^{\lambda_c} \frac{E_{\lambda,b} \left( \lambda, T_p \right) \text{d}\lambda}{E_b} \right] + \alpha_2 \left[ \int_{\lambda_c}^{\infty} \frac{E_{\lambda,b} \left( \lambda, T_p \right) \text{d}\lambda}{E_b} \right] = 0.667 \alpha_1 F_{(0\rightarrow\lambda_c)} + \alpha_2 \left[ 1 - F_{(0\rightarrow\lambda_c)} \right]$$

For $\lambda_c = 2 \mu$m and $T_p = 333$ K, $\lambda_c T = 666 \mu$m·K and, from Table 12.1, $F_{(0\rightarrow\lambda_c)} = 0$. Hence,

$$\varepsilon = \alpha_2 = 0.25$$

Continued …..
PROBLEM 12.111 (Cont.)

(c) \[ q_{\text{net}}^* = \alpha_S q_S^* - \varepsilon \sigma T_p^4 = 634 \text{ W/m}^2 - 0.25 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (333 \text{ K})^4 \]

\[ q_{\text{net}}^* = 460 \text{ W/m}^2 \]

(d) Using the foregoing model with the Radiation/Band Emission Factor option of IHT, the following results were obtained for \( \alpha_S \) and \( \varepsilon \). The absorptivity increases with increasing \( \lambda_c \), as more of the incident solar radiation falls within the region of \( \alpha_1 > \alpha_2 \). Note, however, the limit at \( \lambda = 3 \mu\text{m} \), beyond which there is little change in \( \alpha_S \). The emissivity also increases with increasing \( \lambda_c \), as more of the emitted radiation is at wavelengths for which \( \varepsilon_1 = \alpha_1 > \varepsilon_2 = \alpha_2 \). However, the surface temperature is low, and even for \( \lambda_c = 5 \mu\text{m} \), there is little emission at \( \lambda < \lambda_c \). Hence, \( \varepsilon \) only increases from 0.25 to 0.26 as \( \lambda_c \) increases from 0.7 to 5.0 \( \mu\text{m} \).

The net heat flux increases from 276 W/m\(^2\) at \( \lambda_c = 2 \mu\text{m} \) to a maximum of 477 W/m\(^2\) at \( \lambda_c = 4.2 \mu\text{m} \) and then decreases to 474 W/m\(^2\) at \( \lambda_c = 5 \mu\text{m} \). The existence of a maximum is due to the upper limit on the value of \( \alpha_S \) and the increase in \( \varepsilon \) with \( \lambda_c \).

COMMENTS: Spectrally and directionally selective coatings may be used to enhance the performance of solar collectors.
PROBLEM 12.112

KNOWN: Spectral distribution of $\alpha_{\lambda}$ for two roof coatings.

FIND: Preferred coating for summer and winter use. Ideal spectral distribution of $\alpha_{\lambda}$.

SCHEMATIC:

ASSUMPTIONS: (1) Opaque, diffuse surface behavior, (2) Negligible convection effects and heat transfer from bottom of roof, negligible atmospheric irradiation, (3) Steady-state conditions.

ANALYSIS: From an energy balance on the roof surface

$$\varepsilon \sigma T_s^4 = \alpha_S G_s.$$ 

Hence

$$T_s = \left( \frac{\alpha_S G_s}{\varepsilon \sigma} \right)^{1/4}.$$ 

Solar irradiation is concentrated in the spectral region $\lambda < 4 \mu m$, while surface emission is concentrated in the region $\lambda > 4 \mu m$. Hence, with $\alpha_{\lambda} = \varepsilon_{\lambda}$

Coating A: $\alpha_S \approx 0.8$, $\varepsilon \approx 0.8$

Coating B: $\alpha_S \approx 0.6$, $\varepsilon \approx 0.2$.

Since $(\alpha_S/\varepsilon)_A = 1 < (\alpha_S/\varepsilon)_B = 3$, Coating A would result in the lower roof temperature and is preferred for summer use. In contrast, Coating B is preferred for winter use. The ideal coating is one which minimizes $(\alpha_S/\varepsilon)$ in the summer and maximizes it in the winter.
PROBLEM 12.113

KNOWN: Shallow pan of water exposed to night desert air and sky conditions.

FIND: Whether water will freeze.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Bottom of pan is well insulated, (3) Water surface is diffuse-gray, (4) Sky provides blackbody irradiation, \( G_{\text{sky}} = \sigma T_{\text{sky}}^4 \).

PROPERTIES: Table A-11, Water (300 K): \( \varepsilon = 0.96 \).

ANALYSIS: To estimate the water surface temperature for these conditions, begin by performing an energy balance on the pan of water considering convection and radiation processes.

\[
\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0
\]

\[
\alpha G_{\text{sky}} - \varepsilon E_b h (T_s - T_\infty) = 0
\]

\[
\varepsilon \sigma \left( T_{\text{sky}}^4 - T_s^4 \right) - h (T_s - T_\infty) = 0.
\]

Note that, from Eq. 12.64, \( G_{\text{sky}} = \sigma T_{\text{sky}}^4 \) and from Assumption 3, \( \alpha = \varepsilon \). Substituting numerical values, with all temperatures in kelvin units, the energy balance is

\[
0.96 \times 5.67 \times 10^{-8} \left( \frac{W}{m^2 \cdot K} \right) \left[ (-40 + 273)^4 - T_s^4 \right] K^4 - 5 \left( \frac{W}{m^2 \cdot K} \right) [T_s - (20 + 273)] K = 0
\]

\[
5.443 \times 10^{-8} \left[ 233^4 - T_s^4 \right] - 5[T_s - 293] = 0.
\]

Using a trial-and-error approach, find the water surface temperature,

\( T_s = 268.5 \text{K} \). <br><br>
Since \( T_s < 273 \text{ K} \), it follows that the water surface will freeze under the prescribed air and sky conditions.

COMMENTS: If the heat transfer coefficient were to increase as a consequence of wind, freezing might not occur. Verify that for the given \( T_\infty \) and \( T_{\text{sky}} \), that if \( h \) increases by more than 40%, freezing cannot occur.
**PROBLEM 12.114**

**KNOWN:** Flat plate exposed to night sky and in ambient air at $T_{\text{air}} = 15^\circ \text{C}$ with a relative humidity of 70%. Radiation from the atmosphere or sky estimated as a fraction of the blackbody radiation corresponding to the near-ground air temperature, $G_{\text{sky}} = \varepsilon_{\text{sky}} \sigma T_{\text{air}}$, and for a clear night, $\varepsilon_{\text{sky}} = 0.741 + 0.0062 T_{\text{dp}}$ where $T_{\text{dp}}$ is the dew point temperature ($^\circ$C). Convection coefficient estimated by correlation, $h \left( \text{W} / \text{m}^2 \cdot \text{K} \right) = 1.25 \Delta T^{1/3}$ where $\Delta T$ is the plate-to-air temperature difference (K).

**FIND:** Whether dew will form on the plate if the surface is (a) clean metal with $\varepsilon_m = 0.23$ and (b) painted with $\varepsilon_p = 0.85$.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Surfaces are diffuse, gray, and (3) Backside of plate is well insulated.

**PROPERTIES:** *Psychrometric charts* (Air), $T_{\text{dp}} = 9.4^\circ \text{C}$ for dry bulb temperature $15^\circ \text{C}$ and relative humidity 70%.

**ANALYSIS:** From the schematic above, the energy balance on the plate is

$$\dot{E}_{\text{in}}'' - \dot{E}_{\text{out}}'' = 0$$

$$\alpha_{\text{sky}} G_{\text{sky}} + q_{\text{cv}}' - \varepsilon E_b(T_s) = 0$$

$$\varepsilon \left( 0.741 + 0.0062 T_{\text{dp}}(^\circ \text{C}) \right) \sigma T_{\text{air}}^4 + 1.25(T_{\text{air}} - T_s)^{4/3} \text{ W/ m}^2 - \varepsilon \sigma T_s^4 \text{ W/ m}^2 = 0$$

where $G_{\text{sky}} = \varepsilon_{\text{sky}} \sigma T_{\text{air}}$, $\varepsilon_{\text{sky}} = 0.741 + 0.062 T_{\text{dp}}$ ($^\circ$C); $T_{\text{dp}}$ has units ($^\circ$C); and, other temperatures in kelvins. Since the surface is diffuse-gray, $\alpha_{\text{sky}} = \varepsilon$.

(a) **Clean metallic surface, $\varepsilon_m = 0.23$**

$$0.23 \left( 0.741 + 0.0062 T_{\text{dp}}(^\circ \text{C}) \right) \sigma (15 + 273)^4 K^4$$

$$+ 1.25 \left( 289 - T_{s,m} \right)^{4/3} \text{ W/ m}^2 - 0.23 \sigma T_{s,m}^4 \text{ W/ m}^2 = 0$$

$$T_{s,m} = 282.7 \text{ K} = 9.7^\circ \text{C}$$

(b) **Painted surface, $\varepsilon_p = 0.85$**

$$T_{s,p} = 278.5 \text{ K} = 5.5^\circ \text{C}$$

**COMMENTS:** For the painted surface, $\varepsilon_p = 0.85$, find that $T_s < T_{\text{dp}}$, so we expect dew formation. For the clean, metallic surface, $T_s > T_{\text{dp}}$, so we do not expect dew formation.
KNOWN: Glass sheet, used on greenhouse roof, is subjected to solar flux, \( G_S \), atmospheric emission, \( G_{atm} \), and interior surface emission, \( G_i \), as well as to convection processes.

FIND: (a) Appropriate energy balance for a unit area of the glass, (b) Temperature of the greenhouse ambient air, \( T_{\infty,i} \), for prescribed conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Glass is at a uniform temperature, \( T_g \); (2) Steady-state conditions.

PROPERTIES: Glass: \( \tau_\lambda = 1 \) for \( \lambda \leq 1 \mu m \); \( \tau_\lambda = 0 \) and \( \alpha_\lambda = 1 \) for \( \lambda > 1 \mu m \).

ANALYSIS: (a) Performing an energy balance on the glass sheet with \( \dot{E}_{in} = \dot{E}_{out} = 0 \) and considering two convection processes, emission and three absorbed irradiation terms, find

\[
\alpha_S G_S + \alpha_{atm} G_{atm} + h_0 (T_{\infty,o} - T_g) + \alpha_i G_i + h_i (T_{\infty,i} - T_g) - 2 \varepsilon \sigma T_g^4 = 0
\]

where \( \alpha_S = \) solar absorptivity for absorption of \( G_{\lambda,S} \sim E_{\lambda,b} (\lambda, 5800K) \)

\( \alpha_{atm} = \alpha_i = \) absorptivity of long wavelength irradiation (\( \lambda \gg 1 \mu m \)) = 1

\( \varepsilon = \alpha_\lambda \) for \( \lambda \gg 1 \mu m \), emissivity for long wavelength emission = 1

(b) For the prescribed conditions, \( T_{\infty,i} \) can be evaluated from Eq. (1). As noted above, \( \alpha_{atm} = \alpha_i = 1 \) and \( \varepsilon = 1 \). The solar absorptivity of the glass follows from Eq. 12.47 where \( G_{\lambda,S} \sim E_{\lambda,b} (\lambda, 5800K) \),

\[
\alpha_S = \int_0^{\infty} \alpha_\lambda G_{\lambda,S} d\lambda / G_s = \int_0^{\infty} \alpha_\lambda E_{\lambda,b} (\lambda, 5800K) d\lambda / E_b (5800K)
\]

\[
\alpha_S = \alpha_1 F_0(1\mu m) + \alpha_2 \left[ 1 - F_0(1\mu m) \right] = 0.720 + 1.0[1 - 0.720] = 0.28.
\]

Note that from Table 12.1 for \( \lambda T = 1 \mu m \times 5800K = 5800 \mu m \cdot K \), \( F_0( \lambda ) = 0.720 \). Substituting numerical values into Eq. (1),

\[
0.28 \times 1100 W/m^2 + 1 \times 250 W/m^2 + 55 W/m^2 \cdot K (24 - 27) K + 1 \times 440 W/m^2 + 10 W/m^2 \cdot K (T_{\infty,i} - 27) K - 2 \times 1 \times 5.67 \times 10^{-8} W/m^2 \cdot K (27 + 273)^4 K^4 = 0
\]

find that

\[
T_{\infty,i} = 35.5 \degree C.
\]
**PROBLEM 12.116**

**KNOWN:** Plate temperature and spectral absorptivity of coating.

**FIND:** (a) Solar irradiation, (b) Effect of solar irradiation on plate temperature, total absorptivity, and total emissivity.

**SCHEMATIC:**

![Schematic Diagram](image)

**ASSUMPTIONS:** (1) Steady-state, (2) Opaque, diffuse surface, (3) Isothermal plate, (4) Negligible radiation from surroundings.

**ANALYSIS:** (a) Performing an energy balance on the plate, \(2\alpha_S G_S - 2E = 0\) and

\[
\alpha_S G_S - \varepsilon \sigma T^4 = 0
\]

For \(\lambda T = 4.5 \mu m \times 2000 \text{ K} = 9000 \mu \text{m-K}\), Table 12.1 yields \(F_{\lambda \rightarrow \lambda} = 0.890\). Hence,

\[
\varepsilon = \varepsilon_1 F_{\lambda \rightarrow \lambda} + \varepsilon_2 \left(1 - F_{\lambda \rightarrow \lambda}\right) = 0.95 \times 0.890 + 0.03 \times (1 - 0.890) = 0.849
\]

For \(\lambda T = 4.5 \mu m \times 5800 \text{ K} = 26,100\), \(F_{\lambda \rightarrow \lambda} = 0.993\). Hence,

\[
\alpha_S = \alpha_1 F_{\lambda \rightarrow \lambda} + \alpha_2 \left(1 - F_{\lambda \rightarrow \lambda}\right) = 0.95 \times 0.993 + 0.03 \times 0.007 = 0.944
\]

Hence,

\[
G_S = \left(\varepsilon / \alpha_S\right) \sigma T^4 = \left(0.849 / 0.944\right) 5.67 \times 10^{-8} \text{ W/m}^2\cdot\text{K}^4 (2000 \text{ K})^4 = 8.16 \times 10^5 \text{ W/m}^2
\]

(b) Using the IHT *First Law* Model and the *Radiation* Toolpad, the following results were obtained.

![Graphs](image)

The required solar irradiation increases with \(T\) to the fourth power. Since \(\alpha_S\) is determined by the spectral distribution of solar radiation, its value is fixed. However, with increasing \(T\), the spectral distribution of emission is shifted to lower wavelengths, thereby increasing the value of \(\varepsilon\).
PROBLEM 12.117

KNOWN: Thermal conductivity, spectral absorptivity and inner and outer surface conditions for wall of central solar receiver.

FIND: Minimum wall thickness needed to prevent thermal failure. Collector efficiency.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Outer surface is opaque and diffuse, (3) Spectral distribution of solar radiation corresponds to blackbody emission at 5800 K.

ANALYSIS: From an energy balance at the outer surface, \( \dot{E}_{in} = \dot{E}_{out} \),

\[
\alpha_s \sigma \epsilon_s + \alpha_{sur} G_{sur} = \varepsilon \sigma \left( T_{s,o}^4 - T_{\infty,o}^4 \right) + h_o \left( T_{s,o} - T_{\infty,o} \right) + \frac{T_{s,o} - T_{\infty,i}}{L/k} + \frac{1}{h_i}
\]

Since radiation from the surroundings is in the far infrared, \( \alpha_{sur} = 0.2 \). From Table 12.1, \( \lambda T = (3 \, \mu m \times 5800 \, K) = 17,400 \, \mu m \cdot K \), find \( F_{(0 \rightarrow 3 \, \mu m)} = 0.979 \). Hence,

\[
\alpha_s = \int_0^\infty \frac{\alpha_{\lambda} E_{\lambda,b} (5800 \, K) d\lambda}{E_b} = \alpha_1 F_{(0 \rightarrow 3 \, \mu m)} + \alpha_2 F_{(3 \rightarrow \infty)} = 0.9(0.979) + 0.2(0.021) = 0.885.
\]

From Table 12.1, \( \lambda T = (3 \, \mu m \times 1000 \, K) = 3000 \, \mu m \cdot K \), find \( F_{(0 \rightarrow 3 \, \mu m)} = 0.273 \). Hence,

\[
\varepsilon_s = \int_0^\infty \frac{\varepsilon \lambda E_{\lambda,b} (1000 \, K) d\lambda}{E_b} = \varepsilon_1 F_{(0 \rightarrow 3)} + \varepsilon_2 F_{(3 \rightarrow \infty)} = 0.9(0.273) + 0.2(0.727) = 0.391.
\]

Substituting numerical values in the energy balance, find

\[
0.885 \left( \frac{80,000 \, W / m^2}{25 \, W / m^2 \cdot K} \right) + 0.2 \times 5.67 \times 10^{-8} \, W / m^2 \cdot K^4 + 0.391 \times 5.67 \times 10^{-8} \, W / m^2 \cdot K^4 = 0.391 \times 5.67 \times 10^{-8} \, W / m^2 \cdot K^4
\]

\[
L = 0.129 \, m.
\]

The corresponding collector efficiency is

\[
\eta = \frac{q_{use}}{q_s} = \frac{T_{s,o} - T_{\infty,i}}{\left( L/k + 1/h_i \right)} / q_s
\]

\[
\eta = \frac{300 \, K}{\left( 0.129 \, m / 15 \, W / m \cdot K + 0.001 \, m^2 \cdot K / W \right) / 80,000 \, W / m^2} = 0.391 \text{ or } 39.1\%.
\]

COMMENTS: The collector efficiency could be increased and the outer surface temperature reduced by decreasing the value of L.
PROBLEM 12.118

KNOWN: Dimensions, spectral absorptivity, and temperature of solar receiver. Solar irradiation and ambient temperature.

FIND: (a) Rate of energy collection $q$ and collector efficiency $\eta$, (b) Effect of receiver temperature on $q$ and $\eta$.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Uniform irradiation, (3) Opaque, diffuse surface.

PROPERTIES: Table A.4, air ($T_f = 550$ K): $\nu = 45.6 \times 10^{-6}$ m$^2$/s, $k = 0.0439$ W/m-K, $\alpha = 66.7 \times 10^{-6}$ m$^2$/s, $Pr = 0.683$.

ANALYSIS: (a) The rate of heat transfer to the receiver is $q = \pi DL \left[ \alpha S G_S - \varepsilon \sigma T_s^4 - \bar{h} (T_s - T_{\infty}) \right]$

For $\lambda T = 3 \mu m \times 5800 K = 17,400, F_{(0 \rightarrow \lambda)} = 0.979$. Hence,

$$\alpha_S = \alpha_1 F_{(0 \rightarrow \lambda)} + \alpha_2 \left(1 - F_{(0 \rightarrow \lambda)} \right) = 0.9 \times 0.979 + 0.2(0.021) = 0.885$$

For $\lambda T = 3 \mu m \times 800 K = 2400 \mu m$-K, $F_{(0 \rightarrow \lambda)} = 0.140$. Hence,

$$\varepsilon = \varepsilon_1 F_{(0 \rightarrow \lambda)} + \varepsilon_2 \left(1 - F_{(0 \rightarrow \lambda)} \right) = 0.9 \times 0.140 + 0.2(0.860) = 0.298.$$  

With $Ra_L = g \beta (T_s - T_{\infty}) L^3 / \alpha \nu = 9.8 \text{ m/s}^2 (1/550 \text{ K})(500 \text{ K})(12 \text{ m})^3 / 66.7 \times 10^{-6} \text{ m}^2/\text{s} \times 45.6 \times 10^{-6} \text{ m}^2/\text{s} = 5.06 \times 10^{12}$, Eq. 9.26 yields

$$\frac{Nu_L}{2} = \left[ 0.825 + \frac{0.387 \cdot Ra_L^{1/6}}{1 + \left(0.492 / Pr \right)^{9/16}} \right]^{2/7} = 1867$$

$$\bar{h} = \frac{k}{\nu L} = 1867 \frac{0.0439 \text{ W/m.K}}{12 \text{ m}} = 6.83 \text{ W/m}^2\text{.K}$$

Hence,

$$q = \pi (7 \text{ m} \times 12 \text{ m}) \left[ 0.885 \times 80,000 \text{ W/m}^2 - 0.298 \times 5.67 \times 10^{-8} \text{ W/m}^2\text{.K}^4 \left(800 \text{ K} \right)^4 - 6.83 \text{ W/m}^2\text{.K} \left(500 \text{ K} \right) \right]$$

$$q = 263.9 \text{ m}^2 \left(70,800 - 6,920 - 3415 \right) \text{ W/m}^2 = 1.60 \times 10^7 \text{ W}$$

The collector efficiency is $\eta = q/A_s G_s$. Hence

$$\eta = \frac{1.60 \times 10^7 \text{ W}}{263.9 \text{ m}^2 \left(80,000 \text{ W/m}^2 \right)} = 0.758$$

Continued …..
PROBLEM 12.118 (Cont.)

(b) The IHT Correlations, Properties and Radiation Toolpads were used to obtain the following results.

Losses due to emission and convection increase with increasing $T_s$, thereby reducing $q$ and $\eta$.

**COMMENTS:** The increase in radiation emission is due to the increase in $T_s$, as well as to the effect of $T_s$ on $\varepsilon$, which increases from 0.228 to 0.391 as $T_s$ increases from 600 to 1000 K.
**PROBLEM 12.119**

**KNOWN:** Dimensions and construction of truck roof. Roof interior surface temperature. Truck speed, ambient air temperature, and solar irradiation.

**FIND:** (a) Preferred roof coating, (b) Roof surface temperature, (c) Heat load through roof, (d) Effect of velocity on surface temperature and heat load.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Turbulent boundary layer development over entire roof, (2) Constant properties, (3) Negligible atmospheric (sky) irradiation, (4) Negligible contact resistance.

**PROPERTIES:** Table A.4, Air ($T_{s,o} \approx 300 \text{ K}$, 1 atm): $\nu = 15 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 0.026 \text{ W/m K}$, $Pr = 0.71$.

**ANALYSIS:** (a) To minimize heat transfer through the roof, minimize solar absorption relative to surface emission. Hence, use zinc oxide white for which $\alpha_s = 0.16$ and $\epsilon = 0.93$.

(b) Performing an energy balance on the outer surface of the roof, $\alpha_s G_S + \dot{q}^\text{conv} - E - \dot{q}^\text{cond} = 0$, it follows that

$$\alpha_s G_S + \dot{h}(T_{\infty} - T_{s,o}) = \epsilon \sigma T_{s,o}^4 + (k/t)(T_{s,o} - T_{s,i})$$

where it is assumed that convection is from the air to the roof. With

$$Re_L = \frac{VL}{\nu} = \frac{30 \text{ m/s}(5 \text{ m})}{15 \times 10^{-6} \text{ m}^2/\text{s}} = 10^7$$

$$\overline{Nu}_L = 0.037 \overline{Re}_L^{4/5} Pr^{1/3} = 0.037(10^7)^{4/5}(0.71)^{1/3} = 13,141$$

$$\overline{h} = \frac{\overline{Nu}_L}{k/L} = 13,141(0.026 \text{ W/m K}/5 \text{ m}) = 68.3 \text{ W/m}^2\cdot\text{K}.$$ 

Substituting numerical values in the energy balance and solving by trial-and-error, we obtain

$$T_{s,o} = 295.2 \text{ K}.$$ 

(c) The heat load through the roof is

$$q = (kA_s/t)(T_{s,o} - T_{s,i}) = (0.05 \text{ W/m} \cdot \text{K} \times 10 \text{ m}^2/0.025 \text{ m})35.2 \text{ K} = 704 \text{ W}.$$ 

(d) Using the IHT *First Law* Model with the *Correlations* and *Properties* Toolpads, the following results are obtained.

Continued...
The surface temperature and heat load decrease with decreasing V due to a reduction in the convection heat transfer coefficient and hence convection heat transfer from the air.

**COMMENTS:** The heat load would increase with increasing $\alpha_s/\varepsilon$. 
PROBLEM 12.120

KNOWN: Sky, ground, and ambient air temperatures. Grape of prescribed diameter and properties.

FIND: (a) General expression for rate of change of grape temperature, (b) Whether grapes will freeze in quiescent air, (c) Whether grapes will freeze for a prescribed air speed.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible temperature gradients in grape, (2) Uniform blackbody irradiation over top and bottom hemispheres, (3) Properties of grape are those of water at 273 K, (4) Properties of air are constant at values for $T_{\infty}$, (5) Negligible buoyancy for $V = 1$ m/s.

PROPERTIES: Table A-6, Water (273 K): $c_p = 4217$ J/kg·K, $\rho = 1000$ kg/m$^3$; Table A-4, Air (273 K, 1 atm): $\nu = 13.49 \times 10^{-6}$ m$^2$/s, $k = 0.0241$ W/m·K, $\alpha = 18.9 \times 10^{-6}$ m$^2$/s, $Pr = 0.714$, $\beta = 3.66 \times 10^{-3}$ K$^{-1}$.

ANALYSIS: (a) Performing an energy balance for a control surface about the grape,

$$\frac{dE_{st}}{dt} = \rho_g \frac{\pi D^3}{6} \frac{dT_g}{dt} = h\pi D^2 \left(T_{\infty} - T_g\right) + \frac{\pi D^2}{2} \left(G_{ea} + G_{sky}\right) - E\pi D^2.$$

Hence, the rate of temperature change with time is

$$\frac{dT_g}{dt} = \frac{6}{\rho_g c_p \rho_g D} \left[ h\left(T_{\infty} - T_g\right) + \sigma \left(\left(T_{\infty}^4 + T_{sky}^4\right)/2 - \varepsilon_g T_g^4\right)\right].$$

(b) The grape freezes if $dT_g/dt < 0$ when $T_g = T_{fp} = 268$ K. With

$$Ra_D = \frac{g\beta \left(T_{\infty} - T_g\right) D^3}{\alpha \nu} = \frac{9.8 \text{ m/s}^2 \left(3.66 \times 10^{-3} \text{ K}^{-1}\right) 5 \text{K} \left(0.015 \text{ m}\right)^3}{18.9 \times 10^{-6} \times 13.49 \times 10^{-6} \text{ m}^4/\text{s}^2} = 2374$$

using Eq. 9.35 find

$$\frac{0.589(2374)^{1/4}}{\left[1 + (0.469/Pr)^{9/16}\right]^{4/9}} = 5.17$$

$$h = (k/D) \frac{Nu_D}{D} = [(0.0241 \text{ W/m·K})/(0.015 \text{m})] 5.17 = 8.31 \text{ W/m}^2\cdot\text{K.}$$

Hence, the rate of temperature change is

$$\frac{dT_g}{dt} = \frac{6}{\left(1000 \text{ kg/m}^3\right) 4217 \text{ J/kg·K} \left(0.015 \text{ m}\right)} \left[8.31 \text{ W/m}^2\cdot\text{K} (5 \text{ K}) + 5.67 \times 10^{-8} \text{ W/m}^2\cdot\text{K}^4 \left(273^4 + 235^4\right)/2 - 268^4\right] \text{K}^4$$

Continued …..
\[ \frac{dT_g}{dt} = 9.49 \times 10^{-5} \text{ K} \cdot \text{m}^2 / \text{J} \left[ 41.55 - 48.56 \right] \text{ W/m}^2 = -6.66 \times 10^{-4} \text{ K/s} \]

and since \( \frac{dT_g}{dt} < 0 \), the grape will freeze.

(c) For \( V = 1 \text{ m/s} \),

\[ \text{Re}_D = \frac{V D}{\nu} = \frac{1 \text{ m/s} \times 0.015 \text{ m}}{13.49 \times 10^{-6} \text{ m}^2 / \text{s}} = 1112. \]

Hence with \( (\mu/\mu_s)^{1/4} = 1 \),

\[ \text{Nu}_D = 2 + \left( 0.4 \text{Re}_D^{1/2} + 0.06 \text{Re}_D^{2/3} \right) \text{Pr}^{0.4} = 21.8 \]

\[ \bar{h} = \frac{\text{Nu}_D}{D} = 21.8 \frac{0.0241}{0.015} = 35 \text{ W/m}^2 \cdot \text{K}. \]

Hence the rate of temperature change with time is

\[ \frac{dT_g}{dt} = 9.49 \times 10^{-5} \text{ K} \cdot \text{m}^2 / \text{J} \left[ 35 \text{ W/m}^2 \cdot \text{K} \times \text{K} - 48.56 \text{ W/m}^2 \right] = 0.012 \text{ K/s} \]

and since \( \frac{dT_g}{dt} > 0 \), the grape will not freeze.

**COMMENTS:** With \( Gr_D = Ra_D/Pr = 3325 \) and \( Gr_D / Re_D^2 = 0.0027 \), the assumption of negligible buoyancy for \( V = 1 \text{ m/s} \) is reasonable.
PROBLEM 12.121

KNOWN: Metal disk exposed to environmental conditions and placed in good contact with the earth.

FIND: (a) Fraction of direct solar irradiation absorbed, (b) Emissivity of the disk, (c) Average free convection coefficient of the disk upper surface, (d) Steady-state temperature of the disk (confirm the value 340 K).

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Disk is diffuse, (3) Disk is isothermal, (4) Negligible contact resistance between disk and earth, (5) Solar irradiance has spectral distribution of $E_{\lambda,b}(\lambda, 5800 \text{ K})$.

PROPERTIES: Table A-4, Air (1 atm, $T_f = (T_s + T_\infty)/2 = (340 + 300) \text{ K}/2 = 320 \text{ K}$): $\nu = 17.90 \times 10^{-6} \text{ m}^2/\text{s}$, $k = 0.0278 \text{ W/m} \cdot \text{K}$, $\alpha = 25.5 \times 10^{-6} \text{ m}^2/\text{s}$, $Pr = 0.704$.

ANALYSIS: (a) The solar absorptivity follows from Eq. 12.49 with $G_{\lambda,S} \alpha E_{\lambda,b}(\lambda, 5800 \text{ K})$, and $\alpha_\lambda = \varepsilon_\lambda$, since the disk surface is diffuse.

$$\alpha_S = \int_{0}^{\infty} \alpha_\lambda E_{\lambda,b}(\lambda, 5800 \text{ K}) / E_b(5800 \text{ K})$$

$$\alpha_S = \varepsilon_1 F(0 \rightarrow 1 \mu\text{m}) + \varepsilon_2 \left(1 - F(0 \rightarrow 1 \mu\text{m})\right).$$

From Table 12.1 with

$$\lambda T = 1 \mu\text{m} \times 5800 \text{ K} = 5800 \mu\text{m} \cdot \text{K} \quad \text{find} \quad F(0 \rightarrow \lambda T) = 0.720$$

giving

$$\alpha_S = 0.9 \times 0.720 + 0.2 \left(1 - 0.720\right) = 0.704.$$  \[<\]

Note this value is appropriate for diffuse or direct solar irradiation since the surface is diffuse.

(b) The emissivity of the disk depends upon the surface temperature $T_s$ which we believe to be 340 K. (See part (d)). From Eq. 12.38,

$$\varepsilon = \int_{0}^{\infty} \varepsilon_\lambda E_{\lambda,b}(\lambda, T_s) / E_b(T_s)$$

$$\varepsilon = \varepsilon_1 F(0 \rightarrow 1 \mu\text{m}) + \varepsilon_2 \left(1 - F(0 \rightarrow 1 \mu\text{m})\right)$$

Continued …..
PROBLEM 12.121 (Cont.)

From Table 12.1 with
\[ \lambda T = 1 \mu m \times 340 \text{ K} = 340 \mu m \cdot \text{K} \]
find \( F(0 \rightarrow \lambda T) = 0.000 \)
giving
\[ \varepsilon = 0.9 \times 0.000 + 0.2 \left( 1 - 0.000 \right) = 0.20. \]

(c) The disk is a hot surface facing upwards for which the free convection correlation of Eq. 9.30 is appropriate. Evaluating properties at \( T_f = (T_s + T_\infty)/2 = 320 \text{ K}, \)
\[ \text{Ra}_L = g \beta \Delta T L^3 / \nu \alpha \]  
where \( L = A_s / P = D / 4 \)
\[ \text{Ra}_L = 9.8 \text{ m} / \text{s}^2 \left( 1/320 \text{ K} \right)(340 - 300) \text{ K} (0.4 \text{ m} / 4)^3 / 17.90 \times 10^{-6} \text{ m}^2 / \text{s} \times 25.5 \times 10^{-6} \text{ m}^2 / \text{s} = 3.042 \times 10^6 \]
\[ \text{Nu}_L = \bar{h} L / k = 0.54 \text{Ra}_L^{1/4} \quad 10^4 \leq \text{Ra}_L \leq 10^7 \]
\[ \bar{h} = 0.0278 \text{ W} / \text{m} \cdot \text{K} / (0.4 \text{ m} / 4) \times 0.54 \left( 3.042 \times 10^6 \right)^{1/4} = 6.37 \text{ W} / \text{m}^2 \cdot \text{K}. \]

(d) To determine the steady-state temperature, perform an energy balance on the disk.
\[ \dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \dot{E}_{\text{st}} \]
\[ (\alpha_s G_{S,d} + \alpha G_{sky} - \varepsilon E_b - q''_{\text{conv}}) A_s - q_{\text{cond}} = 0. \]

Since \( G_{sky} \) is predominately long wavelength radiation, it follows that \( \alpha = \varepsilon \). The conduction heat rate between the disk and the earth is
\[ q_{\text{cond}} = k S (T_s - T_{ea}) = k (2D) (T_s - T_{ea}) \]
where \( S \), the conduction shape factor, is that of an isothermal disk on a semi-infinite medium, Table 4.1.
Substituting numerical values, with \( A_s = \pi D^2 / 4, \)
\[ \left[ 0.704 \times 745 \text{ W} / \text{m}^2 + 0.20 \sigma (280 \text{ K})^4 - 0.20 \sigma T_s^4 \right] \pi / 4 (0.4 \text{ m})^2 - 0.52 \text{ W} / \text{m} \cdot \text{K} (2 \times 0.4 \text{ m}) (T_s - 280 \text{ K}) = 0 \]
\[ 65.908 \text{ W} + 8.759 \text{ W} - 1.425 \times 10^{-9} T_s^4 - 0.792 (T_s - 300) - 0.416 (T_s - 280) = 0. \]
By trial-and-error, find
\[ T_s = 339 \text{ K}. \]
so indeed the assumed value of 340 K was proper.

COMMENTS: Note why it is not necessary for this situation to distinguish between direct and diffuse irradiation. Why does \( \alpha_{sky} = \varepsilon \)?
PROBLEM 12.122

KNOWN: Shed roof of weathered galvanized sheet metal exposed to solar insolation on a cool, clear spring day with ambient air at -10°C and convection coefficient estimated by the empirical correlation \( h = 1.0 \Delta T^{1/3} \) (W/m²·K with temperature units of kelvins).

FIND: Temperature of the roof, \( T_s \), (a) assuming the backside is well insulated, and (b) assuming the backside is exposed to ambient air with the same convection coefficient relation and experiences radiation exchange with the ground, also at the ambient air temperature. Comment on whether the roof will be a comfortable place for the neighborhood cat to snooze for these conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) The roof surface is diffuse, spectrally selective, (3) Sheet metal is thin with negligible thermal resistance, and (3) Roof is a small object compared to the large isothermal surroundings represented by the sky and the ground.

ANALYSIS: (a) For the backside-insulated condition, the energy balance, represented schematically below, is

\[
\dot{E}_{in}'' - \dot{E}_{out}'' = 0
\]

\[
\alpha_{sky} E_b(T_{sky}) + \alpha_S G_S - q_{cv}'' - \varepsilon b(T_s) = 0
\]

\[
\alpha_{sky}\sigma T_{sky}^4 + \alpha_S G_S - 1.0(T_s - T_\infty)^{4/3} - \varepsilon\sigma T_s^4 = 0
\]

With \( \alpha_{sky} = \varepsilon \) (see Comment 2) and \( \sigma = 5.67 \times 10^{-8} \) W/m²·K⁴, find \( T_s \).

\[
0.65 \sigma(233 \text{K})^4 + 0.8 \times 600 = 10(T_s - 283 \text{K})^{4/3} - 0.65 \sigma T_s^4 = 0
\]

\[
T_s = 312.5 \text{K} = 39.5^\circ \text{C}
\]

Continued …..
PROBLEM 12.122 (Cont.)

(b) With the backside exposed to convection with the ambient air and radiation exchange with the ground, the energy balance, represented schematically above, is

\[ \alpha_{\text{sky}} E_b(T_{\text{sky}}) + \alpha_{\text{grd}} E_b(T_{\text{grd}}) + \alpha_{S} G_S - 2q_c' - 2\varepsilon E_b(T_s) = 0 \]

Substituting numerical values, recognizing that \( T_{\text{grd}} = T_{\infty} \), and \( \alpha_{\text{grd}} = \varepsilon \) (see Comment 2), find \( T_s \).

\[ 0.65 \sigma (233 \, \text{K})^4 \frac{\text{W}}{\text{m}^2} + 0.65 \sigma (283 \, \text{K})^4 \frac{\text{W}}{\text{m}^2} + 0.8 \times 600 \frac{\text{W}}{\text{m}^2} \]

\[ -2 \times 1.0 \, (T_s - 283 \, \text{K})^{4/3} \frac{\text{W}}{\text{m}^2} - 2 \times 0.65 \sigma T_s^4 = 0 \]

\[ T_s = 299.5 \, \text{K} = 26.5^\circ \text{C} \]

**COMMENTS:**

(1) For the insulated-backside condition, the cat would find the roof quite warm remembering that 43°C represents a safe-to-touch temperature. For the exposed-backside condition, the cat would find the roof comfortable, certainly compared to an area not exposed to the solar insolation (that is, exposed only to the ambient air through convection).

(2) For this spectrally selective surface, the absorptivity for the sky irradiation is equal to the emissivity, \( \alpha_{\text{sky}} = \varepsilon \), since the sky irradiation and surface emission have the same approximate spectral regions. The same reasoning applies for the absorptivity of the ground irradiation, \( \alpha_{\text{grd}} = \varepsilon \).
PROBLEM 12.123

KNOWN: Amplifier operating and environmental conditions.

FIND: (a) Power generation when $T_s = 58^\circ C$ with diffuse coating $\varepsilon = 0.5$, (b) Diffuse coating from among three (A, B, C) which will give greatest reduction in $T_s$, and (c) Surface temperature for the conditions with coating chosen in part (b).

SCHEMATIC:

ASSUMPTIONS: (1) Environmental conditions remain the same with all surface coatings, (2) Coatings A, B, C are opaque, diffuse.

ANALYSIS: (a) Performing an energy balance on the amplifier’s exposed surface, $\dot{E}_{in} - \dot{E}_{out} = 0$, find

$$P_e + A_s \left[ \alpha_S G_S + \alpha_{sky} G_{sky} - \varepsilon E_b - Q_{conv} \right] = 0$$

$$P_e = A_s \left[ \varepsilon \sigma T_s^4 + h \left( T_s - T_\infty \right) - \alpha_S G_S - \alpha_{sky} \sigma T_{sky}^4 \right]$$

$$P_e = 0.13 \times 0.13 \text{ m}^2 \left[ 0.5 \times \sigma (331)^4 + 15 (331 - 300) - 0.5 \times 800 - 0.5 \times \sigma (253)^4 \right] \text{W/m}^2$$

$$P_e = 0.0169 \text{m}^2 \left[ 0.5 \times 680.6 + 465 - 0.5 \times 800 - 0.5 \times 232.3 \right] \text{W/m}^2 = 4887 \text{ W.}$$

(b) From above, recognize that we seek a coating with low $\alpha_S$ and high $\varepsilon$ to decrease $T_s$. Further, recognize that $\alpha_S$ is determined by values of $\alpha_\lambda = \varepsilon_\lambda$ for $\lambda < 3 \mu m$ and $\varepsilon$ by values of $\varepsilon_\lambda$ for $\lambda > 3 \mu m$. Find approximate values as

<table>
<thead>
<tr>
<th>Coating</th>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\varepsilon$</td>
<td>0.5</td>
<td>0.3</td>
<td>0.6</td>
</tr>
<tr>
<td>$\alpha_S$</td>
<td>0.8</td>
<td>0.3</td>
<td>0.2</td>
</tr>
<tr>
<td>$\alpha_S/\varepsilon$</td>
<td>1.6</td>
<td>1</td>
<td>0.333</td>
</tr>
</tbody>
</table>

Note also that $\alpha_{sky} = \varepsilon$. We conclude that coating C is likely to give the lowest $T_s$ since its $\alpha_S/\varepsilon$ is substantially lower than for B and C. While $\alpha_{sky}$ for C is twice that of B, because $G_{sky}$ is nearly 25% that of $G_S$, we expect coating C to give the lowest $T_s$.

(c) With the values of $\alpha_S$, $\alpha_{sky}$ and $\varepsilon$ for coating C from part (b), rewrite the energy balance as

$$P_e / A_s + \alpha_S G_S + \alpha_{sky} \sigma T_{sky}^4 - \varepsilon \sigma T_s^4 - h \left( T_s - T_\infty \right) = 0$$

$$4.887 \text{ W} / \left( 0.13 \text{ m}^2 \right)^2 + 0.2 \times 800 \text{ W} / \text{m}^2 + 0.6 \times 232.3 \text{ W} / \text{m}^2 - 0.6 \times \sigma T_s^4 - 15 (T_s - 300) = 0$$

Using trial-and-error, find $T_s = 316.5 \text{ K} = 43.5^\circ \text{C}$.

COMMENTS: (1) Using coatings A and B, find $T_s = 71$ and $54^\circ \text{C}$, respectively. (2) For more precise values of $\alpha_S$, $\alpha_{sky}$ and $\varepsilon$, use $T_s = 43.5^\circ \text{C}$. For example, at $\lambda T_s = 3 \times (43.5 + 273) = 950 \mu \text{m K}$, $F_{0-\lambda T} = 0.000$ while at $\lambda T_{solar} = 3 \times 5800 = 17.400 \mu \text{m K}$, $F_{0-\lambda T} = 0.98$; we conclude little effect will be seen.
PROBLEM 12.124

KNOWN: Opaque, spectrally-selective horizontal plate with electrical heater on backside is exposed to convection, solar irradiation and sky irradiation.

FIND: Electrical power required to maintain plate at 60°C.

SCHEMATIC:

ASSUMPTIONS: (1) Plate is opaque, diffuse and uniform, (2) No heat lost out the backside of heater.

ANALYSIS: From an energy balance on the plate-heater system, per unit area basis,

\[ E_{in} - E_{out} = 0 \]

\[ q_{elec} + \alpha_S G_S + \alpha_G \text{sky} \]

\[ -\varepsilon E_b \left( T_s \right) - q_{conv} = 0 \]

where \( G_{sky} = \sigma T_{sky}^4 \), \( E_b = \sigma T_s^4 \), and \( q_{conv} = h \left( T_s - T_{\infty} \right) \). The solar absorptivity is

\[ \alpha_S = \int_0^\infty \alpha_\lambda \, G_{\lambda, S} \, d\lambda / \int_0^\infty G_{\lambda} \, d\lambda = \int_0^\infty \alpha_\lambda E_{\lambda, b} \left( \lambda, 5800 \, \text{K} \right) \, d\lambda / \int_0^\infty E_{\lambda, b} \left( \lambda, 5800 \, \text{K} \right) \, d\lambda \]

where \( G_{\lambda, S} \sim E_{\lambda, b} \left( \lambda, 5800 \, \text{K} \right) \). Noting that \( \alpha_\lambda = 1 - \rho_\lambda \),

\[ \alpha_S = \left( 1 - 0.2 \right) F_{(0-2\mu m)} + \left( 1 - 0.7 \right) \left( 1 - F_{(0-2\mu m)} \right) \]

where at \( \lambda T = 2 \, \mu m \times 5800 \, \text{K} = 11,600 \, \mu m \cdot \text{K} \), find from Table 12.1, \( F_{(0-\lambda T)} = 0.941 \),

\[ \alpha_S = 0.80 \times 0.941 + 0.3 \left( 1 - 0.941 \right) = 0.771 \]

The total, hemispherical emissivity is

\[ \varepsilon = \left( 1 - 0.2 \right) F_{(0-2\mu m)} + \left( 1 - 0.7 \right) \left( 1 - F_{(0-2\mu m)} \right) \]

At \( \lambda T = 2 \, \mu m \times 333 \, \text{K} = 666 \, \text{K} \), find \( F_{(0-\lambda T)} = 0.000 \); hence \( \varepsilon = 0.30 \). The total, hemispherical absorptivity for sky irradiation is \( \alpha = \varepsilon = 0.30 \) since the surface is gray for this emission and irradiation process. Substituting numerical values,

\[ q_{elec} = \varepsilon \sigma T_s^4 + h \left( T_s - T_{\infty} \right) - \alpha_S G_S - \alpha_S T_{sky}^4 \]

\[ q_{elec} = 0.30 \times \sigma \left( 333 \, \text{K} \right)^4 + 10 \, \text{W/} \cdot \text{m}^2 \cdot \text{K} \left( 60 - 20 \right) \circ C - 0.771 \times 600 \, \text{W/m}^2 - 0.30 \times 0 \left( 233 \, \text{K} \right)^4 \]

\[ q_{elec} = 209.2 \, \text{W/m}^2 + 400.0 \, \text{W/m}^2 - 462.6 \, \text{W/m}^2 - 50.1 \, \text{W/m}^2 = 96.5 \, \text{W/m}^2. \]

COMMENTS: (1) Note carefully why \( \alpha_{sky} = \varepsilon \) for the sky irradiation.
**PROBLEM 12.125**

**KNOWN:** Chord length and spectral emissivity of wing. Ambient air temperature, sky temperature and solar irradiation for ground and in-flight conditions. Flight speed.

**FIND:** Temperature of top surface of wing for (a) ground and (b) in-flight conditions.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Negligible heat transfer from back of wing surface, (3) Diffuse surface behavior, (4) Negligible solar radiation for $\lambda > 3 \ \mu m$ ($\alpha_S = \alpha_{\lambda \leq 3 \ \mu m} = \varepsilon_{\lambda \leq 3 \ \mu m} = 0.6$), (5) Negligible sky radiation and surface emission for $\lambda \leq 3 \ \mu m$ ($\alpha_{\text{sky}} = \alpha_{\lambda > 3 \ \mu m} = \varepsilon_{\lambda > 3 \ \mu m} = 0.3 = \varepsilon$), (6) Quiescent air for ground condition, (7) Air foil may be approximated as a flat plate, (8) Negligible viscous heating in boundary layer for in-flight condition, (9) The wing span $W$ is much larger than the chord length $L_c$, (10) In-flight transition Reynolds number is $5 \times 10^5$.

**PROPERTIES:** Part (a). *Table A-4*, air ($T_f \approx 325 \ K$): $\nu = 1.84 \times 10^{-5} \ m^2/s$, $\alpha = 2.62 \times 10^{-5} \ m^2/s$, $k = 0.0282 \ W/m \cdot K$, $\beta = 0.00307$. Part (b). Given: $\rho = 0.470 \ kg/m^3$, $\mu = 1.50 \times 10^{-5} \ N \cdot s/m^2$, $k = 0.021 \ W/m \cdot K$, $Pr = 0.72$.

**ANALYSIS:** For both ground and in-flight conditions, a surface energy balance yields

$$\alpha_{\text{sky}} G_{\text{sky}} + \alpha_S G_S = \varepsilon \sigma T_s^4 + \bar{h}(T_s - T_\infty)$$

where $\alpha_{\text{sky}} = \varepsilon = 0.3$ and $\alpha_S = 0.6$.

(a) For the ground condition, $\bar{h}$ may be evaluated from Eq. 9.30 or 9.31, where $L = A_s/P = L_c \times W/2$ ($L_c + W$) = $L_c/2 = 2m$ and $Ra_L = g \beta (T_s - T_\infty) L_c^3/\nu \alpha$. Using the *IHT* software to solve Eq. (1) and accounting for the effect of temperature-dependent properties, the surface temperature is

$$T_s = 350.6 \ K = 77.6^\circ C$$

where $Ra_L = 2.52 \times 10^{10}$ and $\bar{h} = 6.2 \ W/m^2 \cdot K$. Heat transfer from the surface by emission and convection is 257.0 and 313.6 $W/m^2$, respectively.

(b) For the in-flight condition, $Re_L = \rho u_\infty L_c/\mu = 0.470 \ kg/m^3 \times 200 \ m/s \times 4m/1.50 \times 10^{-5} \ N \cdot s/m^2 = 2.51 \times 10^7$. For mixed, laminar/turbulent boundary layer conditions (Section 7.2.3 of text) and a transition Reynolds number of $Re_{x,c} = 5 \times 10^5$.

$$\frac{Nu_L}{L} = \left(0.037 Re_L^{4/5} - 871\right)Pr^{1/3} = 26,800$$

$$\bar{h} = \frac{k}{L} \left(0.021 W/m \cdot K \times 26,800\right) = 141 \ W/m^2 \cdot K$$

Substituting into Eq. (1), a trial-and-error solution yields

$$T_s = 237.7 \ K = -35.3^\circ C$$

Heat transfer from the surface by emission and convection is now 54.3 and 657.6 $W/m^2$, respectively.

**COMMENTS:** The temperature of the wing is strongly influenced by the convection heat transfer coefficient, and the large coefficient associated with flight yields a surface temperature that is within 5$^\circ C$ of the air temperature.
**PROBLEM 12.126**

**KNOWN:** Spectrally selective and gray surfaces in earth orbit are exposed to solar irradiation, \( G_S \), in a direction \( 30^\circ \) from the normal to the surfaces.

**FIND:** Equilibrium temperature of each plate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Plates are at uniform temperature, (2) Surroundings are at 0K, (3) Steady-state conditions, (4) Solar irradiation has spectral distribution of \( E_{\lambda,b}(\lambda, 5800K) \), (5) Back side of plate is insulated.

**ANALYSIS:** Noting that the solar irradiation is directional (at \( 30^\circ \) from the normal), the radiation balance has the form

\[
\alpha_S G_S \cos \theta - \varepsilon E_b(T_s) = 0. \tag{1}
\]

Using \( E_b(T_s) = \sigma T_s^4 \) and solving for \( T_s \), find

\[
T_s = \left[ \left( \frac{\alpha_S}{\varepsilon} \right) \left( \frac{G_S \cos \theta / \sigma}{\varepsilon} \right) \right]^{1/4}. \tag{2}
\]

For the gray surface, \( \alpha_S = \varepsilon = \alpha_\lambda \) and the temperature is independent of the magnitude of the absorptivity.

\[
T_s = \left( \frac{0.95 \times 1353 \text{ W/m}^2 \times \cos 30^\circ}{0.95 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4} \right)^{1/4} = 379 \text{ K}. \tag{\textless}
\]

For the selective surface, \( \alpha_S = 0.95 \) since nearly all the solar spectral power is in the region \( \lambda < 3 \mu \text{m} \). The value of \( \varepsilon \) depends upon the surface temperature \( T_s \) and would be determined by the relation.

\[
\varepsilon = 0.95 F_{(0\to\lambda T_s)} + 0.05 \left[ 1 - F_{(0\to\lambda T_s)} \right] \tag{3}
\]

where \( \lambda = 3 \mu \text{m} \) and \( T_s \) is as yet unknown. To find \( T_s \), a trial-and-error procedure as follows will be used: (1) assume a value of \( T_s \), (2) using Eq. (3), calculate \( \varepsilon \) with the aid of Table 12.1 evaluating \( F_{(0\to\lambda T)} \) at \( \lambda T_s = 3 \mu \text{m} T_s \), (3) with this value of \( \varepsilon \), calculate \( T_s \) from Eq. (2) and compare with assumed value of \( T_s \). The results of the iterations are:

| \( T_s \text{(K)} \), assumed value | 633 | 700 | 666 | 650 | 655 |
| \( \varepsilon \), from Eq. (3)     | 0.098 | 0.125 | 0.110 | 0.104 | 0.106 |
| \( T_s \text{(K)} \), from Eq. (2) | 656 | 629 | 650 | 659 | 656 |

Hence, for the coating, \( T_s \approx 656 \text{K} \). \tag{\textless}

**COMMENTS:** Note the role of the ratio \( \alpha_s/\varepsilon \) in determining the equilibrium temperature of an isolated plate exposed to solar irradiation in space. This is an important property of the surface in spacecraft thermal design and analysis.
PROBLEM 12.127

KNOWN: Spectral, hemispherical emissivity distributions for two panels subjected to solar flux in the deep space environment.

FIND: Steady-state temperatures of the panels.

SCHEMATIC:

ASSUMPTIONS: (1) Surfaces are opaque and diffuse, (2) Panels are oriented normal to solar flux with backside insulated, (3) Steady-state conditions, (4) No convection.

ANALYSIS: An energy balance on the panel is

\[ q_{in}^* - q_{out}^* = 0 \]

\[ \alpha_S G_S - \varepsilon E_b (T_s) = \alpha_S G_S - \varepsilon \sigma T_s^4 = 0 \]

\[ T_s = [ (\alpha_S / \varepsilon)(G_S / \sigma) ]^{1/4} \]

For each panel determine \( \alpha_S \) and \( \varepsilon \). Recognizing that \( G_{\lambda,S} = E_{\lambda,b} (\lambda, 5800K) \), the solar absorptivity from Eq. 12.47 is

\[ \alpha_S = \frac{\int_0^\infty \alpha_{\lambda} G_{\lambda,S} d\lambda}{\int_0^\infty G_{\lambda,S} d\lambda} - \frac{\int_0^\infty \varepsilon_{\lambda} E_{\lambda,b}(\lambda, 5800K)}{E_b(5800K)} \]

Note that \( \varepsilon_{\lambda} = \alpha_{\lambda} \) since the surface is diffuse. Using Eq. 12.65 and Table 12.1 find

**Surface A:**

\[ \alpha_S = 0.5 \times 0.940 + 0.2 \]

\[ \alpha_S = 0.482 \]

\[ \varepsilon = 0.940 \]

\[ \lambda T = 5 \times 5800 = 11,600 \mu m \cdot K, \]

\[ F_{(0\rightarrow2\mu m)} = 0.940 \]

**Surface B:**

\[ \alpha_S = 0.11 \times 0.979 + 0.02 \]

\[ \alpha_S = 0.108 \]

\[ \lambda T = 3 \times 5800 = 17,400 \mu m \cdot K, \]

\[ F_{(0\rightarrow3\mu m)} = 0.979 \]

To determine the total emissivity, we need to know \( T_s \). If \( T_s \leq 400K \), then for \( \lambda T = 3 \mu m \times 400K = 1200K, F_{(0\rightarrow\lambda)} = 0.002 \). That is, there is negligible power for \( \lambda < 3 \mu m \) if \( T_s \leq 400K \), and hence

**Surface A:** \( \varepsilon = \varepsilon_2 = 0.2 \)

**Surface B:** \( \varepsilon = \varepsilon_2 = 0.02 \)

Substituting the solar absorptivity and emissivity values, find

**Surface A:**

\[ T_s = \left( \frac{0.482 \times 1353 \text{ W/m}^2}{0.20 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot K} \right)^{1/4} = 499K \]

**Surface B:**

\[ T_s = \left( \frac{0.108 \times 1353 \text{ W/m}^2}{0.02 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot K} \right)^{1/4} = 599K \]

COMMENTS: (1) Note the assumption that \( T_s \leq 400K \) used for finding \( \varepsilon \) is not satisfied; for better precision, it is necessary to perform an iterative solution. (2) Note the importance of the \( \alpha_S / \varepsilon \) ratio which determines the surface temperature.
PROBLEM 12.128

KNOWN: Radiative properties and operating conditions of a space radiator.

FIND: Equilibrium temperature of the radiator.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible irradiation due to earth emission.

ANALYSIS: From a surface energy balance, $\dot{E}_{\text{in}}^{s} - \dot{E}_{\text{out}}^{s} = 0$.

Hence

$$q_{\text{dis}} + \alpha_S G_S - E = 0.$$ 

Hence

$$T_S = \left( \frac{q_{\text{dis}} + \alpha_S G_S}{\varepsilon \sigma} \right)^{1/4}$$

$$T_S = \left( \frac{1500 \text{ W/m}^2 + 0.5 \times 1000 \text{ W/m}^2}{0.95 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4} \right)^{1/4}$$

or

$$T_S = 439 \text{ K}.$$ 

COMMENTS: Passive thermal control of spacecraft is practiced by using surface coatings with desirable values of $\alpha_S$ and $\varepsilon$. 
PROBLEM 12.129

KNOWN: Spherical satellite exposed to solar irradiation of 1353 m²; surface is to be coated with a checker pattern of evaporated aluminum film, (fraction, F) and white zinc-oxide paint (1 - F).

FIND: The fraction F for the checker pattern required to maintain the satellite at 300 K.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Satellite is isothermal, and (3) No internal power dissipation.

ANALYSIS: Perform an energy balance on the satellite, as illustrated in the schematic, identifying absorbed solar irradiation on the projected area, A_p, and emission from the spherical area A_s.

\[ \dot{E}_{in} - \dot{E}_{out} = 0 \]

\[ (F \cdot \alpha_{S,F} + (1 - F) \cdot \alpha_{S,P}) \cdot G_s \cdot A_p - (F \cdot \varepsilon_f + (1 - F) \cdot \varepsilon_p) \cdot E_b \cdot (T_s) \cdot A_s = 0 \]

where \( A_p = \pi D^2 / 4 \), \( A_s = \pi D^2 \), \( E_b = \sigma T^4 \) and \( \sigma = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \). Substituting numerical values, find F.

\[ (F \times 0.09 + (1 - F) \times 0.22) \times 1353 \text{ W/m}^2 \times (1/4) \]

\[ - (F \times 0.03 + (1 - F) \times 0.85) \sigma (300 \text{ K})^4 \times 1 = 0 \]

\[ F = 0.95 \]

COMMENTS: (1) If the thermal control engineer desired to maintain the spacecraft at 325 K, would the fraction F (aluminum film) be increased or decreased? Verify your opinion with a calculation.

(2) If the internal power dissipation per unit surface area is 150 W/m², what fraction F will maintain the satellite at 300 K?
PROBLEM 12.130

KNOWN: Inner and outer radii, spectral reflectivity, and thickness of an annular fin. Base temperature and solar irradiation.

FIND: (a) Rate of heat dissipation if \( \eta_f = 1 \), (b) Differential equation governing radial temperature distribution in fin if \( \eta_f < 1 \).

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) One-dimensional radial conduction, (3) Adiabatic tip and bottom surface, (4) Opaque, diffuse surface \( \alpha_\lambda = 1 - \rho_\lambda \), \( \varepsilon_\lambda = \alpha_\lambda \).

ANALYSIS: (a) If \( \eta_f = 1 \), \( T(r) = T_b = 400 \text{ K} \) across the entire fin and
\[
q_f = \left[ \varepsilon E_b (T_b) - \alpha S G_S \right] \pi t_0^2
\]

With \( \lambda T = 2 \mu m \times 5800 \text{ K} = 11,600 \mu m \cdot \text{K} \), \( F_{(0\rightarrow2\mu m)} = 0.941 \). Hence \( \alpha_S = \alpha_1 F_{(0\rightarrow2\mu m)} + \alpha_2 \left[ 1 - F_{(0\rightarrow2\mu m)} \right] = 0.2 \times 0.941 + 0.9 \times 0.059 = 0.241 \). With \( \lambda T = 2 \mu m \times 400 \text{ K} = 800 \mu m \cdot \text{K} \), \( F_{(0\rightarrow2\mu m)} = 0 \) and \( \varepsilon = 0.9 \). Hence, for \( G_S = 0 \),
\[
q_f = 0.9 \times 5.67 \times 10^{-8} \, \text{W/m}^2 \cdot \text{K}^4 \left( 400 \text{ K} \right)^4 \pi \left( 0.5 \text{ m} \right)^2 = 1026 \, \text{W}
\]
and for \( G_S = 1000 \, \text{W/m}^2 \),
\[
q_f = 1026 \, \text{W} - 0.241 \left( 1000 \, \text{W/m}^2 \right) \pi \left( 0.5 \text{ m} \right)^2 = (1026 - 189) \, \text{W} = 837 \, \text{W}
\]

(b) Performing an energy balance on a differential element extending from \( r \) to \( r + dr \), we obtain
\[
q_r + \alpha S G_S \left( 2\pi r dr \right) - q_{r+dr} - E \left( 2\pi r dr \right) = 0
\]

where
\[
q_r = -k \left( dT/dr \right) 2\pi rt \quad \text{and} \quad q_{r+dr} = q_r + (dq_r/dr) dr.
\]

Hence,
\[
\alpha S G_S \left( 2\pi r dr \right) - d \left[ -k \left( dT/dr \right) 2\pi rt \right] dr - E \left( 2\pi r dr \right) = 0
\]
\[
2\pi r tk \frac{d^2 T}{dr^2} + 2\pi tk \frac{dT}{dr} + \alpha S G_S 2\pi r - E 2\pi r = 0
\]
\[
kt \left( \frac{d^2 T}{dr^2} + \frac{1}{r} \frac{dT}{dr} \right) + \alpha S G_S - \varepsilon_\lambda T^4 = 0
\]

COMMENTS: The radiator should be constructed of a light weight, high thermal conductivity material (aluminum).
PROBLEM 12.131

KNOWN: Rectangular plate, with prescribed geometry and thermal properties, for use as a radiator in a spacecraft application. Radiator exposed to solar radiation on upper surface, and to deep space on both surfaces.

FIND: Using a computer-based, finite-difference method with a space increment of 0.1 m, find the tip temperature, \( T_L \), and rate of heat rejection, \( q_f \), when the base temperature is maintained at 80°C for the cases: (a) when exposed to the sun, (b) on the dark side of the earth, not exposed to the sun; and (c) when the thermal conductivity is extremely large. Compare the case (c) results with those obtained from a hand calculation assuming the radiator is at a uniform temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (b) Plate-radiator behaves as an extended surface with one-dimensional conduction, and (c) Radiating tip condition.

ANALYSIS: The finite-difference network with 10 nodes and a space increment \( \Delta x = 0.1 \) m is shown in the schematic below. The finite-difference equations (FDEs) are derived for an interior node (nodes 01 - 09) and the tip node (10). The energy balances are represented also in the schematic below where \( q_a \) and \( q_b \) represent conduction heat rates, \( q_S \) represents the absorbed solar radiation, and \( q_{rad} \) represents the radiation exchange with outer space.

finite-difference network, energy balances

Interior node 04

\[
\dot{E}_{in} - \dot{E}_{out} = 0
\]

\[
q_a + q_b + q_S + q_{rad} = 0
\]

\[
k A_c \left( T_{03} - T_{04} \right) / \Delta x + k A_c \left( T_{05} - T_{04} \right) / \Delta x + \alpha_S G_S \left( P / 2 \right) \Delta x + \varepsilon P \Delta x \sigma \left( T_{sur}^4 - T_{04}^4 \right) = 0
\]

where \( P = 2W \) and \( A_c = W \cdot t \).

Tip node 10

\[
q_a + q_S + q_{rad,1} + q_{rad,2} = 0
\]

\[
k A_c \left( T_{09} - T_{10} \right) / \Delta x + \alpha_S G_S \left( P / 2 \right) \left( \Delta x / 2 \right) + \varepsilon A_c \left( T_{sur}^4 - T_{10}^4 \right) + \varepsilon P \left( \Delta x / 2 \right) \sigma \left( T_{sur}^4 - T_{04}^4 \right) = 0
\]

Continued ….
PROBLEM 12.131 (Cont.)

Heat rejection, \( q_f \). From an energy balance on the base node 00,
\[
q_f + q_{01} + q_S + q_{rad} = 0
\]
\[
q_f + kA_c \left( T_{01} - T_{00} \right) / \Delta x + \alpha_S G_S \left( P / 2 \right) \left( \Delta x / 2 \right) + eP \left( \Delta x/2 \right) \sigma \left( T_{sur}^4 - T_{00}^4 \right) = 0
\]

The foregoing nodal equations and the heat rate expression were entered into the IHT workspace to obtain solutions for the three cases. See Comment 2 for the IHT code, and Comment 1 for code validation remarks.

COMMENTS: (1) Case (c) using the IHT code with \( k = 1 \times 10^{10} \) W/m·K corresponds to the condition of the plate at the uniform temperature of the base; that is \( T(x) = T_b \). For this condition, the heat rejection from the upper and lower surfaces and the tip area can be calculated as
\[
q_{f,u} = \varepsilon \sigma \left( T_b^4 - T_{sur}^4 \right) \left[ P \cdot L + A_c \right]
\]
\[
q_{f,u} = 0.65 \sigma \left[ \left( 80 + 273 \right)^4 - 4^4 \right] W / m^2 \left[ 12 + 6 \times 0.012 \right] m^2
\]
\[
q_{f,u} = 9565 W / m^2
\]

Note that the heat rejection rate for the uniform plate is in excellent agreement with the result of the FDE analysis when the thermal conductivity is made extremely large. We have confidence that the code is properly handling the conduction and radiation processes; but, we have not exercised the portion of the code dealing with the absorbed irradiation. What analytical solution/model could you use to validate this portion of the code?

(2) Selection portions are shown below of the IHT code with the 10-nodal FDEs for the temperature distribution and the heat rejection rate.

```c
// Finite-difference equations
// Interior nodes, 01 to 09
k * Ac * (T00 - T01) / deltax + k * Ac * (T02 - T01) / deltax + absS * GS * P/2 * deltax + eps * P * deltax * sigma * (Tsur^4 - T01^4) = 0
......
k * Ac * (T03 - T04) / deltax + k * Ac * (T05 - T04) / deltax + absS * GS * P/2 * deltax + eps * P * deltax * sigma * (Tsur^4 - T04^4) = 0
......
k * Ac * (T08 - T09) / deltax + k * Ac * (T10 - T09) / deltax + absS * GS * P/2 * deltax + eps * P * deltax * sigma * (Tsur^4 - T09^4) = 0

// Tip node 10
k* Ac * (T09 - T10) / deltax + absS * GS * P/2 * (deltax / 2) + eps * P * (deltax / 2) * sigma * (Tsur^4 - T10^4) + eps * Ac * sigma * (Tsur^4 - T09^4) = 0

// Rejection heat rate, energy balance on base node
qf + k * Ac * (T01 - T00) / deltax + absS * GS * (P/4) * (deltax /2) + eps * (P * deltax /2) * sigma * (Tsur^4 - T00^4) = 0
```

Continued .....
(3) To determine the validity of the one-dimensional, extended surface analysis, calculate the Biot number estimating the linearized radiation coefficient based upon the uniform plate condition, $T_b = 80^\circ$C.

$$Bi = \frac{h_{rad}(t/2)}{k}$$

$$h_{rad} = \varepsilon\sigma(T_b + T_{sur})(T_b^2 + T_{sur}^2) \approx \varepsilon\sigma T_b^3 = 2.25 \text{ W} / \text{ m}^2 \cdot \text{K}$$

$$Bi = 2.25 \text{ W} / \text{ m}^2 \cdot \text{K}(0.012 \text{ m}/2) / 300 \text{ W} / \text{ m} \cdot \text{K} = 4.5 \times 10^{-5}$$

Since $Bi \ll 0.1$, the assumption of one-dimensional conduction is appropriate.
PROBLEM 12.132

KNOWN: Directional absorptivity of a plate exposed to solar radiation on one side.

FIND: (a) Ratio of normal absorptivity to hemispherical emissivity, (b) Equilibrium temperature of plate at 0° and 75° orientation relative to sun’s rays.

SCHEMATIC:

ASSUMPTIONS: (1) Surface is gray, (2) Properties are independent of $\phi$.

ANALYSIS: (a) From the prescribed $\alpha_{\theta}(\theta)$, $\alpha_n = 0.9$. Since the surface is gray, $\varepsilon_{\theta} = \alpha_{\theta}$. Hence from Eq. 12.36, which applies for total as well as spectral properties.

$$
\varepsilon = 2 \int_0^{\pi/2} \varepsilon_{\theta} \cos \theta \sin \theta \, d\theta = 2 \left[ 0.9 \frac{\sin^2 \theta}{2} \frac{\pi/3}{0} + 0.1 \frac{\sin^2 \theta}{2} \frac{\pi/2}{\pi/3} \right]
$$

$$
\varepsilon = 2 \left[ 0.9(0.375) + 0.1(0.5 - 0.9) \right] = 0.70.
$$

Hence

$$
\frac{\alpha_n}{\varepsilon} = \frac{0.9}{0.7} = 1.286.
$$

(b) Performing an energy balance on the plate,

$$
\alpha_{\theta} q_s^{\prime} \cos \theta - 2 \varepsilon \sigma T_s^4 = 0
$$

or

$$
T_s = \left[ \frac{\alpha_{\theta} q_s^{\prime} \cos \theta}{2 \varepsilon \sigma} \right]^{1/4}.
$$

Hence for $\theta = 0^\circ$, $\alpha_{\theta} = 0.9$ and $\cos \theta = 1$,

$$
T_s = \left[ \frac{0.9}{2 \times 0.7 \times 5.67 \times 10^{-8} \times 1353} \right]^{1/4} = 352K.
$$

For $\theta = 75^\circ$, $\alpha_{\theta} = 0.1$ and $\cos \theta = 0.259$

$$
T_s = \left[ \frac{0.1}{2 \times 0.7 \times 5.67 \times 10^{-8} \times 1353 \times 0.259} \right]^{1/4} = 145K.
$$

COMMENTS: Since the surface is not diffuse, its absorptivity depends on the directional distribution of the incident radiation.
PROBLEM 12.133

KNOWN: Transmissivity of cover plate and spectral absorptivity of absorber plate for a solar collector.

FIND: Absorption rate for prescribed solar flux and preferred absorber plate coating.

SCHEMATIC:

ASSUMPTIONS: (1) Solar irradiation of absorber plate retains spectral distribution of blackbody at 5800K, (2) Coatings are diffuse.

ANALYSIS: At the absorber plate we wish to maximize solar radiation absorption and minimize losses due to emission. The solar radiation is concentrated in the spectral region $\lambda < 4\mu m$, and for a representative plate temperature of $T \leq 350K$, emission from the plate is concentrated in the spectral region $\lambda > 4\mu m$. Hence, 

$Coating\ A\ is\ vastly\ superior.$

With $G_{S,S} \sim E_{\lambda,b} (5800K)$, it follows from Eq. 12.47

$\alpha_A \approx 0.85 \int (0-4\mu m) + 0.05 \int (4\mu m-\infty).$

From Table 12.1, $\lambda T = 4\mu m \times 5800K = 23,200\mu m-K,$

$\int (0-4\mu m) \approx 0.99.$

Hence

$\alpha_A = 0.85(0.99) + 0.05(1-0.99) \approx 0.85.$

With $G_S = 1000\ W/m^2$ and $\tau = 0.76$ (Ex. 12.9), the absorbed solar flux is

$G_{S,abs} = \alpha_A (\tau G_S) = 0.85 \left( 0.76 \times 1000\ W/m^2 \right)$

$G_{S,abs} = 646\ W/m^2.$

COMMENTS: Since the absorber plate emits in the infrared ($\lambda > 4\mu m$), its emissivity is $\varepsilon_A \approx 0.05$. Hence $(\alpha/\varepsilon)_A = 17$. A large value of $\alpha/\varepsilon$ is desirable for solar absorbers.
PROBLEM 12.134

KNOWN: Spectral distribution of coating on satellite surface. Irradiation from earth and sun.

FIND: (a) Steady-state temperature of satellite on dark side of earth, (b) Steady-state temperature on bright side.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Opaque, diffuse-gray surface behavior, (3) Spectral distributions of earth and solar emission may be approximated as those of blackbodies at 280K and 5800K, respectively, (4) Satellite temperature is less than 500K.

ANALYSIS: Performing an energy balance on the satellite,

\[ \dot{E}_{in} - \dot{E}_{out} = 0 \]

\[ \alpha_E G_E \left( \frac{\pi D^2}{4} \right) + \alpha_S G_S \left( \frac{\pi D^2}{4} \right) - \varepsilon \sigma T_s^4 \left( \frac{\pi D^2}{4} \right) = 0 \]

\[ T_s = \left( \frac{\alpha_E G_E + \alpha_S G_S}{4 \varepsilon \sigma} \right)^{1/4} \]

From Table 12.1, with 98% of radiation below 3\( \mu \)m for \( \lambda T = 17,400 \mu m - K \),

\[ \alpha_S \approx 0.6. \]

With 98% of radiation above 3\( \mu \)m for \( \lambda T = 3 \mu m \times 500K = 1500 \mu m - K \),

\[ \varepsilon \approx 0.3 \quad \alpha_E = 0.3. \]

(a) On dark side,

\[ T_s = \left( \frac{\alpha_E G_E}{4 \varepsilon \sigma} \right)^{1/4} = \left( \frac{0.3 \times 340 W/m^2}{4 \times 0.3 \times 5.67 \times 10^{-8} W/m^2 \cdot K^4} \right)^{1/4} \]

\[ T_s = 197 \text{ K}. \]

(b) On bright side,

\[ T_s = \left( \frac{\alpha_E G_E + \alpha_S G_S}{4 \varepsilon \sigma} \right)^{1/4} = \left( \frac{0.3 \times 340 W/m^2 + 0.6 \times 1353 W/m^2}{4 \times 0.3 \times 5.67 \times 10^{-8} W/m^2 \cdot K^4} \right)^{1/4} \]

\[ T_s = 340 \text{ K}. \]
PROBLEM 12.135

KNOWN: Space capsule fired from earth orbit platform in direction of sun.

FIND: (a) Differential equation predicting capsule temperature as a function of time, (b) Position of capsule relative to sun when it reaches its destruction temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Capsule behaves as lumped capacitance system, (2) Capsule surface is black, (3) Temperature of surroundings approximates absolute zero, (4) Capsule velocity is constant.

ANALYSIS: (a) To find the temperature as a function of time, perform an energy balance on the capsule considering absorbed solar irradiation and emission,

\[ \dot{E}_\text{in} - \dot{E}_\text{out} = \dot{E}_\text{st} \]

\[ G_S \cdot \pi R^2 - \sigma T^4 \cdot 4\pi R^2 = \rho c \left( \frac{4}{3} \right) \pi R^3 \left( \frac{dT}{dt} \right). \]  

(1)

Note the use of the projected capsule area \((\pi R^2)\) and the surface area \((4\pi R^2)\). The solar irradiation will increase with decreasing radius (distance toward the sun) as

\[ G_S(r) = G_{S,e} \left( \frac{r_e}{r} \right)^2 = G_{S,e} \left( \frac{r_e}{(r_e - Vt)} \right)^2 = G_{S,e} \left( \frac{1}{(1 - V t / r_e)} \right)^2 \]  

(2)

where \(r_e\) is the distance of earth orbit from the sun and \(r = r_e - Vt\). Hence, Eq. (1) becomes

\[ \frac{dT}{dt} = \frac{3}{\rho c R} \left[ \frac{G_{S,e}}{4 \left( 1 - V t / r_e \right)^2} - \sigma T^4 \right]. \]

The rate of temperature change is

\[ \frac{dT}{dt} = \frac{3}{\left( 4 \times 10^6 \text{ J/m}^3 \cdot \text{K} \times 1.5\text{m} \right)} \left[ \frac{1353 \text{ W/m}^2}{4 \left( 1 - 16 \times 10^3 \text{ m/s} \times t / 1.5 \times 10^{11} \text{ m} \right)^2} - \sigma T^4 \right] \]

\[ \frac{dT}{dt} = 1.691 \times 10^{-4} \left( 1 - 1.067 \times 10^{-7} t \right)^{-2} - 2.835 \times 10^{-14} T^4 \]

where \(T[K]\) and \(t[s]\). For the initial condition, \(t = 0\), with \(T = 20^\circ C = 293K\),

\[ \frac{dT}{dt}(0) = -3.984 \times 10^{-5} \text{ K/s}. \]

That is, the capsule will cool for a period of time and then begin to heat.

(b) The differential equation cannot be explicitly solved for temperature as a function of time. Using a numerical method with a time increment of \(\Delta t = 5 \times 10^5 \text{ s}\), find

\[ T(t) = 150^\circ C = 423 \text{ K} \quad \text{at} \quad t \approx 5.5 \times 10^6 \text{ s}. \]

Note that in this period of time the capsule traveled \((r_e - r) = Vt = 16 \times 10^3 \text{ m/s} \times 5.5 \times 10^6 = 1.472 \times 10^10 \text{ m}\). That is, \(r = 1.353 \times 10^{11} \text{ m}\).
PROBLEM 12.136

KNOWN: Dimensions and spectral absorptivity of radiator used to dissipate heat to outer space. Radiator temperature. Magnitude and direction of incident solar flux.

FIND: Power dissipation within radiator.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible heat loss through sides and bottom of compartment, (3) Opaque, diffuse surface.

ANALYSIS: Applying conservation of energy to a control surface about the compartment yields

\[ \dot{E}_{\text{in}} + \dot{E}_g = \dot{E}_{\text{out}} \]

\[ \dot{E}_g = (\varepsilon \sigma T_p^4 - \alpha G_s) A. \]

The emissivity can be expressed as

\[ \varepsilon = \int_0^\infty \varepsilon_\lambda \left( E_{\lambda,b}/E_b \right) d\lambda = \varepsilon_1 F_{(0 \rightarrow \lambda_1)} + \varepsilon_2 F_{(\lambda_1 \rightarrow \infty)}. \]

From Table 12.1: \( \lambda_1 T = 1000 \mu m \cdot K \rightarrow F_{(0 \rightarrow \lambda_1)} = 0.000321 \)

\[ \varepsilon = 0.2(0.000321) + 0.8(1-0.000321) = 0.8. \]

The absorptivity can be expressed as

\[ \alpha = \int_0^\infty \alpha_\lambda (G_\lambda/G) d\lambda = \int_0^\infty \alpha_\lambda \left[ E_{\lambda,b}(5800 \text{ K})/E_b(5800 \text{ K}) \right] d\lambda. \]

From Table 12.1: \( \lambda_1 T = 11,600 \mu m \cdot K \rightarrow F_{(0 \rightarrow \lambda_1)} = 0.941, \)

\[ \alpha = 0.2(0.941) + 0.8(0.059) = 0.235. \]

Hence,

\[ \dot{E}_g = \left[ 0.8 \times 5.67 \times 10^{-8} \text{ W} / \text{m}^2 \cdot \text{K}^4 \times (500 \text{ K})^4 - 0.235 \cos 30^\circ \left( 1350 \text{ W} / \text{m}^2 \right) \right] 1 \text{ m}^2 \]

\[ \dot{E}_g = 2560 \text{ W}. \]

COMMENTS: Solar irradiation and plate emission are concentrated at short and long wavelength portions of the spectrum. Hence, \( \alpha \neq \varepsilon \) and the surface is not gray for the prescribed conditions.
PROBLEM 12.137

KNOWN: Solar panel mounted on a spacecraft of area 1 m$^2$ having a solar-to-electrical power conversion efficiency of 12% with specified radiative properties.

FIND: (a) Steady-state temperature of the solar panel and electrical power produced with solar irradiation of 1500 W/m$^2$, (b) Steady-state temperature if the panel were a thin plate (no solar cells) with the same radiative properties and for the same prescribed conditions, and (c) Temperature of the solar panel 1500 s after the spacecraft is eclipsed by the earth; thermal capacity of the panel per unit area is 9000 J/m$^2$-$K$.

SCHEMATIC:

ASSUMPTIONS: (1) Solar panel and thin plate are isothermal, (2) Solar irradiation is normal to the panel upper surface, and (3) Panel has unobstructed view of deep space at 0 K.

ANALYSIS: (a) The energy balance on the solar panel is represented in the schematic below and has the form

\[ \dot{E}_{in} - \dot{E}_{out} = 0 \]

\[ \alpha_S G_S A_p - (\varepsilon_a + \varepsilon_b) E_b (T_{sp}) A_p - P_{elec} = 0 \]  

(1)

where \( E_b (T) = \sigma T^4 \), \( \sigma = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \), and the electrical power produced is

\[ P_{elec} = \varepsilon \cdot G_S A_p \]  

(2)

\[ P_{elec} = 0.12 \times 1500 \text{ W/m}^2 \times 1 \text{ m}^2 = 180 \text{ W} \]

Substituting numerical values into Eq. (1), find

\[ 0.8 \times 1500 \text{ W/m}^2 \times 1 \text{ m}^2 - (0.8 + 0.7) \sigma T_{sp}^4 \times 1 \text{ m}^2 - 180 \text{ W} = 0 \]

\[ T_{sp} = 330.9 \text{ K} = 57.9^\circ \text{C} \]

(b) The energy balance for the thin plate shown in the schematic above follows from Eq. (1) with \( P_{elec} = 0 \) yielding

\[ 0.8 \times 1500 \text{ W/m}^2 \times 1 \text{ m}^2 - (0.8 + 0.7) \sigma T_{p}^4 \times 1 \text{ m}^2 = 0 \]  

(3)

\[ T_p = 344.7 \text{ K} = 71.7^\circ \text{C} \]

Continued …..
PROBLEM 12.137 (Cont.)

(c) Using the lumped capacitance method, the energy balance on the solar panel as illustrated in the schematic below has the form

\[
\dot{E}_{in} - \dot{E}_{out} = \dot{E}_{st}
\]

\[
-(\varepsilon_a + \varepsilon_b)\sigma T_{sp}^4 \cdot A_p = TC'' \cdot A_p \frac{dT_{sp}}{dt}
\]

where the thermal capacity per unit area is \(TC'' = \left(\frac{Mc}{A_p}\right) = 9000 \text{ J/m}^2 \cdot \text{K}\).

Eq. 5.18 provides the solution to this differential equation in terms of \(t = t(T_i, T_{sp})\). Alternatively, use Eq. (4) in the IHT workspace (see Comment 4 below) to find

\[T_{sp}(1500 \text{ s}) = 242.6 \text{ K} = -30.4^\circ \text{C}\]

**COMMENTS:**

(1) For part (a), the energy balance could be written as

\[\dot{E}_{in} - \dot{E}_{out} + \dot{E}_g = 0\]

where the energy generation term represents the *conversion process from thermal energy to electrical energy*. That is,

\[\dot{E}_g = -e \cdot G_S \cdot A_p\]

(2) The steady-state temperature for the thin plate, part (b), is higher than for the solar panel, part (a). This is to be expected since, for the solar panel, some of the absorbed solar irradiation (thermal energy) is converted to electrical power.

(3) To justify use of the lumped capacitance method for the transient analysis, we need to know the effective thermal conductivity or internal thermal resistance of the solar panel.

(4) Selected portions of the IHT code using the *Models Lumped Capacitance* tool to perform the transient analysis based upon Eq. (4) are shown below.

```plaintext
// Energy balance, Model | Lumped Capacitance
/* Conservation of energy requirement on the control volume, CV. */
Edotin - Edotout = Edotst
Edotin = 0
Edotout = Ap \times (+q''\text{rad})
Edostat = \rho \text{vol} \cdot cp \cdot \text{Der(T,t)}
// \rho \text{vol} \cdot cp \times \text{thermal capacitance per unit area, J/m}^2 \cdot \text{K}

// Radiation exchange between Cs and large surroundings
q''\text{rad} = (\varepsilon_a + \varepsilon_b) \times \sigma \times (T^4 - T_{sur}^4)
\sigma = 5.67e-8 // Stefan-Boltzmann constant, W/m^2 \cdot K^4

// Initial condition
// Ti = 57.93 + 273 = 330.9 // From part (a), steady-state condition
T_C = T - 273
```

(c) **Transient energy balance**
**PROBLEM 12.138**

**KNOWN:** Effective sky temperature and convection heat transfer coefficient associated with a thin layer of water.

**FIND:** Lowest air temperature for which the water will not freeze (without and with evaporation).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Bottom of water is adiabatic, (3) Heat and mass transfer analogy is applicable, (4) Air is dry.

**PROPERTIES:** *Table A-4*, Air (273 K, 1 atm): $\rho = 1.287 \text{ kg/m}^3$, $c_p = 1.01 \text{ kJ/kg-K}$, $\nu = 13.49 \times 10^{-6} \text{ m}^2/\text{s}$, $Pr = 0.72$; *Table A-6*, Saturated vapor ($T_s = 273 \text{ K}$): $\rho_A = 4.8 \times 10^{-3} \text{ kg/m}^3$, $h_{fg} = 2502 \text{ kJ/kg}$; *Table A-8*, Vapor-air (298 K): $D_{AB} \approx 0.36 \times 10^{-4} \text{ m}^2/\text{s}$, $Sc = \nu/D_{AB} = 0.52$.

**ANALYSIS:** Without evaporation, the surface heat loss by radiation must be balanced by heat gain due to convection. An energy balance gives

$$q_{\text{conv}} = q_{\text{rad}}$$

or

$$h(T_\infty - T_s) = \varepsilon_s \sigma \left( T_s^4 - T_{\text{sky}}^4 \right).$$

At freezing, $T_s = 273 \text{ K}$. Hence

$$T_\infty = T_s + \frac{\varepsilon_s \sigma}{h} \left( T_s^4 - T_{\text{sky}}^4 \right) = 273 \text{ K} + \frac{5.67 \times 10^{-8} \text{ W/m}^2\cdot\text{K}^4}{25 \text{ W/m}^2\cdot\text{K}} \left[ 274^4 - 243^4 \right] \text{K}^4 = 4.69^\circ \text{C}. <$$

With evaporation, the surface energy balance is now

$$q_{\text{conv}} = q_{\text{evap}} + q_{\text{rad}}$$

or

$$h(T_\infty - T_s) = h_m \left[ \rho_{A,\text{sat}}(T_s) - \rho_{A,\infty} \right] h_{fg} + \varepsilon_s \sigma \left( T_s^4 - T_{\text{sky}}^4 \right).$$

$$T_\infty = T_s + \frac{h_m}{h} \rho_{A,\text{sat}}(T_s) h_{fg} + \frac{\varepsilon_s \sigma}{h} \left( T_s^4 - T_{\text{sky}}^4 \right).$$

Substituting from Eq. 6.92, with $n \approx 0.33$,

$$h_m / h = \left( \rho c_p L_e \right)^{-1} = \left[ \rho c_p \left( Sc/Pr \right)^{0.67} \right]^{-1} = \left[ 1.287 \text{ kg/m}^3 \times 1010 \text{ J/kg} \cdot \text{K} \left( 0.52/0.72 \right)^{0.67} \right]^{-1} = 9.57 \times 10^{-4} \text{ m}^3 \cdot \text{K/J},$$

$$T_\infty = 273 \text{ K} + 9.57 \times 10^{-4} \text{ m}^3 \cdot \text{K/J} \times 4.8 \times 10^{-3} \text{ kg/m}^3 \times 2.5 \times 10^6 \text{ J/kg} + 4.69 \text{ K} = 16.2^\circ \text{C}. <$$

**COMMENTS:** The existence of clear, cold skies and dry air will allow water to freeze for ambient air temperatures well above 0°C (due to radiative and evaporative cooling effects, respectively). The lowest air temperature for which the water will not freeze increases with decreasing $\phi_\infty$, decreasing $T_{\text{sky}}$ and decreasing $h$. 
PROBLEM 12.139

KNOWN: Temperature and environmental conditions associated with a shallow layer of water.

FIND: Whether water temperature will increase or decrease with time.

SCHEMATIC:

ASSUMPTIONS: (1) Water layer is well mixed (uniform temperature), (2) All non-reflected radiation is absorbed by water, (3) Bottom is adiabatic, (4) Heat and mass transfer analogy is applicable, (5) Perfect gas behavior for water vapor.

PROPERTIES: Table A-4, Air (T = 300 K, 1 atm): $\rho_a = 1.161$ kg/m$^3$, $c_{p,a} = 1007$ J/kg·K, $Pr = 0.707$; Table A-6, Water (T = 300 K, 1 atm): $\rho_w = 997$ kg/m$^3$, $c_{p,w} = 4179$ J/kg·K; Vapor (T = 300 K, 1 atm): $\rho_{A,sat} = 0.0256$ kg/m$^3$, $h_{fg} = 2.438 \times 10^6$ J/kg; Table A-8, Water vapor-air (T = 300 K, 1 atm): $D_{AB} \approx 0.26 \times 10^{-4}$ m$^2$/s; with $\nu_a = 15.89 \times 10^{-6}$ m$^2$/s from Table A-4, $Sc = \nu_a/D_{AB} = 0.61$.

ANALYSIS: Performing an energy balance on a control volume about the water,

$$
\dot{E}_{st} = (G_{S,abs} + G_{A,abs} - E - q_{evap}^*)A
$$

$$
\frac{d}{dt}\left(\rho_w c_{p,w} L A T_w\right) = \left[(1 - \rho_s) G_S + (1 - \rho_A) G_A - \varepsilon \sigma T_w^4 - h_m h_{fg} \left(\rho_{A,sat} - \rho_{A,\infty}\right)\right] A
$$

or, with $T_\infty = T_w$, $\rho_{A,\infty} = \phi_\infty \rho_{A,sat}$ and

$$
\rho_w c_{p,w} L \frac{dT_w}{dt} = (1 - \rho_s) G_S + (1 - \rho_A) G_A - \varepsilon \sigma T_w^4 - h_m h_{fg} (1 - \phi_\infty) \rho_{A,sat}.
$$

From Eq. 6.92, with a value of $n = 1/3$,

$$
h_m = \frac{h}{\rho_a c_{p,a} L} = \frac{h}{\rho_a c_{p,a} (Sc/Pr)^{1-n}} = \frac{25 \text{ W/m}^2 \cdot \text{K} (0.707)^{2/3}}{1.161 \text{ kg/m}^3 \times 1007 \text{ J/kg} \cdot \text{K} (0.61)^{2/3}} = 0.0236 \text{ m/s}.
$$

Hence

$$
\rho_w c_{p,w} L \frac{dT_w}{dt} = (1 - 0.3) 600 + (1 - 0) 300 - 0.97 \times 5.67 \times 10^{-8} (300)^4
$$

$$
-0.0236 \times 2.438 \times 10^6 (1 - 0.5) 0.0256
$$

$$
\rho_w c_{p,w} L \frac{dT_w}{dt} = (420 + 300 - 445 - 736) \text{ W/m}^2 = -461 \text{ W/m}^2.
$$

Hence the water will cool.

COMMENTS: (1) Since $T_w = T_\infty$ for the prescribed conditions, there is no convection of sensible energy. However, as the water cools, there will be convection heat transfer from the air. (2) If $L = 1$ m, $(dT_w/dt) = -461/(997 \times 4179 \times 1) = -1.11 \times 10^{-4}$ K/s.
PROBLEM 12.140

KNOWN: Environmental conditions for a metal roof with and without a water film.

FIND: Roof surface temperature (a) without the film, (b) with the film.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Diffuse-gray surface behavior in the infrared (for the metal, \( \alpha_{\text{sky}} = \varepsilon = 0.3 \); for the water, \( \alpha_{\text{sky}} = \varepsilon = 0.9 \)), (3) Adiabatic roof bottom, (4) Perfect gas behavior for vapor.

PROPERTIES: Table A-4, Air (\( T \approx 300 \) K): \( \rho = 1.16 \) kg/m\(^3\), \( c_p = 1007 \) J/kg·K, \( \alpha = 22.5 \times 10^{-6} \) m\(^2\)/s; Table A-6, Water vapor (\( T \approx 303 \) K): \( \nu_g = 32.4 \) m\(^3\)/kg or \( \rho_{A,\text{sat}} = 0.031 \) kg/m\(^3\); Table A-8, Water vapor-air (\( T = 298 \) K): \( D_{AB} = 0.26 \times 10^{-4} \) m\(^2\)/s.

ANALYSIS: (a) From an energy balance on the metal roof

\[
\alpha_S G_S + \alpha_{\text{sky}} G_{\text{sky}} = E + q''_{\text{conv}} \\
0.5 \left( 700 \text{ W/m}^2 \right) + 0.3 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (263 \text{ K})^4 \\
= 0.3 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (Ts^4) + 20 \text{ W/m}^2 \cdot \text{K} (Ts - 303 \text{ K}) \\
= 4.1 \text{ W/m}^2 = 1.70 \times 10^{-8} Ts^4 + 20 (Ts - 303).
\]

From a trial-and-error solution, \( Ts = 316.1 \) K = 43.1°C.

(b) From an energy balance on the water film,

\[
\alpha_S G_S + \alpha_{\text{sky}} G_{\text{sky}} = E + q''_{\text{conv}} + q''_{\text{evap}} \\
0.8 \left( 700 \text{ W/m}^2 \right) + 0.9 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (263 \text{ K})^4 = 0.9 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (Ts^4) \\
+ 20 \text{ W/m}^2 \cdot \text{K} (Ts - 303) + h_m \left( \rho_{A,\text{sat}} (Ts) - 0.65 \times 0.031 \text{ kg/m}^3 \right) h_{fg}.
\]

From Eq. 6.92, assuming \( n = 0.33 \),

\[
h_m = \frac{h}{\rho c_p L e^{0.67}} = \frac{h}{\rho c_p (\alpha / D_{AB})^{0.67}} = \frac{20 \text{ W/m}^2 \cdot \text{K}}{1.16 \text{ kg/m}^3 \times 1007 \text{ J/kg·K} \times \left( 0.225 \times 10^{-4} / 0.260 \times 10^{-4} \right)^{0.67}} = 0.019 \text{ m/s}.
\]

\[
804 \text{ W/m}^2 = 5.10 \times 10^{-8} Ts^4 + 20 (Ts - 303) + 0.019 \left[ \rho_{A,\text{sat}} (Ts) - 0.020 \right] h_{fg}.
\]

From a trial-and-error solution, obtaining \( \rho_{A,\text{sat}} (Ts) \) and \( h_{fg} \) from Table A-6 for each assumed value of \( Ts \), it follows that \( Ts = 302.2 \) K = 29.2°C.

COMMENTS: (1) The film is an effective coolant, reducing \( Ts \) by 13.9°C. (2) With the film \( E \approx 425 \) W/m\(^2\), \( q''_{\text{conv}} \approx -16 \text{ W/m}^2 \) and \( q''_{\text{evap}} \approx 428 \text{ W/m}^2 \).
PROBLEM 12.141

KNOWN: Solar, sky and ground irradiation of a wet towel. Towel dimensions, emissivity and solar absorptivity. Temperature, relative humidity and convection heat transfer coefficient associated with air flow over the towel.

FIND: Temperature of towel and evaporation rate.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Diffuse-gray surface behavior of towel in the infrared \((\alpha_{\text{sky}} = \alpha_g = \varepsilon = 0.96)\), (3) Perfect gas behavior for vapor.

PROPERTIES: Table A-4, Air \((T \approx 300 \text{ K})\): \(\rho = 1.16 \text{ kg/m}^3, c_p = 1007 \text{ J/kg} \cdot \text{K}, \alpha = 0.225 \times 10^{-4} \text{ m}^2/\text{s}\); Table A-6, Water vapor \((T_\infty = 300 \text{ K})\): \(\rho_{A,\text{sat}} = 0.0256 \text{ kg/m}^3\); Table A-8, Water vapor/air \((T = 298 \text{ K})\): \(D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}\).

ANALYSIS: From an energy balance on the towel, it follows that

\[
\alpha_S G_S + 2\alpha_{\text{sky}} G_{\text{sky}} + 2\alpha_g G_g = 2E + 2q_{\text{evap}} + 2q_{\text{conv}}
\]

\[
0.65\times900 \text{ W/m}^2 + 2\times0.96\times200 \text{ W/m}^2 + 2\times0.96\times250 \text{ W/m}^2 = 2\times0.96 \sigma T_s^4 + 2n_A^* h_{fg} + 2h(T_s - T_\infty)
\]

where \(n_A^* = h_m\left[\rho_{A,\text{sat}}(T_s) - \phi_\infty \rho_{A,\text{sat}}(T_\infty)\right]\)

From the heat and mass transfer analogy, Eq. 6.67, with an assumed exponent of \(n = 1/3\),

\[
h_m = \frac{h}{\rho c_p (\alpha / D_{AB})^{2/3}} = \frac{20 \text{ W/m}^2 \cdot \text{K}}{1.16 \text{ kg/m}^3 (1007 \text{ J/kg} \cdot \text{K}) \left(0.225 / 0.260\right)^{2/3}} = 0.0189 \text{ m/s}
\]

From a trial-and-error solution, we find that for \(T_s = 298 \text{ K}\), \(\rho_{A,\text{sat}} = 0.0226 \text{ kg/m}^3\), \(h_{fg} = 2.442 \times 10^6 \text{ J/kg}\) and \(n_A^* = 1.380 \times 10^{-4} \text{ kg/s} \cdot \text{m}^2\). Substituting into Eq. (1),

\[
(585 + 384 + 480) \text{ W/m}^2 = 2\times0.96\times5.67\times10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (298 \text{ K})^4 + 2\times1.380\times10^{-4} \text{ kg/s} \cdot \text{m}^2 \times 2.442\times10^6 \text{ J/kg} + 2\times20 \text{ W/m}^2 \cdot \text{K}(-2 \text{ K})
\]

\[1449 \text{ W/m}^2 = (859 + 674 - 80) \text{ W/m}^2 = 1453 \text{ W/m}^2\]

The equality is satisfied to a good approximation, in which case

\(T_s = 298 \text{ K} = 25^\circ\text{C}\)

and \(n_A = 2 A_s n_A^* = 2(1.50\times0.75) \text{ m}^2 \left(1.38\times10^{-4} \text{ kg/s} \cdot \text{m}^2\right) = 3.11\times10^{-4} \text{ kg/s}\)

COMMENTS: Note that the temperature of the air exceeds that of the towel, in which case convection heat transfer is to the towel. Reduction of the towel’s temperature below that of the air is due to the evaporative cooling effect.
PROBLEM 12.142

KNOWN: Wet paper towel experiencing forced convection heat and mass transfer and irradiation from radiant lamps. Prescribed convection parameters including wet and dry bulb temperature of the air stream, \( T_{wb} \) and \( T_{\infty} \), average heat and mass transfer coefficients, \( \bar{h} \) and \( \bar{m}_h \). Towel temperature \( T_s \).

FIND: (a) Vapor densities, \( \rho_{A,s} \) and \( \rho_{A,\infty} \); the evaporation rate \( n_A \) (kg/s); and the net rate of radiation transfer to the towel \( q_{rad} \) (W); and (b) Emissive power \( E \), the irradiation \( G \), and the radiosity \( J \), using the results from part (a).

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible heat loss from the bottom side of the towel, (3) Uniform irradiation on the towel, and (4) Water surface is diffuse, gray.

PROPERTIES: Table A.6, Water (\( T_s = 310 \) K): \( h_{fg} = 2414 \) kJ/kg.

ANALYSIS: (a) Since \( T_{wb} = T_{\infty} \), the free stream contains water vapor at its saturation condition. The water vapor at the surface is saturated since it is in equilibrium with the liquid in the towel. From Table A.6,

<table>
<thead>
<tr>
<th>T (K)</th>
<th>( v_g ) (m³/kg)</th>
<th>( \rho_g ) (kg/m³)</th>
</tr>
</thead>
<tbody>
<tr>
<td>( T_{\infty} = 290 )</td>
<td>69.7</td>
<td>( \rho_{A,\infty} = 1.435 \times 10^{-2} )</td>
</tr>
<tr>
<td>( T_s = 310 )</td>
<td>22.93</td>
<td>( \rho_{A,s} = 4.361 \times 10^{-2} )</td>
</tr>
</tbody>
</table>

Using the mass transfer convection rate equation, the water evaporation rate from the towel is

\[
q_e = \bar{h} m A_s \left( \rho_{A,s} - \rho_{A,\infty} \right) = 0.027 \text{ m/s} \left( 0.0925 \text{ m} \right)^2 \left( 4.361 - 1.435 \right) \times 10^{-2} \text{ kg/m}^3 \times 6.76 \times 10^{-6} \text{ kg/s} <
\]

To determine the net radiation heat rate \( q_{rad} \), perform an energy balance on the water film,

\[
\dot{E}_{in} - \dot{E}_{out} = 0 \quad q_{rad} - q_{cv} - q_{evap} = 0
\]

\[
q_{rad} = q_{cv} + q_{evap} = \bar{h} m A_s \left( T_s - T_{\infty} \right) + n_A h_{fg}
\]

and substituting numerical values find

\[
q_{rad} = 28.7 \text{ W/m}^2 \cdot \text{K} \left( 0.0925 \text{ m} \right)^2 \left( 310 - 290 \right) \text{ K} + 6.76 \times 10^{-6} \text{ kg/s} \times 2414 \times 10^3 \text{ J/kg} <
\]

\[
q_{rad} = (4.91 + 16.32) \text{ W} = 21.2 \text{ W} <
\]

(b) The radiation parameters for the towel surface are now evaluated. The emissive power is

\[
E = \varepsilon E_b \left( T_s \right) = \varepsilon \sigma T_s^4 = 0.96 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left( 310 \text{ K} \right)^4 = 502.7 \text{ W/m}^2 <
\]

To determine the irradiation \( G \), recognize that the net radiation heat rate can be expressed as,

\[
q_{rad} = (\alpha G - E) A_s \quad 21.2 \text{ W} = (0.96G - 502.7) \text{ W/m}^2 \times (0.0925 \text{ m})^2 \quad G = 3105 \text{ W/m}^2 <
\]

where \( \alpha = \varepsilon \) since the water surface is diffuse, gray. From the definition of the radiosity,

\[
J = E + \rho G = 502.7 + (1 - 0.96) \times 3105 \text{ W/m}^2 = 626.9 \text{ W/m}^2 <
\]

where \( \rho = 1 - \alpha = 1 - \varepsilon \).

COMMENTS: An alternate method to evaluate \( J \) is to recognize that \( q_{rad} = G - J \).
PROBLEM 13.1

KNOWN: Various geometric shapes involving two areas $A_1$ and $A_2$.
FIND: Shape factors, $F_{12}$ and $F_{21}$, for each configuration.
ASSUMPTIONS: Surfaces are diffuse.
ANALYSIS: The analysis is not to make use of tables or charts. The approach involves use of the reciprocity relation, Eq. 13.3, and summation rule, Eq. 13.4. Recognize that reciprocity applies to two surfaces; summation applies to an enclosure. Certain shape factors will be identified by inspection. Note $L$ is the length normal to page.

(a) Long duct (L):

By inspection, $F_{12} = 1.0$

By reciprocity,

$$F_{21} = \frac{A_1}{A_2} F_{12} = \frac{2RL}{(3/4) \cdot 2\pi RL} \times 1.0 = \frac{4}{3\pi} = 0.424$$

(b) Small sphere, $A_1$, under concentric hemisphere, $A_2$, where $A_2 = 2A$

Summation rule $F_{11} + F_{12} + F_{13} = 1$

But $F_{12} = F_{13}$ by symmetry, hence $F_{12} = 0.5$

By reciprocity,

$$F_{21} = \frac{A_1}{A_2} F_{12} = \frac{A_1}{2A_1} \times 0.5 = 0.25.$$

(c) Long duct (L):

By inspection, $F_{12} = 1.0$

By reciprocity,

$$F_{21} = \frac{A_1}{A_2} F_{12} = \frac{2RL}{\pi RL} \times 1.0 = \frac{2}{\pi} = 0.637$$

Summation rule, $F_{22} = 1 - F_{21} = 1 - 0.64 = 0.363$.

(d) Long inclined plates (L):

Summation rule, $F_{11} + F_{12} + F_{13} = 1$

But $F_{12} = F_{13}$ by symmetry, hence $F_{12} = 0.5$

By reciprocity,

$$F_{21} = \frac{A_1}{A_2} F_{12} = \frac{20L}{10(2)^{1/2} L} \times 0.5 = 0.707.$$

(e) Sphere lying on infinite plane

Summation rule, $F_{11} + F_{12} + F_{13} = 1$

But $F_{12} = F_{13}$ by symmetry, hence $F_{12} = 0.5$

By reciprocity,

$$F_{21} = \frac{A_1}{A_2} F_{12} \rightarrow 0 \text{ since } A_2 \rightarrow \infty.$$
(f) Hemisphere over a disc of diameter D/2; find also $F_{22}$ and $F_{23}$.

By inspection, $F_{12} = 1.0$

Summation rule for surface $A_3$ is written as

$$F_{31} + F_{32} + F_{33} = 1.$$ Hence, $F_{32} = 1.0$.

By reciprocity,

$$F_{23} = \frac{A_3}{A_2} - F_{32}$$

$$F_{23} = \left( \frac{\pi D^2}{4} - \frac{\pi (D/2)^2}{4} \right) / \frac{\pi D^2}{2} = 0.375.$$  

By reciprocity,

$$F_{21} = \frac{A_1}{A_2} F_{12} = \frac{\pi [D/2]^2}{\pi D^2/2} \times 1.0 = 0.125.$$  

Summation rule for $A_2$,

$$F_{21} + F_{22} + F_{23} = 1$$ or

$$F_{22} = 1 - F_{21} - F_{23} = 1 - 0.125 - 0.375 = 0.5.$$  

Note that by inspection you can deduce $F_{22} = 0.5$

(g) Long open channel (L):

Summation rule for $A_1$

$$F_{11} + F_{12} + F_{13} = 0$$

but $F_{12} = F_{13}$ by symmetry, hence $F_{12} = 0.50$.

By reciprocity,

$$F_{21} = \frac{A_1}{A_2} F_{12} = \frac{2 \times L}{(2 \pi)} / \frac{4 \times L}{\pi} = \frac{4}{\pi} \times 0.50 = 0.637.$$  

**COMMENTS:** (1) Note that the summation rule is applied to an enclosure. To complete the enclosure, it was necessary in several cases to define a third surface which was shown by dashed lines.

(2) Recognize that the solutions follow a systematic procedure; in many instances it is possible to deduce a shape factor by inspection.
PROBLEM 13.2

KNOWN: Geometry of semi-circular, rectangular and V grooves.

FIND: (a) View factors of grooves with respect to surroundings, (b) View factor for sides of V groove, (c) View factor for sides of rectangular groove.

SCHEMATIC:

ASSUMPTIONS: (1) Diffuse surfaces, (2) Negligible end effects, “long grooves”.

ANALYSIS: (a) Consider a unit length of each groove and represent the surroundings by a hypothetical surface (dashed line).

Semi-Circular Groove:

\[ F_{21} = 1; \quad F_{12} = \frac{A_2}{A_1} F_{21} = \frac{W}{(\pi W/2) \times 1} \]

\[ F_{12} = \frac{2}{\pi}. \]

Rectangular Groove:

\[ F_{4(1,2,3)} = 1; \quad F_{(1,2,3)4} = \frac{A_4}{A_1 + A_2 + A_3} F_{4(1,2,3)} = \frac{W}{H + W + H} \times 1 \]

\[ F_{(1,2,3)4} = \frac{W}{(W + 2H)}. \]

V Groove:

\[ F_{3(1,2)} = 1; \quad F_{(1,2)3} = \frac{A_3}{A_1 + A_2} F_{3(1,2)} = \frac{W}{W/2 + W/2 \sin \theta} \]

\[ F_{(1,2)3} = \sin \theta. \]

(b) From Eqs. 13.3 and 13.4,

\[ F_{12} = 1 - F_{13} = 1 - \frac{A_3}{A_1} F_{31}. \]

From Symmetry,

\[ F_{31} = 1/2. \]

Hence, \[ F_{12} = 1 - \frac{W}{(W/2)/\sin \theta} \times \frac{1}{2} = 1 - \sin \theta. \]

(c) From Fig. 13.4, with \(X/L = H/W = 2\) and \(Y/L \to \infty\),

\[ F_{12} \approx 0.62. \]

COMMENTS: (1) Note that for the V groove, \(F_{13} = F_{23} = F_{(1,2)3} = \sin \theta\). (2) In part (c), Fig. 13.4 could also be used with \(Y/L = 2\) and \(X/L = \infty\). However, obtaining the limit of \(F_{ij}\) as \(X/L \to \infty\) from the figure is somewhat uncertain.
PROBLEM 13.3

KNOWN: Two arrangements (a) circular disk and coaxial, ring shaped disk, and (b) circular disk and coaxial, right-circular cone.

FIND: Derive expressions for the view factor $F_{12}$ for the arrangements (a) and (b) in terms of the areas $A_1$ and $A_2$, and any appropriate hypothetical surface area, as well as the view factor for coaxial parallel disks (Table 13.2, Figure 13.5). For the disk-cone arrangement, sketch the variation of $F_{12}$ with $\theta$ for $0 \leq \theta \leq \pi/2$, and explain the key features.

SCHEMATIC:

ASSUMPTIONS: Diffuse surfaces with uniform radiosities.

ANALYSIS: (a) Define the hypothetical surface $A_3$, a co-planar disk inside the ring of $A_1$. Using the additive view factor relation, Eq. 13.5,

$$A_{(1,3)} F_{(1,3)} = A_1 F_{12} + A_3 F_{32}$$

$$F_{12} = \frac{1}{A_1} \left[ A_{(1,3)} F_{(1,3)} - A_3 F_{32} \right]$$

where the parenthesis denote a composite surface. All the $F_{ij}$ on the right-hand side can be evaluated using Fig. 13.5.

(b) Define the hypothetical surface $A_3$, the disk at the bottom of the cone. The radiant power leaving $A_2$ that is intercepted by $A_1$ can be expressed as

$$F_{21} = F_{23}$$

That is, the same power also intercepts the disk at the bottom of the cone, $A_3$. From reciprocity,

$$A_1 F_{12} = A_2 F_{21}$$

and using Eq. (1),

$$F_{12} = \frac{A_2}{A_1} F_{23}$$

The variation of $F_{12}$ as a function of $\theta$ is shown below for the disk-cone arrangement. In the limit when $\theta \to \pi/2$, the cone approaches a disk of area $A_3$. That is,

$$F_{12} \left( \theta \to \pi/2 \right) = F_{13}$$

When $\theta \to 0$, the cone area $A_2$ diminishes so that

$$F_{12} \left( \theta \to 0 \right) = 0$$
**PROBLEM 13.4**

**KNOWN:** Right circular cone and right-circular cylinder of same diameter D and length L positioned coaxially a distance \( L_0 \) from the circular disk \( A_1 \); hypothetical area corresponding to the openings identified as \( A_3 \).

**FIND:** (a) Show that \( F_{21} = \frac{A_1}{A_2} F_{13} \) and \( F_{22} = 1 - \frac{A_3}{A_2} \), where \( F_{13} \) is the view factor between two, coaxial parallel disks (Table 13.2), for both arrangements, (b) Calculate \( F_{21} \) and \( F_{22} \) for \( L = L_0 = 50 \) mm and \( D_1 = D_3 = 50 \) mm; compare magnitudes and explain similarities and differences, and (c) Magnitudes of \( F_{21} \) and \( F_{22} \) as \( L \) increases and all other parameters remain the same; sketch and explain key features of their variation with \( L \).

**SCHEMATIC:**

![Diagram of cone and cylinder](image)

**ASSUMPTIONS:** (1) Diffuse surfaces with uniform radiosities, and (2) Inner base and lateral surfaces of the cylinder treated as a single surface, \( A_2 \).

**ANALYSIS:** (a) For both configurations,

\[
F_{13} = F_{12} \tag{1}
\]

since the radiant power leaving \( A_1 \) that is intercepted by \( A_3 \) is likewise intercepted by \( A_2 \). Applying reciprocity between \( A_1 \) and \( A_2 \),

\[
A_1 F_{12} = A_2 F_{21} \tag{2}
\]

Substituting from Eq. (1), into Eq. (2), solving for \( F_{21} \), find

\[
F_{21} = \left( \frac{A_1}{A_2} \right) F_{12} = \left( \frac{A_1}{A_2} \right) F_{13} \quad <
\]

Treating the cone and cylinder as two-surface enclosures, the summation rule for \( A_2 \) is

\[
F_{22} + F_{23} = 1 \tag{3}
\]

Apply reciprocity between \( A_2 \) and \( A_3 \), solve Eq. (3) to find

\[
F_{22} = 1 - F_{23} = 1 - \left( \frac{A_3}{A_2} \right) F_{32}
\]

and since \( F_{32} = 1 \), find

\[
F_{22} = 1 - \frac{A_3}{A_2} \quad <
\]

Continued .....
(b) For the specified values of $L$, $L_0$, $D_1$ and $D_2$, the view factors are calculated and tabulated below. Relations for the areas are:

**Disk-cone:**

$$A_1 = \pi D_1^2 / 4 \quad A_2 = \pi D_3 / 2 \left( L^2 + (D_3 / 2)^2 \right)^{1/2} \quad A_3 = \pi D_3^2 / 4$$

**Disk-cylinder:**

$$A_1 = \pi D_1^2 / 4 \quad A_2 = \pi D_3^2 / 4 + \pi D_3 L \quad A_3 = \pi D_3^2 / 4$$

The view factor $F_{13}$ is evaluated from Table 13.2, coaxial parallel disks (Fig. 13.5); find $F_{13} = 0.1716$.

<table>
<thead>
<tr>
<th>Disk-cone</th>
<th>$F_{21}$</th>
<th>$F_{22}$</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disk-cylinder</td>
<td>0.0767</td>
<td>0.553</td>
</tr>
</tbody>
</table>

It follows that $F_{21}$ is greater for the disk-cone (a) than for the cylinder-cone (b). That is, for (a), surface $A_2$ sees more of $A_1$ and less of itself than for (b). Notice that $F_{22}$ is greater for (b) than (a); this is a consequence of $A_{2,b} > A_{2,a}$.

(c) Using the foregoing equations in the IHT workspace, the variation of the view factors $F_{21}$ and $F_{22}$ with $L$ were calculated and are graphed below.

![Graph of view factors](image)

Note that for both configurations, when $L = 0$, find that $F_{21} = F_{13} = 0.1716$, the value obtained for coaxial parallel disks. As $L$ increases, find that $F_{22} \to 1$; that is, the interior of both the cone and cylinder see mostly each other. Notice that the changes in both $F_{21}$ and $F_{22}$ with increasing $L$ are greater for the disk-cylinder; $F_{21}$ decreases while $F_{22}$ increases.

**COMMENTS:** From the results of part (b), why isn’t the sum of $F_{21}$ and $F_{22}$ equal to unity?
PROBLEM 13.5

KNOWN: Two parallel, coaxial, ring-shaped disks.

FIND: Show that the view factor \( F_{12} \) can be expressed as

\[
F_{12} = \frac{1}{A_1} \left[ A_{(1,3)} F_{(1,3)(2,4)} - A_3 F_{3(2,4)} - A_4 \left( F_{4(1,3)} - F_{43} \right) \right]
\]

where all the \( F_{ij} \) on the right-hand side of the equation can be evaluated from Figure 13.5 (see Table 13.2) for coaxial parallel disks.

SCHEMATIC:

ASSUMPTIONS: Diffuse surfaces with uniform radiosities.

ANALYSIS: Using the additive rule, Eq. 13.5, where the parenthesis denote a composite surface,

\[
F_{1(2,4)} = F_{12} + F_{14}
\]

\[
F_{12} = F_{1(2,4)} - F_{14}
\]

Relation for \( F_{1(2,4)} \):

Using the additive rule

\[
A_{(1,3)} F_{(1,3)(2,4)} = A_1 F_{1(2,4)} + A_3 F_{3(2,4)}
\]

where the check mark denotes a \( F_{ij} \) that can be evaluated using Fig. 13.5 for coaxial parallel disks.

Relation for \( F_{14} \):

Apply reciprocity

\[
A_1 F_{14} = A_4 F_{41}
\]

and using the additive rule involving \( F_{41} \),

\[
A_1 F_{14} = A_4 \left[ F_{4(1,3)} - F_{43} \right]
\]

Relation for \( F_{12} \):

Substituting Eqs. (2) and (4) into Eq. (1),

\[
F_{12} = \frac{1}{A_1} \left[ A_{(1,3)} F_{(1,3)(2,4)} - A_3 F_{3(2,4)} - A_4 \left( F_{4(1,3)} - F_{43} \right) \right]
\]

COMMENTS: (1) The \( F_{ij} \) on the right-hand side can be evaluated using Fig. 13.5.

(2) To check the validity of the result, substitute numerical values and test the behavior at special limits. For example, as \( A_3, A_4 \to 0 \), the expression reduces to the identity \( F_{12} = F_{12} \).
PROBLEM 13.6

KNOWN: Long concentric cylinders with diameters $D_1$ and $D_2$ and surface areas $A_1$ and $A_2$.

FIND: (a) The view factor $F_{12}$ and (b) Expressions for the view factors $F_{22}$ and $F_{21}$ in terms of the cylinder diameters.

SCHEMATIC:

ASSUMPTIONS: (1) Diffuse surfaces with uniform radiosities and (2) Cylinders are infinitely long such that $A_1$ and $A_2$ form an enclosure.

ANALYSIS: (a) View factor $F_{12}$. Since the infinitely long cylinders form an enclosure with surfaces $A_1$ and $A_2$, from the summation rule on $A_1$, Eq. 13.4,

\[ F_{11} + F_{12} = 1 \]

and since $A_1$ doesn’t see itself, $F_{11} = 0$, giving

\[ F_{12} = 1 \]  \hspace{1cm} (2)

That is, the inner surface views only the outer surface.

(b) View factors $F_{22}$ and $F_{21}$. Applying reciprocity between $A_1$ and $A_2$, Eq. 13.3, and substituting from Eq. (2),

\[ A_1 F_{12} = A_2 F_{21} \]

\[ F_{21} = \frac{A_1}{A_2} F_{12} = \frac{\pi D_1 L}{\pi D_2 L} \times 1 = \frac{D_1}{D_2} \]  \hspace{1cm} (4)

From the summation rule on $A_2$, and substituting from Eq. (4),

\[ F_{21} + F_{22} = 1 \]

\[ F_{22} = 1 - F_{21} = 1 - \frac{D_1}{D_2} \]  \hspace{1cm} <
PROBLEM 13.7

KNOWN: Right-circular cylinder of diameter \( D \), length \( L \) and the areas \( A_1, A_2, \) and \( A_3 \) representing the base, inner lateral and top surfaces, respectively.

FIND: (a) Show that the view factor between the base of the cylinder and the inner lateral surface has the form

\[
F_{12} = 2 \left( 1 + \frac{L}{D} \right) - \frac{L}{D} 
\]

where \( H = L/D \), and (b) Show that the view factor for the inner lateral surface to itself has the form

\[
F_{22} = 1 + \left( 1 + \left( 1 + \frac{L}{D} \right)^{1/2} \right)
\]

SCHEMATIC:

ASSUMPTIONS: Diffuse surfaces with uniform radiosities.

ANALYSIS: (a) Relation for \( F_{12} \), base-to-inner lateral surface. Apply the summation rule to \( A_1 \), noting that \( F_{11} = 0 \)

\[
F_{11} + F_{12} + F_{13} = 1
\]

\[
F_{12} = 1 - F_{13} \quad (1)
\]

From Table 13.2, Fig. 13.5, with \( i = 1, j = 3 \),

\[
F_{13} = \frac{1}{2} \left( S - \left[ S^2 - 4 \left( \frac{D_3}{D_1} \right)^2 \right]^{1/2} \right) \quad (2)
\]

\[
S = 1 + \frac{1 + \frac{R_3^2}{R_1^2}}{2} = \frac{1}{R_1^2} + 2 = 4H^2 + 2 \quad (3)
\]

where \( R_1 = R_3 = R = D/2L \) and \( H = L/D \). Combining Eqs. (2) and (3) with Eq. (1), find after some manipulation

Continued .....
PROBLEM 13.7 (Cont.)

\[ F_{12} = 1 - \frac{1}{2} \left\{ 4 H^2 + 2 - \left[ (4 H^2 + 2)^2 - 4 \right]^{1/2} \right\} \]

\[ F_{12} = 2 H \left[ (1 + H^2)^{1/2} - H \right] \]  \hspace{1cm} (4)

(b) Relation for \( F_{22} \), inner lateral surface. Apply summation rule on \( A_2 \), recognizing that \( F_{23} = F_{21} \).

\[ F_{21} + F_{22} + F_{23} = 1 \quad F_{22} = 1 - 2 F_{21} \]  \hspace{1cm} (5)

Apply reciprocity between \( A_1 \) and \( A_2 \).

\[ F_{21} = \left( \frac{A_1}{A_2} \right) F_{12} \]  \hspace{1cm} (6)

and substituting into Eq. (5), and using area expressions

\[ F_{22} = 1 - 2 \frac{A_1}{A_2} F_{12} = 1 - 2 \frac{D}{4L} F_{12} = 1 - \frac{1}{2} H F_{12} \]  \hspace{1cm} (7)

where \( A_1 = \pi D^2 / 4 \) and \( A_2 = \pi DL \).

Substituting from Eq. (4) for \( F_{12} \), find

\[ F_{22} = 1 - \frac{1}{2} H \left[ (1 + H^2)^{1/2} - H \right] = 1 + H - (1 + H^2)^{1/2} \]  \hspace{1cm} <
PROBLEM 13.8

KNOWN: Arrangement of plane parallel rectangles.

FIND: Show that the view factor between $A_1$ and $A_2$ can be expressed as

$$F_{12} = \frac{1}{2A_1} \left[ A_{(1,4)} F_{(1,4)(2,3)} - A_1 F_{13} - A_4 F_{42} \right]$$

where all $F_{ij}$ on the right-hand side of the equation can be evaluated from Fig. 13.4 (see Table 13.2) for aligned parallel rectangles.

SCHEMATIC:

ASSUMPTIONS: Diffuse surfaces with uniform radiosity.

ANALYSIS: Using the additive rule where the parenthesis denote a composite surface,

$$A_{(1,4)} F^*_{(1,4)(2,3)} = A_1 F^*_{13} + A_1 F_{12} + A_4 F_{43} + A_4 F^*_4$$  \hspace{1cm} (1)

where the asterisk (*) denotes that the $F_{ij}$ can be evaluated using the relation of Figure 13.4. Now, find suitable relation for $F_{43}$. By symmetry,

$$F_{43} = F_{21}$$  \hspace{1cm} (2)

and from reciprocity between $A_1$ and $A_2$,

$$F_{21} = \frac{A_1}{A_2} F_{12}$$  \hspace{1cm} (3)

Multiply Eq. (2) by $A_4$ and substitute Eq. (3), with $A_4 = A_2$,

$$A_4 F_{43} = A_4 F_{21} = A_4 \frac{A_1}{A_2} F_{12} = A_1 F_{12}$$  \hspace{1cm} (4)

Substituting for $A_4 F_{43}$ from Eq. (4) into Eq. (1), and rearranging,

$$F_{12} = \frac{1}{2A_1} \left[ A_{(1,4)} F^*_{(1,4)(2,3)} - A_1 F^*_{13} - A_4 F^*_4 \right]$$
PROBLEM 13.9

KNOWN: Two perpendicular rectangles not having a common edge.

FIND: (a) Shape factor, $F_{12}$, and (b) Compute and plot $F_{12}$ as a function of $Z_b$ for $0.05 \leq Z_b \leq 0.4$ m; compare results with the view factor obtained from the two-dimensional relation for perpendicular plates with a common edge, Table 13.1.

SCHEMATIC:

ASSUMPTIONS: (1) All surfaces are diffuse, (2) Plane formed by $A_1 + A_3$ is perpendicular to plane of $A_2$.

ANALYSIS: (a) Introducing the hypothetical surface $A_3$, we can write

$$F_{2(3,1)} = F_{23} + F_{21}.$$  \quad (1)

Using Fig. 13.6, applicable to perpendicular rectangles with a common edge, find

$$F_{23} = 0.19 : \quad \text{with } Y = 0.3, \quad X = 0.5, \quad Z = Z_a - Z_b = 0.2, \quad \text{and } \frac{Y}{X} = \frac{0.3}{0.5} = 0.6, \quad \frac{Z}{X} = \frac{0.2}{0.5} = 0.4$$

$$F_{2(3,1)} = 0.25 : \quad \text{with } Y = 0.3, \quad X = 0.5, \quad Z_a = 0.4, \quad \text{and } \frac{Y}{X} = \frac{0.3}{0.5} = 0.6, \quad \frac{Z}{X} = \frac{0.4}{0.5} = 0.8$$

Hence from Eq. (1)

$$F_{21} = F_{2(3,1)} - F_{23} = 0.25 - 0.19 = 0.06$$

By reciprocity,

$$F_{12} = \frac{A_2 F_{21}}{A_1} = \frac{0.5 \times 0.3 \text{ m}^2}{0.5 \times 0.2 \text{ m}^2} \times 0.06 = 0.09$$  \quad (2) <

(b) Using the IHT Tool – View Factors for Perpendicular Rectangles with a Common Edge and Eqs. (1,2) above, $F_{12}$ was computed as a function of $Z_b$. Also shown on the plot below is the view factor $F_{(3,1)2}$ for the limiting case $Z_b \rightarrow Z_a$. 

![View Factors Plot](image)
KNOWLEDGE: Arrangement of perpendicular surfaces without a common edge.

FIND: (a) A relation for the view factor $F_{14}$ and (b) The value of $F_{14}$ for prescribed dimensions.

SCHEMATIC:

ASSUMPTIONS: (1) Diffuse surfaces.

ANALYSIS: (a) To determine $F_{14}$, it is convenient to define the hypothetical surfaces $A_2$ and $A_3$.

From Eq. 13.6,
\[
(A_1 + A_2)F_{(1,2)}(3,4) = A_1 F_{(3,4)} + A_2 F_{2(3,4)}
\]

where $F_{(1,2)(3,4)}$ and $F_{2(3,4)}$ may be obtained from Fig. 13.6. Substituting for $A_1 F_{(3,4)}$ from Eq. 13.5 and combining expressions, find
\[
F_{14} = \frac{1}{A_1} \left[ (A_1 + A_2)F_{(1,2)(3,4)} - A_1 F_{13} - A_2 F_{2(3,4)} \right].
\]

Substituting for $A_1 F_{13}$ from Eq. 13.6, which may be expressed as
\[
(A_1 + A_2)F_{(1,2)3} = A_1 F_{13} + A_2 F_{23}.
\]

The desired relation is then
\[
F_{14} = \frac{1}{A_1} \left[ (A_1 + A_2)F_{(1,2)(3,4)} + A_2 F_{23} - (A_1 + A_2)F_{(1,2)3} - A_2 F_{2(3,4)} \right]. \tag{1}
\]

(b) For the prescribed dimensions and using Fig. 13.6, find these view factors:

- Surfaces $(1,2)(3,4)$: \(\frac{Y}{X} = \frac{L_1 + L_2}{W} = 1\), \(\frac{Z}{X} = \frac{L_3 + L_4}{W} = 1.45\), \(F_{(1,2)(3,4)} = 0.22\)

- Surfaces $23$: \(\frac{Y}{X} = \frac{L_2}{W} = 0.5\), \(\frac{Z}{X} = \frac{L_3}{W} = 1\), \(F_{23} = 0.28\)

- Surfaces $(1,2)3$: \(\frac{Y}{X} = \frac{L_1 + L_2}{W} = 1\), \(\frac{Z}{X} = \frac{L_3}{W} = 1\), \(F_{(1,2)3} = 0.20\)

- Surfaces $2(3,4)$: \(\frac{Y}{X} = \frac{L_2}{W} = 0.5\), \(\frac{Z}{X} = \frac{L_3 + L_4}{W} = 1.5\), \(F_{2(3,4)} = 0.31\)

Using the relation above, find
\[
F_{14} = \frac{1}{(WL_1)}\left[ (WL_1 + WL_2)0.22 + (WL_2)0.28 - (WL_1 + WL_2)0.20 - (WL_2)0.31 \right]\]

\[
F_{14} = [2(0.22) + 1(0.28) - 2(0.20) - 1(0.31)] = 0.01. \tag{2}
\]
PROBLEM 13.11

KNOWN: Arrangements of rectangles.

FIND: The shape factors, \( F_{12} \).

SCHEMATIC:

ASSUMPTIONS: (1) Diffuse surface behavior.

ANALYSIS: (a) Define the hypothetical surfaces shown in the sketch as \( A_3 \) and \( A_4 \). From the additive view factor rule, Eq. 13.6, we can write

\[
A_{(1,3)} F_{(1,3)}(2,4) = A_1 F_{12} + A_1 F_{14} + A_3 F_{32} + A_3 F_{34}
\]

Note carefully which factors can be evaluated from Fig. 13.6 for perpendicular rectangles with a common edge. (See \( \sqrt{\cdot} \)). It follows from symmetry that

\[
A_1 F_{12} = A_4 F_{43}.
\]

Using reciprocity,

\[
A_4 F_{43} = A_3 F_{34}, \quad \text{then} \quad A_1 F_{12} = A_3 F_{34}.
\]

Solving Eq. (1) for \( F_{12} \) and substituting Eq. (3) for \( A_3 F_{34} \), find that

\[
F_{12} = \frac{1}{2A_1} \left[ A_{(1,3)} F_{(1,3)}(2,4) - A_1 F_{14} - A_3 F_{32} \right].
\]

Evaluate the view factors from Fig. 13.6:

<table>
<thead>
<tr>
<th>( F_{ij} )</th>
<th>Y/X</th>
<th>Z/X</th>
<th>( F_{ij} )</th>
</tr>
</thead>
<tbody>
<tr>
<td>(1,3) (2,4)</td>
<td>( \frac{6}{9} = 0.67 )</td>
<td>( \frac{6}{9} = 0.67 )</td>
<td>0.23</td>
</tr>
<tr>
<td>14</td>
<td>( \frac{6}{6} = 1 )</td>
<td>( \frac{6}{6} = 1 )</td>
<td>0.20</td>
</tr>
<tr>
<td>32</td>
<td>( \frac{6}{3} = 2 )</td>
<td>( \frac{6}{3} = 2 )</td>
<td>0.14</td>
</tr>
</tbody>
</table>

Substituting numerical values into Eq. (4) yields

\[
F_{12} = \frac{1}{2 \times (6 \times 6) m^2} \left[ (6 \times 9) m^2 \times 0.23 - (6 \times 6) m^2 \times 0.20 - (6 \times 3) m^2 \times 0.14 \right]
\]

\[
F_{12} = 0.038.
\]

Continued …..
PROBLEM 13.11 (Cont.)

(b) Define the hypothetical surface $A_3$ and divide $A_2$ into two sections, $A_{2A}$ and $A_{2B}$. From the additive view factor rule, Eq. 13.6, we can write

$$A_{1,3} F_{(1,3)2} = A_{1} F_{12} + A_{3} F_{3(2A)} + A_{3} F_{3(2B)}. \quad (5)$$

Note that the view factors checked can be evaluated from Fig. 13.4 for aligned, parallel rectangles. To evaluate $F_{3(2A)}$, we first recognize a relationship involving $F_{(2A)1}$ will eventually be required. Using the additive rule again,

$$A_{2A} F_{(2A)(1,3)} = A_{2A} F_{(2A)1} + A_{2A} F_{(2A)3}. \quad (6)$$

Note that from symmetry considerations,

$$A_{2A} F_{(2A)(1,3)} = A_{1} F_{12} \quad (7)$$

and using reciprocity, Eq. 13.3, note that

$$A_{2A} F_{2A3} = A_{3} F_{3(2A)} \quad (8)$$

Substituting for $A_{3} F_{3(2A)}$ from Eq. (8), Eq. (5) becomes

$$A_{(1,3)} F_{(1,3)2} = A_{1} F_{12} + A_{2A} F_{(2A)3} + A_{3} F_{3(2B)}. \quad (9)$$

Substituting for $A_{2A} F_{(2A)3}$ from Eq. (6) using also Eq. (7) for $A_{2A} F_{(2A)(1,3)}$ find that

$$A_{(1,3)} F_{(1,3)2} = A_{1} F_{12} + \left( A_{1} F_{12} - A_{2A} F_{(2A)1} \right) + A_{3} F_{3(2B)} \quad (9)$$

and solving for $F_{12}$, noting that $A_1 = A_{2A}$ and $A_{(1,3)} = A_2$

$$F_{12} = \left[ \frac{1}{2A_1} \right] \left( A_{2A} F_{(1,3)2} + A_{2A} F_{(2A)1} - A_{3} F_{3(2B)} \right). \quad (10)$$

Evaluate the view factors from Fig. 13.4:

<table>
<thead>
<tr>
<th>$F_{ij}$</th>
<th>$X/L$</th>
<th>$Y/L$</th>
<th>$F_{ij}$</th>
</tr>
</thead>
<tbody>
<tr>
<td>(1,3) 2</td>
<td>1/2 = 1</td>
<td>1/2 = 1.5</td>
<td>0.25</td>
</tr>
<tr>
<td>(2A)1</td>
<td>1/2 = 1</td>
<td>1/2 = 0.5</td>
<td>0.11</td>
</tr>
<tr>
<td>3(2B)</td>
<td>1/2 = 1</td>
<td>1/2 = 1</td>
<td>0.20</td>
</tr>
</tbody>
</table>

Substituting numerical values into Eq. (10) yields

$$F_{12} = \frac{1}{2(0.5 \times 1)m^2} \left[ (1.5 \times 1.0) m^2 \times 0.25 + (0.5 \times 1) m^2 \times 0.11 - (1 \times 1) m^2 \times 0.20 \right]$$

$$F_{12} = 0.23. \quad <$$
PROBLEM 13.12

KNOWN: Two geometrical arrangements: (a) parallel plates and (b) perpendicular plates with a common edge.

FIND: View factors using “crossed-strings” method; compare with appropriate graphs and analytical expressions.

SCHEMATIC:

(a) Parallel plates

(b) Perpendicular plates with common edge

ASSUMPTIONS: Plates infinite extent in direction normal to page.

ANALYSIS: The “crossed-strings” method is applicable to surfaces of infinite extent in one direction having an obstructed view of one another.

\[ F_{12} = \left( \frac{1}{2} w_1 \right) \left[ (ac + bd) - (ad + bc) \right]. \]

(a) Parallel plates: From the schematic, the edge and diagonal distances are

\[ ac = bd = \left( w_1^2 + L^2 \right)^{1/2}, \quad bc = ad = L. \]

With \( w_1 \) as the width of the plate, find

\[ F_{12} = \frac{1}{2w_1} \left[ 2 \left( \frac{w_1^2 + L^2}{2} \right)^{1/2} - 2L \right] = \frac{1}{2 \times 4} \left[ 2 \left( \frac{4^2 + 1^2}{2} \right)^{1/2} - 2 \times 1 \right] = 0.781. \]

Using Fig. 13.4 with \( X/L = 4/1 = 4 \) and \( Y/L = \infty \), find \( F_{12} \approx 0.80 \). Also, using the first relation of Table 13.1,

\[ F_{ij} = \left[ \left( W_i + W_j \right)^2 + 4 \right]^{1/2} - \left[ \left( W_i - W_j \right)^2 + 4 \right]^{1/2} \]

where \( w_i = w_j = w_1 \) and \( W = w/L = 4/1 = 4 \), find

\[ F_{12} = \left[ \left( 4 + 4 \right)^2 + 4 \right]^{1/2} - \left[ \left( 4 - 4 \right)^2 + 4 \right]^{1/2} \]

\[ = 0.781. \]

(b) Perpendicular plates with a common edge: From the schematic, the edge and diagonal distances are

\[ ac = w_1, \quad bd = L, \quad ad = \left( w_1^2 + L^2 \right), \quad bc = 0. \]

With \( w_1 \) as the width of the horizontal plates, find

\[ F_{12} = \left( \frac{1}{2w_1} \right) \left[ 2 \left( \frac{w_1^2 + L^2}{2} \right)^{1/2} - \left( \frac{w_1^2 + L^2}{2} \right)^{1/2} + 0 \right] \]

\[ = \frac{1}{2 \times 4} \left[ 2 \left( \frac{4^2 + 1^2}{2} \right)^{1/2} - \left( \frac{4^2 + 1^2}{2} \right)^{1/2} + 0 \right] = 0.110. \]

From the third relation of Table 13.1, with \( w_i = w_1 = 4 \) m and \( w_j = L = 1 \) m, find

\[ F_{ij} = \left[ 1 + \left( \frac{w_j}{w_i} \right) \right] - \left[ 1 + \left( \frac{w_j}{w_i} \right)^2 \right]^{1/2} / 2 \]

\[ F_{12} = \left[ 1 + \left( \frac{1}{4} \right) \right] - \left[ 1 + \left( \frac{1}{4} \right)^2 \right]^{1/2} / 2 = 0.110. \]
PROBLEM 13.13

KNOWN:  Parallel plates of infinite extent (1,2) having aligned opposite edges.

FIND:  View factor \( F_{12} \) by using (a) appropriate view factor relations and results for opposing parallel plates and (b) Hottel’s string method described in Problem 13.12

SCHEMATIC:

ASSUMPTIONS:  (1) Parallel planes of infinite extent normal to page and (2) Diffuse surfaces with uniform radiosity.

ANALYSIS:  From symmetry consideration \((F_{12} = F_{14})\) and Eq. 13.5, it follows that
\[
F_{12} = \left(\frac{1}{2}\right) \left[ F_{13} - F_{14} \right]
\]
where \(A_3\) and \(A_4\) have been defined for convenience in the analysis. Each of these view factors can be evaluated by the first relation of Table 13.1 for parallel plates with midlines connected perpendicularly.

\[
F_{13} : \quad W_1 = \frac{w_1}{L} = 2 \quad W_2 = \frac{w_2}{L} = 2
\]

\[
F_{13} = \frac{\left(\frac{w_1 + w_2}{2}\right)^2 + 4}{2w_1} = \frac{\left(\frac{w_2 - w_1}{2}\right)^2 + 4}{2w_1} = \frac{(2 + 2)^2 + 4}{2 \times 2} = \frac{(2 - 2)^2 + 4}{2 \times 2} = 0.618
\]

\[
F_{1(2,3,4)} : \quad W_1 = \frac{w_1}{L} = 2 \quad W_{(2,3,4)} = \frac{3w_2}{L} = 6
\]

\[
F_{1(2,3,4)} = \frac{(2 + 6)^2 + 4}{2 \times 2} - \frac{(6 - 2)^2 + 4}{2 \times 2} = 0.944.
\]

Hence, find 
\[
F_{12} = \left(\frac{1}{2}\right) \left[ 0.944 - 0.618 \right] = 0.163.
\]

(b) Using Hottel’s string method,
\[
F_{12} = \left(\frac{1}{2}w_1\right) \left[ (ac + bd) - (ad + bc) \right]
\]

\[
a = \left(1 + 4^2\right)^{1/2} = 4.123
\]

\[
b = 1
\]

\[
ad = \left(1^2 + 2^2\right)^{1/2} = 2.236
\]

\[
bc = ad = 2.236
\]

and substituting numerical values find
\[
F_{12} = \left(\frac{1}{2} \times 2\right) \left[ (4.123+1) - (2.236 + 2.236) \right] = 0.163.
\]

COMMENTS:  Remember that Hottel’s string method is applicable only to surfaces that are of infinite extent in one direction and have unobstructed views of one another.
**PROBLEM 13.14**

**KNOWN:** Two small diffuse surfaces, \(A_1\) and \(A_2\), on the inside of a spherical enclosure of radius \(R\).

**FIND:** Expression for the view factor \(F_{12}\) in terms of \(A_2\) and \(R\) by two methods: (a) Beginning with the expression \(F_{ij} = q_{ij} / A_i J_i\) and (b) Using the view factor integral, Eq. 13.1.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Surfaces \(A_1\) and \(A_2\) are diffuse and (2) \(A_1\) and \(A_2 \ll R^2\).

**ANALYSIS:** (a) The view factor is defined as the fraction of radiation leaving \(A_i\) which is intercepted by surface \(j\) and, from Section 13.1.1, can be expressed as

\[
F_{ij} = \frac{q_{ij}}{A_i J_i} \quad (1)
\]

From Eq. 12.5, the radiation leaving intercepted by \(A_1\) and \(A_2\) on the spherical surface is

\[
q_{1\rightarrow 2} = \left(J_1 / \pi\right) A_1 \cos \theta_1 \cdot \omega_{2-1} \quad (2)
\]

where the solid angle \(\omega_{2-1}\) subtends with respect to \(A_1\) is

\[
\omega_{2-1} = \frac{A_{2,n}}{r^2} = \frac{A_2 \cos \theta_2}{r^2} \quad (3)
\]

From the schematic above,

\[
\cos \theta_1 = \cos \theta_2 \quad r = 2R \cos \theta_1 \quad (4,5)
\]

Hence, the view factor is

\[
F_{ij} = \frac{\left(J_1 / \pi\right) A_1 \cos \theta_1 \cdot A_2 \cos \theta_2 / 4R^2 \cos \theta_1}{A_i J_i} = \frac{A_2}{4\pi R^2} \quad <
\]

(b) The view factor integral, Eq. 13.1, for the small areas \(A_1\) and \(A_2\) is

\[
F_{12} = \frac{1}{A_1} \int_{A_1} \int_{A_2} \frac{\cos \theta_1 \cos \theta_2}{\pi r^2} dA_1 dA_2 = \frac{\cos \theta_1 \cos \theta_2 A_2}{\pi r^2}
\]

and from Eqs. (4,5) above,

\[
F_{12} = \frac{A_2}{\pi R^2} \quad <
\]

**COMMENTS:** Recognize the importance of the second assumption. We require that \(A_1, A_2 \ll R^2\) so that the areas can be considered as of differential extent, \(A_1 = dA_1\), and \(A_2 = dA_2\).
PROBLEM 13.15

KNOWN: Disk $A_1$, located coaxially, but tilted $30^\circ$ of the normal, from the diffuse-gray, ring-shaped disk $A_2$. Surroundings at 400 K.

FIND: Irradiation on $A_1$, $G_1$, due to the radiation from $A_2$.

SCHEMATIC:

ASSUMPTIONS: (1) $A_2$ is diffuse-gray surface, (2) Uniform radiosity over $A_2$, (3) The surroundings are large with respect to $A_1$ and $A_2$.

ANALYSIS: The irradiation on $A_1$ is

$$G_1 = \frac{q_{21}}{A_1} = \left( F_{21} \cdot J_2 A_2 \right) / A_1$$  \hspace{1cm} (1)

where $J_2$ is the radiosity from $A_2$ evaluated as

$$J_2 = \varepsilon_2 E_{b,2} + \rho_2 G_2 = \varepsilon_2 T_2^4 + (1-\varepsilon_2) T_{\text{sur}}^4$$

$$J_2 = 0.7 \times 5.67 \times 10^{-8} \text{W/m}^2 \cdot \text{K}^4 (600 \text{ K})^4 + (1 - 0.7) 5.67 \times 10^{-8} \text{W/m}^2 \cdot \text{K}^4 (400 \text{ K})^4$$

$$J_2 = 5144 + 436 = 5580 \text{ W/m}^2.$$  \hspace{1cm} (2)

Using the view factor relation of Eq. 13.8, evaluate view factors between $A_1'$, the normal projection of $A_1$, and $A_3$ as

$$F_{13} = \frac{D_1^2}{D_1^2 + 4L^2} = \frac{(0.004 \text{ m})^2}{(0.004 \text{ m})^2 + 4(1 \text{ m})^2} = 4.00 \times 10^{-6}$$

and between $A_1'$ and $(A_2 + A_3)$ as

$$F_{1(23)} = \frac{D_2^2}{D_2^2 + 4L^2} = \frac{(0.012 \text{ m})^2}{(0.012 \text{ m})^2 + 4(1 \text{ m})^2} = 3.60 \times 10^{-5}$$

giving

$$F_{12} = F_{1(23)} - F_{13} = 3.60 \times 10^{-5} - 4.00 \times 10^{-6} = 3.20 \times 10^{-5}.$$  \hspace{1cm} (3)

From the reciprocity relation it follows that

$$F_{21} = A_1' F_{12} / A_2 = (A_1 \cos \theta_1 / A_2) F_{12} = 3.20 \times 10^{-5} \cos \theta_1 (A_1 / A_2).$$ \hspace{1cm} (4)

By inspection we note that all the radiation striking $A_1'$ will also intercept $A_1$; that is

$$F_{21} = F_{21}'.$$

Hence, substituting for Eqs. (3) and (4) for $F_{21}$ into Eq. (1), find

$$G_1 = \left( 3.20 \times 10^{-5} \cos \theta_1 (A_1 / A_2) \right) J_2 A_2 / A_1 = 3.20 \times 10^{-5} \cos \theta_1 \cdot J_2$$  \hspace{1cm} (5)

$$G_1 = 3.20 \times 10^{-5} \cos (30^\circ) \times 5580 \text{ W/m}^2 = 27.7 \mu\text{W/m}^2.$$  \hspace{1cm} <

COMMENTS: (1) Note from Eq. (5) that $G_1 \sim \cos \theta_1$ such that $G_1$ is a maximum when $A_1$ is normal to disk $A_2$. 

PROBLEM 13.16

KNOWN: Heat flux gauge positioned normal to a blackbody furnace. Cover of furnace is at 350 K while surroundings are at 300 K.

FIND: (a) Irradiation on gage, \( G_g \), considering only emission from the furnace aperture and (b) Irradiation considering radiation from the cover and aperture.

ASSUMPTIONS: (1) Furnace aperture approximates blackbody, (2) Shield is opaque, diffuse and gray with uniform temperature, (3) Shield has uniform radiosity, (4) \( A_g << R^2 \), so that \( \omega_{g-f} = A_g/R^2 \), (5) Surroundings are large, uniform at 300 K.

ANALYSIS: (a) The irradiation on the gauge due only to aperture emission is

\[
G_g = q_{f-g} / A_g = \left( I_{c,f} \cdot A_f \cos \theta_{f} \cdot \omega_{g-f} \right) / A_g = \frac{\sigma T_f^4}{\pi} \cdot \frac{A_g}{R^2} \cdot \frac{A_g}{A_g}
\]

\[
G_g = \frac{\sigma T_f^4}{\pi R^2} A_f = \frac{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (1000 \text{ K})^4}{\pi (1 \text{ m})^2} \times \left( \frac{\pi}{4} \left( 0.005 \text{ m} \right)^2 \right) = 354.4 \text{ mW/m}^2.
\]

(b) The irradiation on the gauge due to radiation from the aperture (a) and cover (c) is

\[
G_g = G_{g,a} + \frac{F_{c-g} \cdot J_c A_c}{A_g}
\]

where \( F_{c-g} \) and the cover radiosity are

\[
F_{c-g} = F_{c-c} \left( A_g / A_c \right) \approx \frac{D_c^2}{4R^2 + D_c^2} \cdot \frac{A_g}{A_c}
\]

\[
J_c = \varepsilon_c E_b \left( T_c \right) + \rho_c G_c
\]

but \( G_c = E_b \left( T_{surf} \right) \) and \( \rho_c = 1 - \alpha_c = 1 - \varepsilon_c \), \( J_c = \varepsilon_c \sigma T_c^4 + (1 - \varepsilon_c) \sigma T_{surf}^4 = (170.2 + 387.4) \text{ W/m}^2 \). Hence, the irradiation is

\[
G_g = G_{g,a} + \frac{1}{A_g} \left( \frac{D_c^2}{4R^2 + D_c^2} \cdot \frac{A_g}{A_c} \right) \left[ \varepsilon_c \sigma T_c^4 + (1 - \varepsilon_c) \sigma T_{surf}^4 \right] A_c
\]

\[
G_g = 354.4 \text{ mW/m}^2 + \left( \frac{0.10^2}{4 \times 1^2 + 0.10^2} \right) \left[ 0.2 \times \sigma (350)^4 + (1 - 0.2) \times \sigma (300)^4 \right] \text{ W/m}^2
\]

\[
G_g = 354.4 \text{ mW/m}^2 + 424.4 \text{ mW/m}^2 + 916.2 \text{ mW/m}^2 = 1,695 \text{ mW/m}^2.
\]

COMMENTS: (1) Note we have assumed \( A_f << A_c \) so that effect of the aperture is negligible. (2) In part (b), the irradiation due to radiosity from the shield can be written also as \( G_{g,c} = q_{c-g} / A_g = (J_c / \pi) \cdot A_c / \omega_{g-c} / A_g \) where \( \omega_{g-c} = A_g / R^2 \). This is an excellent approximation since \( A_c << R^2 \).
PROBLEM 13.17

KNOWN: Temperature and diameters of a circular ice rink and a hemispherical dome.

FIND: Net rate of heat transfer to the ice due to radiation exchange with the dome.

SCHEMATIC:

ASSUMPTIONS: (1) Blackbody behavior for dome and ice.

ANALYSIS: From Eq. 13.13 the net rate of energy exchange between the two blackbodies is

\[ q_{21} = A_2 F_{21} \sigma \left( T_2^4 - T_1^4 \right) \]

From reciprocity, \( A_2 F_{21} = A_1 F_{12} = \left( \frac{\pi D_1^2}{4} \right) \)

\[ A_2 F_{21} = \left( \frac{\pi}{4} \right)(25 \text{ m})^2 1 = 491 \text{ m}^2. \]

Hence

\[ q_{21} = 491 \text{ m}^2 \left( 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \right) \left[ (288 \text{ K})^4 - (273 \text{ K})^4 \right] \]

\[ q_{21} = 3.69 \times 10^4 \text{ W}. \]

COMMENTS: If the air temperature, \( T_\infty \), exceeds \( T_1 \), there will also be heat transfer by convection to the ice. The radiation and convection transfer to the ice determine the heat load which must be handled by the cooling system.
PROBLEM 13.18

KNOWN: Surface temperature of a semi-circular drying oven.

FIND: Drying rate per unit length of oven.

SCHEMATIC:

ASSUMPTIONS: (1) Blackbody behavior for furnace wall and water, (2) Convection effects are negligible and bottom is insulated.

PROPERTIES: Table A-6, Water (325 K): \( h_{fg} = 2.378 \times 10^6 \text{ J/kg} \).

ANALYSIS: Applying a surface energy balance,

\[
q_{12} = q_{\text{evap}} = \dot{m} h_{fg}
\]

where it is assumed that the net radiation heat transfer to the water is balanced by the evaporative heat loss. From Eq. 13.13

\[
q_{12} = A_1 F_{12} \sigma \left( T_1^4 - T_2^4 \right).
\]

From inspection and the reciprocity relation, Eq. 13.3,

\[
F_{12} = \frac{A_2}{A_1} F_{21} = \frac{D \cdot L}{(\pi D / 2) \cdot L} \times 1 = 0.637.
\]

Hence

\[
\dot{m} = \frac{\dot{m} \pi D}{2} \frac{T_1^4 - T_2^4}{h_{fg}}
\]

\[
\dot{m} = \frac{\pi (1 \text{ m})}{2} \times 0.637 \times 5.67 \times 10^{-8} \frac{W}{m^2 \cdot K^4} \frac{(1200 \text{ K}) - (325 \text{ K})^4}{2.378 \times 10^6 \text{ J/kg}}
\]

or

\[
\dot{m} = 0.0492 \text{ kg/s} \cdot \text{m}.
\]

COMMENTS: Air flow through the oven is needed to remove the water vapor. The water surface temperature, \( T_2 \), is determined by a balance between radiation heat transfer to the water and the convection of latent and sensible energy from the water.
**PROBLEM 13.19**

**KNOWN:** Arrangement of three black surfaces with prescribed geometries and surface temperatures.

**FIND:** (a) View factor \( F_{13} \), (b) Net radiation heat transfer from \( A_1 \) to \( A_3 \).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Interior surfaces behave as blackbodies, (2) \( A_2 \gg A_1 \).

**ANALYSIS:** (a) Define the enclosure as the interior of the cylindrical form and identify \( A_4 \). Applying the view factor summation rule, Eq. 13.4,

\[
F_{11} + F_{12} + F_{13} + F_{14} = 1. \tag{1}
\]

Note that \( F_{11} = 0 \) and \( F_{14} = 0 \). From Eq. 13.8,

\[
F_{12} = \frac{D^2}{D^2 + 4L^2} = \frac{(3m)^2}{(3m)^2 + 4(2m)^2} = 0.36. \tag{2}
\]

From Eqs. (1) and (2),

\[
F_{13} = 1 - F_{12} = 1 - 0.36 = 0.64. \tag{<}
\]

(b) The net heat transfer rate from \( A_1 \) to \( A_3 \) follows from Eq. 13.13,

\[
q_{13} = A_1 F_{13} \sigma \left( T_1^4 - T_3^4 \right) \]

\[
q_{13} = 0.05m^2 \times 0.64 \times 5.67 \times 10^{-8} W/m^2 \cdot K^4 \left( 1000^4 - 500^4 \right) K^4 = 1700 W. \tag{<}
\]

**COMMENTS:** Note that the summation rule, Eq. 13.4, applies to an enclosure; that is, the total region above the surface must be considered.
PROBLEM 13.20

KNOWN: Furnace diameter and temperature. Dimensions and temperature of suspended part.

FIND: Net rate of radiation transfer per unit length to the part.

SCHEMATIC:

ASSUMPTIONS: (1) All surfaces may be approximated as blackbodies.

ANALYSIS: From symmetry considerations, it is convenient to treat the system as a three-surface enclosure consisting of the inner surfaces of the vee (1), the outer surfaces of the vee (2) and the furnace wall (3). The net rate of radiation heat transfer to the part is then

\[ q_{1,2} = A_3 F_{31} \sigma \left( T_w^4 - T_p^4 \right) + A_3 F_{32} \sigma \left( T_w^4 - T_p^4 \right) \]

From reciprocity,

\[ A_3 F_{31} = A_1 F_{13} = 2L \times 0.5 = 1m \]

where surface 3 may be represented by the dashed line and, from symmetry, \( F_{13} = 0.5 \). Also,

\[ A_3 F_{32} = A_2 F_{23} = 2L \times 1 = 2m \]

Hence,

\[ q_{1,2} = (1 + 2) \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left( 1000^4 - 300^4 \right) \text{K}^4 = 1.69 \times 10^5 \text{ W/m} \]

COMMENTS: With all surfaces approximated as blackbodies, the result is independent of the tube diameter. Note that \( F_{11} = 0.5 \).
PROBLEM 13.21

KNOWN: Coaxial, parallel black plates with surroundings. Lower plate (A_2) maintained at prescribed temperature T_2 while electrical power is supplied to upper plate (A_1).

FIND: Temperature of the upper plate T_1.

SCHEMATIC:

ASSUMPTIONS: (1) Plates are black surfaces of uniform temperature, and (2) Backside of heater on A_1 insulated.

ANALYSIS: The net radiation heat rate leaving A_1 is

\[
P_e = \sum_{j=1}^{N} q_{ij} = A_1 f_{12} \sigma \left( T_1^4 - T_2^4 \right) + A_1 f_{13} \sigma \left( T_1^4 - T_3^4 \right)
\]

\[
P_e = A_1 \sigma \left[ f_{12} \left( T_1^4 - T_2^4 \right) + f_{13} \left( T_1^4 - T_3^4 \right) \right]
\]  \(\text{(1)}\)

From Fig. 13.5 for coaxial disks (see Table 13.2),

\[
R_1 = \eta / L = 0.10 \, \text{m} / 0.20 \, \text{m} = 0.5 \quad R_2 = r_2 / L = 0.20 \, \text{m} / 0.20 \, \text{m} = 1.0
\]

\[
S = 1 + \frac{1 + R_2^2}{R_1^2} = 1 + \frac{1 + 1^2}{(0.5)^2} = 9.0
\]

\[
f_{12} = \frac{1}{2} \left\{ S - \left[ S^2 - 4 \left( r_2 / \eta \right)^2 \right]^{1/2} \right\} = \frac{1}{2} \left\{ 9 - \left[ 9^2 - 4 \left( 0.2 / 0.1 \right)^2 \right]^{1/2} \right\} = 0.469.
\]

From the summation rule for the enclosure A_1, A_2 and A_3 where the last area represents the surroundings with T_3 = T_{sur},

\[
f_{12} + f_{13} = 1 \quad f_{13} = 1 - f_{12} = 1 - 0.469 = 0.531.
\]

Substituting numerical values into Eq. (1), with \( A_1 = \pi D_1^2 / 4 = 3.142 \times 10^{-2} \, \text{m}^2 \),

\[
17.5 \, \text{W} = 3.142 \times 10^{-2} \, \text{m}^2 \times 5.67 \times 10^{-8} \, \text{W} / \text{m}^2 \cdot \text{K}^4 \left[ 0.469 \left( T_1^4 - 500^4 \right) \text{K}^4 + 0.531 \left( T_1^4 - 300^4 \right) \text{K}^4 \right]
\]

\[
9.823 \times 10^9 = 0.469 \left( T_1^4 - 500^4 \right) + 0.531 \left( T_1^4 - 300^4 \right)
\]

find by trial-and-error that \( T_1 = 456 \, \text{K}. \)

COMMENTS: Note that if the upper plate were adiabatic, T_1 = 427 K.
PROBLEM 13.22

KNOWN: Tubular heater radiates like blackbody at 1000 K.

FIND: (a) Radiant power from the heater surface, $A_2$, intercepted by a disc, $A_1$, at a prescribed location $q_{2\rightarrow 1}$; irradiation on the disk, $G_1$; and (b) Compute and plot $q_{2\rightarrow 1}$ and $G_1$ as a function of the separation distance $L_1$ for the range $0 \leq L_1 \leq 200$ mm for disk diameters $D_1 = 25,$ and 50 and 100 mm.

SCHEMATIC:

ASSUMPTIONS: (1) Heater surface behaves as blackbody with uniform temperature.

ANALYSIS: (a) The radiant power leaving the inner surface of the tubular heater that is intercepted by the disk is

$$q_{2\rightarrow 1} = (A_2 E_{b2}) F_{21}$$

(1)

where the heater is surface 2 and the disk is surface 1. It follows from the reciprocity rule, Eq. 13.3, that

$$F_{21} = \frac{A_1}{A_2} F_{12}$$

(2)

Define now the hypothetical disks, $A_3$ and $A_4$, located at the ends of the tubular heater. By inspection, it follows that

$$F_{14} = F_{12} + F_{13}$$

or

$$F_{12} = F_{14} - F_{13}$$

(3)

where $F_{14}$ and $F_{13}$ may be determined from Fig. 13.5. Substituting numerical values, with $D_3 = D_4 = D_2$,

$$F_{13} = 0.08 \quad \text{with} \quad \frac{L}{r_1} = \frac{L_1 + L_2}{D_1/2} = \frac{200}{50/2} = 8 \quad \frac{r_1}{L} = \frac{D_3/2}{L_1 + L_2} = \frac{100/2}{200} = 0.25$$

$$F_{14} = 0.20 \quad \text{with} \quad \frac{L}{r_1} = \frac{L_1}{D_1/2} = \frac{100}{50/2} = 4 \quad \frac{r_1}{L} = \frac{D_4/2}{L_1} = \frac{100/2}{100} = 0.5$$

Substituting Eq. (3) into Eq. (2) and then into Eq. (1), the result is

$$q_{2\rightarrow 1} = A_1 (F_{14} - F_{13}) E_{b2}$$

$$q_{2\rightarrow 1} = \left[ \pi \left(50 \times 10^{-3}\right)^2 \cdot 4 \right] \left(0.20 - 0.08\right) \times 5.67 \times 10^{-8} \ W/m^2 \cdot K^4 \left(1000 \ K\right)^4 = 13.4 W$$

where $E_{b2} = \sigma T_s^4$. The irradiation $G_1$ originating from emission leaving the heater surface is

$$G_1 = \frac{q_{2\rightarrow 1}}{A_1} = \frac{13.4 \ W}{\pi \left(0.050 \ m\right)^2 / 4} = 6825 \ W/m^2.$$  

Continued …..
PROBLEM 13.22 (Cont.)

(b) Using the foregoing equations in *IHT* along with the *Radiation Tool-View Factors for Coaxial Parallel Disks*, $G_1$ and $q_{s \rightarrow 1}$ were computed as a function of $L_1$ for selected values of $D_1$. The results are plotted below.

In the upper left-hand plot, $G_1$ decreases with increasing separation distance. For a given separation distance, the irradiation decreases with increasing diameter. With values of $D_1 = 25$ and $50$ mm, the irradiation values are only slightly different, which diminishes as $L_1$ increases. In the upper right-hand plot, the radiant power from the heater surface reaching the disk, $q_{s \rightarrow 2}$, decreases with increasing $L_1$ and decreasing $D_1$. Note that while $G_1$ is nearly the same for $D_1 = 25$ and $50$ mm, their respective $q_{s \rightarrow 2}$ values are quite different. Why is this so?
PROBLEM 13.23

KNOWN: Dimensions and temperatures of an enclosure and a circular disc at its base.

FIND: Net radiation heat transfer between the disc and portions of the enclosure.

SCHEMATIC:

ASSUMPTIONS: (1) Blackbody behavior for disc and enclosure surfaces, (2) Area of disc is much less than that of the hypothetical surfaces, \((A_1/A_2) \ll 1\) and \((A_1/A_3) \ll 1\).

ANALYSIS: From Eq. 13.13 the net radiation exchange between the disc (1) and the hemispherical dome (d) is

\[ q_{ld} = A_1 F_{ld} \sigma (T_1^4 - T^4). \]

However, since all of the radiation intercepted by the dome must pass through the hypothetical area \(A_2\), it follows from Eq. 13.8 of Example 13.1,

\[ F_{ld} = F_{12} = \frac{D^2}{4L^2 + D^2} = \frac{1}{(2L/D)^2 + 1} = \frac{1}{1.44 + 1} = 0.410. \]

Hence

\[ q_{ld} = \frac{\pi}{4} (0.02 \text{ m})^2 \times 0.41 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K} \left[ (1000 \text{ K})^4 - (300 \text{ K})^4 \right] \]

\[ q_{ld} = 7.24 \text{ W}. \]

Similarly, the net radiation exchange between the disc (1) and the cylindrical ring (r) of length \(L/3\) is

\[ q_{lr} = A_1 F_{lr} \sigma (T_1^4 - T^4) \]

where

\[ F_{lr} = F_{13} - F_{12} = \frac{D^2}{4(2L/3)^2 + D^2} - 0.41 = 0.61 - 0.41 = 0.20. \]

Hence

\[ q_{lr} = \frac{\pi}{4} (0.02 \text{ m})^2 \times 0.2 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K} \left[ (1000 \text{ K})^4 - (300 \text{ K})^4 \right] \]

\[ q_{lr} = 3.53 \text{ W}. \]
**PROBLEM 13.24**

**KNOWN:** Circular plate ($A_1$) maintained at 600 K positioned coaxially with a conical shape ($A_2$) whose backside is insulated. Plate and cone are black surfaces and located in large, insulated enclosure at 300 K.

**FIND:** (a) Temperature of the conical surface $T_2$ and (b) Electric power required to maintain plate at 600 K.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Plate and cone are black, (3) Cone behaves as insulated, reradiating surface, (4) Surroundings are large compared to plate and cone.

**ANALYSIS:** (a) Recognizing that the plate, cone, and surroundings from a three-(black) surface enclosure, perform a radiation balance on the cone.

$$q_2 = 0 = q_{23} + q_{21} = A_2 F_{23} \sigma \left( T_2^4 - T_3^4 \right) + A_2 F_{21} \sigma \left( T_2^4 - T_1^4 \right)$$

where the view factor $F_{21}$ can be determined from the coaxial parallel disks relation (Table 13.2 or Fig. 13.5) with $R_i = r_i/L = 250/500 = 0.5$, $R_j = 0.5$, $S = 1 + \left(1 + R_j^2\right)/R_i^2 = 1 + (1 + 0.5^2)/0.5^2 = 6.00$, and noting $F_{21}' = F_{21}$.

$$F_{21} = 0.5 \left\{ S - \left[ S^2 - 4 \left( R_i/ R_j \right)^2 \right]^{1/2} \right\} = 0.5 \left\{ 6 - \left[ 6^2 - 4 \left( 0.5/0.5 \right)^2 \right]^{1/2} \right\} = 0.172.$$

For the enclosure, the summation rule provides, $F_{23}' = 1 - F_{21}' = 1 - 0.172 = 0.828$. Hence,

$$0.828 \left( T_2^4 - 300^4 \right) = 0 + 0.172 \left( T_2^4 - 600^4 \right)$$

$$T_2 = 413 \text{ K.}$$

(b) The power required to maintain the plate at $T_2$ follows from a radiation balance,

$$q_1 = q_{12} + q_{13} = A_1 F_{12} \sigma \left( T_1^4 - T_2^4 \right) + A_1 F_{13} \sigma \left( T_1^4 - T_3^4 \right)$$

where $F_{12} = A_2 F_{21}' / A_1 = 0.172$ and $F_{13} = 1 - F_{12} = 0.828$,

$$q_1 = \left( \pi 0.5^2 / 4 \right) m^2 \sigma \left[ 0.172 \left( 600^4 - 413^4 \right) K^4 + 0.828 \left( 600^4 - 300^4 \right) K^4 \right]$$

$$q_1 = 1312 \text{ W.}$$
PROBLEM 13.25

KNOWN: Conical and cylindrical furnaces \((A_2)\) as illustrated and dimensioned in Problem 13.2 (S) supplied with power of 50 W. Workpiece \((A_1)\) with insulated backside located in large room at 300 K.

FIND: Temperature of the workpiece, \(T_1\), and the temperature of the inner surfaces of the furnaces, \(T_2\). Use expressions for the view factors \(F_{21}\) and \(F_{22}\) given in the statement for Problem 13.2 (S).

SCHEMATIC:

ASSUMPTIONS: (1) Diffuse, black surfaces with uniform radiosities, (2) Backside of workpiece is perfectly insulated, (3) Inner base and lateral surfaces of the cylindrical furnace treated as single surface, (4) Negligible convection heat transfer, (5) Room behaves as large, isothermal surroundings.

ANALYSIS: Considering the furnace surface \((A_2)\), the workpiece \((A_1)\) and the surroundings \((A_s)\) as an enclosure, the net radiation transfer from \(A_1\) and \(A_2\) follows from Eq. 13.14,

\[
\begin{align*}
\text{Workpiece} & \quad q_{A_1} = 0 = A_1 F_{12} (E_b - E_b) + A_1 F_{1s} (E_b - E_{bs}) \\
\text{Furnace} & \quad q_{A_2} = 50 W = A_2 F_{21} (E_b - E_{b1}) + A_2 F_{2s} (E_b - E_{bs})
\end{align*}
\]

where \(E_b = \sigma T^4\) and \(\sigma = 5.67 \times 10^{-8} \text{ W/m}^2\cdot\text{K}^4\). From summation rules on \(A_1\) and \(A_2\), the view factors \(F_{1s}\) and \(F_{2s}\) can be evaluated. Using reciprocity, \(F_{12}\) can be evaluated.

\[
F_{1s} = 1 - F_{12} \quad F_{2s} = 1 - F_{21} - F_{22} \quad F_{12} = (A_2 / A_1) F_{21}
\]

The expressions for \(F_{21}\) and \(F_{22}\) are provided in the schematic. With \(A_1 = \pi D_1^2 / 4\) the \(A_2\) are:

\[
\begin{align*}
\text{Cone:} & \quad A_2 = \pi D_3 / 2 \left( L^2 + (D_3/2)^2 \right)^{1/2} \\
\text{Cylinder:} & \quad A_2 = \pi D_3^2 / 4 + \pi D_3 L
\end{align*}
\]

Examine Eqs (1) and (2) and recognize that there are two unknowns, \(T_1\) and \(T_2\), and the equations must be solved simultaneously. Using the foregoing equations in the IHT workspace, the results are

\[
T_1 = 544 \text{ K} \quad T_2 = 828 \text{ K}
\]

COMMENTS: (1) From the IHT analysis, the relevant view factors are: \(F_{12} = 0.1716; F_{1s} = 0.8284; F_{21} = 0.07673, F_{22} = 0.5528; F_{21} = 0.03431, F_{22} = 0.80\).

(2) That both furnace configurations provided identical results may not, at first, be intuitively obvious. Since both furnaces \((A_2)\) are black, they can be represented by the hypothetical black area \(A_3\) (the opening of the furnaces). As such, the analysis is for an enclosure with the workpiece \((A_1)\), the furnace represented by the disk \(A_3\) (at \(T_2\)), and the surroundings. As an exercise, perform this analysis to confirm the above results.
PROBLEM 13.26

KNOWN: Furnace constructed in three sections: insulated circular (2) and cylindrical (3) sections, as well as, an intermediate cylindrical section (1) with imbedded electrical resistance heaters. Cylindrical sections (1,3) are of equal length.

FIND: (a) Electrical power required to maintain the heated section at \( T_1 = 1000 \) K if all the surfaces are black, (b) Temperatures of the insulated sections, \( T_2 \) and \( T_3 \), and (c) Compute and plot \( q_1, T_2 \) and \( T_3 \) as functions of the length-to-diameter ratio, with \( 1 \leq L/D \leq 5 \) and \( D = 100 \) mm.

SCHEMATIC:

ASSUMPTIONS: (1) All surfaces are black, (2) Areas (1, 2, 3) are isothermal.

ANALYSIS: (a) To complete the enclosure representing the furnace, define the hypothetical surface \( A_4 \) as the opening at \( 0 \) K with unity emissivity. For each of the enclosure surfaces 1, 2, and 3, the energy balances following Eq. 13.13 are

\[
\begin{align*}
q_1 &= A_1 F_{12} (E_{b1} - E_{b2}) + A_1 F_{13} (E_{b1} - E_{b3}) + A_1 F_{14} (E_{b1} - E_{b4}) \\
0 &= A_2 F_{21} (E_{b2} - E_{b1}) + A_2 F_{23} (E_{b2} - E_{b3}) + A_2 F_{24} (E_{b2} - E_{b4}) \\
0 &= A_3 F_{31} (E_{b3} - E_{b1}) + A_3 F_{32} (E_{b3} - E_{b2}) + A_3 F_{34} (E_{b3} - E_{b4})
\end{align*}
\]

where the emissive powers are

\[
E_{b1} = \sigma T_1^4 \quad E_{b2} = \sigma T_2^4 \quad E_{b3} = \sigma T_3^4 \quad E_{b4} = 0
\]

For this four surface enclosure, there are \( N^2 = 16 \) view factors and \( N (N - 1)/2 = 4 \times 3/2 = 6 \) must be directly determined (by inspection or formulas) and the remainder can be evaluated from the summation rule and reciprocity relation. By inspection,

\[
F_{22} = 0 \quad F_{44} = 0
\]

From the coaxial parallel disk relation, Table 13.2, find \( F_{24} \)

\[
S = 1 + \frac{1 + R_4^2}{R_2^2} = 1 + \frac{1 + (0.250)^2}{(0.250)^2} = 18.00
\]

\[
R_2 = r_2 / L = 0.050 \text{ m} / 0.200 \text{ m} = 0.250 \quad R_4 = r_4 / L = 0.250
\]

\[
F_{24} = 0.5 \left\{ S - S^2 - 4 \left( \frac{r_4}{r_2} \right)^2 \right\}^{-1/2} = 0.0557
\]

Consider the three-surface enclosure \( 1 - 2 - 2' \) and find \( F_{11} \) as beginning with the summation rule,

Continued .....
PROBLEM 13.26 (Cont.)

\[ F_{11} = 1 - F_{12} - F_{12}' \]  \hspace{1cm} (11)

where, from symmetry, \( F_{12} = F_{12}' \), and using reciprocity,

\[ F_{12} = A_2 F_{21} / A_1 = \left( \pi D^2 / 4 \right) F_{23} / \left( \pi DL / 2 \right) = DF_{21} / 2L \]  \hspace{1cm} (12)

and from the summation rule on \( A_2 \)

\[ F_{21} = 1 - F_{22}' = 1 - 0.172 = 0.828 \]  \hspace{1cm} (13)

Using the coaxial parallel disk relation, Table 13.2, to find \( F_{221} \),

\[ S = 1 + \frac{1 + R_2^2}{R_2^2} = 1 + \frac{1 + 0.50^2}{0.50^2} = 6.000 \]

\[ R_2 = r_2 / L = 0.050 \text{ m} / (0.200 / 2 \text{ m}) = 0.500 \quad \text{R}_2' = 0.500 \]

\[ F_{22'} = 0.5 \left\{ S - \left[ S^2 - 4 \left( r_2' / r_2 \right)^2 \right]^{1/2} \right\} \]

\[ F_{22'} = 0.5 \left\{ 6 - \left[ 6^2 - 4 \left( 1 \right)^2 \right]^{1/2} \right\} = 0.1716 \]

Evaluating \( F_{12} \) from Eq. (12), find

\[ F_{12} = 0.100 \text{ m} \times 0.828 / 2 \times 0.200 \text{ m} = 0.2071 \]

and evaluating \( F_{11} \) from Eq. (11), find

\[ F_{11} = 1 - 2 \times F_{12} = 1 - 2 \times 0.207 = 0.586 \]

From symmetry, recognize that \( F_{33} = F_{11} \) and \( F_{43} = F_{21} \). To this point we have directly determined six view factors (underlined in the matrix below) and the remaining \( F_{ij} \) can be evaluated from the summation rules and appropriate reciprocity relations. The view factors written in matrix form, \([F_{ij}]\) are.

\[
\begin{bmatrix}
0.5858 & 0.2071 & 0.1781 & 0.02896 \\
0.8284 & 0 & 0.1158 & 0.05573 \\
0.1781 & 0 & 0.5858 & 0.2071 \\
0.1158 & 0.02896 & 0.8284 & 0
\end{bmatrix}
\]

Knowing all the required view factors, the energy balances and the emissive powers, Eqs. (4-6), can be solved simultaneously to obtain:

\[ q_1 = 255 \text{ W} \quad E_{b2} = 5.02 \times 10^4 \text{ W} / \text{ m}^2 \quad E_{b3} = 2.79 \times 10^4 \text{ W} / \text{ m}^2 \]

\[ T_2 = 970 \text{ K} \quad T_3 = 837.5 \text{ K} \]

Continued .....
PROBLEM 13.26 (Cont.)

(b) Using the energy balances, Eqs. (1-3), along with the IHT Radiation Tool, View Factors, Coaxial parallel disks, a model was developed to calculate $q_1$, $T_2$, and $T_3$ as a function of length $L$ for fixed diameter $D = 100$ m. The results are plotted below.

For fixed diameter, as the overall length increases, the power required to maintain the heated section at $T_1 = 1000$ K decreases. This follows since the furnace opening area is a smaller fraction of the enclosure surface area as $L$ increases. As $L$ increases, the bottom surface temperature $T_2$ increases as $L$ increases and, in the limit, will approach that of the heated section, $T_1 = 1000$ K. As $L$ increases, the temperature of the insulated cylindrical section, $T_3$, increases, but only slightly. The limiting value occurs when $E_{b3} = 0.5 \times E_{b1}$ for which $T_3 \rightarrow 840$ K. Why is that so?
PROBLEM 13.27

KNOWN: Dimensions and temperature of a rectangular fin array radiating to deep space.

FIND: Expression for rate of radiation transfer per unit length from a unit section of the array.

SCHEMATIC:

ASSUMPTIONS: (1) Surfaces may be approximated as blackbodies, (2) Surfaces are isothermal, (3) Length of array (normal to page) is much larger than W and L.

ANALYSIS: Deep space may be represented by the hypothetical surface $A'_3$, which acts as a blackbody at absolute zero temperature. The net rate of radiation heat transfer to this surface is therefore equivalent to the rate of heat rejection by a unit section of the array.

$$q'_3 = A'_1 F_{13} \sigma \left( T_1^4 - T_3^4 \right) + A'_2 F_{23} \sigma \left( T_2^4 - T_3^4 \right)$$

With $A'_2 F_{23} = A'_3 F_{32} = A'_1 F_{12}$, $T_1 = T_2 = T$ and $T_3 = 0$,

$$q'_3 = A'_1 (F_{13} + F_{12}) \sigma T^4 = W \sigma T^4$$

Radiation from a unit section of the array corresponds to emission from the base. Hence, if blackbody behavior can, indeed, be maintained, the fins do nothing to enhance heat rejection.

COMMENTS: (1) The foregoing result should come as no surprise since the surfaces of the unit section form an isothermal blackbody cavity for which emission is proportional to the area of the opening. (2) Because surfaces 1 and 2 have the same temperature, the problem could be treated as a two-surface enclosure consisting of the combined (1, 2) and 3. It follows that $q'_3 = q'(1,2)3 = A'(1,2)$

$$F_{(1,2)3} \sigma T^4 = A'_3 F_{3(1,2)} \sigma T^4 = W \sigma T^4$$

(3) If blackbody behavior cannot be achieved ($\varepsilon_1, \varepsilon_2 < 1$), enhancement would be afforded by the fins.
PROBLEM 13.28

KNOWN: Dimensions and temperatures of side and bottom walls in a cylindrical cavity.

FIND: Emissive power of the cavity.

SCHEMATIC:

ASSUMPTIONS: (1) Blackbody behavior for surfaces 1 and 2

ANALYSIS: The desired emissive power is defined as

\[ E = \frac{q_3}{A_3} \]

where

\[ q_3 = A_1 \varepsilon_{13} E_{b1} + A_2 \varepsilon_{23} E_{b2}. \]

From symmetry, \( F_{23} = F_{21} \), and from reciprocity, \( F_{21} = (A_1/A_2) F_{12} \). With \( F_{12} = 1 - F_{13} \), it follows that

\[ q_3 = A_1 \varepsilon_{13} E_{b1} + A_1 (1 - F_{13}) E_{b2} = A_1 E_{b2} + A_1 \varepsilon_{13} (E_{b1} - E_{b2}). \]

Hence, with \( A_1 = A_3 \),

\[ E = \frac{q_3}{A_3} = E_{b2} + \varepsilon_{13} (E_{b1} - E_{b2}) = \sigma T_2^4 + \varepsilon_{13} \sigma \left( T_1^4 - T_2^4 \right). \]

From Fig. 13.15, with \( (L/r_i) = 4 \) and \( (r_j/L) = 0.25 \), \( F_{13} = 0.05 \). Hence

\[ E = 5.67 \times 10^{-8} \text{W/m}^2 \cdot \text{K}^4 + 0.05 \times 5.67 \times 10^{-8} \text{W/m}^2 \cdot \text{K}^4 (1000^4 - 700^4) \text{K}^4 \]

\[ E = 1.36 \times 10^4 \text{W/m}^2 + 0.22 \times 10^4 \text{W/m}^2 \]

\[ E = 1.58 \times 10^4 \text{W/m}^2 \].
PROBLEM 13.29

KNOWN: Aligned, parallel discs with prescribed geometry and orientation.

FIND: Net radiative heat exchange between the discs.

SCHEMATIC:

ASSUMPTIONS: (1) Surfaces behave as blackbodies, (2) $A_1 \ll A_2$.

ANALYSIS: The net radiation exchange between the two black surfaces follows from Eq. 13.13 written as

$$q_{12} = A_1 F_{12} \sigma \left( T_1^4 - T_2^4 \right).$$

The view factor can be determined from Eq. 13.8 which is appropriate for a small disc, aligned and parallel to a much larger disc.

$$F_{ij} = \frac{D_j^2}{D_j^2 + 4L^2}$$

where $D_j$ is the diameter of the larger disk and $L$ is the distance of separation. It follows that

$$F_{12} = F_{10} - F_{1i} = 0.00990 - 0.00559 = 0.00431$$

where

$$F_{10} = D_0^4 / \left( D_0^2 + 4L^2 \right) = 0.2^2 \text{m}^2 / \left( 0.2^2 \text{m}^2 + 4 \times 1 \text{m}^2 \right) = 0.00990$$

$$F_{1i} = D_i^4 / \left( D_i^2 + 4L^2 \right) = 0.15^2 \text{m}^2 / \left( 0.15^2 \text{m}^2 + 4 \times 1 \text{m}^2 \right) = 0.00559.$$ 

The net radiation exchange is then

$$q_{12} = \frac{\pi (0.03m)^2}{4} \times 0.00431 \times 5.67 \times 10^{-8} \frac{W}{m^2 \cdot K^4} \left( 500^4 - 1000^4 \right) K^4 = -0.162 W.$$ 

COMMENTS: $F_{12}$ can be approximated using solid angle concepts if $D_o \ll L$. That is, the view factor for $A_1$ to $A_o$ (whose diameter is $D_o$) is

$$F_{1o} = \frac{\omega_{o-1}}{\pi} = \frac{A_o / L^2}{\pi} = \frac{\pi D_o^2}{4\pi L^2} = \frac{D_o^2}{4L^2}.$$ 

Numerically, $F_{1o} = 0.0100$ and it follows $F_{1i} \approx D_i^2 / 4L^2 = 0.00563$. This gives $F_{12} = 0.00437$. An analytical expression can be obtained from Ex. 13.1 by replacing the lower limit of integration by $D_i/2$, giving

$$F_{12} = L^2 \left[ -1 / \left( D_o^2 / 4 + L^2 \right) + 1 / \left( D_i^2 / 4 + L^2 \right) \right] = 0.00431.$$
PROBLEM 13.30

KNOWN: Two black, plane discs, one being solid, the other ring-shaped.

FIND: Net radiative heat exchange between the two surfaces.

SCHEMATIC:

ASSUMPTIONS: (1) Discs are parallel and coaxial, (2) Discs are black, diffuse surfaces, (3) Convection effects are not being considered.

ANALYSIS: The net radiative heat exchange between the solid disc, \( A_1 \), and the ring-shaped disc, \( A_2 \), follows from Eq. 13.13.

\[
q_{12} = A_1 F_{12} \sigma \left( T_1^4 - T_2^4 \right)
\]

The view factor \( F_{12} \) can be determined from Fig. 13.5 after some manipulation. Define these two hypothetical surfaces:

\[
A_3 = \frac{\pi D_0^2}{4}, \text{ located co-planar with } A_2, \text{ but a solid surface}
\]

\[
A_4 = \frac{\pi D_1^2}{4}, \text{ located co-planar with } A_2, \text{ representing the missing center.}
\]

From view factor relations and Fig. 13.5, it follows that

\[
F_{12} = F_{13} - F_{14} = 0.62 - 0.20 = 0.42
\]

\[
F_{14}: \frac{r_4}{L} = \frac{40/2}{20} = 1, \quad \frac{L}{r_4} = \frac{20}{80/2} = 0.5, \quad F_{14} = 0.20
\]

\[
F_{13}: \frac{r_3}{L} = \frac{80/2}{20} = 2, \quad \frac{L}{r_3} = \frac{20}{80/2} = 0.5, \quad F_{13} = 0.62.
\]

Hence

\[
q_{12} = \left( \pi 0.80^2 / 4 \right) m^2 \times 0.42 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left( 300^4 - 1000^4 \right) \text{K}^4
\]

\[
q_{12} = -11.87 \text{ kW}.
\]

Assuming negligible radiation exchange with the surroundings, the negative sign implies that \( q_1 = -11.87 \text{ kW} \) and \( q_2 = 11.87 \text{ kW} \).
PROBLEM 13.31

KNOWN: Radiometer viewing a small target area (1), A₁, with a solid angle \( \omega = 0.0008 \) sr. Target has an area \( A₁ = 0.004 \text{ m}^2 \) and is diffuse, gray with emissivity \( \varepsilon = 0.8 \). The target is heated by a ring-shaped disc heater (2) which is black and operates at \( T₂ = 1000 \text{ K} \).

FIND: (a) Expression for the radiant power leaving the target which is collected by the radiometer in terms of the target radiosity, \( J₁ \), and relevant geometric parameters; (b) Expression for the target radiosity in terms of its irradiation, emissive power and appropriate radiative properties; (c) Expression for the irradiation on the target, \( G₁ \), due to emission from the heater in terms of the heater emissive power, the heater area and an appropriate view factor; numerically evaluate \( G₁ \); and (d) Determine the radiant power collected by the radiometer using the foregoing expressions and results.

SCHEMATIC:

ASSUMPTIONS: (1) Target is diffuse, gray, (2) Target area is small compared to the square of the separation distance between the sample and the radiometer, and (3) Negligible irradiation from the surroundings onto the target area.

ANALYSIS: (a) From Eq. (12.5) with \( I₁ = I₁,e+r = J₁/\pi \), the radiant power leaving the target collected by the radiometer is

\[
q₁راد = \dfrac{J₁}{\pi} A₁ \cos \theta₁ \omega_{\text{rad-1}}
\]

where \( \theta₁ = 0° \) and \( \omega_{\text{rad-1}} \) is the solid angle the radiometer subtends with respect to the target area.

(b) From Eq. 13.16, the radiosity is the sum of the emissive power plus the reflected irradiation.

\[
J₁ = E₁ + \rho G₁ = \varepsilon E_{b₁} + (1-\varepsilon) G₁
\]

where \( E_{b₁} = \sigma T₁^4 \) and \( \rho = 1 - \varepsilon \) since the target is diffuse, gray.

(c) The irradiation onto \( G₁ \) due to emission from the heater area \( A₂ \) is

\[
G₁ = \dfrac{q₂\rightarrow₁}{A₁}
\]

where \( q₂\rightarrow₁ \) is the radiant power leaving \( A₂ \) which is intercepted by \( A₁ \) and can be written as

\[
q₂\rightarrow₁ = A₂ F₂₁ E_{b₂}
\]

where \( E_{b₂} = \sigma T₂^4 \). \( F₂₁ \) is the fraction of radiant power leaving \( A₂ \) which is intercepted by \( A₁ \). The view factor \( F₁₂ \) can be written as

Continued …..
PROBLEM 13.31 (Cont.)

\[ F_{12} = F_{1-o} \quad F_{1-i} = 0.5 - 0.2 = 0.3 \]

where from Eq. 13.8,

\[ F_{1-o} = \frac{D_o^2}{D_o^2 + 4L^2} = \frac{0.5^2}{0.5^2 + 4(0.25)^2} = 0.5 \]  \hspace{1cm} (3)

\[ F_{1-i} = \frac{D_i^2}{D_i^2 + 4L^2} = \frac{0.25^2}{0.25^2 + 4(0.25)^2} = 0.2 \]

and from the reciprocity rule,

\[ F_{21} = \frac{A_1 F_{12}}{A_2} = \frac{0.0004 m^2 \times 0.3}{\pi / 4 (0.5^2 - 0.25^2) m^2} = 0.000815 \]

Substituting numerical values into Eq. (3), find

\[ G_1 = \frac{\pi / 4 (0.5^2 - 0.25^2) m^2 \times 0.000815 \times 5.67 \times 10^{-8} W/m^2 \cdot K^4 (1000 K)^4}{0.0004 m^2} \]

\[ G_1 = 17,013 W/m^2 \]

(d) Substituting numerical values into Eq. (1), the radiant power leaving the target collected by the radiometer is

\[ q_{i \to rad} = \left( 6238 W/m^2 / \pi \text{ sr} \right) \times 0.0004 m^2 \times 1 \times 0.0008 \text{ sr} = 635 \mu W \]

where the radiosity, \( J_1 \), is evaluated using Eq. (2) and \( G_1 \).

\[ J_1 = 0.8 \times 5.67 \times 10^{-8} W/m^2 \cdot K^4 \times (500 K)^4 + (1 - 0.8) \times 17,013 W/m^2 \]

\[ J_1 = (2835 + 3403) W/m^2 = 6238 W/m^2 \]

**COMMENTS:**

(1) Note that the emitted and reflected irradiation components of the radiosity, \( J_1 \), are of the same magnitude.

(2) Suppose the surroundings were at room temperature, \( T_{sur} = 300 K \). Would the reflected irradiation due to the surroundings contribute significantly to the radiant power collected by the radiometer? Justify your conclusion.
**PROBLEM 13.32**

**KNOWN:** Thin-walled, black conical cavity with opening \( D = 10 \text{ mm} \) and depth of \( L = 12 \text{ mm} \) that is well insulated from its surroundings. Temperature of meter housing and surroundings is \( 25.0 ^\circ \text{C} \).

**FIND:** Optical (radiant) flux of laser beam, \( G_\text{in} \) \( (\text{W/m}^2) \), incident on the cavity when the fine-wire thermocouple indicates a temperature rise of \( 10.1^\circ \text{C} \).

**SCHEMATIC:**

[Diagram of the cavity with dimensions and laser beam]

**ASSUMPTIONS:** (1) Cavity surface is black and perfectly insulated from its mounting material in the meter, (2) Negligible convection heat transfer from the cavity surface, and (3) Surroundings are large, isothermal.

**ANALYSIS:** Perform an energy balance on the walls of the cavity considering absorption of the laser irradiation, absorption from the surroundings and emission.

\[
\dot{E}_\text{in} - \dot{E}_\text{out} = 0
\]

\[
A_\text{o} G_\text{o} + A_\text{o} G_\text{sur} - A_\text{o} E_\text{b} (T_c) = 0
\]

where \( A_\text{o} = \pi D^2/4 \) represents the opening of the cavity. All of the radiation entering or leaving the cavity passes through this hypothetical surface. Hence, we can treat the cavity as a black disk at \( T_c \).

Since \( G_\text{sur} = E_\text{b} (T_\text{sur}) \), and \( E_\text{b} = \sigma T^4 \) with \( \sigma = 5.67 \times 10^{-8} \text{ W/m}^2\text{K}^4 \), the energy balance has the form

\[
G_\text{o} + \sigma (25.0 + 273)^4 K^4 - \sigma (25.0 + 10.1 + 273)^4 K^4 = 0
\]

\[
G_\text{o} = 63.8 \text{ W/m}^2
\]
PROBLEM 13.33

KNOWN: Electrically heated sample maintained at \( T_s = 500 \, \text{K} \) with diffuse, spectrally selective coating. Sample is irradiated by a furnace located coaxial to the sample at a prescribed distance. Furnace has isothermal walls at \( T_f = 3000 \, \text{K} \) with \( \varepsilon_f = 0.7 \) and an aperture of 25 mm diameter. Sample experiences convection with ambient air at \( T_\infty = 300 \, \text{K} \) and \( h = 20 \, \text{W/m}^2\cdot\text{K} \). The surroundings of the sample are large with a uniform temperature \( T_{\text{sur}} = 300 \, \text{K} \). A radiation detector sensitive to only power in the spectral region 3 to 5 \( \mu\text{m} \) is positioned at a prescribed location relative to the sample.

FIND: (a) Electrical power, \( P_e \), required to maintain the sample at \( T_s = 500 \, \text{K} \), and (b) Radiant power incident on the detector within the spectral region 3 to 5 \( \mu\text{m} \) considering both emission and reflected irradiation from the sample.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state condition, (2) Furnace is large, isothermal enclosure with small aperture and radiates as a blackbody, (3) Sample coating is diffuse, spectrally selective, (4) Sample and detector areas are small compared to their separation distance squared, (5) Surroundings are large, isothermal.

ANALYSIS: (a) Perform an energy balance on the sample mount, which experiences electrical power dissipation, convection with ambient air, absorbed irradiation from the furnace, absorbed irradiation from the surroundings and emission,

\[
E_{\text{in}}' - E_{\text{out}}' = 0
\]

\[
P_e + \left[ -h(T_s - T_\infty) + \alpha_f G_f + \alpha_{\text{sur}} G_{\text{sur}} - \varepsilon E_b(T_s) \right] A_s = 0 \quad (1)
\]

where \( E_b(T_s) = \sigma T_s^4 \) and \( A_s = \pi D_s^2 / 4 \).

Irradiations on the sample: The irradiation from the furnace aperture onto the sample can be written as

\[
G_f = \frac{q_f \rightarrow s}{A_s} = \frac{A_f F_b E_b f}{A_s} = \frac{A_f F_b \sigma T_f^4}{A_s}
\]

(2)

where \( A_f = \pi D_f^2 / 4 \) and \( A_s = \pi D_s^2 / 4 \). The view factor between the furnace aperture and sample follows from the relation for coaxial parallel disks, Table 13.2,

\[
R_f = r_f / L_{sf} = 0.0125 \, \text{m} / 0.750 \, \text{m} = 0.01667 \quad R_s = r_s / L_{sf} = 0.0100 \, \text{m} / 0.750 \, \text{m} = 0.01333
\]

\[
S = 1 + \frac{1 + R_s^2}{R_f^2} = 1 + \frac{1 + 0.01333^2}{0.01667^2} = 3600.2
\]

Continued …..
PROBLEM 13.33 (Cont.)

\[ F_{sf} = 0.5 \left\{ S - \left[ S^2 - 4 \left( \frac{r_s}{r_f} \right)^2 \right]^{1/2} \right\} = 0.5 \left\{ 3600 - \left[ 3600^2 - 4 \left( 0.05/0.0625 \right)^2 \right]^{1/2} \right\} = 0.000178 \]

Hence the irradiation from the furnace is

\[ G_f = \frac{\pi \left( 0.025 \text{ m} \right)^2 / 4 \times 0.000178 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left( 3000 \text{ K} \right)^4}{\pi \left( 0.020^2 \text{ m}^2 / 4 \right)} = 1277 \text{ W/m}^2 \]

The irradiation from the surroundings which are large compared to the sample is

\[ G_{\text{sur}} = \sigma T_{\text{sur}}^4 = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K} \left( 300 \text{ K} \right)^4 = 459 \text{ W/m}^2 \]

**Emissivity of the Sample:** The total hemispherical emissivity in terms of the spectral distribution can be written following Eq. 12.38 and Eq. 12.30,

\[ \varepsilon = \int_0^\infty \varepsilon_\lambda E_{\lambda, b} (T_s) d\lambda / \sigma T^4 = \varepsilon_1 F(0-\lambda T_s) + \varepsilon_2 \left[ 1 - F(0-\lambda T_s) \right] \]

\[ \varepsilon = 0.8 \times 0.066728 + 0.2 \left[ 1 - 0.066728 \right] = 0.240 \]

where, from Table 12.1, with \( \lambda T_s = 4 \mu m \times 500 \text{ K} = 2000 \mu m \cdot \text{K}, F(0-\lambda T) = 0.066728. \]

**Absorptivity of the Sample:** The total hemispherical absorptivity due to irradiation from the furnace follows from Eq. 12.46,

\[ \alpha_f = \varepsilon_1 F(0-\lambda f) + \varepsilon_2 \left[ 1 - F(0-\lambda f) \right] = 0.8 \times 0.945098 + 0.2 \left[ 1 - 0.945098 \right] = 0.767 \]

where, from Table 12.1, with \( \lambda f = 4 \mu m \times 3000 \text{ K} = 12000 \mu m \cdot \text{K}, F(0-\lambda T) = 0.945098. \) The total hemispherical absorptivity due to irradiation from the surroundings is

\[ \alpha_{\text{sur}} = \varepsilon_1 F(0-\lambda_{\text{sur}}) + \varepsilon_2 \left[ 1 - F(0-\lambda_{\text{sur}}) \right] = 0.8 \times 0.00234 + 0.2 \left[ 1 - 0.002134 \right] = 0.201 \]

where, from Table 12.1, with \( \lambda_{\text{sur}} = 4 \mu m \times 300 \text{ K} = 1200 \mu m \cdot \text{K}, F(0-\lambda T) = 0.002134. \)

**Evaluating the Energy Balance:** Substituting numerical values into Eq. (1),

\[ P_e = \left[ +20 \text{ W/m}^2 \cdot \text{K} \left( 500 - 300 \right) \text{K} - 0.767 \times 1277 \text{ W/m}^2 \right] -0.201 \times 459 \text{ W/m}^2 + 0.240 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left( 500 \text{ K} \right)^4 \pi \left( 0.020 \text{ m} \right)^2 / 4 \]

\[ P_e = 1.256 \text{ W} - 0.308 \text{ W} - 0.029 \text{ W} + 0.267 \text{ W} = 1.19 \text{ W} \]

(b) The radiant power leaving the sample which is incident on the detector and within the spectral region, \( \Delta \lambda = 3 \) to 5\( \mu m \), follows from Eq. 12.5 with Eq. 12.30,

\[ q_{s-d, \Delta \lambda} = \left[ E_{s, \Delta \lambda} + G_{f, \text{ref}, \Delta \lambda} + G_{\text{sur,ref}, \Delta \lambda} \left( 1 / \pi \right) A_s \cos \theta_s \cdot A_d \cos \theta_d / L_{sd}^2 \right] \]

where \( \theta_s = 45^\circ \) and \( \theta_d = 0^\circ. \) The emitted component is

\[ E_{s, \Delta \lambda} = \int_3^{5 \mu m} \varepsilon_{\lambda, b} E_{\lambda, b} (T_s) \]

\[ E_{s, \Delta \lambda} = \left\{ \varepsilon_1 \left[ F(0-3 \mu m, T_s) - F(0-4 \mu m, T_s) \right] + \varepsilon_2 \left[ F(0-5 \mu m, T_s) - F(0-4 \mu m, T_s) \right] \right\} \sigma T_s^4 \]

Continued …..
PROBLEM 13.33 (Cont.)

\[ E_{s, \Delta \lambda} = \{0.8[0.066728 - 0.013754] + 0.2[0.16169 - 0.066728]\} \sigma (500K)^4 = 217.5 \text{ W/m}^2 \]

where, from Table 12.1, \( F(0-3\mu m, T_s) = 0.013754 \) at \( \lambda T = 3 \mu m \times 500 \text{ K} = 1500 \mu m \cdot \text{K} \);
\( F(0-4\mu m, T_s) = 0.066728 \) at \( \lambda = 4 \mu m \times 500 \text{ K} = 2000 \mu m \cdot \text{K} \); and \( F(0-5\mu m, T_s) = 0.16169 \) at \( \lambda T = 5 \mu m \times 500 \text{ K} = 2500 \mu m \cdot \text{K} \).

The reflected irradiation from the furnace component is

\[ G_{f, \text{ref}, \Delta \lambda} = \int_{3}^{5\mu m} (1 - \varepsilon_{\lambda}) G_{f, \lambda} d\lambda \]

where \( G_{f, \lambda} = E_{\lambda, b}(T_f) \), using band emission factors,

\[ G_{f, \text{ref}, \Delta \lambda} = \{1 - (1 - \varepsilon_{\lambda}) \}[F(0-4\mu m, T_f) - F(0-3\mu m, T_f)] + (1 - \varepsilon_{\lambda})[F(0-5\mu m, T_f) - F(0-4\mu m, T_f)]G_f \]

\[ G_{f, \text{ref}, \Delta \lambda} = \{0.2[0.9451 - 0.8900] + 0.8[0.9700 - 0.9451]\}1277 \text{ W/m}^2 = 39.51 \text{ W/m}^2 \]

where, from Table 12.1, \( F(0-3\mu m, T_f) = 0.8900 \) at \( \lambda T_f = 3 \mu m \times 300 \text{ K} = 9000 \mu m \cdot \text{K} \);
\( F(0-4\mu m, T_f) = 0.9451 \) at \( \lambda T_f = 4 \mu m \times 300 \text{ K} = 12,000 \mu m \cdot \text{K} \); and, \( F(0-5\mu m, T_f) = 0.9700 \) at \( \lambda T_f = 5 \mu m \times 300 \text{ K} = 15,000 \mu m \cdot \text{K} \).

The reflected irradiation from the surroundings component is

\[ G_{\text{sur, ref}, \Delta \lambda} = \int_{3}^{5\mu m} (1 - \varepsilon_{\lambda}) G_{\text{ref}, \lambda} d\lambda \]

where \( G_{\text{ref, \lambda}} = E_{\lambda, b}(T_{\text{sur}}) \), using band emission factors,

\[ G_{\text{sur, ref}, \Delta \lambda} = \{1 - \varepsilon_{\lambda}\}[F(0-4\mu m, T_{\text{sur}}) - F(0-3\mu m, T_{\text{sur}})] + \varepsilon_{\lambda}[F(0-5\mu m, T_{\text{sur}}) - F(0-4\mu m, T_{\text{sur}})]G_{\text{sur}} \]

\[ G_{\text{sur, ref}, \Delta \lambda} = \{0.2[0.002134 - 0.0001685] - 0.8[0.013754 - 0.002134]\}459 \text{ W/m}^2 = 4.44 \text{ W/m}^2 \]

where, from Table 12.1, \( F(0-3\mu m, T_{\text{sur}}) = 0.0001685 \) at \( \lambda T_{\text{sur}} = 3 \mu m \times 300 \text{ K} = 900 \mu m \cdot \text{K} \);
\( F(0-4\mu m, T_{\text{sur}}) = 0.002134 \) at \( \lambda T_{\text{sur}} = 4 \mu m \times 300 \text{ K} = 1200 \mu m \cdot \text{K} \); and, \( F(0-5\mu m, T_{\text{sur}}) = 0.013754 \) at \( \lambda T_{\text{sur}} = 5 \mu m \times 300 \text{ K} = 1500 \mu m \cdot \text{K} \). Returning to Eq. (3), find

\[ q_{sd, \Delta \lambda} = [217.5 + 39.51 + 4.44] \text{ W/m}^2 \left(\frac{1}{\pi}\right) \left[8\pi \left(0.020 \text{ m}\right)^2 / 4\right] \cos 45^\circ \times 8 \times 10^{-5} \text{ m}^2 \times \cos 0^\circ / (1 \text{ m})^2 = 1.48 \mu \text{W} \]

COMMENTS: (1) Note that \( F_{fs} \) is small, since \( A_f, A_s \ll L_{sf}^2 \). As such, we could have evaluated \( q_{fs} \) using Eq. 12.5 and found

\[ G_f = \frac{E_{b, f} / \pi A_f}{A_s / L_{sf}^2} = 1276 \text{ W/m}^2 \]

(2) Recognize in the analysis for part (b), Eq. (3), the role of the band emission factors in calculating the fraction of total radiant power for the emitted and reflected irradiation components.
PROBLEM 13.34

KNOWN: Water-cooled heat flux gage exposed to radiant source, convection process and surroundings.

FIND: (a) Net radiation exchange between heater and gage, (b) Net transfer of radiation to the gauge per unit area of the gage, (c) Net heat transfer to the gage per unit area of gage, (d) Heat flux indicated by gage described in Problem 3.98.

SCHEMATIC:

ASSUMPTIONS: (1) Heater and gauge are parallel, coaxial discs having blackbody behavior, (2) \( A_g \ll A_h \), (3) Surroundings are large compared to \( A_h \) and \( A_g \).

ANALYSIS: (a) The net radiation exchange between the heater and the gage, both with blackbody behavior, is given by Eq. 13.13 having the form

\[
q_{h-g} = A_h F_{hg} \sigma \left( T_h^4 - T_g^4 \right) = A_g F_{gh} \sigma \left( T_h^4 - T_g^4 \right).
\]

Note the use of reciprocity, Eq. 13.3, for the view factors. From Eq. 13.8,

\[
F_{gh} = D_h^2 / \left( 4L^2 + D_h^2 \right) = (0.2m)^2 / \left( 4 \times 0.5^2 m^2 + 0.2^2 m^2 \right) = 0.0385.
\]

\[
q_{h-g} = \left( \pi 0.01^2 m^2 / 4 \right) \times 0.0385 \times 5.67 \times 10^{-8} W / m^2 \cdot K^4 \times \left[ 800^4 - 290^4 \right] K^4 = 69.0 \text{ mW}.
\]

(b) The net radiation to the gage per unit area will involve exchange with the heater and the surroundings. Using Eq. 13.14,

\[
q_{\text{net,rad}} = -q_{g} / A_g = q_{h-g} / A_g + q_{\text{sur-g}} / A_g.
\]

The net exchange with the surroundings is

\[
q_{\text{sur-g}} = \frac{69.0 \times 10^{-3} W}{\pi (0.01 m)^2 / 4} + (1 - 0.0385) \times 5.67 \times 10^{-8} W / m^2 \cdot K^4 \times \left[ 300^4 - 290^4 \right] K^4 = 934.5 \text{ W} / m^2.
\]

(c) The net heat transfer rate to the gage per unit area of the gage follows from the surface energy balance

\[
q_{\text{net,in}} = q_{\text{net,rad}} + q_{\text{conv}}
\]

\[
q_{\text{net,in}} = 934.5 \text{ W} / m^2 + 15 \text{ W} / m^2 \cdot K (300 - 290) K
\]

\[
q_{\text{net,in}} = 1085 \text{ W} / m^2.
\]

(d) The heat flux gage described in Problem 3.98 would experience a net heat flux to the surface of 1085 W/m². The irradiation to the gage from the heater is \( G_g = q_{h-g} / A_g = F_{gh} \sigma T_h^4 = 894 \text{ W/m}^2 \).

Since the gage responds to net heat flux, there would be a systematic error in sensing irradiation from the heater.
PROBLEM 13.35

KNOWN: Long cylindrical heating element located a given distance above an insulated wall exposed to cool surroundings.

FIND: Maximum temperature attained by the wall and temperature at location A.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Insulated wall, (3) Negligible conduction in wall, (4) All surfaces are black.

ANALYSIS: Consider an elemental area at point \( x = 0 \); this is the location that will attain the maximum temperature. Since the wall is insulated and conduction is negligible, the net radiation leaving \( dA_0 \) is zero. From Eq. 13.13,

\[
q_0 = q_{0\text{,sur}} + q_{0\text{,h}} = F_{0\text{,h}} \sigma \left( T_0^2 - T_h^4 \right) + F_{0\text{,sur}} \left( T_0^5 - T_{\text{sur}}^4 \right) = 0
\]

where \( F_{0\text{,sur}} = 1 - F_{0\text{,h}} \) and \( F_{0\text{,h}} \) can be found from the relation for a cylinder and parallel rectangle, Table 13.1, with \( s_1 = 2 \text{ mm}, s_2 = 0 \text{ mm}, L = 40 \text{ mm}, \) and \( r = R = 10 \text{ mm}. \)

\[
F_{0\text{,h}} = \frac{r}{s_1 - s_2} \left[ \tan^{-1} \frac{s_1}{L} - \tan^{-1} \frac{s_2}{L} \right] = \frac{10 \text{ mm}}{2 \text{ mm}} \left[ \tan^{-1} \frac{2}{40} - \tan^{-1} 0 \right] = 0.25
\]

Rearranging Eq. (1) and substituting numerical values, find

\[
T_0^4 = \left[ T_h^4 + \frac{(1 - F_{0\text{,h}})}{F_{0\text{,h}}} T_{\text{sur}}^4 \right] \left[ 1 + \frac{1 - F_{0\text{,h}}}{F_{0\text{,h}}} \right]^{-1}
\]

For the point A located at \( x = 40 \text{ mm} \), use the same relation of Table 13.1 to find \( F_{A\text{,h}} \) (for this point, \( s_1 = 41 \text{ mm}, s_2 = 39 \text{ mm}, r = R = 10 \text{ mm}, L = 40 \text{ mm}).

\[
F_{A\text{,h}} = \frac{10 \text{ mm}}{(41 - 39) \text{ mm}} \left[ \tan^{-1} \frac{41}{40} - \tan^{-1} \frac{39}{40} \right] = 0.125.
\]

Substituting numerical values into Eq. (3), find

\[
T_A^4 = \left[ (700 \text{ K})^4 + \frac{1 - 0.125}{0.125} (300 \text{ K})^4 \right] \left[ 1 + \frac{1 - 0.125}{0.125} \right] T_0 = 439 \text{ K}.
\]

COMMENTS: Note the importance of the assumptions that the wall is insulated and conduction is negligible. In calculating \( F_{0\text{,h}} \) and \( F_{A\text{,h}} \) we are finding the view factor for a small area or point. Hence, we need only specify that \( s_1 - s_2 \) is very small compared to \( L \).
KNOWN: Diameter and pitch of in-line tubes occupying evacuated space between parallel plates of prescribed temperature. Temperature and flowrate \( \dot{m} \) of water through the tubes.

FIND: (a) Tube surface temperature \( T_s \) for \( \dot{m} = 0.20 \text{ kg/s} \), (b) Effect of \( \dot{m} \) on \( T_s \).

SCHEMATIC:

ASSUMPTIONS: (1) Surfaces behave as blackbodies, (2) Negligible tube wall conduction resistance, (3) Fully-developed tube flow.

PROPERTIES: Table A-6, water \((T_m = 300 \text{ K})\): \( \mu = 855 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 \), \( k = 0.613 \text{ W/m} \cdot \text{K} \), \( Pr = 5.83 \).

ANALYSIS: (a) Performing an energy balance on a single tube, it follows that \( q_{ps} = q_{conv} \), or

\[
A_p F_{ps} \sigma \left( T_p^4 - T_s^4 \right) = h A_s \left( T_s - T_m \right)
\]

From Table 13.1 and \( D/S = 0.75 \), the view factor is

\[
F_{ps} = 1 - \left( 1 - \left( \frac{D}{S} \right)^2 \right)^{1/2} + \left( \frac{D}{S} \right) \tan^{-1} \left( \frac{S^2 - D^2}{D^2} \right)^{1/2} = 0.881
\]

With \( \text{Re}_D = 4 \dot{m} / (\pi D \mu) = 4(0.20 \text{ kg/s}) / (\pi (0.015 \text{ m}) 855 \times 10^{-6} \text{ N} \cdot \text{s/m}^2) = 19,856 \), fully-developed turbulent flow may be assumed, in which case Eq. 8.60 yields

\[
h = \frac{k}{D} \left( 0.023 \text{Re}_D^{4/5} Pr^{0.4} \right) = \frac{0.613 \text{ W/m} \cdot \text{K}}{0.015 \text{ m}} (0.023)(19,856)^{4/5} (5.83)^{0.4} = 5220 \text{ W/m}^2 \cdot \text{K}
\]

Hence, with \( (A_p/A_s) = 2S/\pi D = 0.849 \),

\[
T_s - T_m = \frac{F_{ps} \sigma}{h} A_p \left( T_p^4 - T_s^4 \right) = \frac{0.881 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4}{5220 \text{ W/m}^2 \cdot \text{K}} (0.849) \left( T_p^4 - T_s^4 \right)
\]

With \( T_m = 300 \text{ K} \) and \( T_p = 1000 \text{ K} \), a trial-and-error solution yields

\( T_s = 308 \text{ K} \)  

(b) Using the Correlations and Radiation Toolpads of IHT to evaluate the convection coefficient and view factor, respectively, the following results were obtained.

The decrease in \( T_s \) with increasing \( \dot{m} \) is due to an increase in \( h \) and hence a reduction in the convection resistance.

COMMENTS: Due to the large value of \( h \), \( T_s \ll T_p \).
PROBLEM 13.37

KNOWN: Insulated wall exposed to a row of regularly spaced cylindrical heating elements.

FIND: Required operating temperature of the heating elements for the prescribed conditions.

SCHEMATIC:

Assumptions:
1. Upper and lower walls are isothermal and infinite,
2. Lower wall is insulated,
3. All surfaces are black,
4. Steady-state conditions.

Analysis:
Perform an energy balance on the insulated wall considering convection and radiation.

\[
\dot{E}^e_{\text{in}} - \dot{E}^e_{\text{out}} = -q^e_1 - q^e_{\text{conv}} = 0
\]

where \(q^e_1\) is the net radiation leaving the insulated wall per unit area. From Eq. 13.13,

\[
q^e_1 = q^e_{1e} + q^e_{12} = F_{1e} \sigma (T_1^4 - T_e^4) + F_{12} \sigma (T_1^4 - T_2^4)
\]

where \(F_{12} = 1 - F_{1e}\). Using Newton’s law of cooling for \(q^e_{\text{conv}}\) solve for \(T_e\).

\[
T_e^4 = T_1^4 + \frac{(1-F_{1e})}{F_{1e}}(T_1^4 - T_2^4) + \frac{h}{\sigma F_{1e}} (T_1 - T_\infty).
\]

The view factor between the insulated wall and the tube row follows from the relation for an infinite plane and row of cylinders, Table 13.1,

\[
F_{1e} = 1 - \left[1 - \left(\frac{D}{S}\right)^2\right]^{1/2} + \left(\frac{D}{S}\right) \tan^{-1}\left(\frac{s^2 - D^2}{2D^2}\right)^{1/2}
\]

\[
F_{1e} = 1 - \left[1 - \left(\frac{10}{20}\right)^2\right]^{1/2} + \left(\frac{10}{20}\right) \tan^{-1}\left(\frac{20^2 - 10^2}{100}\right)^{1/2} = 0.658.
\]

Substituting numerical values, find

\[
T_e^4 = \left[(500^4 \right)^4 + \frac{1-0.658}{0.658 (500^4 - 300^4) K^4} + \frac{200 \text{ W/m}^2 \cdot K}{5.67 \times 10^{-8} \text{ W/m}^2 \cdot K^4} \times \frac{1}{0.658 (500 - 450) K}
\]

\[
T_e = 774 \text{ K}.
\]

Comments:
Always express temperatures in kelvins when considering convection and radiation terms in an energy balance. Why is \(F_{1e}\) independent of the distance between the row of tubes and the wall:
PROBLEM 13.38

KNOWN: Surface radiative properties, diameter and initial temperature of a copper rod placed in an evacuated oven of prescribed surface temperature.

FIND: (a) Initial heating rate, (b) Time \( t_h \) required to heat rod to 1000 K, (c) Effect of convection on heating time.

SCHEMATIC:

\[ T_{\infty} = 1650 \text{ K}, \quad h \]

\[ T_i = 300 \text{ K}, \quad T_{\text{sur}} = 1650 \text{ K} \]

ASSUMPTIONS: (1) Copper may be treated as a lumped capacitance, (b) Radiation exchange between rod and oven may be approximated as blackbody exchange.

PROPERTIES: Table A-1, Copper (300 K): \( \rho = 8933 \text{ kg/m}^3 \), \( c_p = 385 \text{ J/kg K} \), \( k = 401 \text{ W/m-K} \).

ANALYSIS: (a) Performing an energy balance on a unit length of the rod, \( \dot{E}_{\text{in}} = \dot{E}_{\text{st}} \), or

\[
q = \frac{M c_p}{\rho} \frac{dT}{dt} = \rho \left( \frac{\pi D^2}{4} \right) \cdot 1 \frac{dT}{dt} c_p
\]

Neglecting convection, \( q = q_{\text{rad}} = A_1 F_{12} \sigma \left( T_{\text{sur}}^4 - T^4 \right) = A_1 F_{12} \sigma \left( T_{\text{sur}}^4 - T_i^4 \right) \), where \( A_1 = \pi D \times 1 \) and \( F_{12} = 1 \). It follows that

\[
\frac{dT}{dt} = \frac{\sigma \pi D \left( T_{\text{sur}}^4 - T_i^4 \right)}{\rho \left( \frac{\pi D^2}{4} \right) \cdot 1 c_p} = \frac{4 \sigma \left( T_{\text{sur}}^4 - T_i^4 \right)}{\rho D c_p} \quad (1)
\]

\[
\frac{dT}{dt} = \frac{4 \left[ (1650 \text{ K})^4 - (300 \text{ K})^4 \right]}{8933 \text{ kg/m}^3 \cdot \left( 0.01 \text{ m} \right)^3 \cdot 385 \text{ J/kg K}} = 48.8 \text{ K/s}. \quad (2)
\]

(b) Using the IHT Lumped Capacitance Model to numerically integrate Eq. (2), we obtain

\[ t_s = 15.0 \text{ s} \]

(c) With convection, \( q = q_{\text{rad}} + q_{\text{conv}} = A_1 F_{12} \sigma \left( T_{\text{sur}}^4 - T_i^4 \right) + h A_1 \left( T_{\infty} - T \right) \), and the energy balance becomes

\[
\frac{dT}{dt} = \frac{4 \sigma \left( T_{\text{sur}}^4 - T_i^4 \right)}{\rho D c_p} + \frac{4 h \left( T_{\infty} - T \right)}{\rho D c_p}
\]

Performing the numerical integration for the three values of \( h \), we obtain

<table>
<thead>
<tr>
<th>( h ) (W/m²-K)</th>
<th>10</th>
<th>100</th>
<th>500</th>
</tr>
</thead>
<tbody>
<tr>
<td>( t_h ) (s)</td>
<td>14.6</td>
<td>12.0</td>
<td>6.8</td>
</tr>
</tbody>
</table>

COMMENTS: With an initial value of \( h_{\text{rad},i} = \sigma \left( T_{\text{sur}}^4 - T_i^4 \right) / (T_{\text{sur}} - T) = 311 \text{ W/m}^2 \cdot \text{K} \), \( Bi = h_{\text{rad}} \cdot (D/4)/k = 0.002 \) and the lumped capacitance assumption is justified for parts (a) and (b). With \( h = 500 \text{ W/m}^2 \cdot \text{K} \) and \( h + h_{\text{r},i} = 811 \text{ W/m-K} \) in part (c), \( Bi = 0.005 \) and the lumped capacitance approximation is also valid.
PROBLEM 13.39

KNOWN: Long, inclined black surfaces maintained at prescribed temperatures.

FIND: (a) Net radiation exchange between the two surfaces per unit length, (b) Net radiation transfer to surface A₂ with black, insulated surface positioned as shown below; determine temperature of this surface.

SCHEMATIC:

ASSUMPTIONS: (1) Surfaces behave as blackbodies, (2) Surfaces are very long in direction normal to page.

ANALYSIS: (a) The net radiation exchange between two black surfaces is given by Eq. 13.13,

\[ q_{12} = A_1 F_{12} \sigma \left( T_1^4 - T_2^4 \right) \]

Noting that \( A_1 = \text{width} \times \text{length} \) and that from symmetry, \( F_{12} = 0.5 \), find

\[ q'_{12} = \frac{q_{12}}{\ell} = 0.1 \text{ m} \times 0.5 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left( 1000^4 - 800^4 \right) \text{K}^4 = 1680 \text{ W/m.} \]

(b) With the insulated, black surface \( A_3 \) positioned as shown above, a three-surface enclosure is formed. From an energy balance on the node representing \( A_2 \), find

\[ -q'_{2} = q'_{32} + q'_{12} \]

\[ -q_{2} = A_3 F_{32} \left[ E_{b3} - E_{b2} \right] + A_1 F_{12} \left[ E_{b1} - E_{b2} \right]. \]

To find \( E_{b3} \), which at present is not known, perform an energy balance on the node representing \( A_3 \). Note that \( A_3 \) is adiabatic and, hence \( q_{3} = 0 \), \( q_{13} = q_{32} \).

\[ A_1 F_{13} \left[ E_{b1} - E_{b3} \right] = A_3 F_{32} \left[ E_{b3} - E_{b2} \right] \]

Since \( F_{13} = F_{23} = 0.5 \) and \( A_1 = A_3 \), it follows that

\[ E_{b3} = (1/2) \left[ E_{b1} + E_{b2} \right] \]

and

\[ -q'_{2} = (A_3 / \ell) F_{32} \left[ \left( E_{b1} + E_{b2} \right) / 2 - E_{b2} \right] + q'_{12} \]

\[ -q_{2} = 0.1 \text{ m} \times 0.5 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left[ \left( 1000^4 + 800^4 \right) / 2 - 800^4 \right] \text{K}^4 \]

\[ + 1680 \text{ W/m} = 2517 \text{ W/m}. \]

Noting that \( E_{b3} = \sigma T_3^4 = (1/2) \left[ E_{b1} + E_{b2} \right] \), it follows that

\[ T_3 = \left[ \left( T_1^4 + T_2^4 \right) / 2 \right]^{1/4} = \left[ \left( 1000^4 + 800^4 \right) / 2 \right]^{1/4} \text{K} = 916 \text{ K}. \]
**PROBLEM 13.40**

**KNOWN:** Electrically heated tube suspended in a large vacuum chamber.

**FIND:** (a) Electrical power supplied to the heater, $P_e$, to maintain it at $T_1 = 127^\circ C$, and (b) Compute and plot $P_e$ as a function of tube length $L$ for the range $25 \leq L \leq 250$ mm for tube temperatures of $T_1 = 127, 177$ and $227^\circ C$.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) All surfaces are blackbodies, (2) Tube of area $A_1$ is isothermal, (3) The surroundings are very large compared to the tube.

**ANALYSIS:** (a) Recognize that the surroundings can be represented by the surfaces $A_2$ and $A_3$, which are blackbodies at $T_{sur}$. This situation then permits calculation of necessary shape factors.

The net radiative heat rate from the heater, surface $A_1$, follows from Eq. 13.14, with $T_2 = T_3 = T_{sur}$ as

$$P_e = q_1 = A_1 F_{12} \sigma \left( T_1^4 - T_2^4 \right) + A_1 F_{13} \sigma \left( T_1^4 - T_3^4 \right).$$

Note that $F_{12} = F_{13}$ from symmetry considerations. Write now the summation rule for surface $A_2$

$$F_{21} + F_{22} + F_{23} = 1 \quad \text{or} \quad F_{21} = 1 - F_{23}$$

where $F_{23}$ is determined from Fig. 13.5 using

$$\frac{r_1}{L} = \frac{0.75/2}{0.33} = 1.14 \quad \frac{L}{r_1} = \frac{0.33}{0.75/2} = 0.88$$

giving $F_{23} = 0.37$. Hence $F_{21} = 1 - 0.37 = 0.63$. Using reciprocity, find now $F_{12}$

$$F_{12} = \frac{A_2}{A_1} F_{21} = \frac{\pi D^2/4}{\pi DL} \times F_{21} = \frac{\pi \left( 75^2/4 \right)}{\pi \left( 75 \times 33 \right)} \times 0.63 = 0.36.$$  

Noting that $F_{12} = F_{13}$ and that $T_2 = T_3$, the electrical power using Eq. (1) with numerical values can be written as,

Continued ......
(b) Using the energy balance Eq. (1) of the foregoing analysis with the IHT Radiation Tool-View Factors, Coaxial parallel disks, $P_e$ was computed as a function of $L$ for selected tube temperatures.

As the tube length $L$ increases, the heater power $P_e$ required to maintain the tube at $T_1$ increases. Note that for small values of $L$, say $L < 100$ mm, $P$ is linear with $L$. For larger values of $L$, $P_e$ is not linear with $L$. Why is this so? What is the relationship between $P_e$ and $L$ for $L >> 300$ mm?
**PROBLEM 13.41**

**KNOWN:** Two horizontal, very large parallel plates with prescribed surface conditions and temperatures.

**FIND:** (a) Irradiation to the top plate, $G_1$, (b) Radiosity of the top plate, $J_1$, (c) Radiosity of the lower plate, $J_2$, (d) Net radiative exchange between the plates per unit area of the plates.

**SCHEMATIC:**

![Schematic of two parallel plates with temperatures $T_1 = 1000K$, $\varepsilon_1 = 1$ and $T_2 = 500K$, $\varepsilon_2 = 0.8$]

**ASSUMPTIONS:** (1) Plates are sufficiently large to form a two surface enclosure and (2) Surfaces are diffuse-gray.

**ANALYSIS:**

(a) The irradiation to the upper plate is defined as the radiant flux incident on that surface. The irradiation to the upper plate $G_1$ is comprised of flux emitted by surface 2 and reflected flux emitted by surface 1.

$$G_1 = \varepsilon_2 E_{b2} + \rho_2 E_{b1} = \varepsilon_2 \sigma T_2^4 + (1 - \varepsilon_2) \sigma T_1^4$$

$$G_1 = 0.8 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left(1000 \text{ K}\right)^4 + (1 - 0.8) \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left(500 \text{ K}\right)^4$$

$$G_1 = 2835 \text{ W/m}^2 + 11,340 \text{ W/m}^2 = 14,175 \text{ W/m}^2.$$  

(b) The radiosity is defined as the radiant flux leaving the surface by emission and reflection. For the blackbody surface 1, it follows that

$$J_1 = E_{b1} = \sigma T_1^4 = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left(1000 \text{ K}\right)^4 = 56,700 \text{ W/m}^2.$$  

(c) The radiosity of surface 2 is then,

$$J_2 = \varepsilon_2 E_{b2} + \rho_2 G_2.$$  

Since the upper plate is a blackbody, it follows that $G_2 = E_{b1}$ and

$$J_2 = \varepsilon_2 E_{b1} + \rho_2 E_{b1} = \varepsilon_2 \sigma T_2^4 + (1 - \varepsilon_2) \sigma T_1^4 = 14,175 \text{ W/m}^2.$$  

Note that $J_2 = G_1$. That is, the radiant flux leaving surface 2 ($J_2$) is incident upon surface 1 ($G_1$).

(d) The net radiation heat exchange per unit area can be found by three relations.

$$q_1^* = J_1 - G_1 = (56,700 - 14,175) \text{ W/m}^2 = 42,525 \text{ W/m}^2$$

$$q_{12}^* = J_1 - J_2 = (56,700 - 14,175) \text{ W/m}^2 = 42,525 \text{ W/m}^2$$

The exchange relation, Eq. 13.24, is also appropriate with $\varepsilon_1 = 1$,

$$q_1 = -q_2 = q_{12}^*$$

$$q_1^* = \varepsilon_2 \sigma \left(T_1^4 - T_2^4 \right) = 0.8 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left(1000^4 - 500^4 \right) \text{K}^4 = 42,525 \text{ W/m}^2.$$
PROBLEM 13.42

KNOWN: Dimensions and temperature of a flat-bottomed hole.

FIND: (a) Radiant power leaving the opening, (b) Effective emissivity of the cavity, \( \varepsilon_e \), (c) Limit of \( \varepsilon_e \) as depth of hole increases.

SCHEMATIC:

ASSUMPTIONS: (1) Hypothetical surface \( A_2 \) is a blackbody at 0 K, (2) Cavity surface is isothermal, opaque and diffuse-gray.

ANALYSIS: Approximating \( A_2 \) as a blackbody at 0 K implies that all of the radiation incident on \( A_2 \) from the cavity results (directly or indirectly) from emission by the walls and escapes to the surroundings. It follows that for \( A_2 \), \( \varepsilon_2 = 1 \) and \( J_2 = E_{b2} = 0 \).

(a) From the thermal circuit, the rate of radiation loss through the hole (\( A_2 \)) is

\[
q_1 = (E_{b1} - E_{b2}) \left[ \frac{1 - \varepsilon_1}{\varepsilon_1 A_1} + \frac{1}{A_1 F_{12}} + \frac{1 - \varepsilon_2}{\varepsilon_2 A_2} \right].
\]

Noting that \( F_{21} = 1 \) and \( A_1 F_{12} = A_2 F_{21} \), also that

\[
A_1 = \pi D^2 / 4 + \pi DL = \pi D (D / 4 + L) = \pi (0.006 \text{ m})(0.006 \text{ m} / 4 + 0.024 \text{ m}) = 4.807 \times 10^{-4} \text{ m}^2
\]

\[
A_2 = \pi D^2 / 4 = \pi (0.006 \text{ m})^2 / 4 = 2.827 \times 10^{-5} \text{ m}^2.
\]

Substituting numerical values with \( E_b = \sigma T^4 \), find

\[
q_1 = 5.67 \times 10^{-8} \text{ W / m}^2 \cdot \text{K}^4 \left(1000^4 - 0\right) \frac{\varepsilon_1}{\varepsilon_1 A_1} \left[1 - 0.8 \right] \frac{1}{0.8 \times 4.807 \times 10^{-4} \text{ m}^2} + \frac{1}{2.827 \times 10^{-5} \text{ m}^2} 0
\]

\[
q_1 = 1.580 \text{ W}.
\]

(b) The effective emissivity, \( \varepsilon_e \), of the cavity is defined as the ratio of the radiant power leaving the cavity to that from a blackbody having the same area of the cavity opening and at the temperature of the inner surfaces of the cavity. For the cavity above,

\[
\varepsilon_e = \frac{q_1}{A_2 \sigma T_1^4}
\]

\[
\varepsilon_e = \frac{1.580 \text{ W}}{2.827 \times 10^{-5} \text{ m}^2 \left(5.67 \times 10^{-8} \text{ W / m}^2 \cdot \text{K}^4 \right)(1000 \text{ K})^4} = 0.986.
\]

(c) As the depth of the hole increases, the term \( (1 - \varepsilon_1) / \varepsilon_1 A_1 \) goes to zero such that the remaining term in the denominator of Eq. (1) is \( 1/A_1 F_{12} = 1/A_2 F_{21} \). That is, as \( L \) increases, \( q_1 \to A_2 F_{21} E_{b1} \). This implies that \( \varepsilon_e \to 1 \) as \( L \) increases. For \( L/D = 10 \), one would expect \( \varepsilon_e = 0.999 \) or better.
PROBLEM 13.43

KNOWN: Long V-groove machined in an isothermal block.

FIND: Radiant flux leaving the groove to the surroundings and effective emissivity.

SCHEMATIC:

ASSUMPTIONS: (1) Groove surface is diffuse-gray, (2) Groove is infinitely long, (3) Block is isothermal.

ANALYSIS: Define the hypothetical surface $A_2$ with $T_2 = 0 \, \text{K}$. The net radiation leaving $A_1$, $q_1$, will pass to the surroundings. From the two surface enclosure analysis, Eq. 13.23,

$$q_1 = -q_2 = \frac{\sigma \left( T_1^4 - T_2^4 \right)}{\frac{1 - \varepsilon_1}{\varepsilon_1 A_1} + \frac{1 - \varepsilon_2}{\varepsilon_2 A_2} + A_1 F_{12} + A_2 F_{21}}$$

Recognize that $\varepsilon_2 = 1$ and that from reciprocity, $A_1 F_{12} = A_2 F_{21}$ where $F_{21} = 1$. Hence,

$$q_1 = \frac{\sigma \left( T_1^4 - T_2^4 \right)}{\frac{1 - \varepsilon_1 A_2}{\varepsilon_1 A_1} + 1}$$

With $A_2/A_1 = 2\ell \tan 20^\circ / (2\ell / \cos 20^\circ) = \sin 20^\circ$, find

$$q_1 = \frac{5.67 \times 10^{-8} \, \text{W/m}^2 \cdot \text{K}^4 \left( 1000^4 - 0 \right) \text{K}^4}{(1 - 0.6) / 0.6 \times \sin 20^\circ + 1} = 46.17 \, \text{KW/m}^2.$$

The effective emissivity of the groove follows from the definition given in Problem 13.42 as the ratio of the radiant power leaving the cavity to that from a blackbody having the area of the cavity opening and at the same temperature as the cavity surface. For the present situation,

$$\varepsilon_e = \frac{q_1 \sigma T_1^4}{E_b (T_1)} = \frac{q_1 \sigma T_1^4}{5.67 \times 10^{-8} \, \text{W/m}^2 \cdot \text{K}^4 \left( 1000 \, \text{K} \right)^4} = 0.814.$$

COMMENTS: Note the use of the hypothetical surface defined as black at 0 K. This surface does not emit and absorbs all radiation on it; hence, is the radiant power to the surroundings.
PROBLEM 13.44

KNOWN: Conical cavity formed in an isothermal, opaque, diffuse-gray material of emissivity $\varepsilon$ and temperature $T$.

FIND: Radiant power leaving the opening of the cavity in terms of $T$, $\varepsilon$, $r_o$, and $L$.

SCHEMATIC:

ASSUMPTIONS: (1) Material is opaque, diffuse-gray, and isothermal, (2) Cavity opening is hypothetical black surface at $0$ K.

ANALYSIS: Define $A_o$, the opening of the cavity, as a black surface at $T_o = 0$ K. Considering $A_o$ and $A_c$ as a two surface, diffuse-gray enclosure, the radiant power leaving the cavity opening is

$$ q_{cavity} = -q_o = \left[ E_b(T) - E_b(T_o) \right]/\left[ \frac{1 - \varepsilon}{\varepsilon A_c} + \frac{1}{A_c F_{co}} + \frac{1 - \varepsilon_o}{\varepsilon o A_o} \right] $$

Recognizing that $E_b(T_o) = 0$ and $\varepsilon_o = 1$ and also, using reciprocity,

$$ A_c F_{co} = A_o F_{oc} $$

and from the enclosure, note $F_{oc} = 1$. Hence,

$$ q_{cavity} = \frac{E_b(T)}{\frac{1 - \varepsilon}{\varepsilon A_c} + \frac{1}{A_c F_{co}}} = \frac{\sigma T^4}{\frac{1 - \varepsilon}{\varepsilon A_c} + \frac{1}{A_o F_{oc}}} = \frac{A_o \sigma T^4}{\frac{1 - \varepsilon}{\varepsilon A_c} + 1} \cdot \frac{A_o}{A_c} \cdot 1 \cdot \frac{1}{1 - \varepsilon} $$

(1)

Noting that $A_o = \pi r_o^2$ and $A_c = \pi r_o \left( L^2 + r_o^2 \right)^{1/2}$, find

$$ q_{cavity} = \frac{\pi r_o^2 \cdot \sigma T^4}{\frac{1 - \varepsilon}{\varepsilon} \left[ \left( \frac{L}{r_o} \right)^2 + 1 \right]^{1/2} + 1} < \frac{1}{\varepsilon} $$

COMMENTS: When $L$ increases or $A_o/A_c \ll 1$, the radiant power approaches that of a blackbody according to Eq. (1).
**PROBLEM 13.45**

**KNOWN:** Cavities formed by a cone, cylinder, and sphere having the same opening size \( d \) and major dimension \( L \) with prescribed wall emissivity.

**FIND:** (a) View factor between the inner surface of each cavity and the opening of the cavity; (b) Effective emissivity of each cavity as defined in Problem 13.42, if the walls are diffuse-gray with \( \varepsilon_w \); and (c) Compute and plot \( \varepsilon_e \) as a function of the major dimension-to-opening size ratio, \( L/d \), over the range from 1 to 10 for wall emissivities of \( \varepsilon_w = 0.5, 0.7, \) and 0.9.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Diffuse-gray surfaces, (2) Uniform radiosity over the surfaces.

**ANALYSIS:** (a) Using the summation rule and reciprocity, determine the view factor \( F_{12} \) for each of the cavities considered as a two-surface enclosure.

**Cone:**

\[
F_{12} = \frac{A_2}{A_1} F_{21} = \left( \frac{\pi d^2 / 4}{\pi d / 2 + (d / 2)^2} \right)^{1/2} = \left( \frac{1}{2} \right) \left[ \left( \frac{L}{d} \right)^2 + 1 / 4 \right]^{-1/2}
\]

**Cylinder:**

\[
F_{12} = \frac{A_2}{A_1} F_{21} = \left( \frac{\pi d^2 / 4}{\pi dL + \pi d^2 / 4} \right) = \left( 1 + 4L / d \right)^{-1}
\]

**Sphere:**

\[
F_{12} = \frac{A_2}{A_1} F_{21} = \left( \frac{\pi d^2 / 4}{\pi D^2 - \pi d^2 / 4} \right) = \left( 4D^2 / d^2 - 1 \right)^{-1}
\]

(b) The effective emissivity of the cavity is defined as

\[
\varepsilon_{\text{eff}} = \frac{q_{12}}{q_c}
\]

where \( q_c = A_2 \sigma T_1^4 \) which presumes the opening is a black surface at \( T_1 \) and for the two-surface enclosure,

\[
q_{12} = \frac{\sigma \left( T_1^4 - T_2^4 \right)}{(1 - \varepsilon_1) / \varepsilon_1 A_1 + 1 / A_1 F_{12} + (1 - \varepsilon_2) / \varepsilon_2 A_2} = \frac{A_1 \sigma T_1^4}{(1 - \varepsilon_1) / \varepsilon_1 + 1 / F_{12}}
\]

since \( T_2 = 0K \) and \( \varepsilon_2 = 1 \). Hence, since \( A_2 / A_1 = F_{12} \) for all the cavities, with \( \varepsilon_1 = \varepsilon_w \)

\[
\varepsilon_{\text{eff}} = \frac{1}{F_{12} (1 - \varepsilon_w) / \varepsilon_w + 1}
\]

**Cone:**

\[
\varepsilon_{\text{eff}} = \frac{1}{\left\{ \left( 1/2 \right) \left[ \left( L / d \right)^2 + 1 / 4 \right]^{-1/2} (1 - \varepsilon_w) / \varepsilon_w + 1 \right\}^{1/2}}
\]

Continued …..
**PROBLEM 13.45 (Cont.)**

*Cylinder:*

\[
\varepsilon_{\text{eff}} = \frac{1}{\left[1 + 4L/d \right]^{-1} \left(1 - \varepsilon_w \right) / \varepsilon_w + 1}
\]  

(2)

*Sphere:*

\[
\varepsilon_{\text{eff}} = \frac{1}{\left[4D^2/d^2 - 1 \right]^{-1} \left(1 - \varepsilon_w \right) / \varepsilon_w + 1}
\]  

(3)

(c) Using the *IHT* Workspace with eqs. (1,2,3), the effective emissivity was computed as a function of $L/d$ (cone, cylinder and sphere) for selected wall emissivities. The results are plotted below.

In Fig. 1, $\varepsilon_{\text{eff}}$ is shown as a function of $L/d$ for $\varepsilon_w = 0.7$. For larger $L/d$, the sphere has the highest $\varepsilon_{\text{eff}}$ and the cone the lowest. Figures 2, 3 and 4 illustrate the $\varepsilon_{\text{eff}}$ vs. $L/d$ for each of the cavity types. As expected, $\varepsilon_{\text{eff}}$ increases with increasing wall emissivity.

Note that for the spherical cavity, with $L/d \geq 5$, $\varepsilon_{\text{eff}} > 0.98$ even with $\varepsilon_w$ as low as 0.5. This feature makes the use of spherical cavities for high performance radiometry applications attractive since $\varepsilon_{\text{eff}}$ is not very sensitive to $\varepsilon_w$.

**COMMENTS:** In Fig. 1, intercomparing $\varepsilon_{\text{eff}}$ for the three cavity types, can you give a physical explanation for the results?
PROBLEM 13.46

KNOWN: Very long diffuse, gray, thin-walled tube of 1-m radius contained inside a long black duct of square cross-section, 3.2 m × 3.2 m. Top portion is open as shown schematically.

FIND: (a) Net radiant heat transfer rate per unit length of the tube from the opening, \( q'_1 = q_1 / L \), and the effective emissivity of the opening, \( \varepsilon_{\text{eff}} \), for the condition when \( \theta = 45^\circ \) and (b) Compute and plot \( q'_1 \) and \( \varepsilon_{\text{eff}} \) as a function of \( \theta \) for the range \( 0 \leq \theta \leq 180^\circ \).

SCHEMATIC:

ASSUMPTIONS: (1) Tube is very long compared to its radius \( R \) and duct dimension, (2) Interior of cylinder is diffuse, gray, (3) Interior of the duct is black.

ANALYSIS: (a) Consider the two-surface enclosure formed by the inner surface of the tube, \( A_1 \), and the hypothetical surface formed by the opening, \( A_3 \). The surface \( A_3 \) behaves as a blackbody (\( \varepsilon_3 = 1 \)) at a temperature \( T_3 = T_2 = 300 \text{ K} \). The net heat rate leaving the opening follows from Eq. 13.23.

\[
q_1 = -q_3 = \frac{\sigma \left( T_1^4 - T_2^4 \right)}{(1 - \varepsilon_1) / \varepsilon_1 A_1 + 1 / A_1 F_{13} + (1 - \varepsilon_3) / \varepsilon_3 A_3}
\]

The view factor \( F_{13} \) can be determined from the reciprocity relation recognizing that \( F_{31} = 1 \).

\[
F_{13} = A_3 F_{31} / A_1 = 1.414L \times 1 / 4.712L = 0.300
\]

where the areas \( A_1 \) and \( A_3 \) are, with \( \theta = 45^\circ \),

\[
A_1 = 2R (\pi - \theta) L = 2 \times 1 \text{ m} \left[ \pi - 45 \times \pi / 180 \right] \times L = 4.712L
\]

\[
A_3 = 2R \sin \theta L = 2 \times 1 \text{ m} \sin 45^\circ \times L = 1.414L
\]

Substituting numerical values, find

\[
q_1 = -q_3 = \frac{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left(1000^4 - 300^4 \right) \text{K}^4}{(1 - 0.1) / \left(0.1 \times 4.712L\right) + 1 / \left(4.712L \times 0.300\right) + 0}
\]

\[q_1 / L = -q_3 / L = 21,487 \text{ W/m} \]

Continued ….
PROBLEM 13.46 (Cont.)

The effective emissivity of the opening is the ratio of the radiant power leaving the opening to that of a blackbody having the area of the opening \( A_3 \) and a temperature of the inner surface of the cavity \( T_1 \).

\[
\varepsilon_{\text{eff}} = \frac{q_1}{A_3 \sigma T_1^3} = \frac{q_1 / L}{(A_3 / L) \sigma T_1^4}
\]

\[
\varepsilon_{\text{eff}} = \frac{21,487 \text{ W/m}}{1.414 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (1000 \text{ K})^4} = 0.268
\]

(b) Using the foregoing equations, Eqs. (1-5), in the IHT workspace, \( q_1' = q_1 / L \) and \( \varepsilon_{\text{eff}} \) as a function of \( \theta \) were computed and are plotted below.

Note that \( q_1' = 0 \) when \( \theta = 0^\circ \) since the tube is closed and no power leaves the tube. At \( \theta = 180^\circ \), the area of the tube has been reduced to zero and hence, \( q_1' = 0 \). For small values of \( \theta \), \( \varepsilon_{\text{eff}} \) is highest and decreases as \( \theta \) increases, to the limit \( \varepsilon_{\text{eff}} = \varepsilon_1 = 0.1 \).
**PROBLEM 13.47**

**KNOWN:** Temperature, emissivity and dimensions of a rectangular fin array radiating to deep space.

**FIND:** (a) Rate of radiation transfer per unit length from a unit section to space, (b) Effect of emissivity on heat rejection.

**SCHEMATIC:**

![Diagram of a rectangular fin array](image)

**ASSUMPTIONS:** (1) Diffuse/gray surface behavior, (2) Length of array (normal to page) is much larger than W and L, (3) Isothermal surfaces.

**ANALYSIS:** (a) Since the sides and base of the U-section have the same temperature and emissivity, they can be treated as a single surface and the U-section becomes a two-surface enclosure. Deep space may be represented by the hypothetical surface $A'_3$, which acts as a blackbody at absolute zero temperature. From Eq. (13.23), with $T_1 = T_2 = T$ and $\varepsilon_1 = \varepsilon_2 = \varepsilon$,

$$q'_{(1,2)3} = \frac{\sigma (T^4 - T_3^4)}{1 - \varepsilon} + \frac{1}{A'_{(1,2)} F_{(1,2)3}} + \frac{1 - \varepsilon}{\varepsilon A'_3}$$

where $A'_{(1,2)} = 2L + W$, $A'_3 = W$, $A'_{(1,2)} F_{(1,2)3} = A'_3 F_{3(1,2)} = W$. Hence,

$$q'_{(1,2)3} = \frac{\sigma T^4}{1 - \varepsilon} + \frac{1}{W} + \frac{1 - \varepsilon}{\varepsilon W}$$

$$q'_{(1,2)3} = \frac{5.67 \times 10^{-8} W/m^2 \cdot K^4 (325 K)^4}{1 - 0.70\frac{0.70 (0.275m)}{0.025m}} = 15.2 W/m$$

(b) For $\varepsilon = 0.7$ emission from the base of the U-section is $q'_b = \varepsilon A'_1 \sigma T^4 = 0.7 \times 0.025m \
\times 5.67 \times 10^{-8} W/m^2 \cdot K^4 (325 K)^4 = 11.1 W/m$. The effect of $\varepsilon$ on $q'_{(1,2)3}$ and $q'_b$ is shown as follows.

Continued …..
The effect of the fins on heat transfer enhancement increases with decreasing emissivity.

**COMMENTS:** Note that, if the surfaces behaved as blackbodies ($\varepsilon_1 = \varepsilon_2 = 1.0$), the U-section becomes a blackbody cavity for which heat rejection is simply $A_3' E_b(T) = q'_{b}$. Hence, it is no surprise that the $q'_b \rightarrow q'(1,2)3$ as $\varepsilon \rightarrow 1$ in the foregoing figure. For $\varepsilon = 1$, no enhancement is provided by the fins.
**PROBLEM 13.48**

**KNOWN:** Power dissipation of electronic device and thermal resistance associated with attachment to inner wall of a cubical container. Emissivity of outer surface of container and wall temperature of service bay.

**FIND:** Temperatures of cubical container and device.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state, (2) Device and container are isothermal, (3) Heat transfer from the container is exclusively by radiation exchange with bay (small surface in a large enclosure), (4) Container surface may be approximated as diffuse/gray.

**ANALYSIS:** From Eq. (13.27)

\[ P_e = q = \sigma \left( 6W^2 \right) \epsilon_c \left( T_{s,c}^4 - T_{\text{sur}}^4 \right) \]

\[ T_{s,c} = \left[ \frac{q}{\sigma \left( 6W^2 \right) \epsilon_c \left( T_{\text{sur}}^4 \right)} + T_{s,c}^4 \right]^{1/4} \]

\[ T_{s,c} = \left[ \frac{50 \text{ W}}{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times 6(0.12 \text{ m})^2 \times 0.8} + (150 \text{ K})^4 \right]^{1/4} = 339.4 \text{ K} = 66.4^\circ \text{C} \]

With \( q = \left( T_d - T_{s,c} \right) / R_t \),

\[ T_d = q R_t + T_{s,c} = 50 \text{ W} \times 0.1 \text{ K/W} + 66.4^\circ \text{C} = 71.4^\circ \text{C} \]

**COMMENTS:** If the temperature of the device is too large to insure reliable operation, it may be reduced by increasing \( \epsilon_c \) or \( W \).
PROBLEM 13.49

KNOWN: Long, thin-walled horizontal tube with radiation shield having an air gap of 10 mm. Emissivities and temperatures of surfaces are prescribed.

FIND: Radiant heat transfer from the tube per unit length.

SCHEMATIC:

ASSUMPTIONS: (1) Tube and shield are very long, (2) Surfaces at uniform temperatures, (3) Surfaces are diffuse-gray.

ANALYSIS: The long tube and shield form a two surface enclosure, and since the surfaces are diffuse-gray, the radiant heat transfer from the tube, according to Eq. 13.23, is

\[ q_{12} = \frac{\sigma (T_1^4 - T_2^4)}{\frac{1-\varepsilon_1}{A_1} + \frac{1-\varepsilon_2}{A_2}} \]  

By inspection, \( F_{12} = 1 \). Note that

\[ A_1 = \pi D_1 \ell \quad \text{and} \quad A_2 = \pi D_2 \ell \]

where \( \ell \) is the length of the tube and shield. Dividing Eq. (1) by \( \ell \), find the heat rate per unit length,

\[ \dot{q}_{12} = \frac{q_{12}}{\ell} = \frac{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K} \left[ (273+120)^4 - (273+35)^4 \right]}{0.8\pi \left( 100 \times 10^{-3} \text{ m} \right) + \pi \left( 100 \times 10^{-3} \text{ m} \right) \times 1 + 0.1\pi \left( 120 \times 10^{-3} \text{ m} \right)} \]

\[ \dot{q}_{12} = \frac{842.3 \text{ W/m}^2}{(0.7958 + 3.183 + 23.87) \text{ m}^{-1}} = 30.2 \text{ W/m} \]

COMMENTS: Recognize that convective heat transfer would be important in this annular air gap. Suitable correlations to estimate the heat transfer coefficient are given in Chapter 9.
PROBLEM 13.50

KNOWN: Long electrical conductor with known heat dissipation is cooled by a concentric tube arrangement.

FIND: Surface temperature of the conductor.

SCHEMATIC:

ASSUMPTIONS: (1) Surfaces are diffuse-gray, (2) Conductor and cooling tube are concentric and very long, (3) Space between surfaces is evacuated.

ANALYSIS: The heat transfer by radiation exchange between the conductor and the concentric, cooled cylinder is given by Eq. 13.25. For a unit length,

\[
q_{12} = \frac{q_{12}}{\ell} = \sigma \cdot 2\pi \eta \left( T_1^4 - T_2^4 \right) \left[ \frac{1}{\varepsilon_1} + \frac{1 - \varepsilon_2}{\varepsilon_2} \left( \frac{\eta}{r_2} \right) \right]
\]

where \( A_1 = 2\pi \eta \cdot \ell \). Solving for \( T_1 \) and substituting numerical values, find

\[
T_1 = \left\{ T_2^4 + \frac{q_{12}}{\sigma \cdot 2\pi \eta} \left[ \frac{1}{\varepsilon_1} + \frac{1 - \varepsilon_2}{\varepsilon_2} \left( \frac{\eta}{r_2} \right) \right] \right\}^{1/4}
\]

\[
T_1 = \left\{ (27 + 273)^4 K^4 + \frac{6 \text{ W/m}}{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times 2\pi (0.005 \text{m}) \left[ \frac{1}{0.6} + \frac{1 - 0.9}{0.9} \left( \frac{5}{25} \right) \right]} \right\}^{1/4}
\]

\[
T_1 = \left\{ (300 \text{ K})^4 + 3.368 \times 10^9 \text{K}^4 [1.667 + 0.00222] \right\}^{1/4}
\]

\[
T_1 = 342.3 \text{ K} = 69^\circ \text{C}.
\]

COMMENTS: (1) Note that Eq. (1) implies that \( F_{12} = 1 \). From Eq. (2) by comparison of the second term in the brackets involving \( \varepsilon_2 \), note that the influence of \( \varepsilon_2 \) is small. This follows since \( r_1 << r_2 \).
PROBLEM 13.51

KNOWN: Arrangement for direct thermophotovoltaic conversion of thermal energy to electrical power.

FIND: (a) Radiant heat transfer between the inner and outer surface per unit area of the outer surface, (b) Power generation per unit outer surface area if semiconductor has 10% conversion efficiency for radiant power in the 0.6 to 2.0 µm range.

SCHEMATIC:

ASSUMPTIONS: (1) Surfaces are diffuse-gray, (2) Surfaces approximate long, concentric cylinder, two-surface enclosure with negligible end effects.

ANALYSIS: (a) For this two-surface enclosure, the net radiation exchange per unit area of the outer surface is,

\[
q_{io} = \frac{A_i}{A_o} \left( \frac{\sigma (T_i^4 - T_o^4)}{1 + \frac{1 - \varepsilon_o}{\varepsilon_i} \left( \frac{\eta_i}{r_o} \right)} \right)
\]

and since \( A_i/A_o = 2\pi r_i/2\pi r_o = \eta_i/r_o \), the heat flux at surface \( A_o \) is

\[
q_{io} = \left( \frac{0.0125}{0.190} \right) \left( \frac{5.67 \times 10^{-8} W/m^2 \cdot K^4 \left( 1948^4 - 293^4 \right) K^4}{1 + \frac{1 - 0.5}{0.9} \left( \frac{0.125}{0.190} \right)} \right) = 45.62 kW/m^2.
\] (2)

(b) The power generation per unit area of surface \( A_o \) can be expressed as

\[
P_e^o = \eta_e \cdot G_{abs} (0.6 \rightarrow 2.0 \mu m)
\]

where \( \eta_e \) is the semiconductor conversion efficiency and \( G_{abs} (0.6 \rightarrow 2.0 \mu m) \) represents the absorbed irradiation on \( A_o \) in the prescribed wavelength interval. The total absorbed irradiation is \( G_{abs,t} = q_{io}/A_o \) and has the spectral distribution of a blackbody at \( T_i \) since \( T_o^4 \ll T_i^4 \) and \( A_i \) is gray. Hence, we can write Eq. (3) as

\[
P_e^o = \eta_e \cdot \left( q_{io}/A_o \right) \left[ F(0 \rightarrow 2 \mu m) - F(0 \rightarrow 0.6 \mu m) \right].
\] (4)

From Table 12.2: \( \lambda T = 2 \times 1948 = 3896 \mu m-K, \ F(0-\lambda T) = 0.461; \ \lambda T = 0.6 \times 1948 = 1169 \mu m-K, \ F(0-\lambda T) = 0.0019 \). Hence

\[
P_e^o = 0.1 \left( 45.62 kW/m^2 \right) \left[ 0.461 - 0.0019 \right] = 2.09 kW/m^2.
\] (5)

That is, the unit produces 2.09 kW per unit area of the outer surface.
PROBLEM 13.52

KNOWN: Temperatures and emissivities of spherical surfaces which form an enclosure.

FIND: Evaporation rate of oxygen stored in inner container.

SCHEMATIC:

![Diagram showing liquid oxygen inside a container with outer container and vents labeled with dimensions and temperatures]  
- $D_i = 0.8\,m$  
- $T_i = 95\,K$  
- $\varepsilon_i = 0.05$  
- $D_o = 1.2\,m$  
- $T_o = 280\,K$  
- $\varepsilon_o = 0.05$

PROPERTIES: Oxygen (given): $h_{fg} = 2.13 \times 10^5 \,\text{J/kg}$.

ASSUMPTIONS: (1) Opaque, diffuse-gray surfaces, (2) Evacuated space between surfaces, (3) Negligible heat transfer along vent and support assembly.

ANALYSIS: From an energy balance on the inner container, the net radiation heat transfer to the container may be equated to the evaporative heat loss

$$q_{oi} = \dot{m}h_{fg}.$$  

Substituting from Eq. (13.26), where $q_{oi} = -q_{io}$ and $F_{io} = 1$

$$\dot{m} = \frac{-\sigma \left( \pi D_i^2 \right) \left( T_i^4 - T_o^4 \right)}{h_{fg} \left[ \frac{1}{\varepsilon_i} + 1 - \varepsilon_0 \left( \frac{r_i}{r_o} \right)^2 \right]}$$

$$\dot{m} = \frac{-5.67 \times 10^{-8} \,\text{W/m}^2\cdot\text{K}^4 \times \pi (0.8\,m)^2 \left( 95^4 - 280^4 \right) \,\text{K}^4}{2.13 \times 10^5 \,\text{J/kg} \left[ \frac{1}{0.05} + \frac{0.95}{0.05} \left( \frac{0.4}{0.6} \right)^2 \right]}$$

$$\dot{m} = 1.14 \times 10^{-4} \,\text{kg/s}.$$

COMMENTS: This loss could be reduced by insulating the outer surface of the outer container and/or by inserting a radiation shield between the containers.
PROBLEM 13.53

KNOWN: Emissivities, diameters and temperatures of concentric spheres.

FIND: (a) Radiation transfer rate for black surfaces.  (b) Radiation transfer rate for diffuse-gray surfaces, (c) Effects of increasing the diameter and assuming blackbody behavior for the outer sphere. (d) Effect of emissivities on net radiation exchange.

SCHEMATIC:

ASSUMPTIONS: (1) Blackbody or diffuse-gray surface behavior.

ANALYSIS: (a) Assuming blackbody behavior, it follows from Eq. 13.13

\[
q_{12} = A_1 F_{12} \sigma \left( T_1^2 - T_2^2 \right) = \pi (0.8 \text{ m})^2 \left( 1 \right) 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left[ (400 \text{ K})^4 - (300 \text{ K})^4 \right] = 1995 \text{ W.} <
\]

(b) For diffuse-gray surface behavior, it follows from Eq. 13.26

\[
q_{12} = \frac{\sigma A_1 \left( T_1^4 - T_2^4 \right)}{\frac{1}{\varepsilon_1} + \frac{1 - \varepsilon_2}{\varepsilon_2} \left( \frac{r_1}{r_2} \right)^2} = \frac{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (0.8 \text{ m})^2 \left[ 400^4 - 300^4 \right] \text{K}^4}{1 \left( 0.5 + \frac{1 - \varepsilon_2}{\varepsilon_2} \left( \frac{0.4}{0.6} \right)^2 \right)} = 191 \text{ W.} <
\]

(c) With D_2 = 20 m, it follows from Eq. 13.26

\[
q_{12} = \frac{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K} \pi (0.8 \text{ m})^2 \left[ \left( 400 \text{ K} \right)^4 - \left( 300 \text{ K} \right)^4 \right]}{1 \left( 0.5 + \frac{1 - \varepsilon_2}{\varepsilon_2} \left( \frac{0.4}{10} \right)^2 \right)} = 983 \text{ W.} <
\]

With \( \varepsilon_2 = 1 \), instead of 0.05, Eq. 13.26 reduces to Eq. 13.27 and

\[
q_{12} = \sigma A_1 \varepsilon_1 \left( T_1^4 - T_2^4 \right) = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (0.8 \text{ m})^2 \left( 0.5 \right) \left[ (400 \text{ K})^4 - (300 \text{ K})^4 \right] = 998 \text{ W.} <
\]

Continued …..
PROBLEM 13.53 (Cont.)

(d) Using the *IHT Radiation* Tool Pad, the following results were obtained

![Graph showing radiation heat rate vs. emissivity]

Net radiation exchange increases with $\varepsilon_1$ and $\varepsilon_2$, and the trends are due to increases in emission from and absorption by surfaces 1 and 2, respectively.

**COMMENTS:** From part (c) it is evident that the actual surface emissivity of a large enclosure has a small effect on radiation exchange with small surfaces in the enclosure. Working with $\varepsilon_2 = 1.0$ instead of $\varepsilon_2 = 0.05$, the value of $q_{12}$ is increased by only $(998 - 983)/983 = 1.5\%$. In contrast, from the results of (d) it is evident that the surface emissivity $\varepsilon_2$ of a small enclosure has a large effect on radiation exchange with interior objects, which increases with increasing $\varepsilon_1$. 
PROBLEM 13.54

KNOWN: Two radiation shields positioned in the evacuated space between two infinite, parallel planes.

FIND: Steady-state temperature of the shields.

SCHEMATIC:

ASSUMPTIONS: (1) All surfaces are diffuse-gray and (2) All surfaces are parallel and of infinite extent.

ANALYSIS: The planes and shields can be represented by a thermal circuit from which it follows that

\[
q_1^* = -q_2^* = \frac{\sigma (T_1^4 - T_2^4)}{R_1^* + R_2^* + R_3^*} = \frac{\sigma (T_{s1}^4 - T_{s2}^4)}{R_1^*} = \frac{\sigma (T_{s1}^4 - T_{s2}^4)}{R_2^*} = \frac{\sigma (T_{s2}^4 - T_2^4)}{R_3^*}.
\]

Since all the emissivities involved are equal, 
\[
R_1^* = \frac{A_1}{A_1 + A_2} = 1 = R_2^* = R_3^*,
\]

so that

\[
T_{s1}^4 = T_1^4 - \frac{R_1^*}{R_1^* + R_2^* + R_3^*} (T_1^4 - T_2^4) = T_1^4 - \left(\frac{1}{3}\right) (T_1^4 - T_2^4)
\]

\[
T_{s1}^4 = (600 \text{ K})^4 - (1/3) (600^4 - 325^4) \text{K}^4 \quad T_{s1} = 548 \text{ K}
\]

\[
T_{s2}^4 = T_2^4 + \frac{R_3^*}{R_1^* + R_2^* + R_3^*} (T_1^4 - T_2^4) = T_2^4 + (1/3) (T_1^4 - T_2^4)
\]

\[
T_{s2}^4 = (325 \text{ K})^4 + (1/3) (600^4 - 325^4) \text{K}^4 \quad T_{s2} = 474 \text{ K}
\]
PROBLEM 13.55

KNOWN: Two large, infinite parallel plates that are diffuse-gray with temperatures and emissivities of $T_1$ and $\varepsilon_1$ and $T_2$ and $\varepsilon_2$.

FIND: Show that the ratio of the radiation transfer rate with multiple shields, $N$, of emissivity $\varepsilon_s$ to that with no shields, $N = 0$, is

$$\frac{q_{12,N}}{q_{12,0}} = \frac{\left[1/\varepsilon_1 + 1/\varepsilon_2 - 1\right]}{\left[1/\varepsilon_1 + 1/\varepsilon_2 - 1\right] + N\left[2/\varepsilon_s - 1\right]}$$

where $q_{12,N}$ and $q_{12,0}$ represent the radiation heat rate with $N$ and $N = 0$ shields, respectively.

SCHEMATIC:

ASSUMPTIONS: (1) Plane infinite planes with diffuse-gray surfaces and uniform radiosities, and (2) Shield has negligible thermal conduction resistance.

ANALYSIS: Representing the parallel plates by the resistance network shown above for the “no-shield” condition, $N = 0$, with $F_{12} = 1$, the heat rate per unit area follows from Eq. 13.24 (see also Fig. 13.11) as

$$q_{12,0} = \frac{E_{b1} - E_{b2}}{1/\varepsilon_1 + 1/\varepsilon_2 - 1} \quad (1)$$

With the addition of each shield as shown in the schematic above, three resistance elements are added to the network: two surface resistances, $(1 - \varepsilon_s)/\varepsilon_s$, and one space resistance, $1/F_{ij} = 1$. Hence, for the “$N$-shield” condition,

$$q_{12,N} = \frac{E_{b1} - E_{b2}}{1/\varepsilon_1 + 1/\varepsilon_2 - 1} + N \frac{2(1 - \varepsilon_s)/\varepsilon_s + 1}{2} \quad (2)$$

The ratio of the heat rates is obtained by dividing Eq. (2) by Eq. (1),

$$\frac{q_{12,N}}{q_{12,0}} = \frac{\left[1/\varepsilon_1 + 1/\varepsilon_2 - 1\right]}{\left[1/\varepsilon_1 + 1/\varepsilon_2 - 1\right] + N\left[2/\varepsilon_s - 1\right]}$$

COMMENTS: Can you derive an expression to determine the temperature difference across pairs of the $N$-shields?
PROBLEM 13.56

KNOWN: Emissivities of two large, parallel surfaces.

FIND: Heat shield emissivity needed to reduce radiation transfer by a factor of 10.

SCHEMATIC:

\[ \begin{array}{c}
\text{Radiation shield} \\
\uparrow \quad \epsilon_1 = 0.8 \\
\downarrow \\
\epsilon_2 = 0.8 \\
\end{array} \]

ASSUMPTIONS: (a) Diffuse-gray surface behavior, (b) Negligible conduction resistance for shield, (c) Same emissivity on opposite sides of shield.

ANALYSIS: For this arrangement, \( F_{13} = F_{32} = 1 \).

Without \((wo)\) the shield, it follows from Eq. 13.24,

\[
(q_{12})_{wo} = \frac{A_T \sigma \left( T_1^4 - T_2^4 \right)}{1 + \frac{1}{\epsilon_1} - \frac{1}{\epsilon_2}}.
\]

With \((w)\) the shield it follows from Eq. 13.28,

\[
(q_{12})_w = \frac{A_T \sigma \left( T_1^4 - T_2^4 \right)}{1 + \frac{1}{\epsilon_1} + \frac{2}{\epsilon_2} - \frac{2}{\epsilon_3}}.
\]

Hence, the heat rate ratio is

\[
\frac{(q_{12})_w}{(q_{12})_{wo}} = 0.1 = \frac{1 + \frac{1}{\epsilon_1} - \frac{1}{\epsilon_2}}{1 + \frac{1}{\epsilon_1} + \frac{2}{\epsilon_2} - \frac{2}{\epsilon_3}} = \frac{1 + \frac{1}{\epsilon_1} - \frac{1}{\epsilon_2}}{1 + \frac{1}{\epsilon_1} + \frac{2}{\epsilon_2} - \frac{2}{\epsilon_3}}.
\]

Solving, find

\[ \epsilon_3 = 0.138. \]

COMMENTS: The foregoing result is independent of \( T_1 \) and \( T_2 \). It is only necessary that the temperatures be maintained at fixed values, irrespective of whether or not the shield is in place.
PROBLEM 13.57

KNOWN: Surface emissivities of a radiation shield inserted between parallel plates of prescribed temperatures and emissivities.

FIND: (a) Effect of shield orientation on radiation transfer, (b) Effect of shield orientation on shield temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Diffuse-gray surface behavior, (2) Shield is isothermal.

ANALYSIS: (a) On a unit area basis, the network representation of the system is

Hence the total radiation resistance,

is independent of orientation. Since \( q = (E_{b1} - E_{b2})/R \), the heat transfer rate is independent of orientation.

(b) Considering that portion of the circuit between \( E_{b1} \) and \( E_{bs} \), it follows that

Hence,

It follows that, since \( E_{bs} \) increases with decreasing \( f(\varepsilon_s) \) and \((1 - 2\varepsilon_s)/2\varepsilon_s < (1 - \varepsilon_s)/\varepsilon_s\), \( E_{bs} \) is larger when the high emissivity \((2\varepsilon_s)\) side faces plate 1. Hence \( T_s \) is larger for case (b).
PROBLEM 13.58

KNOWN: End of propellant tank with radiation shield is subjected to solar irradiation in space environment.

FIND: (a) Temperature of the shield, $T_s$, and (b) Heat flux to the tank, $q_t^* \left( \text{W} / \text{m}^2 \right)$.

SCHEMATIC:

ASSUMPTIONS: (1) All surfaces are diffuse-gray, (2) View factor between shield and tank is unity, $F_{st} = 1$, (3) Space surroundings are black at 0 K, (4) Resistance of shield for conduction is negligible.

ANALYSIS: (a) Perform a radiation balance on the shield. From the schematic,

$$
\alpha_s G_s - \varepsilon_1 E_b(T_s) - q_{st}^* = 0
$$

(1)

where $q_{st}^*$ is the net heat exchange between the shield and the tank. Considering these two surfaces as large, parallel planes, from Eq. 13.24,

$$
q_{st}^* = \sigma \left( T_s^4 - T_t^4 \right) / \left[ \frac{1}{\varepsilon_2} + \frac{1}{\varepsilon_1} - 1 \right].
$$

(2)

Substituting $q_{st}^*$ from Eq. (2) into Eq. (1), find

$$
\alpha_s G_s - \varepsilon_1 \sigma T_s^4 - \sigma \left( T_s^4 - T_t^4 \right) / \left[ \frac{1}{\varepsilon_2} + \frac{1}{\varepsilon_1} - 1 \right] = 0.
$$

Solving for $T_s$, find

$$
T_s = \left[ \frac{\alpha_s G_s + \sigma T_t^4 / \left[ \frac{1}{\varepsilon_2} + \frac{1}{\varepsilon_1} - 1 \right]}{\sigma \left( \varepsilon_1 + 1 / \left[ \frac{1}{\varepsilon_2} + \frac{1}{\varepsilon_1} - 1 \right] \right)} \right]^{1/4}.
$$

Since the shield is diffuse-gray, $\alpha_s = \varepsilon_1$ and then

$$
T_s = \left[ \frac{0.05 \times 1250 \text{ W/m}^2 + \sigma (100)^4 \left[ \frac{1}{1/0.05 + 1/0.1 - 1} \right]}{\sigma \left( 0.05 + 1 / \left[ 1/0.05 + 1/0.1 - 1 \right] \right)} \right]^{1/4} = 338 \text{ K}.
$$

(b) The heat flux to the tank can be determined from Eq. (2),

$$
q_t^* = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot K^4 \left( 338^4 - 100^4 \right) K^4 / \left[ 1/0.05 + 1/0.1 - 1 \right] = 25.3 \text{ W/m}^2.
$$
PROBLEM 13.59

KNOWN: Black panel at 77 K in large vacuum chamber at 300 K with radiation shield having \( \varepsilon = 0.05 \).

FIND: Net heat transfer by radiation to the panel.

SCHEMATIC:

ASSUMPTIONS: (1) Chamber is large compared to shield, (2) Shape factor between shield and plate is unity, (3) Shield is diffuse-gray, (4) Shield is thin, negligible thermal conduction resistance.

ANALYSIS: The arrangement lends itself to a network representation following Figs. 13.10 and 13.11.

Noting that \( F_{2s} = F_{s1} = 1 \), and that \( A_2 F_{2s} = A_s F_{s2} \), the heat rate is

\[
q_1 = (E_{b2} - E_{b1})/\Sigma R_1 = \sigma \left( T_2^4 - T_1^4 \right) \left[ \frac{1}{A_s} + 2 \left( \frac{1 - \varepsilon_s}{\varepsilon_s A_s} \right) + \frac{1}{A_s} \right].
\]

Recognizing that \( A_s = A_1 \) and multiplying numerator and denominator by \( A_1 \) gives

\[
q_1 = A_1 \sigma \left( T_2 - T_1^4 \right) \left[ 2 + 2 \left( \frac{1 - \varepsilon_s}{\varepsilon_s} \right) \right].
\]

Substituting numerical values, find

\[
q_1 = \frac{\pi 0.1^2 m^2}{4} \times 5.67 \times 10^{-8} W/m^2 \cdot K^4 \left( 300^4 - 77^4 \right) K^4 \left[ 2 + 2 \left( \frac{1 - 0.05}{0.05} \right) \right],
\]

\[
q_1 = 89.8 \text{ mW}.
\]

COMMENTS: In using the network representation, be sure to designate direction of the net heat rate. In this situation, we have shown \( q_1 \) as the net rate into the surface \( A_1 \). The temperature of the shield, \( T_s = 253 \text{ K} \), follows from the relation

\[
q_1 = (E_{bs} - E_{b1})/\left[ \frac{1 - \varepsilon_s}{\varepsilon_s A_s} + \frac{1}{A_1 F_{s1}} \right].
\]
**PROBLEM 13.60**

**KNOWN:** Dense cryogenic piping array located close to furnace wall.

**FIND:** Number of radiation shields, N, to be installed such that the temperature of the shield closest to the array, \( T_{s,N} \), is less than 30°C.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) The ice-covered dense piping array approximates a plane surface, (2) Piping array and furnace wall can be represented by infinite parallel plates, (3) Surfaces are diffuse-gray, and (4) Convection effects are negligible.

**ANALYSIS:** Treating the piping array and furnace wall as infinite parallel plates, the net heat rate by radiation exchange with N shields of identical emissivity, \( \varepsilon_s \), on both sides follows from extending the network of Fig. 13.12 to account for the resistances of N shields. (See Problem 13.14 (S).) For each shield added, two surface resistances and one space resistance are added,

\[
q_{fp} = \frac{\sigma \left(T_f^4 - T_p^4\right)}{\left[1/\varepsilon_f + 1/\varepsilon_p - 1\right] + N \left[2/\varepsilon_s - 1\right]} \tag{1}
\]

where \( \sigma = 5.67 \times 10^{-8} \text{ W/m}^2\cdot\text{K}^4 \). The requirement that the N-th shield (next to the piping array) has a temperature \( T_{s,N} \leq 30°C \) will be satisfied when

\[
q_{fp} \leq \frac{\sigma \left(T_{s,N}^4 - T_p^4\right)}{\left[1/\varepsilon_s + 1/\varepsilon_p - 1\right]} \tag{2}
\]

Using the foregoing equations in the IHT workspace, find that \( T_{s,N} = 30°C \) when \( N = 8.60 \). So that \( T_{s,N} \) is less than 30°C, the number of shields required is

\[ N = 9 \]

**COMMENTS:** Note that when \( N = 0 \), Eq. (1) reduces to the case of two parallel plates. Show for the case with one shield, \( N = 1 \), that Eq. (1) is identical to Eq. 13.28.
PROBLEM 13.61

KNOWN: Concentric tube arrangement with diffuse-gray surfaces.

FIND: (a) Heat gain by the cryogenic fluid per unit length of the inner tube (W/m), (b) Change in heat gain if diffuse-gray shield with $\varepsilon_s = 0.02$ is inserted midway between inner and outer surfaces.

SCHEMATIC:

ASSUMPTIONS: (1) Surfaces are diffuse-gray, (2) Space between tubes is evacuated.

ANALYSIS: (a) For the no shield case, the thermal circuit is shown at right. It follows that the net heat gain per unit tube length is

$$-q_1' = \frac{q_{oi}}{L} = \left( E_{bo} - E_{bi} \right) / \left[ \frac{1 - \varepsilon_o}{\varepsilon_o D_o} + \frac{1}{\pi D_i F_{io}} + \frac{1 - \varepsilon_i}{\varepsilon_i \pi D_i} \right]$$

where $A = \pi DL$. Note that $F_{io} = 1$ and $E_b = \sigma T^4$ giving

$$-q_1' = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left( 300^4 - 77^4 \right) \text{K}^4 / \left[ \frac{1 - 0.05}{0.05\pi \times 50 \times 10^{-3}} + \frac{1}{\pi 20 \times 10^{-3} \times 1} + \frac{1 - 0.02}{0.02\pi \times 20 \times 10^{-3}} \right] \text{m}^{-1}$$

$$-q_1' = 457 \text{ W/m}^2 / [121.0 + 15.9 + 779.8] \text{m}^{-1} = 0.501 \text{ W/m}.$$  

(b) For the with shield case, the thermal circuit will include three additional resistances.

From the network, it follows that $-q_i = (E_{bo} - E_{bi}) / \Sigma R_i$. With $F_{is} = F_{so} = 1$, find

$$-q_i' = 457 \text{ W/m}^2 / \left[ \frac{121.0 + 1891.3 + 15.9 + 779.8}{0.251 \text{ W/m}} \right] \text{m}^{-1}$$

$$-q_i' = 457 \text{ W/m}^2 / [121.0 + 9.1 + 891.3 + 15.9 + 779.8] \text{m}^{-1} = 0.251 \text{ W/m}.$$  

The change (percentage) in heat gain per unit length of the tube as a result of inserting the radiation shield is

$$\frac{q_{i,s}' - q_{i,ns}'}{q_{i,ns}} \times 100 = \frac{0.251 - 0.501}{0.501} \times 100 = -49\%.$$
**PROBLEM 13.62**

**KNOWN:** Heated tube with radiation shield whose exterior surface is exposed to convection and radiation processes.

**FIND:** Operating temperature for the tube under the prescribed conditions.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) No convection in space between tube and shield, (3) Surroundings are large compared to the shield and are isothermal, (4) Tube and shield are infinitely long, (5) Surfaces are diffuse-gray, (6) Shield is isothermal.

**ANALYSIS:** Perform an energy balance on the shield.

\[
\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0
\]

\[
q_{12} - q_{\text{conv}} - q_{\text{rad}} = 0
\]

where \(q_{12}\) is the net radiation exchange between the tube and inner surface of the shield, which from Eq. 13.25 is,

\[
q_{12} = \frac{A_1 \sigma (T_1^4 - T_2^4)}{1 + \frac{1 - \varepsilon_{2,i}}{\varepsilon_{2,i}} \frac{D_1}{D_2}}
\]

Using appropriate rate equations for \(q_{\text{conv}}\) and \(q_{\text{rad}}\), the energy balance is

\[
\frac{A_1 \sigma (T_1^4 - T_2^4)}{1 + \frac{1 - \varepsilon_{2,i}}{\varepsilon_{2,i}} \frac{D_1}{D_2}} - h A_2 (T_2 - T_\infty) - \varepsilon_{2,o} A_2 \sigma (T_2^4 - T_{\text{sur}}^4) = 0
\]

where \(\varepsilon_1 = 1\). Substituting numerical values, with \(A_1/A_2 = D_1/D_2\), and solving for \(T_1\),

\[
\frac{(20/60) \times 5.67 \times 10^{-8} \text{ W/ m}^2 \cdot \text{K}^4 \left(T_1^4 - 315^4\right) K^4}{1 + (1 - 0.01/0.01)(20/60)} - 10 \text{ W/ m}^2 \cdot \text{K} (315 - 300) K - 0.1 \times 5.67 \times 10^{-8} \text{ W/ m}^2 \cdot \text{K}^4 \left(315^4 - 290^4\right) K^4 = 0
\]

\(T_1 = 745 \text{ K} = 472^\circ \text{C}.

**COMMENTS:** Note that all temperatures are expressed in kelvins. This is a necessary practice when dealing with radiation and convection modes.
**PROBLEM 13.63**

**KNOWN:** Cylindrical-shaped, three surface enclosure with lateral surface insulated.

**FIND:** Temperatures of the lower plate $T_1$ and insulated side surface $T_3$.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Surfaces have uniform radiosity or emissive power, (2) Upper and insulated surfaces are diffuse-gray, (3) Negligible convection.

**ANALYSIS:** Find the temperature of the lower plate $T_1$ from Eq. 13.30

\[
q_1 = \frac{\sigma}{(1 - \varepsilon_1)\varepsilon_1 A_1 + \left[ A_1 F_{12} + \left( \frac{1}{A_1 A_{13}} \right) + \left( \frac{1}{A_2 A_{23}} \right) \right]^{-1}} - \frac{1 - \varepsilon_2}{\varepsilon_2 A_2}
\]  

From Table 13.2 for parallel coaxial disks,

\[
R_1 = \frac{r_1}{L} = 0.1/0.2 = 0.5 \quad R_2 = \frac{r_2}{L} = 0.1/0.2 = 0.5
\]

\[
S = 1 + \left( R_2^2 \right)/R_1^2 = 1 + (1 + 0.5^2)/0.5^2 = 6.0
\]

\[
F_{12} = 1/2 \left( S - \left( S^2 - 4 \left( \frac{r_2}{r_1} \right)^2 \right)^{1/2} \right) = 1/2 \left( 6 - \left( 6^2 - 4(0.5/0.5)^2 \right)^{1/2} \right) = 0.172.
\]

Using the summation rule for the enclosure, $F_{13} = 1 - F_{12} = 1 - 0.172 = 0.828$, and from symmetry, $F_{23} = F_{13}$. With $A_1 = A_2 = \pi D^2/4 = \pi(0.2 \text{ m})^2/4 = 0.03142 \text{ m}^2$ and substituting numerical values into Eq. (1), obtain

\[
10,000 \text{ W} = \frac{0.03142 \text{ m}^2 \times 5.67 \times 10^{-8} \text{ W/m}^2\text{K}^4 (T_1^4 - 473^4) K^4}{0 + \left[ 0.172 + \left( \frac{1}{0.828} \right) \right]^{-1} \left( 1 - 0.8 \right)/0.8}
\]

\[
10,000 = 4.540 \times 10^9 (T_1^4 - 473^4) \quad T_1 = 1225 \text{ K}.
\]

The temperature of the insulated side surface can be determined from the radiation balance, Eq. 13.31, with $A_1 = A_2$,\n
\[
\frac{J_1 - J_3}{1/F_{13}} - \frac{J_3 - J_2}{1/F_{23}} = 0
\]

where $J_1 = \sigma T_1^4$ and $J_2$ can be evaluated from Eq. 13.19,

Continued ….
PROBLEM 13.63 (Cont.)

\[ q_2 = \frac{E_b - J_2}{(1 - \varepsilon_2)/\varepsilon_2 A_2} \]

\[-10,000 \, \text{W} = \frac{5.67 \times 10^{-8} \, \text{W} / \text{m}^2 \cdot \text{K}^4 (473 \, \text{K})^4 - J_2}{(1 - 0.8)/(0.8 \times 0.03142 \, \text{m}^2)} \]

find \( J_2 = 82,405 \, \text{W/m}^2 \). Substituting numerical values into Eq. (2),

\[
\frac{5.67 \times 10^{-8} \, \text{W} / \text{m}^2 \cdot \text{K}^4 (1225 \, \text{K})^4 - J_3 - 82,405 \, \text{W/m}^2}{1/0.172} = 0
\]

find \( J_3 = 105,043 \, \text{W/m}^2 \). Hence, for this insulated, re-radiating (adiabatic) surface,

\[ E_b = \sigma T_3^4 = 105,043 \, \text{W/m}^2 \quad T_3 = 1167 \, \text{K}. \]

\(<
PROBLEM 13.64

KNOWN: Furnace in the form of a truncated conical section, floor (1) maintained at $T_1 = 1000$ K by providing a heat flux $q''_{1,in} = 2200$ W/m$^2$; lateral wall (3) perfectly insulated; radiative properties of all surfaces specified.

FIND: (a) Temperature of the upper surface, $T_2$, and of the lateral wall $T_3$, and (b) $T_2$ and $T_3$ if all the furnace surfaces are black instead of diffuse-gray, with all other conditions remain unchanged. Explain effect of $\varepsilon_2$ on your results.

SCHEMATIC:

ASSUMPTIONS: (1) Furnace is a three-surface, diffuse-gray enclosure, (2) Surfaces have uniform radiosities, (3) Lateral surface is adiabatic, and (4) Negligible convection effects.

ANALYSIS: For the three-surface enclosure, write the radiation surface energy balances, Eq. 13.21, to find the radiosities of the three surfaces.

$$\frac{E_{b,1} - J_1}{(1-\varepsilon_1)/\varepsilon_1 A_1} = \frac{J_1 - J_2}{1/A_1 F_{12}} + \frac{J_1 - J_3}{1/A_1 F_{13}}$$

$$\frac{E_{b,2} - J_2}{(1-\varepsilon_2)/\varepsilon_2 A_2} = \frac{J_2 - J_1}{1/A_2 F_{21}} + \frac{J_2 - J_3}{1/A_2 F_{23}}$$

$$\frac{E_{b,3} - J_3}{(1-\varepsilon_3)/\varepsilon_3 A_3} = \frac{J_3 - J_1}{1/A_3 F_{31}} + \frac{J_3 - J_2}{1/A_3 F_{32}}$$

where the blackbody emissive powers are of the form $E_b = \sigma T^4$ with $\sigma = 5.67 \times 10^{-8}$ W/m$^2$·K$^4$. From Eq. 13.19, the net radiation leaving $A_1$ is

$$q_1 = \frac{E_{b,1} - J_1}{(1-\varepsilon_1)/\varepsilon_1 A_1}$$

$$q_1 = q''_{1,in} \cdot A_1 = 2200 \text{ W/m}^2 \times \pi(0.040 \text{ m})^2 / 4 = 2.76 \text{ W}$$

Continued …..
Since the lateral surface is adiabatic,

\[ q_3 = \frac{E_{b,3} - J_3}{(1 - \varepsilon_3)/\varepsilon_3 A_3} = 0 \]  

(5)

from which we recognize \( E_{b,3} = J_3 \), but will find that as an outcome of the analysis. For the enclosure, \( N = 3 \), there are \( N^2 = 9 \) view factors, for which \( N (N - 1)/2 = 3 \) must be directly determined. Calculations for the \( F_{ij} \) are summarized in Comments.

With the foregoing five relations, we can determine the five unknowns: \( J_1, J_2, J_3, E_{b,2}, \) and \( E_{b,3} \). The temperatures \( T_2 \) and \( T_3 \) will be evaluated from the relation \( E_b = \sigma T^4 \). Using this analysis approach with the relations in the IHT workspace, the results for (a) the diffuse-gray surfaces and (b) black surfaces are tabulated below.

<table>
<thead>
<tr>
<th></th>
<th>( J_1 ) (kW/m(^2))</th>
<th>( J_2 ) (kW/m(^2))</th>
<th>( J_3 ) (kW/m(^2))</th>
<th>( T_2 ) (K)</th>
<th>( T_3 ) (K)</th>
</tr>
</thead>
<tbody>
<tr>
<td>(a) Diffuse-gray</td>
<td>55.76</td>
<td>45.30</td>
<td>53.48</td>
<td>896</td>
<td>986</td>
</tr>
<tr>
<td>(b) Black</td>
<td>56.70</td>
<td>46.24</td>
<td>54.42</td>
<td>950</td>
<td>990</td>
</tr>
</tbody>
</table>

**COMMENTS:**

(1) From the tabulated results, it follows that the temperatures of the lateral and top surfaces will be higher when the surfaces are black, rather than diffuse-gray as specified.

(2) From Eq. (5) for the net heat radiation leaving the lateral surface, \( A_3 \), the rate is zero since the wall is adiabatic. The consequences are that the blackbody emissive power and the radiosity are equal, and that the emissivity of the surface has no effect in the analysis. That is, this surface emits and absorbs at the same rate; the net is zero.

(3) For the enclosure, \( N = 3 \), there are \( N^2 = 9 \) view factors, for which

\[ N (N - 1)/2 = 3 \times 2 / 2 = 3 \]

must be directly determined. We used the IHT Tools | Radiation | View Factors Relations model that sets up the summation rules and reciprocity relations for the \( N \) surfaces. The user is required to specify the 3 \( F_{ij} \) that must be determined directly; by inspection, \( F_{11} = F_{22} = 0 \); and \( F_{12} \) can be evaluated using the parallel coaxial disk relation, Table 13.2 (Fig. 13.5). This model is also provided in IHT to simplify the calculation task. The results of the view factor analysis are:

\[ F_{12} = 0.03348 \quad F_{13} = 0.9665 \]

\[ F_{21} = 0.1339 \quad F_{23} = 0.8661 \]

(4) An alternative method of solution for part (a) is to treat the enclosure of part (a) as described in Section 13.3.5. For part (b), the black enclosure analysis is described in Section 13.2. We chose to use the net radiation method, Section 13.3.1, to develop a general 3-surface enclosure code in IHT that can also handle black surfaces (caution: use \( \varepsilon = 0.999 \), not 1.000).
PROBLEM 13.65

KNOWN: Two aligned, parallel square plates with prescribed temperatures.

FIND: Net radiative transfer from surface 1 for these plate conditions: (a) black, surroundings at 0 K, (b) black with connecting, re-radiating walls, (c) diffuse-gray with radiation-free surroundings at 0 K, (d) diffuse-gray with re-radiating walls.

SCHEMATIC:

ASSUMPTIONS: (1) Plates are black or diffuse-gray, (2) Surroundings are at 0 K.

ANALYSIS: (a) The view factor for the aligned, parallel plates follows from Fig. 13.4, X/L = 0.4 m/0.8 m = 0.5, Y/L = 0.4 m/0.8 m = 0.5, F_{12} = F_{21} = 0.075. When the plates are black with surroundings at 0 K, from Eq. 13.13, 
\[
q_1 = q_{12} + q_{1(f\text{sur})} = A_1 F_{12} (E_{b1} - E_{b2}) + A_1 F_{1(f\text{sur})} (E_{b1} - E_{b(sur)})
\]
\[
q_1 = (0.4 \times 0.4) m^2 [0.075(3544 - 23,224) + (1 - 0.075)(3544 - 0)] W / m^2 = 288 W.
\]

(b) When the plates are black with connecting re-radiating walls, from Eq. 13.30 with F_{1R} = R_{2R} = 1 - F_{12} = 0.925,
\[
q_1 = \frac{A_1 [E_{b1} - E_{b2}]}{F_{12} + (1/F_{1R} + 1/F_{2R})^{-1}} = \frac{(0.4 m)^2 [3544 - 23,224] W / m^2}{0.075 + (1/0.925 + 1/0.925)^{-1}} = -1,692 W.
\]

(c) When the plates are diffuse-gray (\(\varepsilon_1 = 0.6\) and \(\varepsilon_2 = 0.8\)) with the surroundings at 0 K, using Eq. 13.20 or Eq. 13.19, with \(E_{b3} = J_3 = 0\),
\[
q_1 = A_1 F_{12} (J_1 - J_2) + A_1 F_{13} (J_1 - J_3) = (E_{b1} - J_1)/[(1-\varepsilon_1)/\varepsilon_1 A_1].
\]
The radiosities must be determined from energy balances, Eq. 13.21, on each of the surfaces,
\[
\frac{E_{b1} - J_1}{(1-\varepsilon_1)/\varepsilon_1} = F_{12} (J_1 - J_2) + F_{13} (J_1 - J_3)
\]
\[
\frac{E_{b2} - J_2}{(1-\varepsilon_2)/\varepsilon_2} = F_{21} (J_2 - J_1) + F_{23} (J_2 - J_3)
\]
\[
\frac{3.544 - J_1}{(1-0.6)/0.6} = 0.075 (J_1 - J_2) + 0.925 J_1
\]
\[
\frac{23.224 - J_2}{(1-0.8)/0.8} = 0.075 (J_2 - J_1) + 0.925 J_2.
\]
Find \(J_1 = 2682 W/m^2\) and \(J_2 = 18,542 W/m^2\). Combining these results,
\[
q_1 = (0.4 m)^2 (0.075)(2682 - 18,542) W / m^2 + (0.4 m)^2 (0.925)(2682 - 0) W / m^2 = 207 W.
\]

(d) When the plates are diffuse-gray with connecting re-radiating walls, use Eq. 13.30,
\[
q_1 = \frac{A_1 [E_{b1} - E_{b2}]}{(1-\varepsilon_1)/\varepsilon_1 + [F_{12} + (1/F_{1R} + 1/F_{2R})^{-1}]^{-1} + (1-\varepsilon_2)/\varepsilon_2}
\]
\[
q_1 = \frac{(0.4 m)^2 [3544 - 23,244] W / m^2}{(1-0.6)/0.6 + [0.075 + (1/0.925 + 1/0.925)^{-1}]^{-1} + (1-0.8)/0.8} = -1133 W.
\]
**PROBLEM 13.66**

**KNOWN:** Parallel, aligned discs located in a large room; one disk is insulated, the other is at a prescribed temperature.

**FIND:** Temperature of the insulated disc.

**SCHEMATIC:**

![Diagram](image)

**ASSUMPTIONS:** (1) Surfaces are diffuse-gray, (2) Surroundings are large, with uniform temperature, behaving as a blackbody, (3) Negligible convection.

**ANALYSIS:** From an energy balance on surface $A_2$,

\[
q_2 = 0 = \frac{J_2}{1/A_2 F_{21}} - \frac{J_1}{1/A_2 F_{23}} + \frac{J_3}{1/A_2 F_{23}}.
\]

Note that $q_2 = 0$ since the surface is adiabatic. Since $A_3$ is a blackbody, $J_3 = \varepsilon_3 T_3^4$; since $A_2$ is adiabatic, $J_2 = \varepsilon_2 T_2^4$. From Fig. 13.5 and the summation rule for surface $A_1$,

\[
F_{12} = 0.62 \text{ with } \frac{r_1}{L} = 0.2 \quad \text{and} \quad \frac{L}{r_1} = 0.1 = 0.5, \quad F_{13} = 1 - F_{12} = 1 - 0.62 = 0.38.
\]

Hence, Eq. (1) with $J_3 = 5.67 \times 10^{-8} \times 300^4 \text{ W/m}^2$ becomes

\[
\frac{J_2}{1/A_2 \times 0.62} + 459.3 \text{ W/m}^2 = 0 \quad -0.62 J_1 + 1.00 J_2 = 174.5
\]

(2,3)

The radiation balance on surface $A_1$ with $E_{b3} = 5.67 \times 10^{-8} \times 500^4 \text{ W/m}^2$ becomes

\[
\frac{E_{b1} - J_1}{(1 - \varepsilon_1) / \varepsilon_1 A_1} = \frac{J_1 - J_2}{1/A_1 F_{12}} + \frac{J_1 - J_3}{1/A_1 F_{13}}.
\]

(4)

\[
\frac{3543.8 - J_1}{(1 - 0.6)/0.6 A_1} = \frac{J_1 - J_2}{1/A_1 \times 0.62} + \frac{J_1 - 459.3}{1/A_1 \times 0.38} = 2.50 J_1 - 0.62 J_2 = 5490.2
\]

(5,6)

Solve Eqs. (3) and (6) to find $J_2 = 1815 \text{ W/m}^2$ and since $E_{b2} = J_2$,

\[
T_2 = \left( \frac{E_{b2}}{\sigma} \right)^{1/4} = \left( \frac{1815 \text{ W/m}^2}{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4} \right)^{1/4} = 423 \text{ K}.
\]

**COMMENTS:** A network representation would help to visualize the exchange relations. However, it is useful to approach the problem by recognizing there are two unknowns in the problem: $J_1$ and $J_2$; hence two radiation balances must be written. Note also the significance of $J_2 = E_{b2}$ and $J_3 = E_{b3}$.
**PROBLEM 13.67**

**KNOWN:** Thermal conditions in oven used to cure strip coatings.

**FIND:** Electrical power requirement.

**SCHEMATIC:**

![Diagram of oven with labeled dimensions: D=0.02m, T_1=1700K, ε_1=0.9, T_2=600K, s_1=0.06m, s_2=0.02m, L=0.08m.]

**ASSUMPTIONS:** (1) Diffuse-gray surfaces, (2) Furnace wall is reradiating, (3) Negligible end effects.

**ANALYSIS:** The net radiant power leaving the heater surface per unit length is

\[ q'_1 = \frac{E_{b1} - E_{b2}}{1 - \varepsilon_1 + \frac{\varepsilon_1 A'_1}{A'_1 F_{12} + \left(1/A'_1 F_{1R} + 1/A'_2 F_{2R}\right)^{-1}} + \frac{1 - \varepsilon_2}{\varepsilon_2 A'_2}} \]

where \( A'_1 = \pi D = \pi (0.02 \text{ m}) = 0.0628 \text{ m} \) and \( A'_2 = 2(s_1 - s_2) = 0.08 \text{ m} \). The view factor between the heater and one of the strips is

\[ F_{21} = \frac{D/2}{s_1 - s_2} \left[ \tan^{-1}\frac{s_1}{L} - \tan^{-1}\frac{s_2}{L} \right] = 0.01 \left[ \frac{\tan^{-1}0.06}{0.08} - \tan^{-1}0.02}{0.08} \right] = 0.10 \]

and using the view factor relations find

\[ A'_1 F_{12} = A'_2 F_{21} = 0.08 \text{ m} \times 0.10 = 0.008 \text{ m} \]
\[ F_{1R} = 1 - F_{12} = 1 - 0.127 = 0.873 \]
\[ F_{2R} = 1 - F_{21} = 1 - 0.10 = 0.90. \]

Hence, with \( E_b = \sigma T^4 \),

\[ q'_1 = \frac{5.67 \times 10^{-8} \left[ (1700)^4 - (600)^4 \right]}{1 - 0.9} + \frac{1}{0.9 \times 0.0628 + 0.008 + \left[1/(0.0628 \times 0.873) + 1/(0.08 \times 0.90)\right]} + \frac{1 - 0.4}{0.4 \times 0.08} \]

\[ q'_1 = \frac{4.66 \times 10^5}{1.77 + 25.56 + 18.75} = 10,100 \text{ W/m}. \]

**COMMENTS:** The radiosity for \( A_1 \) and \( A_2 \) follow from Eq. 13.19,

\[ J_1 = E_{b1} - (1 - \varepsilon_1)q'_1 \varepsilon_1 A'_1 = 4.56 \times 10^5 \text{ W/m}^2 \]
\[ J_2 = E_{b2} + (1 - \varepsilon_2)q'_1 \varepsilon_2 A'_2 = 1.97 \times 10^5 \text{ W/m}^2. \]

From Eq. 13.31, find \( J_R \) and hence \( T_R \) as

\[ 0.0628 \times 0.873(J_1 - J_R) - 0.08 \times 0.90(J_R - J_2) = 0 \]

\[ J_R = 3.08 \times 10^5 \text{ W/m}^2 = \sigma T_R^4 \quad T_R = 1527 \text{ K}. \]
PROBLEM 13.68

KNOWN: Surface temperature and emissivity of molten alloy and distance of surface from top of container. Container diameter.

FIND: Net rate of radiation heat transfer from surface of melt.

SCHEMATIC:

ASSUMPTIONS: (1) Opaque, diffuse, gray behavior for surface of melt, (2) Large surroundings may be represented by a hypothetical surface of temperature \( T = T_{\text{sur}} \) and \( \varepsilon = 1 \), (3) Negligible convection at exposed side wall, (4) Adiabatic side wall.

ANALYSIS: With negligible convection at an adiabatic side wall, the surface may be treated as reradiating. Hence, from Eq. (13.30), with \( A_1 = A_2 \),

\[
q_1 = \frac{A_1 (E_{b1} - E_{b2})}{1 + \frac{1}{\varepsilon_1} \left( \frac{1}{F_{12} + \left[ \left( \frac{1}{F_{1R}} \right) + \left( \frac{1}{F_{2R}} \right) \right]^{-1}} \right) + \frac{1}{\varepsilon_2}}
\]

With \( R_i = R_j = (D/2)/L = 1.25 \) and \( S = \left[ 1 + \left( \frac{1 + R_j^2}{R_i^2} \right) \right] = 2.640 \), Table 13.2 yields

\[
F_{12} = \frac{1}{2} \left\{ S - \left[ S^2 - 4 \left( r_2 / \eta \right)^2 \right]^{1/2} \right\} = 0.458
\]

Hence,

\[
F_{1R} = F_{2R} = 1 - F_{12} = 0.542 \quad \text{and}
\]

\[
q_1 = \frac{\pi (0.25m)^2 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left( (900^4 - 300^4) \right) \text{K}^4}{1 - 0.55 + \frac{1}{0.55} \left( \frac{0.458 (3.69)^{-1} + 0}{1} \right)} = 3295 \text{ W}
\]
**PROBLEM 13.69**

**KNOWN:** Blackbody simulator design consisting of a heated circular plate with an opening over a well insulated hemispherical cavity.

**FIND:** (a) Radiant power leaving the opening (aperture), \( D_a = r_o/2 \), (b) Effective emissivity of the cavity, \( \varepsilon_e \), defined as the ratio of the radiant power leaving the cavity to the rate at which the circular plate would emit radiation if it were black, (c) Temperature of hemispherical surface, \( T_{hc} \), and (d) Compute and plot \( \varepsilon_e \) and \( T_{hc} \) as a function of the opening aperture in the circular plate, \( D_a \), for the range \( r_o/8 \leq D_a \leq r_o/2 \), for plate emissivities of \( \varepsilon_p = 0.5, 0.7 \) and 0.9.

**SCHEMATIC:**

![Schematic Diagram](image)

**ASSUMPTIONS:** (1) Plate and hemispherical surface are diffuse-gray, (2) Uniform radiosity over these same surfaces.

**ANALYSIS:** (a) The simulator can be treated as a three-surface enclosure with one re-radiating surface \( (A_2) \) and the opening \( (A_3) \) as totally absorbing with no emission into the cavity \( (T_3 = 300 \, \text{K}) \). The radiation leaving the cavity is the net radiation leaving \( A_1 \), \( q_1 \) which is equal to \(-q_3\). Using Eq. 13.30,

\[
q_{cav} = q_1 = -q_3 = \frac{\sigma(T_1^4 - T_3^4)}{(1 - \varepsilon_1)/\varepsilon_1 A_1 + \left[ A_1 F_{13} + \left[ \left( 1/A_1 F_{12} \right) + (1/A_3 F_{32}) \right] \right]^{-1} + (1 - \varepsilon_3)/\varepsilon_3 A_3}
\]

Using the summation rule and reciprocity, evaluate the required view factors:

\[
F_{11} + F_{12} + F_{13} = 1 \quad F_{13} = 0 \quad F_{12} = 1
\]

\[
F_{31} + F_{32} + F_{33} = 1 \quad F_{32} = 1.
\]

Substituting numerical values with \( \varepsilon_3 = 1 \), \( T_3 = 300 \, \text{K} \), \( A_1 = \pi \left( r_o^2 - \left( r_o/4 \right)^2 \right) = 15\pi r_o^2 / 16 = 2.945 \times 10^{-2} \, \text{m}^2 \), \( A_3 = \pi \left( r_o/4 \right)^2 = 1.963 \times 10^{-3} \, \text{m}^2 \) and \( A_1/A_3 = 15 \), and multiplying numerator and denominator by \( A_1 \),

\[
q_{cav} = q_1 = \frac{A_1 \sigma(T_1^4 - T_3^4)}{(1 - \varepsilon_1)/\varepsilon_1 + \left[ F_{13} + \left[ \left( 1/F_{12} \right) + (A_1/A_3 F_{32}) \right] \right]^{-1} + 0}
\]

Continued …..
PROBLEM 13.69 (Cont.)

\[ q_{cav} = q_1 = \frac{2.945 \times 10^{-2} \text{ m}^2 \times 5.67 \times 10^{-8} \text{ W/ m}^2 \cdot \text{K}^4 \left(600^4 - 300^4\right) \text{K}^4}{(1-0.9)/0.9 + \left\{0 + [1 + (15/1)]^{-1}\right\}^{-1} + 0} = 12.6 \text{ W} \]

(b) The effective emissivity is the ratio of the radiant power leaving the cavity to that from a blackbody having the area of the opening and temperature of the inner surface of the cavity. That is,

\[ \varepsilon_e = \frac{q_{cav}}{A_3 \sigma T_1^4} = \frac{12.6 \text{ W}}{1.963 \times 10^{-3} \text{ m}^2 \times 5.67 \times 10^{-8} \text{ W/ m}^2 \cdot \text{K}^4 \times (600 \text{ K})^4} = 0.873 \]  

(c) From a radiation balance on \( A_1 \), find \( J_1 \),

\[ q_1 = 12.6 \text{ W} = \frac{E_{b1} - J_1}{(1 - \varepsilon_1) / \varepsilon_1 A_1} = \frac{\sigma 600^4 - J_1}{(1 - 0.9) / 0.9 A_1} \quad J_1 = 7301 \text{ W/ m}^2 \]  

From a radiation balance on \( A_2 \) with \( J_3 = E_{b3} = \sigma T_3^4 = 459.9 \text{ W/ m}^2 \) and \( J_2 = \sigma T_2^4 \), find

\[ \frac{J_2 - J_1}{1/A_1 F_1} + \frac{J_2 - J_3}{1/A_3 F_3} = \frac{J_2 - 7301 \text{ W/ m}^2}{1/2.945 \times 10^{-2} \text{ m}^2} + \frac{J_2 - 459.9}{1/1.963 \times 10^{-3} \text{ m}^2} = 0 \]  

\[ J_2 = 6873 \text{ W/ m}^2 \quad T_2 = 590 \text{ K}. \]

(d) Using the foregoing equations in the IHT workspace, \( \varepsilon_e \) and \( T_2 \) were computed and plotted as a function of the opening, \( D_a \), for selected plate emissivities, \( \varepsilon_p \).

From the upper-left graph, \( \varepsilon_e \) decreases with increasing opening, \( D_a \), as expected. In the limit as \( D_a \rightarrow 0, \varepsilon_e \rightarrow 1 \) since the cavity becomes a complete enclosure. From the upper-right graph, \( T_{hc} \), the temperature of the re-radiating hemispherical surface decreases as \( D_a \) increases. In the limit as \( D_a \rightarrow 0, T_2 \) will approach the plate temperature, \( T_p = 600 \text{ K} \). The effect of decreasing the plate emissivity is to decrease \( \varepsilon_e \) and decrease \( T_2 \). Why is this so?

Continued ….
COMMENTS: The IHT Radiation, Tool, Radiation Tool, Radiation Exchange Analysis, Three-Surface Enclosure with Re-radiating Surface, is especially convenient to perform the parametric analysis of part (c). A copy of the IHT workspace that can generate the above graphs is shown below.

```plaintext
// Radiation Tool – Radiation Exchange Analyses, Reradiating Surface
/* For the three-surface enclosure A1, A3 and the reradiating surface A2, the net rate of radiation transfer from the surface A1 to surface A3 is */
q1 = (E_b1 – E_b3) / ((1 – eps1)/(eps1 * A1) + 1/(A1 * F13 + 1/(1/(A1 * F12) + 1/(A3 * F32)))) + (1 – eps3)/(eps3 * A3) // Eq 13.30
/* The net rate of radiation transfer from surface A3 to surface A1 is */
q3 = q1
/* From a radiation energy balance on A2, */
(J2 – J1) / (1/(A2 * F21)) + (J2 – J3)/(1/(A2 * F23)) = 0 // Eq 13.31
/* where the radiosities J1 and J3 are determined from the radiation rate equations expressed in terms of the surface resistances, Eq 13.22 */
q1 = (E_b1 – J1) / ((1 – eps1) / (eps1 * A1))
q3 = (E_b3 – J3) / ((1 – eps3) / (eps3 * A3))
// The blackbody emissive powers for A1 and A3 are
E_b1 = sigma * T1^4
E_b3 = sigma * T3^4
// For the reradiating surface,
J2 = E_b2
E_b2 = sigma * T2^4 // Stefan-Boltzmann constant, W/m^2*K^4
sigma = 5.67E-8

// Effective emissivity:
epseff = q1 / (A3 * E_b1) // Eq (3)

// Areas:
A1 = pi * (ro^2 - ra^2)
A2 = 0.5 * pi * (2 * ro)^2 // Hemisphere, As = 0.5 * pi * D^2
A3 = pi * ra^2

// Assigned Variables
T1 = 600 // Plate temperature, K
eps1 = 0.9 // Plate emissivity
T3 = 300 // Opening temperature, K; Tsur
eps3 = 0.9999 // Opening emissivity; not zero to avoid divide-by-zero error
ro = 0.1 // Hemisphere radius, m
Da = 0.05 // Opening diameter; range ro/8 to ro/2; 0.0125 to 0.050
Da_mm = Da * 1000 // Scaling for plot
Ra = Da / 2 // Opening radius
```

PROBLEM 13.70

KNOWN: Long hemi-cylindrical shaped furnace comprised of three zones.

FIND: (a) Heat rate per unit length of the furnace which must be supplied by the gas burners and (b) Temperature of the insulating brick.

SCHEMATIC:

ASSUMPTIONS: (1) Surfaces are opaque, diffuse-gray or black, (2) Surfaces have uniform temperatures and radiosities, (3) Surface 3 is perfectly insulated, (4) Negligible convection, (5) Steady-state conditions.

ANALYSIS: (a) From an energy balance on the ceramic plate, the power required by the burner is $q_1 = q'_1$, the net radiation leaving $A_1$; hence

$$q'_1 = A_1 F_{12} (J_1 - J_2) + A_1 F_{13} (J_1 - J_3) = 0 + A_1 F_{13} (J_1 - J_3) \quad (1)$$

since $F_{12} = 0$. Note that $J_2 = E_{b2} = \sigma T_2^4$ and that $J_1$ and $J_3$ are unknown. Hence, we need to write two radiation balances.

$A_1$:

$$\frac{E_{bl} - J_1}{(1 - \varepsilon_1)/\varepsilon_1 A_1} = q'_1 = 0 + A_1 F_{13} (J_1 - J_3) \quad (2)$$

$A_3$:

$$0 = A_3 F_{31} (J_3 - J_1) + A_3 F_{32} (J_3 - E_{b2})$$

$$J_3 = \frac{J_1 + E_{b2}}{2} \quad (3)$$

since $F_{31} = F_{23}$. Substituting Eq. (3) into (2), find

$$(371,589 - J_1) / (1 - 0.85) / 0.85 = 1 \left[ J_1 - (J_1 + 3,544) / 2 \right]$$

$$J_1 = 341,748 \text{ W/m}^2 \quad J_3 = 172,646 \text{ W/m}^2$$

using $E_{bl} = \sigma T_1^4 = 371,589 \text{ W/m}^2$ and $E_{b2} = \sigma T_2^4 = 3544 \text{ W/m}^2$. Substituting into Eq. (1), find

$$q'_1 = 1 \text{ m} \times 1 (341,748 - 172,646) \text{ W/m}^2 = 169 \text{ kW/m.} \quad <$$

(b) The temperature of the insulating brick, acting as a reradiating surface, is

$$J_3 = E_{b3} = \sigma T_3^4$$

$$T_3 = (J_3 / \sigma)^{1/4} = \left(172,646 \text{ W/m}^2 / 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \right)^{1/4} = 1320 \text{ K.} \quad <$$
PROBLEM 13.71

KNOWN: Steam producing still heated by radiation.

FIND: (a) Factor by which the vapor production could be increased if the cylindrical side of the heater were insulated rather than open to the surroundings, and (b) Compute and plot the net heat rate of radiation transfer to the still, as a function of the separation distance $L$ for the range $15 \leq L \leq 100$ mm for heater temperatures of 600, 800, 1000°C considering the cylindrical sides to be insulated.

SCHEMATIC:

ASSUMPTIONS: (1) Still and heater surfaces are black, (2) Surroundings are isothermal and large compared to still heater surfaces, (3) Insulation is diffuse-gray, (4) Negligible convection.

ANALYSIS: (a) The vapor production will be proportional to the net radiation exchange to the still. For the case when the sides are open (o) to the surroundings, the net radiation exchange leaving $A_2$ is from Eq. 13.13.

$$q_{2,o} = q_{21} + q_{2s} = A_2 F_{21} \sigma \left( T_2^4 - T_1^4 \right) + A_2 F_{2s} \sigma \left( T_2^4 - T_{sur}^4 \right)$$

where $F_{2s} = 1 - F_{21}$ and $F_{21}$ follows from Fig. 13.5 with $L/r_i = 100/100 = 1$, $r_j/L = 100/100 = 1$.

$$F_{21} = 0.38$$

With $A_2 = \pi D^2 / 4$, find

$$q_{2,o} = \pi \left( \frac{0.200 \text{m}}{2} \right)^2 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left\{ 0.38 \left( 373^4 - 1273^4 \right) K^4 + (1 - 0.38) \left( 373^4 - 300^4 \right) K^4 \right\}$$

$$q_{2,o} = -1752 \text{ W.} \quad \text{w/o insulation}$$

With the cylindrical side insulated (i), a three-surface, re-radiating enclosure is formed. Eq. 13.30 can be used to evaluate $q_{2,i}$ and with $\varepsilon_2 = \varepsilon_1 = 1$, the relation is

$$q_{2,i} = \frac{\sigma \left( T_2^4 - T_1^4 \right)}{A_1 F_{12} + \left[ (1/A_1 F_{1R}) + (1/A_2 F_{2R}) \right]^{-1}}$$

Recall $F_{12} = 0.38$ and $F_{1R} = 1 - F_{12} = 1 - 0.38 = 0.62$, giving

$$q_{2,i} = \pi \left( \frac{0.100 \text{ m}}{2} \right)^2 \left\{ 0.38 + (1/0.62 + 1/0.62)^{-1} \right\} \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K} \left( 373^4 - 1273^4 \right) K^4$$

$$q_{2,i} = -3204 \text{ W.} \quad \text{w insulation}$$

Continued …..
PROBLEM 13.71 (Cont.)

Hence, the vapor production rate is increased by a factor

\[
\frac{q_{2\text{, insul}}}{q_{2\text{, open}}} = \frac{3204 \text{ W}}{1752 \text{ W}} = 1.83
\]

That is, the vapor production is increased by 83%.

(b) The IHT Radiation Tool – Radiation Exchange Analysis for the Three-Surface Enclosure with a reradiating surface can be used directly to compute the net heat rate to the still, \( q_1 = q_2 \), as a function of the separation distance \( L \) for selected heater temperatures \( T_1 \). The results are plotted below.

![Graph showing heat rate vs. separation distance for different heater temperatures.](image)

Note that the heat rate for all values of \( T_1 \) decreases as expected with increasing separation distances, but not markedly. For any separation distance, increasing the heater temperature greatly influences the heat rate. For example, at \( L = 50 \text{ mm} \), increasing \( T_1 \) from 600 to 800 K, causes a nearly 6 fold increase in the heat rate. But increasing \( T_1 \) from 800 to 1000 K causes only a 2 fold increase in the heat rate.

COMMENTS: When assigning the emissivity variables (\( \varepsilon_1, \varepsilon_2, \varepsilon_3 \)) in the IHT model mentioned above, set \( \varepsilon = 0.999 \), rather than 1.0, to avoid a “division by zero” error message. You could also call up the Radiation Tool, View Factor Coaxial Parallel Disk to calculate \( F_{12} \).
PROBLEM 13.72

KNOWN: Furnace with cylindrical heater and re-radiating, insulated walls.
FIND: (a) Power required to maintain steady-state conditions, (b) Temperature of wall area.

SCHEMATIC:

ASSUMPTIONS: (1) Surfaces are diffuse-gray, (2) Furnace is of length $\ell$ where $\ell \gg w$, (3) Convection is negligible.

ANALYSIS: (a) Consider the furnace as a three surface enclosure with the walls, $A_R$, represented as a re-radiating surface. The power that must be supplied to the heater is determined by Eq. 13.30.

$$q_1 = \frac{\sigma (T_1^4 - T_2^4)}{(1-\varepsilon_1)/\varepsilon_1 A_1 + \left[ \frac{1}{A_1 F_{12}} + \left( \frac{1}{A_2 F_{2R}} \right) \right]^{-1} + (1-\varepsilon_2)/\varepsilon_2 A_2}$$

Note that $A_1 = \pi d \ell$ and $A_2 = w \ell$. By inspection and the summation rule, find $F_{12} = 60^\circ/360^\circ = 0.167$, $F_{1R} = 1 - F_{12} = 1 - 0.167 = 0.833$, and $F_{2R} \approx 1$. With $q'_1 = q_1/\ell$, 

$$q'_1 = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot K^4 \left( 1500^4 - 500^4 \right) K^4$$

$$0 + \left[ \pi \left( 10 \times 10^{-3} \right) m \times 0.167 + \left[ \frac{1}{\pi} \left( 10 \times 10^{-3} m \times 0.83 \right) + \left( 1/1m \times 1 \right) \right]^{-1} \right]^{-1} \times (1-0.6)/0.6 \times 1 \text{ m} = 8518 \text{ W/m.}$$

(b) To determine the wall temperature, apply the radiation balance, Eq. 13.31,

$$J_1 - J_R = \frac{J_R - J_2}{(1/A_1 F_{1R})} \quad \text{or} \quad J_1 - J_R = \frac{J_R - J_2}{(1/A_2 F_{2R})} \quad \text{or} \quad J_1 - J_R = \frac{J_R - J_2}{(1/\pi 10^{-3} m \times 0.83)}.$$

$$J_R = \sigma T_R^4 = (J_1 + 38.21 J_2)/39.21.$$  \hspace{1cm} (1)

Since $A_1$ is a blackbody, $J_1 = E_{b1} = \sigma T_1^4$. To determine $J_2$, use Eq. 13.19. Noting that $q'_1 = -q'_2$, find 

$$q_2 = \frac{(E_{b2} - J_2) / (1-\varepsilon_2)/\varepsilon_2 A_2}{J_2 = \frac{E_{b2} - q_2 (1-\varepsilon_2) / \varepsilon_2 A_2}{J_2 = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot K^4 \left( 500^4 - 922 \right) \text{ W/m}^2 \cdot (1/1m)} = 9222 \text{ W/m}^2.$$

Substituting this value for $J_2$ into Eq. (1), the wall temperature can be calculated.

$$J_R = \left( 5.67 \times 10^{-8} \text{ W/m}^2 \cdot K^4 \left( 1500^4 + 38.21 \times 9222 \right) \right)/39.21 = 16,308 \text{ W/m}^2$$

$$T_R = \left( J_R / \sigma \right)^{1/4} = \left( 16,308 \text{ W/m}^2 / 5.67 \times 10^{-8} \text{ W/m}^2 \cdot K^4 \right)^{1/4} = 732 \text{ K.}$$

COMMENTS: Considering the entire wall as a single re-radiating surface may be a poor assumption since $J_R$ is not likely to be uniform over this large an area. It would be appropriate to consider several isothermal zones for improved accuracy.
PROBLEM 13.73

KNOWN: Circular furnace with one end \((A_1)\) and the lateral surface \((A_2)\) black. Other end \((A_3)\) is insulated.

FIND: (a) Net radiation heat transfer from each surface and (b) Temperature of \(A_3\), and (c) Compute and plot \(T_3\) as a function of tube length \(L\) for the range \(0.1 \leq L \leq 0.5\) m with \(D = 0.3\) m.

SCHEMATIC:

ASSUMPTIONS: (1) Surface \(A_3\) is diffuse-gray, (2) Uniform radiosity over \(A_3\).

ANALYSIS: (a) Since \(A_3\) is insulated, the net radiation from \(A_3\) is \(q_3 = 0\). Using Eq. 13.30, find

\[
q_1 = -q_2 = \sigma \left[ \left( \frac{1}{A_1} \right) + \left( \frac{1}{A_1 F_{13}} \right) + \left( \frac{1}{A_2 F_{23}} \right) \right]^{-1} (1 - \varepsilon_1) \varepsilon_1 A_1 + (1 - \varepsilon_2) \varepsilon_2 A_2
\]

and since \(\varepsilon_1 = \varepsilon_2 = 1\),

\[
q_1 = -q_2 = \sigma \left[ \frac{1}{A_1 F_{12}} + \left( \frac{1}{A_1 F_{13}} \right) + \left( \frac{1}{A_2 F_{23}} \right) \right]^{-1}
\]

Considering \(A_1\) and \(A_3\) as coaxial parallel disks, from Table 13.2 (Fig. 13.5) find \(F_{13}\),

\[
F_{13} = 0.5 \left( \frac{S}{R_1 / R_2} \right) = 0.5 \left( \frac{S}{1.15 / 0.3} \right) = 0.172.
\]

From the summation rule and symmetry \(F_{12} = 1 - F_{13} = 1 - 0.172 = 0.828\).

From reciprocity, with \(F_{32} = F_{12}\)

\[
F_{23} = A_3 F_{32} / A_2 = \left( \frac{\pi D^2}{4} \right) F_{12} / \left( \pi D L \right) = DF_{12} / 4L = 0.3 m \times 0.828 / 4 \times 0.3 m = 0.207.
\]

With \(A_1 = \pi D^2 / 4 = \pi (0.3 m)^2 / 4 = 0.07069 m^2\) and \(A_2 = \pi D L = \pi (0.3 m)(0.3 m) = 0.2827 m^2\),

\[
q_1 = -q_2 = \left\{ 0.07069 m^2 \times 0.828 + \left[ \left( \frac{1}{1.07069 m^2} \times 0.172 \right) \right]^{-1} \right\} \times 5.67 \times 10^{-8} \left( 500^4 - 400^4 \right) K^4
\]

\(< 143 W
\)

(b) From the radiation balance on \(A_3\), Eq. 13.31, find \(T_3\), with \(J_1 = E_{b1}\) and \(J_2 = E_{b2}\),

\[
\frac{E_{b1} - J_3}{\left( \frac{1}{A_1 F_{13}} \right)} - \frac{J_3 - E_{b2}}{\left( \frac{1}{A_2 F_{23}} \right)} = 0
\]

\[
\sigma \left( 500 K \right)^4 - J_3 \left( \frac{1}{1.07069 m^2 \times 0.172} \right) - J_3 - \sigma \left( 400 K \right)^4 \left( \frac{1}{1.07069 m^2 \times 0.172} \right) = 0
\]

\[
J_2 = E_{b3} = \sigma T_3^4 = 1811 W / m^2
\]

\(< T_3 = 423 K
\)

(c) Using the IHT Radiation Tools – Radiation Exchange Analysis, Three surface enclosure with a reradiating surface and View Factors, Three-dimensional geometries, Coaxial parallel disks – andContinued …..
appropriate view factor relations developed in part (a), $T_3$ was computed as a function of $L$ with the diameter, $D = 0.3$ m, and is plotted below.

Note that $T_3$ decreases with increasing tube length. In the limit as $L \to \infty$, $T_3$ will approach $T_2$. In the limit as $L \to 0$, $T_3$ will approach $T_1$. Is this intuitively satisfying?

**COMMENTS:** The *IHT* workspace used for the part (c) analysis is copied below.

```plaintext
// Radiation Tool:

esps2 = 0.9999 // Emissivity; avoiding “divide-by-zero error”
T2 = 400 // Temperature, K
L = 0.3 // Length, m
```
PROBLEM 13.74

KNOWN: Very long, triangular duct with walls that are diffuse-gray.

FIND: (a) Net radiation transfer from surface $A_1$ per unit length of duct, (b) The temperature of the insulated surface, (c) Influence of $\varepsilon_3$ on the results; comment on exactness of results.

SCHEMATIC:

![Diagram of a very long triangular duct with walls that are diffuse-gray.]

ASSUMPTIONS: (1) Surfaces are diffuse-gray, (2) Duct is very long; end effects negligible.

ANALYSIS: (a) The duct approximates a three-surface enclosure for which the third surface ($A_3$) is re-radiating. Using Eq. 13.30 with $A_3 = A_R$, the net exchange is

$$q_1 = -q_2 = \frac{E_{b1} - E_{b2}}{1 + \frac{(1 - \varepsilon_1)}{\varepsilon_1 A_1 + \frac{1}{A_1 F_{12} + (1/A_1 F_{1T} + 1/A_2 F_{2R})} + \frac{(1 - \varepsilon_2)}{\varepsilon_2 A_2}}}}$$

From symmetry, $F_{12} = F_{1R} = F_{2R} = 0.5$. With $A_1 = A_2 = w \cdot \ell$, where $\ell$ is the length normal to the page and $w = 1$ m,

$$q_1^* = q_1 / \ell = \left(\frac{q_1}{A_1}\right) w$$

$$q_1^* = \frac{(56,700 - 13,614)}{1 - 0.33} \times 1 = 9874 \text{ W/m.}$$

(b) From a radiation balance on $A_R$,

$$q_R = q_3 = 0 = \frac{E_{b3} - J_1}{(A_3 F_{31})^{-1}} + \frac{E_{b3} - J_2}{(A_3 F_{32})^{-1}}$$

or

$$E_{b3} = \frac{J_1 + J_2}{2}.$$ 

To evaluate $J_1$ and $J_2$, use Eq. 13.19,

$$J_i = E_{b,i} - q_i \frac{1 - \varepsilon_i}{\varepsilon_i A_i}$$

$$J_1 = 56,700 - \left(9874 \times 0.33\right) = 36,653 \text{ W/m}^2$$

$$J_2 = 13,614 - \left(-9874 \times 0.5\right) = 23,488 \text{ W/m}^2$$

From Eq. (2), now find

$$T_3 = \left(\frac{E_{b3}}{\sigma}\right)^{1/4} = \left(\frac{[J_1 + J_2] / 2}{2 \sigma}\right)^{1/4} = \left(\frac{36,653 + 23,488}{2 (5.67 \times 10^{-5}) \text{ W/m}^2 \cdot K^4}\right)^{1/4} = 853 \text{ K.}$$

(c) Since $A_3$ is adiabatic or re-radiating, $J_3 = E_{b3}$. Therefore, the value of $\varepsilon_3$ is of no influence on the radiation exchange or on $T_3$. In using Eq. (1), we require uniform radiosity over the surfaces. This requirement is not met near the corners. For best results we should subdivide the areas such that they represent regions of uniform radiosity. Of course, the analysis then becomes much more complicated.
PROBLEM 13.75

KNOWN: Dimensions for aligned rectangular heater and coated plate. Temperatures of heater, plate and large surroundings.

FIND: (a) Electric power required to operate heater, (b) Heater power required if reradiating sidewalls are added, (c) Effect of coating emissivity and electric power.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Blackbody behavior for surfaces and surroundings (Parts (a) and (b)).

ANALYSIS: (a) For $\epsilon_1 = \epsilon_2 = 1$, the net radiation leaving $A_1$ is

$$q_{elec} = q_1 = A_1 F_{12} \sigma \left( T_1^4 - T_2^4 \right) + A_1 F_{sur} \sigma \left( T_1^4 - T_{sur}^4 \right).$$

From Fig. 13.4, with $Y/L = 1/0.5 = 2$ and $X/L = 2/0.5 = 4$, the view factors are $F_{12} \approx 0.5$ and $F_{sur} \approx 1 - 0.5 = 0.5$. Hence,

$$q_{elec} = \left(2 \text{m}^2\right)0.5 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left[ \left(700 \text{ K}\right)^4 - \left(400 \text{ K}\right)^4 \right]$$

$$+ \left(2 \text{m}^2\right)0.5 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left[ \left(700 \text{ K}\right)^4 - \left(300 \text{ K}\right)^4 \right] = 12,162 + 13,154 \text{ W} = 25,316 \text{ W}.$$

(b) With the reradiating walls, the net radiation leaving $A_1$ is $q_{elec} = q_1 = q_{12}$. From Eq. 13.30 with $\epsilon_1 = \epsilon_2 = 1$ and $A_1 = A_2$,

$$q_{elec} = A_1 \sigma \left( T_1^4 - T_2^4 \right) \left\{ F_{12} + \left[1/F_{1R} + 1/F_{2R}\right] \right\}^{-1}$$

$$q_{elec} = \left(2 \text{m}^2\right)5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left[ \left(700 \text{ K}\right)^4 - \left(400 \text{ K}\right)^4 \right] \times 0.5 + \left[1/0.5 + 1/0.5\right]^{-1}$$

$$q_{elec} = 18,243 \text{ W}.$$ 

(c) Separately using the IHT Radiation Tool Pad for a three-surface enclosure, with one surface reradiating, and to perform a radiation exchange analysis for a three-surface enclosure, with one surface corresponding to large surroundings, the following results were obtained.

Continued …..
PROBLEM 13.75 (Cont.)

In both cases, the required heater power decreases with decreasing \( \varepsilon_2 \), and the trend is attributed to a reduction in \( \alpha_2 = \varepsilon_2 \) and hence to a reduction in the rate at which radiant energy must be absorbed by the surface to maintain the prescribed temperature.

**COMMENTS:** With the reradiating walls in part (b), it follows from Eq. 13.31 that

\[
J_R = E_{bR} = (J_1 + J_2)/2 = (E_{b1} + E_{b2})/2.
\]

Hence, \( T_R = 604 \) K. The reduction in \( q_{\text{elec}} \) resulting from use of the walls is due to the enhancement of radiation to the heater, which, in turn, is due to the presence of the high temperature walls.
**PROBLEM 13.76**

**KNOWN:** Configuration and operating conditions of a furnace. Initial temperature and emissivity of steel plate to be treated.

**FIND:** (a) Heater temperature, (b) Sidewall temperature.

**SCHEMATIC:**

![Radiant heaters](image)

- Heater temperature, \(E_b = 1.5 \times 10^5 \text{ W} \)
- Steel plate, \(\varepsilon = 0.4, T_2 = 300 \text{ K} \)

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Opaque, diffuse-gray surface behavior, (3) Negligible convection, (4) Sidewalls are re-radiating.

**ANALYSIS:**

(a) From Eq. 13.30

\[
q_1 = \frac{1 - \varepsilon_1}{\varepsilon_1 A_1} + \frac{E_b}{\varepsilon_2 A_2} = \frac{1.5 \times 10^5}{4} = 3.417 \text{ W/m}^2
\]

Note that \(A_1 = A_2 = 4 \text{ m}^2\) and \(E_b = \sigma T_2^4 = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \), where \(T_2 = 300 \text{ K} \). From Fig. 13.4, with \(X/L = Y/L = 1, F_{12} = 0.2\); hence \(F_{1R} = 1 - F_{12} = 0.8\), and \(F_{2R} = F_{1R} = 0.8\). With \((1 - \varepsilon_1)/\varepsilon_1 = 0.25\), and \((1 - \varepsilon_2)/\varepsilon_2 = 1.5\), find

\[
\frac{1.5 \times 10^5}{4} = \frac{E_b - 459}{1 - F_{1R}} = \frac{E_b - 459}{0.8}
\]

\[
E_b = 1.28 \times 10^5 \text{ W/m}^2 + 459 \text{ W/m}^2 = 1.29 \times 10^5 \text{ W/m}^2 = \sigma T_1^4
\]

\[
T_1 = \left(1.29 \times 10^5 / 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \right)^{1/4} = 1228 \text{ K}
\]

(b) From Eq. 13.31, it follows that, with \(A_1 F_{1R} = A_2 F_{2R}\),

\[
J_R = \sigma T_R^4 = \frac{J_1 + J_2}{2}
\]

From Eq. 13.19,

\[
J_1 = E_b - \frac{(1 - \varepsilon_1)}{\varepsilon_1 A_1} q_1 = 1.29 \times 10^5 / 0.8 \times 4 = 1.196 \times 10^5 \text{ W/m}^2
\]

With \(q_2 = q_1 = -1.5 \times 10^5 \text{ W}\),

\[
J_2 = E_b - \frac{(1 - \varepsilon_2)}{\varepsilon_2 A_2} q_2 = 459 + \frac{0.6}{0.4 \times 4} = 5.67 	imes 10^4 \text{ W/m}^2
\]

\[
T_R = \left(\frac{1.196 \times 10^5 / 5.67 \times 10^4}{2 \times 5.67 \times 10^{-8}} \right)^{1/4} = 1117 \text{ K}
\]

**COMMENTS:** (1) The above results are approximate, since the process is actually transient. (2) \(T_1\) and \(T_R\) will increase with time as \(T_2\) increases.
**PROBLEM 13.76**

**KNOWN:** Configuration and operating conditions of a furnace. Initial temperature and emissivity of steel plate to be treated.

**FIND:** (a) Heater temperature, (b) Sidewall temperature.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Opaque, diffuse-gray surface behavior, (3) Negligible convection, (4) Sidewalls are re-radiating.

**ANALYSIS:** (a) From Eq. 13.30

\[
q_1 = \frac{E_{b1} - E_{b2}}{1 - \varepsilon_1} + \frac{1}{A_1} F_{12} + \left[\left(\frac{A_1 F_{1R}}{\varepsilon_1 A_1} \right)^{-1} + \left(\frac{A_2 F_{2R}}{\varepsilon_2 A_2} \right)^{-1}\right]^{-1} = 1.5 \times 10^5 \text{ W}
\]

Note that \(A_1 = A_2 = 4 \text{ m}^2\) and \(E_{b2} = \sigma T_2^4 = 5.67 \times 10^{-8} \text{ W/m}^2\cdot\text{K}^4\) (300 K) \(= 459 \text{ W/m}^2\). From Fig. 13.4, with \(X/L = Y/L = 1\), \(F_{12} = 0.2\); hence \(F_{1R} = 1 - F_{12} = 0.8\), and \(F_{2R} = F_{1R} = 0.8\). With \((1 - \varepsilon_1)/\varepsilon_1 = 0.25\) and \((1 - \varepsilon_2)/\varepsilon_2 = 1.5\), find

\[
\frac{1.5 \times 10^5 \text{ W}}{4 \text{ m}^2} = \frac{E_{b1} - 459 \text{ W/m}^2}{0.25 + \frac{1}{0.2 + [1.25 + 1.25]^{-1}}} + 1.5 = \frac{E_{b1} - 459 \text{ W/m}^2}{3.417}.
\]

\(E_{b1} = 1.28 \times 10^5 \text{ W/m}^2 + 459 \text{ W/m}^2 = 1.29 \times 10^5 \text{ W/m}^2 = \sigma T_1^4\)

\(T_1 = \left(1.29 \times 10^5 \text{ W/m}^2 / 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4\right)^{1/4} = 1228 \text{ K.}\)

(b) From Eq. 13.31, it follows that, with \(A_1 F_{1R} = A_2 F_{2R}\),

\[J_R = \sigma T_R^4 = (J_1 + J_2)/2\]

From Eq. 13.19,

\[J_1 = E_{b1} - \frac{(1 - \varepsilon_1)}{\varepsilon_1 A_1} q_1 = 1.29 \times 10^5 \text{ W/m}^2 - \frac{0.2 \times 1.5 \times 10^5 \text{ W}}{0.8 \times 4 \text{ m}^2} = 1.196 \times 10^5 \text{ W/m}^2\]

With \(q_2 = q_1 = - 1.5 \times 10^5 \text{ W},\)

\[J_2 = E_{b2} - \frac{(1 - \varepsilon_2)}{\varepsilon_2 A_2} q_2 = 459 \text{ W/m}^2 + \frac{0.6}{0.4 \times 4 \text{ m}^2} 1.5 \times 10^5 \text{ W} = 5.67 \times 10^4 \text{ W/m}^2\]

\[T_R = \left(\frac{1.196 \times 10^5 \text{ W/m}^2 + 5.67 \times 10^4 \text{ W/m}^2}{2 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4}\right)^{1/4} = 1117 \text{ K.}\]

**COMMENTS:** (1) The above results are approximate, since the process is actually transient. (2) \(T_1\) and \(T_R\) will increase with time as \(T_2\) increases.
PROBLEM 13.77

KNOWN: Dimensions, surface radiative properties, and operating conditions of an electrical furnace.

FIND: (a) Equivalent radiation circuit, (b) Furnace power requirement and temperature of a heated plate.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Opaque, diffuse-gray surfaces, (3) Negligible plate temperature gradients, (4) Back surfaces of heater are adiabatic, (5) Convection effects are negligible.

ANALYSIS: (a) Since there is symmetry about the plate, only one-half (top or bottom) of the system need be considered. Moreover, the plate must be adiabatic, thereby playing the role of a re-radiating surface.

(b) Note that $A_1 = A_3 = 4 \text{ m}^2$ and $A_2 = (0.5 \text{ m} \times 2 \text{ m})4 = 4 \text{ m}^2$. From Fig. 13.4, with $X/L = Y/L = 4$, $F_{13} = 0.62$. Hence $F_{12} = 1 - F_{13} = 0.38$, and $F_{32} = F_{12} = 0.38$.

It follows that

$A_1 F_{12} = 4 (0.38) = 1.52 \text{ m}^2$

$A_1 F_{13} = 4 (0.62) = 2.48 \text{ m}^2$, \hspace{1cm} $(1 - \varepsilon_1)/\varepsilon_1 A_1 = 0.1/3.6 \text{ m}^2 = 0.0278 \text{ m}^{-2}$

$A_3 F_{32} = 4 (0.38) = 1.52 \text{ m}^2$, \hspace{1cm} $(1 - \varepsilon_2)/\varepsilon_2 A_2 = 0.7/1.2 \text{ m}^2 = 0.583 \text{ m}^{-2}$.

Also,

$E_{b1} = \sigma T_1^4 = 5.67 \times 10^{-8} \text{ W} / \text{ m}^2 \cdot \text{K}^4 (800 \text{ K})^4 = 23,224 \text{ W} / \text{ m}^2$,

$E_{b2} = \sigma T_2^4 = 5.67 \times 10^{-8} \text{ W} / \text{ m}^2 \cdot \text{K}^4 (400 \text{ K})^4 = 1452 \text{ W} / \text{ m}^2$.

The system forms a three-surface enclosure, with one surface re-radiating. Hence the net radiation transfer from a single heater is, from Eq. 13.30,

$$ q_1 = \frac{E_{b1} - E_{b2}}{1/\varepsilon_1 A_1 + [1/A_1 F_{13} + 1/A_3 F_{32}]^{-1}} = \frac{1 - \varepsilon_2}{\varepsilon_2 A_2} $$

Continued ….
PROBLEM 13.77 (Cont.)

\[
q_1 = \frac{(23,224 - 1452)}{(0.0278 + 0.4061 + 0.583)} \text{W/m}^2 = 21.4 \text{ kW}.
\]

The furnace power requirement is therefore \( q_{\text{elec}} = 2q_1 = 43.8 \text{ kW} \), with

\[
q_1 = \frac{E_{b1} - J_1}{(1 - \epsilon_1)/\epsilon_1 A_1}.
\]

where

\[
J_1 = E_{b1} - q_1 \frac{1 - \epsilon_1}{\epsilon_1 A_1} = 23,224 \text{ W/m}^2 - 21,400 \text{ W} \times 0.0278 \text{ m}^{-2}
\]

\[
J_1 = 22,679 \text{ W/m}^2.
\]

Also,

\[
J_2 = E_{b2} - q_2 \frac{1 - \epsilon_2}{\epsilon_2 A_2} = 1,452 \text{ W/m}^2 - (21,400 \text{ W}) \times 0.583 \text{ m}^{-2}
\]

\[
J_2 = 13,928 \text{ W/m}^2.
\]

From Eq. 13.31,

\[
\frac{J_1 - J_3}{1/A_1 F_3} = \frac{J_3 - J_2}{1/A_2 F_2}
\]

\[
\frac{J_1 - J_3}{A_1 F_1} = \frac{A_3 F_3}{2.48} = 0.613
\]

\[
1.613J_3 = J_1 + 0.613J_2 = 22,629 + 8537 = 31,166 \text{ W/m}^2
\]

\[
J_3 = 19,321 \text{ W/m}^2
\]

Since \( J_3 = E_{b3} \),

\[
T_3 = (E_{b3}/\sigma)^{1/4} = \left(\frac{19,321/5.67 \times 10^{-8}}{5.67 \times 10^{-8}}\right)^{1/4} = 764 \text{ K}.
\]

COMMENTS: (1) To reduce \( q_{\text{elec}} \), the sidewall temperature \( T_2 \), should be increased by insulating it from the surroundings. (2) The problem must be solved by simultaneously determining \( J_1, J_2 \) and \( J_3 \) from the radiation balances of the form

\[
\frac{E_{b1} - J_1}{(1 - \epsilon_1)/\epsilon_1 A_1} = A_1 F_1 (J_1 - J_2) + A_1 F_3 (J_1 - J_3)
\]

\[
\frac{E_{b2} - J_2}{(1 - \epsilon_2)/\epsilon_2 A_2} = A_2 F_2 (J_2 - J_1) + A_2 F_3 (J_2 - J_3)
\]

\[
0 = A_1 F_3 (J_3 - J_1) + A_2 F_3 (J_3 - J_2).
\]
PROBLEM 13.78

KNOWN: Geometry and surface temperatures and emissivities of a solar collector.

FIND: Net rate of radiation transfer to cover plate due to exchange with the absorber plates.

SCHEMATIC:

ASSUMPTIONS: (1) Isothermal surfaces with uniform radiosity, (2) Absorber plates behave as blackbodies, (3) Cover plate is diffuse-gray and opaque to thermal radiation exchange with absorber plates, (4) Duct end effects are negligible.

ANALYSIS: Applying Eq. 13.21 to the cover plate, it follows that

\[
E_{b1} - J_1 = \frac{1 - \varepsilon_1}{\varepsilon_1 A_1} \sum_{j=1}^{N} \frac{J_1 - J_j}{(A_1 F_{ij})^{-1}} = \frac{1 - \varepsilon_1}{\varepsilon_1 A_1} \left[ A_1 F_{12} (J_1 - J_2) + A_1 F_{13} (J_1 - J_3) \right].
\]

From symmetry, \( F_{12} = F_{13} = 0.5 \). Also, \( J_2 = E_{b2} \) and \( J_3 = E_{b3} \). Hence

\[
E_{b1} - J_1 = 0.0556 (2J_1 - E_{b2} - E_{b3})
\]

or with \( E_b = \sigma T^4 \),

\[
1.111J_1 = E_{b1} + 0.0556 (E_{b2} + E_{b3})
\]

\[
1.111J_1 = 5.67 \times 10^{-8} (298)^4 \text{ W/m}^2 + 0.0556 \left[ 5.67 \times 10^{-8} (333)^4 + (343)^4 \right] \text{ W/m}^2
\]

\[
J_1 = 476.64 \text{ W/m}^2
\]

From Eq. 13.19 the net rate of radiation transfer \emph{from} the cover plate is then

\[
q_1 = \frac{E_{b1} - J_1}{(1 - \varepsilon_1)/\varepsilon_1 A_1} = \frac{5.67 \times 10^{-8} (298)^4 - 476.64}{(1-0.9)/0.9 (\ell)} = (-265.5\ell) \text{ W}.
\]

The net rate of radiation transfer \emph{to} the cover plate per unit length is then

\[
q_1' = (q_1/\ell) = 266 \text{ W/m}.
\]

COMMENTS: Solar radiation effects are not relevant to the foregoing problem. All such radiation transmitted by the cover plate is completely absorbed by the absorber plate.
**PROBLEM 13.79**

**KNOWN:** Cylindrical peep-hole of diameter D through a furnace wall of thickness L. Temperatures prescribed for the furnace interior and surroundings outside the furnace.

**FIND:** Heat loss by radiation through the peep-hole.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Furnace interior and exterior surroundings are large, isothermal surroundings for the peep-hole openings, (3) Furnace refractory wall is adiabatic and diffuse-gray with uniform radiosity.

**ANALYSIS:** The open-ends of the cylindrical peep-hole \((A_1\) and \(A_2\)) and the cylindrical lateral surface of the refractory material \((A_R)\) form a diffuse-gray, three-surface enclosure. The hypothetical areas \(A_1\) and \(A_2\) behave as black surfaces at the respective temperatures of the large surroundings to which they are exposed. Since \(A_r\) is adiabatic, it behaves as a re-radiating surface, and its emissivity has no effect on the analysis. From Eq. 13.30, the net radiation leaving \(A_1\) passes through the enclosure into the outer surroundings.

\[
q_1 = q_2 = \frac{1 - \varepsilon_1}{\varepsilon_1 A_1} + \frac{E_{b1} - E_{b2}}{1 + \frac{1 - \varepsilon_2}{\varepsilon_2 A_2}}
\]

Since \(\varepsilon_1 = \varepsilon_2 = 1\), and with \(E_b = \sigma T^4\) where \(\sigma = 5.67 \times 10^{-8}\) W/m\(^2\)K\(^4\),

\[
q_1 = \left\{A_1 F_{12} + \left[\left(\frac{1}{A_1 F_{1R}} + \frac{1}{A_2 F_{2R}}\right)^{-1}\right]\sigma (T_1^4 - T_2^4)\right\}
\]

where \(A_1 = A_2 = \pi D^2/4\). The view factor \(F_{12}\) can be determined from Table 13.2 (Fig. 13.5) for the coaxial parallel disks \((R_1 = R_2 = 125/(2 \times 250) = 0.25\) and \(S = 17.063\) as \(F_{12} = 0.05573\)

From the summation rule on \(A_1\), with \(F_{11} = 0\),

\[
F_{11} + F_{12} + F_{1R} = 1
\]

\[
F_{1R} = 1 - F_{12} = 1 - 0.05573 = 0.9443
\]

and from symmetry of the enclosure,

\[
F_{2R} = F_{1R} = 0.9443
\]

Substituting numerical values into the rate equation, find the heat loss by radiation through the peep-hole to the exterior surroundings as

\[
q_{\text{loss}} = q_1 = 1046\ W <
\]

**COMMENTS:** If you held your hand 50 mm from the exterior opening of the peep-hole, how would that feel? It is standard, safe practice to use optical protection when viewing the interiors of high temperature furnaces as used in petrochemical, metals processing and power generation operations.
**PROBLEM 13.80**

**KNOWN:** Composite wall comprised of two large plates separated by sheets of refractory insulation of thermal conductivity \( k = 0.05 \text{ W/m·K} \); gaps between the sheets of width \( w = 10 \text{ mm} \), located at \( 1 \text{-m} \) spacing, allow radiation transfer between the plates.

**FIND:** (a) Heat loss by radiation through the gap per unit length of the composite wall (normal to the page), and (b) fraction of the total heat loss through the wall that is due to radiation transfer through the gap.

**SCHEMATIC:**

![Schematic](image)

**ASSUMPTIONS:**
1. Steady-state conditions,
2. Surfaces are diffuse-gray with uniform radiosities,
3. Refractory insulation surface in the gap is adiabatic,
4. Heat flow through the wall is one-dimensional between the plates in the direction of the gap centerline.

**ANALYSIS:**

(a) The gap of thickness \( w \) and infinite extent normal to the page can be represented by a diffuse-gray, three-surface enclosure formed by the plates \( A_1 \) and \( A_2 \) and the refractory walls, \( A_R \). Since \( A_R \) is adiabatic, it behaves as a re-radiating surface, and its emissivity has no effect on the analysis. From Eq. 13.30, the net radiation leaving the plate \( A_1 \) passes through the gap into plate \( A_2 \).

\[
q_1 = -q_2 = \frac{E_b - E_b}{A_1 F_{12} + \left[ \frac{1}{A_1 F_{1R}} + \frac{1}{A_2 F_{2R}} \right]^{-1}} + \frac{1 - \varepsilon_2}{\varepsilon_2 A_2}
\]

where \( E_b = \sigma T^4 \) with \( \sigma = 5.67 \times 10^{-8} \text{ W/m}^2\cdot\text{K}^4 \) and \( A_1 = A_2 = w \cdot \ell \), but making \( \ell = 1 \text{ m} \) to obtain \( q_1 \) (W/m).

The view factor \( F_{12} \) can be determined from Table 13.2 (Fig. 13.4) for aligned parallel rectangles where \( \bar{X} = X/L = \infty \) since \( X \to \infty \) and \( \bar{Y} = Y/L = W/L = 10/50 = 0.2 \) giving

\[
F_{12} = 0.09902
\]

From the summation rule on \( A_1 \), with \( F_{11} = 0 \),

\[
F_{11} + F_{12} + F_{1R} = 1 \quad F_{1R} = 1 - F_{12} = 1 - 0.09902 = 0.901
\]

and from symmetry of the enclosure,

\[
F_{2R} = F_{1R} = 0.901.
\]

Continued .....
PROBLEM 13.80 (Cont.)

Substituting numerical values into the rate equation, find the heat loss through the gap due to radiation as

\[ q_{\text{rad}} = q_1 = 37 \text{ W/m} \]

(b) The conduction heat rate per unit length (normal to the page) for a 1 - m section is

\[ q_{\text{cond}} = k \frac{1}{L} (T_1 - T_2) = 0.05 \text{ W/mK} \times 1 \text{ m} \frac{(400 - 35) \text{K}}{0.050 \text{ mm}} \]

\[ q_{\text{cond}} = 365 \text{ W/m} \]

The fraction of the total heat transfer through the 1 - m section due to radiation is

\[ \frac{q_{\text{rad}}}{q_{\text{tot}}} = \frac{37}{365 + 37} = 9.2\% \]

We conclude that if the installation process for the sheet insulation can be accomplished with a smaller gap, there is an opportunity to reduce the cost of operating the furnace.
PROBLEM 13.81

KNOWN: Diameter, temperature and emissivity of a heated disk. Diameter and emissivity of a hemispherical radiation shield. View factor of shield with respect to a coaxial disk of prescribed diameter, emissivity and temperature.

FIND: (a) Equivalent circuit, (b) Net heat rate from the hot disk.

SCHEMATIC:

ASSUMPTIONS: (1) Surfaces may be approximated as diffuse/gray, (2) Surface 4 is reradiating, (3) Negligible convection.

ANALYSIS: (a) The equivalent circuit is shown in the schematic. Since surface 4 is treated as reradiating, the net transfer of radiation from surface 1 is equal to the net transfer of radiation to surface 3 ($q_1 = -q_3$).

(b) From the thermal circuit, the desired heat rate may be expressed as

$$ q_1 = \frac{E_{b1} - E_{b3}}{1 - \frac{\varepsilon_1}{\varepsilon_1 A_1} + \frac{1}{A_1 F_{12}} + \frac{2(1 - \varepsilon_2)}{\varepsilon_2 A_2} + \left[ \frac{A_2 F_{23}}{A_2 F_{24}} + \frac{1}{A_3 F_{34}} \right]^{-1} + \frac{1 - \varepsilon_1}{\varepsilon_3 A_3} } $$

where $A_1 = A_3 = \pi D_1^2 / 4 = \pi (0.05 \text{ m})^2 / 4 = 1.963 \times 10^{-3} \text{ m}^2$, $A_2 = \pi D_1^2 / 2 = 2A_1 = 3.925 \times 10^{-3} \text{ m}^2$, $F_{12} = 1$, and $F_{24} = 1 - F_{23} = 0.7$. With $F_{34} = 1 - F_{32} = 1 - F_{23}(A_2 / A_3) = 1 - 0.3(2) = 0.4$, it follows that

Continued ….
PROBLEM 13.81 (Cont.)

\[ q_1 = \frac{A_1\sigma \left(T_1^4 - T_3^4\right)}{\frac{1 - \varepsilon_1}{\varepsilon_1 A_1} + \frac{1}{F_{12}} + \frac{2(1 - \varepsilon_2)}{\varepsilon_2 A_2} + \left[ \frac{A_2}{A_1} F_{23} + \frac{1}{A_1 A_1} + \frac{1}{A_1 A_2 F_{24}} + \frac{1}{A_1 A_3 F_{34}} \right]^{-1} + \frac{1 - \varepsilon_3}{\varepsilon_3}} \]

\[ q_1 = \frac{A_1\sigma \left(T_1^4 - T_3^4\right)}{0.667 + 1 + 49 + \left[ 0.6 + \frac{1}{1.4 + 0.4} \right]^{-1} + 1.5} \]

\[ q_1 = 0.0188 \left(1.963 \times 10^{-3} \text{ m}^2\right) \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left(900^4 - 400^4\right) \text{K}^4 \]

\[ q_1 = 1.32 \text{ W} \]

**COMMENTS:** Radiation transfer from 1 to 3 is impeded and enhanced, respectively, by the radiation shield and the reradiating walls. However, the dominant contribution to the total radiative resistance is made by the shield.
**PROBLEM 13.82**

**KNOWN:** Diameter, temperature and emissivity of a cylindrical heater. Dimensions, temperature, and emissivity of a reflector. Temperature of large surroundings.

**FIND:** (a) Equivalent circuit and values of associated resistances and driving potentials, (b) Required electric power per unit length of heater.

**SCHEMATIC:**

![Schematic Diagram](image)

**ASSUMPTIONS:** (1) Surfaces are diffuse-gray, (2) Surroundings form a large enclosure which may be represented by a hypothetical surface of temperature $T_3 = T_{\text{sur}}$ and emissivity $\varepsilon_3 = 1$.

**ANALYSIS:** (a) The circuit is shown in the schematic, where the hypothetical surface is part of a three-surface enclosure. On a unit length basis, the circuit resistances are

$$\frac{1 - \varepsilon_1}{\varepsilon_1 A_1} = \frac{0.2}{0.8(\pi)(0.03 \text{ m})} = 2.65 \text{ m}^{-1}$$

$$\frac{1}{A_1 F_{12}} = \frac{1}{\pi (0.03 \text{ m})0.625} = 16.98 \text{ m}^{-1}$$

$$\frac{1}{A_1 F_{13}} = \frac{1}{\pi (0.03 \text{ m})0.375} = 28.30 \text{ m}^{-1}$$

$$\frac{1}{A_2 F_{23}} = \frac{1}{A_3 F_{32}} = \frac{1}{(0.15 \text{ m})0.764} = 8.73 \text{ m}^{-1}$$

$$\frac{1 - \varepsilon_2}{\varepsilon_2 A_2} = \frac{0.9}{0.1(0.30 \text{ m})} = 30 \text{ m}^{-1}$$

The view factor $F_{13}$ is obtained from the summation rule, where $F_{13} = 1 - F_{12} = 1 - 0.625 = 0.375$. Similarly, $F_{32} = 1 - F_{31}$, where $F_{31} = F_{13} \left( A_1 / A_3 \right) = 0.375(\pi D/W) = 0.375\pi(0.03 \text{ m}/0.15 \text{ m}) = 0.236$. Hence, $F_{32} = 0.764$. The potentials are

Continued ….
PROBLEM 13.82 (Cont.)

\[ E_{b1} = \sigma T_1^4 = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (945 \text{ K})^4 = 45,220 \text{ W/m}^2 \]

\[ E_{b2} = \sigma T_2^4 = 5.67 \times 10^{-4} \text{ W/m}^2 \cdot \text{K}^4 (385 \text{ K})^4 = 1246 \text{ W/m}^2 \]

\[ E_{b3} = \sigma T_3^4 = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (300 \text{ K})^4 = 459 \text{ W/m}^2 \]

(b) The required heater power may be obtained by applying Eq. (13.19) to node 1. Hence,

\[ q'_1 = \frac{E_{b1} - J_1}{(1 - \varepsilon_1) / \varepsilon_1 A_1'} \]

The radiosity may be obtained by applying radiation balances to nodes J_1 and J_2:

\[ \frac{E_{b1} - J_1}{(1 - \varepsilon_1) / \varepsilon_1 A_1'} = \frac{J_1 - J_2}{1/A_1'F_{12}} + \frac{J_1 - E_{b3}}{1/A_1'F_{13}} \]

\[ \frac{E_{b2} - J_2}{(1 - \varepsilon_2) / \varepsilon_2 A_2'} = \frac{J_2 - J_1}{1/A_2'F_{21}} + \frac{J_2 - E_{b3}}{1/A_2'F_{23}} \]

Substituting the known potentials and solving, we obtain \( J_1 = 37,600 \text{ W/m}^2 \) and \( J_2 = 11,160 \text{ W/m}^2 \). Hence

\[ q'_1 = \frac{(45,220 - 37,600) \text{ W/m}^2}{2.65 \text{ m}^{-1}} = 2875 \text{ W/m} \]

COMMENTS: Additional power would have to be supplied to compensate for heat transfer by free convection from the heater to the air.
**PROBLEM 13.83**

**KNOWN:** Cylindrical cavity with prescribed geometry, wall emissivity, and temperature.

**FIND:** Net radiation heat transfer from the cavity assuming the surroundings of the cavity are at 300 K.

**SCHEMATIC:**

![Cylindrical cavity schematic](image)

- $T_{\text{sur}} = 300K$
- $L = 50\text{ mm}$
- $D = 100\text{ mm}$
- $A_1 = \pi D^2 / 4 = 7.85 \times 10^{-3} \text{ m}^2$
- $A_2 = \pi DL = 1.57 \times 10^{-2} \text{ m}^2$
- $F_{13} = F_{31} = 0.38$
- $F_{32} = F_{12} = 0.62$
- $F_{21} = F_{23} = 0.310$
- $T_1 = T_2 = 1500 \text{ K}$
- $\varepsilon_1 = \varepsilon_2 = 0.6$

**ASSUMPTIONS:** (1) Cavity interior surfaces are diffuse-gray, (2) Surroundings are much larger than the cavity opening $A_3$; $T_3 = T_{\text{sur}} = 300 \text{ K}$ and $\varepsilon_3 = 1$.

**ANALYSIS:** The net radiation heat transfer from the cavity is $-q_3$, which from Eq. 13.20 is,

$$q_3 = A_3 F_{31} (J_3 - J_1) + A_3 F_{32} (J_3 - J_2). $$ (1)

While $J_3 = E_{b3}$ since $\varepsilon_3 = 1$, $J_1$ and $J_2$ are unknown and must be obtained from the radiation balances, Eq. 13.21.

$$\frac{E_{bi} - J_i}{(1 - \varepsilon_i)/\varepsilon_i A_i} = \sum_{j=1}^{N} \frac{J_i - J_j}{(A_i F_{ij})^{-1}} $$ (2)

From Fig. 13.5 with $L/r_1 = 0.050/0.050 = 1$ and $r_3/L = 1$, find $F_{13} = 0.38$. From summation rule and reciprocity: $F_{32} = F_{12} = 1 - F_{12} = 0.62$ and $F_{21} = F_{23} = (A_3 F_{32})/A_2 = 0.310$. Note also, $E_{b1} = E_{b2} = \sigma T_1^4 = \sigma(1500K)^4 = 287,044 \text{ W/m}^2$ and $J_3 = E_{b3} = \sigma T_3^4 = 459.3 \text{ W/m}^2$.

**A1:**

$$\frac{287,044 - J_1}{(1 - 0.6)/0.6} = J_1 - J_2 + \frac{J_1 - J_3}{(0.62)^{-1} (0.38)^{-1}}$$

$$2.5J_1 - 0.62J_2 = 430,741 $$ (3)

**A2:**

$$\frac{287,044 - J_2}{(1 - 0.6)/0.6} = J_2 - J_1 + \frac{J_2 - J_3}{(0.31)^{-1} (0.31)^{-1}}$$

$$-0.31J_1 + 2.140J_2 = 430,708 $$ (4)

Solving Eqs. (3) and (4) simultaneously, find $J_1 = 230,491 \text{ W/m}^2$ and $J_2 = 234,654 \text{ W/m}^2$, and from Eq. (1), find

$$q_3 = 7.854 \times 10^{-3} \text{ m}^2 [0.38(459.3 - 230,491) + 0.62(459.3 - 234,654)] \text{ W/m}^2 = -1827 \text{ W}.$$

Hence, 1827 W are transferred from the cavity to the surroundings.
PROBLEM 13.84

KNOWN: Circular furnace with prescribed temperatures and emissivities of the lateral and end surfaces.

FIND: Net radiative heat transfer from each surface.

SCHEMATIC:

\[ A_3, T_3 = 800 K, \varepsilon_3 = 0.8 \]
\[ A_2, T_2 = 500 K, \varepsilon_2 = 0.5 \]
\[ A_1, T_1 = 400 K, \varepsilon_1 = 0.4 \]

D = 0.3 m
L = 0.3 m

ASSUMPTIONS: (1) Surfaces are isothermal and diffuse-gray.

ANALYSIS: To calculate the net radiation heat transfer from each surface, we need to determine its radiosity. First, evaluate terms which will be required.

\[ E_{b1} = \sigma T_1^4 = 1452 \text{ W/m}^2 \]
\[ A_1 = A_2 = \frac{\pi D^2}{4} = 0.07069 \text{ m}^2 \]
\[ F_{12} = F_{21} = 0.17 \]
\[ E_{b2} = \sigma T_2^4 = 3544 \text{ W/m}^2 \]
\[ A_3 = \pi DL = 0.2827 \text{ m}^2 \]
\[ F_{23} = F_{32} = 0.83 \]
\[ E_{b3} = \sigma T_3^4 = 23,224 \text{ W/m}^2 \]

The view factor \( F_{12} \) results from Fig. 13.5 with \( L/r_1 = 2 \) and \( r_j/L = 0.5 \). The radiation balances using Eq. 13.21, omitting units for convenience, are:

\[ (1) \]
\[ A_1 : \frac{1452 - J_1}{(1 - 0.4)} = 0.07069 \times 0.17 (J_1 - J_2) + 0.07069 \times 0.83 (J_1 - J_3) \]
\[ -2.500J_1 + 0.2550J_2 + 1.2450J_3 = -1452 \]

\[ A_2 : \frac{3544 - J_2}{(1 - 0.5)} = 0.07069 \times 0.17 (J_2 - J_1) + 0.07069 \times 0.83 (J_2 - J_3) \]
\[ -0.1700J_1 - 2.0000J_2 + 0.8300J_3 = -3544 \]

\[ A_3 : \frac{23,224 - J_3}{(1 - 0.8)} = 0.07069 \times 0.83 (J_3 - J_1) + 0.07069 \times 0.83 (J_3 - J_2) \]
\[ 0.05189J_1 + 0.05189J_2 - 1.1037J_3 = -23,224 \]

Solving Eqs. (1) – (3) simultaneously, find
\[ J_1 = 12,877 \text{ W/m}^2 \]
\[ J_2 = 12,086 \text{ W/m}^2 \]
\[ J_3 = 22,216 \text{ W/m}^2 \]

Using Eq. 13.22, the net radiation heat transfer for each surface follows:

\[ q_i = \sum_{j=1}^{N} A_i F_{ij} (J_i - J_j) \]

\[ A_1 : q_1 = 0.07069 \times 0.17 (12,877 - 12,086) W + 0.07069 \times 0.83 (12,877 - 22,216) W = -538 W \]
\[ A_2 : q_2 = 0.07069 \times 0.17 (12,086 - 12,877) W + 0.07069 \times 0.83 (12,086 - 22,216) W = -603 W \]
\[ A_3 : q_3 = 0.07069 \times 0.83 (22,216 - 12,877) W + 0.07069 \times 0.83 (22,216 - 12,086) W = 1141 W \]

COMMENTS: Note that \( \Sigma q_i = 0 \). Also, note that \( J_2 < J_1 \) despite the fact that \( T_2 > T_1 \); note the role emissivity plays in explaining this.
PROBLEM 13.85

KNOWN: Four surface enclosure with all sides of equal area; temperatures of three surfaces are specified while the fourth is re-radiating.

FIND: Temperature of the re-radiating surface $A_4$.

SCHEMATIC:

![Diagram of a four-sided enclosure with specified temperatures and emissivities](image)

ASSUMPTIONS: (1) Surfaces are diffuse-gray, (2) Surfaces have uniform radiosities.

ANALYSIS: To determine the temperature of the re-radiating surface $A_4$, it is necessary to recognize that $J_4 = E_{b4} = \sigma T_4^4$ and that the $J_i$ ($i = 1$ to 4) values must be evaluated by simultaneously solving four radiation balances of the form, Eq. 13.21,

$$\frac{E_{bi} - J_i}{(1 - \varepsilon_i)/\varepsilon_i A_i} = \sum_{j=1}^{N} \frac{J_i - j}{A_i F_{ij}}$$

For simplicity, set $A_1 = A_2 = A_3 = A_4 = 1 \text{ m}^2$ and from symmetry, it follows that all view factors will be $F_{ij} = 1/3$. The necessary emissive powers are of the form $E_{bi} = \sigma T_i^4$.

$E_{b1} = \sigma(700 \text{ K})^4 = 13,614 \text{ W/m}^2$, $E_{b2} = \sigma(500 \text{ K})^4 = 3544 \text{ W/m}^2$, $E_{b3} = \sigma(300 \text{ K})^4 = 459 \text{ W/m}^2$.

The radiation balances are:

$A_1$: 

$$\frac{13,614 - J_1}{(1 - 0.7)/0.7} = \frac{1}{3} (J_1 - J_2) + \frac{1}{3} (J_1 - J_3) + \frac{1}{3} (J_1 - J_4); -1.42857J_1 + 0.14826J_2 + 0.14826J_3 + 0.14826J_4 = -13,614$$

$A_2$: 

$$\frac{3544 - J_2}{(1 - 0.5)/0.5} = \frac{1}{3} (J_2 - J_1) + \frac{1}{3} (J_2 - J_3) + \frac{1}{3} (J_2 - J_4) \cdot 0.33333J_1 - 2.00000J_2 + 0.33333J_3 + 0.33333J_4 = -3544$$

$A_3$: 

$$\frac{459 - J_3}{(1 - 0.3)/0.3} = \frac{1}{3} (J_3 - J_1) + \frac{1}{3} (J_3 - J_2) + \frac{1}{3} (J_3 - J_4) \cdot 0.77778J_1 + 0.77778J_2 - 3.33333J_3 + 0.77778J_4 = -459$$

$A_4$: 

$$0 = \frac{1}{3} (J_4 - J_1) + \frac{1}{3} (J_4 - J_2) + \frac{1}{3} (J_4 - J_3) \cdot 0.33333J_1 + 0.33333J_2 + 0.33333J_3 - 1.00000J_4 = 0$$

Solving this system of equations simultaneously, find

$J_1 = 11,572 \text{ W/m}^2$, $J_2 = 6031 \text{ W/m}^2$, $J_3 = 6088 \text{ W/m}^2$, $J_4 = 7897 \text{ W/m}^2$.

Since the radiosity and emissive power of the re-radiating surface are equal,

$T_4^4 = J_4 / \sigma$

$$T_4 = \left(7897 \text{ W/m}^2 / 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4\right)^{1/4} = 611 \text{ K}.$$<

COMMENTS: Note the values of the radiosities; are their relative values what you would have expected? Is the value of $T_4$ reasonable?
**PROBLEM 13.86**

**KNOWN:** A room with electrical heaters embedded in ceiling and floor; one wall is exposed to the outdoor environment while the other three walls are to be considered as insulated.

**FIND:** Net radiation heat transfer from each surface.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Diffuse-gray surfaces, (2) Surfaces are isothermal and irradiated uniformly, (3) Negligible convection effects, (4) $A_5 = A_{5A} + A_{5B}$.

**ANALYSIS:** To determine the net radiation heat transfer from each surface, find the surface radiosities using Eq. 13.20.

\[
q_i = \sum_{j=1}^{5} A_i F_{ij} (J_i - J_j)
\]

To determine the value of $J_i$, energy balances must be written for each of the five surfaces. For surfaces 1, 2, and 3, the form is given by Eq. 13.21.

\[
\frac{E_{bi} - J_i}{(1 - \varepsilon_i) / \varepsilon_i A_i} = \sum_{j=1}^{5} \frac{J_i - J_j}{(A_i F_{ij})^{-1}} \quad i = 1, 2, \text{ and } 3.
\]

For the insulated or adiabatic surfaces, Eq. 13.22 is appropriate with $q_i = 0$; that is

\[
q_i = \sum_{j=1}^{N} \frac{J_i - J_j}{(A_i F_{ij})^{-1}} = 0 \quad i = 4 \text{ and } 5.
\]

In order to write the energy balances by Eq. (2) and (3), we will need to know view factors. Using Fig. 13.4 (parallel rectangles) or Fig. 13.5 (perpendicular rectangles) find:

- $F_{12} = F_{21} = 0.39, \quad X/L = 10/4 = 2.5, \quad Y/L = 6/4 = 1.5$
- $F_{13} = F_{14} = 0.19, \quad Z/X = 4/10 = 0.4, \quad Y/X = 6/10 = 0.6$
- $F_{34} = F_{43} = 0.19, \quad X/L = 10/6 = 1.66, \quad Y/L = 4/6 = 0.67$
- $F_{24} = F_{13} = 0.19, \quad Z/X = 4/10 = 0.4, \quad Y/X = 6/10 = 0.6$

Note the use of symmetry in the above relations. Using reciprocity, find,

\[
F_{32} = \frac{A_2}{A_3} F_{23} = \frac{A_2}{A_3} F_{13} = \frac{60}{40} \times 0.19 = 0.285; \quad F_{31} = \frac{A_1}{A_3} F_{13} = \frac{60}{40} \times 0.19 = 0.285
\]

\[
F_{51} = \frac{A_1}{A_5} F_{15} = \frac{60}{48} \times 0.23 = 0.288; \quad F_{53} = \frac{A_3}{A_5} F_{35} = \frac{40}{48} \times 0.25 = 0.208.
\]

From the summation view factor relation,

\[
F_{15} = 1 - F_{12} - F_{13} - F_{14} = 1 - 0.39 - 0.19 - 0.19 = 0.23
\]

\[
F_{35} = 1 - F_{31} - F_{32} - F_{34} = 1 - 0.285 - 0.285 - 0.19 = 0.24
\]

Continued …..
Using Eq. (2), now write the energy balances for surfaces 1, 2, and 3. (Note $E_b = \sigma T^4$).

\[
\begin{align*}
\frac{544.2 - J_1}{1 - 0.8/0.8 \times 60} &= J_1 - J_2 + J_1 - J_3 + J_1 - J_4 + J_1 - J_5 \\
0.1250J_1 + 0.0975J_2 + 0.0475J_3 + 0.570J_5 &= -544.2
\end{align*}
\] (4)

\[
\begin{align*}
\frac{617.2 - J_2}{1 - 0.9/0.9 \times 60} &= J_2 - J_1 + J_2 - J_3 + J_2 - J_4 + J_2 - J_5 \\
+0.0433J_1 - 1.111J_2 + 0.02111J_3 + 0.02111J_4 + 0.02556J_5 &= -617.2
\end{align*}
\] (5)

\[
\begin{align*}
\frac{390.1 - J_3}{1 - 0.7/0.7 \times 40} &= J_3 - J_1 + J_3 - J_2 + J_3 - J_4 + J_3 - J_5 \\
+0.1221J_1 + 0.1221J_2 - 1.4284J_3 + 0.08143J_4 + 0.1028J_5 &= -390.1
\end{align*}
\] (6)

Using Eq. (3), now write the energy balances for surfaces 4 and 5 noting $q_4 = q_5 = 0$.

\[
\begin{align*}
0 &= J_4 - J_1 + J_4 - J_2 + J_4 - J_3 + J_4 - J_5 \\
0.285J_1 + 0.285J_2 + 0.19J_3 - 1.0J_4 + 0.24J_5 &= 0
\end{align*}
\] (7)

\[
\begin{align*}
0 &= J_5 - J_1 + J_5 - J_2 + J_5 - J_3 + J_5 - J_4 \\
0.288J_1 + 0.288J_2 + 0.208J_3 + 0.208J_4 - 0.992J_5 &= 0
\end{align*}
\] (8)

Note that Eqs. (4) – (8) represent a set of simultaneous equations which can be written in matrix notation following treatment of Section 13.3.2. That is, $[A][J] = [C]$ with

\[
A = \begin{bmatrix}
-1.250 & 0.0975 & 0.0475 & 0.0475 & 0.0575 \\
0.0433 & -1.111 & 0.02111 & 0.02111 & 0.02556 \\
0.1221 & 0.1221 & -1.4284 & 0.08143 & 0.1028 \\
0.285 & 0.285 & 0.190 & -1.000 & 0.240 \\
0.288 & 0.288 & 0.208 & 0.208 & -0.992
\end{bmatrix}
\]

and

\[
C = \begin{bmatrix}
-544.2 \\
-617.2 \\
-390.1 \\
0 \\
0
\end{bmatrix}
\]

where the $J_i$ were found using a computer routine. The net radiation heat transfer from each of the surfaces can now be evaluated using Eq. (1).

\[
q_1 = A_1 F_{12}(J_1 - J_2) + A_1 F_{13}(J_1 - J_3) + A_1 F_{14}(J_1 - J_4) + A_1 F_{15}(J_1 - J_5)
\]

\[
q_1 = 60 \text{ m}^2 \left[0.39(545.1 - 607.9) + 0.19(545.1 - 441.5) + 0.23(545.1 - 541.0)\right] \text{ W/m}^2 = -200 \text{ W} < 0
\]

\[
q_2 = 60 \text{ m}^2 \left[0.39(607.9 - 545.1) + 0.19(607.9 - 441.5) + 0.23(607.9 - 541.0)\right] \text{ W/m}^2 = 5037 \text{ W} < 0
\]

\[
q_3 = 40 \text{ m}^2 \left[0.285(441.5 - 545.1) + 0.285(441.5 - 607.9) + 0.24(441.5 - 541.0)\right] \text{ W/m}^2 = -4799 \text{ W} < 0
\]

Since $A_4$ and $A_5$ are insulated (adiabatic), $q_4 = q_5 = 0$.

**COMMENTS:** (1) Note that the sum of $q_1 + q_2 + q_3 = +38$ W; this indicates a precision of less than 1% resulted from the solution of the equations. (2) The net radiation for the ceiling, $A_1$, is into the surface. Recognize that the embedded heaters function to offset heat losses to the room air by convection.
**PROBLEM 13.87**

**KNOWN:** Cylindrical cavity closed at bottom with opening at top surface.

**FIND:** Rate at which radiation passes through cavity opening and effective emissivity for these conditions: (a) All interior surfaces are black and at 600 K, (b) Bottom surface of the cavity $\varepsilon = 0.6$, $T = 600$ K; other surfaces are re-radiating, (c) All surfaces are at 600 K with emissivity 0.6, (d) For the cavity configurations of parts (b) and (c), compute and plot $\varepsilon_e$ as a function of the interior surface emissivity over the range 0.6 to 1.0 with all other conditions remaining the same.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Surfaces are opaque, diffuse and gray, (2) Surfaces as subsequently defined have uniform radiosity, (3) Re-radiating surfaces are adiabatic, and (4) Surroundings are at 0 K so that $T_1 = 0$ K and $\varepsilon_1 = 1.0$.

**ANALYSIS:** Define the hypothetical surface $A_1$, the cavity opening, having $T_1 = 0$ K for which $E_{b.1} = J_1 = 0$. The radiant power passing through the cavity opening $A_1$ will be $-q_1$ due to exchange within the four-surface enclosure. The effective emissivity of the cavity is defined as the rate of the radiant power leaving the cavity to that from a blackbody having the same area of the cavity opening and at the temperature of the inner surface of the cavity. That is,

$$\varepsilon_e = -q_1 / A_1 \sigma T^4$$  \hspace{1cm} (1)

where $T$ is the cavity surface temperature. Recognizing that the analysis will require knowledge of view factors, begin by evaluating them now.

For this four-surface enclosure ($N=4$), $N(N-1)/2 = 6$ view factors must be directly determined. The remaining $N^2 - 6 = 10$ can be determined by the summation rules and the reciprocity relations. By inspection,

(1-4): $F_{11} = 0$, $F_{14} = 0$, $F_{22} = 0$, $F_{44} = 0$

Using the view factor equation for coaxial parallel disks, Table 13.2, or Fig. 13.5, evaluate $F_{21}$,

(5): $F_{21} = 0.030$ with $r_f/L = 7.5/40 = 0.188$, $L/r_i = 40/15 = 2.67$.

Considering the top and bottom surfaces, use the additive rule, Eq. 13.5,

(6): $F_{24} = F_{2(1.4)} - F_{21}$ \hspace{1cm} (2)

where $F_{2(1.4)}$ can be evaluated using the coaxial parallel disk relations again

$F_{2(1.4)} = 0.111$ with $r_{(1.4)}/L = 15/40 = 0.375$, $L/r_2 = 40/15 = 2.67$

Substituting numerical values, find

$F_{24} = 0.111 - 0.030 = 0.081$

Continued ….
PROBLEM 13.87 (Cont.)

Using the summation rule for each surface, plus appropriate reciprocity relations, the remaining view factors can be determined. Written as a matrix, the $F_{ij}$ are

$$
\begin{pmatrix}
0^* & 0.120 & 0.880 & 0 \\
0.0300^* & 0 & 0.889 & 0.0811^* \\
0.0413 & 0.167 & 0.667 & 0.125 \\
0^* & 0.108 & 0.892 & 0^*
\end{pmatrix}
$$

The $F_{ij}$ shown with an asterisk were independently determined.

(a) When all the internal surfaces of the cavity are black at 600 K, the cavity opening emits as a black surface and the effective emissivity is unity. Using Eq. 13.14, the heat rate leaving $A_1$ is

$$
q_1 = \sum_{i=1}^{3} A_1 F_{ij} \sigma \left( T_i^4 - T_1^4 \right) = \sigma \left( T_1^4 - T_1^4 \right) A_1 \left[ F_{12} + F_{13} + F_{14} \right]
$$

$$
q_1 = 5.67 \times 10^{-8} \, W/m^2 \cdot K^4 \left( 0^4 - 600^4 \right) \times 1.767 \times 10^{-4} \, m^2 \times [0.120 + 0.880 + 0] = -1.298 \, W
$$

From Eq. (1), it follows that the effective emissivity must be unity.

$$
\varepsilon_1 = 1
$$

(b) When the bottom surface of the cavity is $T_2 = 600$ K with $\varepsilon_2 = 0.6$ and all other surfaces are re-radiating, an enclosure analysis to obtain $q_1$ involves use of Eqs. 13.21 and 13.22. The former will be used on $A_2$ and the latter on the remaining areas.

$$
A_2: \quad \frac{E_{b2} - J_2}{(1-\varepsilon_2)/\varepsilon_2 A_2} = \frac{J_2 - J_1 + J_2 - J_3 + J_2 - J_4}{1/A_2 F_{21} + 1/A_2 F_{23} + 1/A_2 F_{24}}
$$

$$
= \frac{7384 - J_2}{(1-0.6)/0.6 A_2} = \frac{J_2 - 0 + J_2 - J_3 + J_2 - J_4}{1/0.03 A_2 + 1/0.889 A_2 + 1/0.811 A_2}
$$

where $E_{b2} = \sigma T_2^4 = \sigma (600K)^4 = 7348 \, W/m^2$ and $J_1 = E_{b1} = \sigma T_1^4 = \sigma (0)^4 = 0 \, W/m^2$.

$$
A_3: \quad 0 = \frac{J_3 - J_1 + J_3 - J_2 + J_3 - J_4}{1/A_3 F_{31} + 1/A_3 F_{32} + 1/A_3 F_{34}}
$$

$$
0 = \frac{J_3 - 0 + J_3 - J_2 + J_3 - J_4}{1/0.0413 A_3 + 1/0.167 A_3 + 1/0.125 A_3}
$$

$$
A_4: \quad 0 = \frac{J_4 - J_1 + J_4 - J_2 + J_4 - J_3}{1/A_4 F_{41} + 1/A_4 F_{42} + 1/A_4 F_{43}}
$$

$$
0 = 0 + \frac{J_4 - J_2 + J_4 - J_3}{1/0.108 A_4 + 1/0.892 A_4}
$$

Solving Eqs. (4,5,6) simultaneously, find

<table>
<thead>
<tr>
<th>$J_1$</th>
<th>$J_2$</th>
<th>$J_3$</th>
<th>$J_4 (W/m^2)$</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6450</td>
<td>5284</td>
<td>5378</td>

and the heat rate leaving surface $A_1$ is

Continued …..
PROBLEM 13.87 (Cont.)

\[
q_1 = \frac{J_1 - J_2}{1/A_1F_{12}} + \frac{J_1 - J_3}{1/A_1F_{13}} + \frac{J_1 - J_4}{1/A_1F_{14}} = 0.9529 \text{ W} \tag{7}
\]

From Eq. (1), the cavity effective emissivity

\[
\epsilon_e = \frac{-q_1}{A_1\sigma T_2^4} = \frac{0.9529 \text{ W}}{1.767 \times 10^{-4} \text{ m}^2 \sigma (600 \text{ K})^4} = 0.734
\]

(c) When all the interior surfaces are at 600K ($T_2 = T_3 = T_4 = 600$ K) and $\epsilon = 0.6$ ($\epsilon_2 = \epsilon_3 = \epsilon_4 = 0.6$), apply the radiation surfaces energy balances using Eq. 13.21 to $A_2$, $A_3$, and $A_4$

\[
A_2: \quad \frac{E_{b2} - J_2}{(1-\epsilon_2)/\epsilon_2A_2} = \frac{J_2 - J_1}{1/A_2F_{21}} + \frac{J_2 - J_3}{1/A_2F_{23}} + \frac{J_2 - J_4}{1/A_2F_{24}}
\]

\[
7384 - J_2 = \frac{J_2 - 0}{1/0.03A_2} + \frac{J_2 - J_3}{1/0.89A_2} + \frac{J_2 - J_4}{1/0.81A_2}
\tag{8}
\]

\[
A_3: \quad \frac{E_{b3} - J_3}{(1-\epsilon_3)/\epsilon_3A_3} = \frac{J_3 - J_1}{1/A_3F_{31}} + \frac{J_3 - J_2}{1/A_3F_{32}} + \frac{J_3 - J_4}{1/A_3F_{34}} = \frac{J_3 - 0}{1/0.04A_3} + \frac{J_3 - J_2}{1/0.16A_3} + \frac{J_3 - J_4}{1/0.12A_3}
\tag{9}
\]

\[
A_4: \quad \frac{E_{b4} - J_4}{(1-\epsilon_4)/\epsilon_4A_4} = \frac{J_4 - J_1}{1/A_4F_{41}} + \frac{J_4 - J_2}{1/A_4F_{42}} + \frac{J_4 - J_3}{1/A_4F_{43}} = 0 + \frac{J_4 - J_2}{1/0.11A_4} + \frac{J_4 - J_3}{1/0.89A_4}
\tag{10}
\]

Solving Eqs. (8, 9, 10) simultaneously, find

\[
\begin{align*}
J_1 & = 0 \\
J_2 & = 7192 \\
J_3 & = 7164 \\
J_4 & = 7276
\end{align*}
\]

and the heat rate leaving surface $A_1$ is

\[
q_1 = \frac{J_1 - J_2}{1/A_1F_{12}} + \frac{J_1 - J_3}{1/A_1F_{13}} + \frac{J_1 - J_4}{1/A_1F_{14}} = -1.267 \text{ W}
\]

From Eq. (1), the cavity effectiveness is

\[
\epsilon_e = \frac{-q_1}{A_1\sigma T_2^4} = \frac{1.267 \text{ W}}{1.767 \times 10^{-4} \text{ m}^2 \sigma (600 \text{ K})^4} = 0.976
\]

(d) For the cavity configurations of parts (b) and (c) and selected cavity depths, $\epsilon_e$ was computed as a function of the interior surface emissivity $\epsilon = \epsilon_2 = \epsilon_4$ using an IHT model. The model included the following tools: Radiation-View Factors: Relations and Formulas (Coaxial parallel disks); Radiation-Radiation Surface Energy Balance Relations. See comment 2 below.

Continued …..
PROBLEM 13.87 (Cont.)

For the cavity configurations of part (b) – radiating surfaces $A_3$ and $A_4$ – the $\varepsilon_e$ vs. $\varepsilon_2$ plot shows that for all cavity depths, the effective emissivity increases as the emissivity of the bottom surface, $\varepsilon_2$, increases. Note that even when $\varepsilon_2 = 1$, the cavity effective emissivity is always less than unity. Why must that be so? The effect of increasing the cavity depth is to increase the effective emissivity.

For the cavity configuration of part (c) – all interior surfaces at 600 K and $\varepsilon = 0.6$ – the effective emissivity increases with increasing interior surface emissivity. In the limit when $\varepsilon \rightarrow 1$, $\varepsilon_e \rightarrow 1$ as expected, and the cavity performs as an isothermal enclosure. The effective emissivity increases with increasing cavity depth.

COMMENTS: (1) This arrangement of a cavity, referred to as a cylindrical cavity with a lid ($A_4$), is widely used for radiometric applications to calibrate radiometers, radiation thermometers, and heat flux gages. The effective emissivity can be improved by constructing the cavity with a conical bottom surface (rather than a flat bottom). Why do you think this is so?

(2) The IHT model used to generate the part (b) graphical results is quite extensive. It is good practice to build the code in pieces, beginning with evaluation of the view factors. To avoid divide-by-zero errors, use small values for variables which are zero, such as $F_{22} = 1e^{-20}$. Also, set unity emissivity values as 0.9999 rather than 1.0. The set of equations is very stiff, especially because of the re-radiating surface where $T_3$ and $T_4$ are unknowns. You should provide Initial Guess minimum values for $T_3$ and $T_4$ (> 0, positive) and unknown radiosities (> 0, positive).
PROBLEM 13.88

KNOWN: Cylindrical furnace of diameter $D = 90$ mm and overall length $L = 180$ mm. Heating elements maintain the refractory lining ($\varepsilon = 0.8$) of section (1), $L_1 = 135$ mm, at $T_1 = 800^\circ$C. The bottom (2) and upper (3) sections are refractory lined, but are insulated. Furnace operates in a spacecraft environment.

FIND: Power required to maintain the furnace operating conditions with the surroundings at $23^\circ$C.

SCHEMATIC:

ASSUMPTIONS: (1) All surfaces are diffuse gray, (2) Uniform radiosity over the sections 1, 2, and 3, and (3) Negligible convection effects.

ANALYSIS: By defining the furnace opening as the hypothetical area $A_4$, the furnace can be represented as a four-surface enclosure as illustrated above. The power required to maintain $A_1$ at $T_1$ is $q_1$, the net radiation leaving $A_1$. To obtain $q_1$ following the methodology of Section 13.2.2, we must determine the radiosity at all surfaces by simultaneously solving the radiation energy balance equations for each surface which will be of the form, Eqs. 13.20 or 13.21.

$$q_1 = \frac{E_{bi} - J_1}{(1 - \varepsilon_1) / \varepsilon_1 A_1} = \sum_{j=1}^{N} \frac{J_j - J_j}{1/A_1 F_{ij}}$$

Since $\varepsilon_4 = 1$, $J_4 = E_{b4}$, so we only need to perform three energy balances, for $A_1$, $A_2$, and $A_3$, respectively

$$A_1: \frac{E_{bi} - J_1}{(1 - \varepsilon_1) / \varepsilon_1 A_1} = \frac{J_1 - J_2}{1/A_1 F_{12}} + \frac{J_1 - J_3}{1/A_1 F_{13}} + \frac{J_1 - J_4}{1/A_1 F_{14}}$$

$$A_2: 0 = \frac{J_2 - J_1}{1/A_2 F_{21}} + \frac{J_2 - J_3}{1/A_2 F_{23}} + \frac{J_2 - J_4}{1/A_2 F_{24}}$$

$$A_3: 0 = \frac{J_3 - J_1}{1/A_3 F_{31}} + \frac{J_3 - J_2}{1/A_3 F_{32}} + \frac{J_3 - J_4}{1/A_3 F_{34}}$$

Note that $q_2 = q_3 = 0$ since the surfaces are insulated (adiabatic). Recognize that in the above equation set, there are three equations and three unknowns: $J_1$, $J_2$, and $J_3$. From knowledge of $J_1$, $q_1$ can be determined using Eq. (1). Next we need to evaluate the view factors. There are $N^2 = 4^2 = 16$ view factors and $N(N - 1)/2 = 6$ must be independently evaluated, while the remaining can be determined by the summation rule and appropriate reciprocity relations. The six independently determined $F_{ij}$ are:

By inspection: (1) $F_{22} = 0$ (2) $F_{44} = 0$

Coaxial parallel disks: From Fig. 13.5 or Table 13.5, Continued ….
PROBLEM 13.88 (Cont.)

\[
F_{24} = 0.5 \left\{ S - \left[ S^2 - 4 \left( \frac{r_4}{r_2} \right)^2 \right]^{1/2} \right\}
\]

(3) \[
F_{24} = 0.5 \left\{ 18 - \left[ 18^2 - 4 \left( 1 \right)^2 \right]^{1/2} \right\} = 0.05573
\]

\[
S = 1 + \frac{1 + R_4^2}{R_2^2} = 1 + \frac{1 + 0.250^2}{0.250^2} = 18.00 \quad R_2 = \frac{r_2}{L_2} = 45/180 = 0.250 \quad R_4 = \frac{r_4}{L} = 0.250
\]

Enclosure 1-2-2': from the summation rule for \( A_2 \),

(4) \[
F_{21} = 1 - F_{22'} = 1 - 0.09167 = 0.9083
\]

where \( F_{22'} \) can be evaluated from the coaxial parallel disk relation, Table 13.5. For these surfaces, \( R_2 = \frac{r_2}{L_1} = 45/135 = 0.333 \), \( R_2' = \frac{r_2}{L_1} = 0.333 \), and \( S = 11.00 \). From the summation rule for \( A_1 \),

(5) \[
F_{11} = 1 - F_{12} - F_{12'} = 1 - 0.1514 - 0.1514 = 0.6972
\]

and by symmetry \( F_{12} = F_{12'} \) and using reciprocity

\[
F_{12} = A_2 F_{21}/A_1 = \left[ \pi \left( 0.090 m \right) \left( 2/4 \right) \right] \times 0.9083 / \pi \times 0.090 m \times 0.135 m = 0.1514
\]

Enclosure 2'-3-4': from the summation rule for \( A_4 \),

(6) \[
F_{43} = 1 - F_{42'} - F_{44} = 1 - 0.3820 - 0 = 0.6180
\]

where \( F_{44} = 0 \) and using the coaxial parallel disk relation from Table 13.5, with \( R_4 = \frac{r_4}{L_2} = 45/45 = 1 \), \( R_2' = \frac{r_2}{L_2} = 1 \), and \( S = 3 \).

The View Factors: Using summation rules and appropriate reciprocity relations, the remaining 10 view factors can be evaluated. Written in matrix form, the \( F_{ij} \) are

\[
\begin{bmatrix}
0.6972^* & 0.1514 & 0.09704 & 0.05438 \\
0.9083^* & 0^* & 0.03597 & 0.05573^* \\
0.2911 & 0.01798 & 0.3819 & 0.3090 \\
0.3262 & 0.05573 & 0.6180^* & 0^*
\end{bmatrix}
\]

The \( F_{ij} \) shown with an asterisk were independently determined.

From knowledge of the relevant view factors, the energy balances, Eqs. (3, 4, 5), can be solved simultaneously to obtain the radiosities,

\[
J_1 = 73,084 \text{ W/m}^2 \quad J_2 = 67,723 \text{ W/m}^2 \quad J_3 = 36,609 \text{ W/m}^2
\]

The net heat rate leaving \( A_1 \) can be evaluated using Eq. (1) written as

\[
q_1 = \frac{E_{bl1} - J_1}{(1 - \varepsilon_1)/\varepsilon_1A_1} = \frac{(75,159 - 73,084) \text{ W/m}^2}{(1 - 0.8)/0.8 \times 0.03817 \text{ m}^2} = 317 \text{ W}
\]

where \( E_{bl1} = \sigma T_1^4 = \sigma (800 + 273K)^4 = 75,159 \text{ W/m}^2 \) and \( A_1 = \pi DL_1 = \pi \times 0.090m \times 0.135m = 0.03817 \text{ m}^2 \).

COMMENTS: (1) Recognize the importance of defining the furnace opening as the hypothetical area \( A_4 \) which completes the four-surface enclosure representing the furnace. The temperature of \( A_4 \) is that of the surroundings and its emissivity is unity since it absorbs all radiation incident on it. (2) To obtain the view factor matrix, we used the IHT Tool, Radiation, View Factor Relations, which permits you to specify the independently determined \( F_{ij} \) and the tool will calculate the remaining ones.
**PROBLEM 13.89**

**KNOWN:** Rapid thermal processing (RTP) tool consisting of a lamp bank to heat a silicon wafer with irradiation onto its front side. The backside of the wafer (1) is the top of a cylindrical enclosure whose lateral (2) and bottom (3) surfaces are water cooled. An aperture (4) on the bottom surface provides for optical access to the wafer.

**FIND:** (a) Lamp irradiation, \( G_{\text{lamp}} \), required to maintain the wafer at 1300 K; heat removal rate by the cooling coil, and (b) Compute and plot the fractional difference \( (E_{b1} - J_1)/E_{b1} \) as a function of the enclosure aspect ratio, \( L/D \), for the range \( 0.5 \leq L/D \leq 2.5 \) with \( D = 300 \text{ mm} \) fixed for wafer emissivities of \( \varepsilon_1 = 0.75, 0.8, \) and 0.85; how sensitive is this parameter to the enclosure surface emissivity, \( \varepsilon_2 = \varepsilon_3 \).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Enclosure surfaces are diffuse, gray, (2) Uniform radiosity over the enclosure surfaces, (3) No heat losses from the top side of the wafer.

**ANALYSIS:** (a) The wafer-cylinder system can be represented as a four-surface enclosure. The aperture forms a hypothetical surface, \( A_4 \), at \( T_4 = T_2 = T_3 = 300 \text{ K} \) with emissivity \( \varepsilon_4 = 1 \) since it absorbs all radiation incident on it. From an energy balance on the wafer, the absorbed lamp irradiation on the front side of the wafer, \( \alpha_w G_{\text{lamp}} \), will be equal to the net radiation leaving the backside (enclosure-side) of the wafer, \( q_1 \). To obtain \( q_1 \), following the methodology of Section 13.2.2, we must determine the radiosity of all the enclosure surfaces by simultaneously solving the radiation energy balance equations for each surface, which will be of the form, Eqs. 13.20 or 13.21.

\[
q_i = \frac{E_{b1} - J_1}{(1 - \varepsilon_i)/\varepsilon_i A_i} = \sum_{j=1}^{N} \frac{J_i - J_j}{1/A_i F_{ij}} \quad \text{(1,2)}
\]

Since \( \varepsilon_4 = 1 \), \( J_4 = E_{b4} \), we only need to perform three energy balances, for \( A_1, A_2 \) and \( A_3 \), respectively,

\[
A_1: \quad \frac{E_{b1} - J_1}{(1 - \varepsilon_1)/A_1} = \frac{J_1 - J_2}{1/A_1 F_{21}} + \frac{J_1 - J_3}{1/A_1 F_{23}} + \frac{J_1 - J_4}{1/A_1 F_{24}} \quad \text{(3)}
\]

\[
A_2: \quad \frac{E_{b2} - J_1}{(1 - \varepsilon_2)/A_2} = \frac{J_2 - J_1}{1/A_2 F_{21}} + \frac{J_2 - J_3}{1/A_2 F_{23}} + \frac{J_2 - J_4}{1/A_2 F_{24}} \quad \text{(4)}
\]

Continued …..
PROBLEM 13.89 (Cont.)

A3: \[
\frac{E_{b3} - J_3}{(1 - \varepsilon_3)/A_3} = \frac{J_3 - J_1}{1/A_3F_{31}} + \frac{J_3 - J_2}{1/A_3F_{32}} + \frac{J_3 - J_4}{1/A_3F_{34}} \tag{5}
\]

Recognize that in the above equation set, there are three equations and three unknowns: \( J_1, J_2, \) and \( J_3 \). From knowledge of the radiosities, the desired heat rate can be determined using Eq. (1). The required \textit{lamp irradiation},

\[
\alpha_w G_{\text{lamp}} A_1 = q_1 = \frac{E_{b1} - J_1}{(1 - \varepsilon_1)/\varepsilon_1 A_1} \tag{6}
\]

and the heat removal rate by the cooling coil, \( q_{\text{coil}} \), on surfaces \( A_2 \) and \( A_3 \), is

\[
q_{\text{coil}} = -(q_2 + q_3) \tag{7}
\]

where the net radiation leaving \( A_2 \) and \( A_3 \) are, from Eq. (1),

\[
q_2 = \frac{E_{b2} - J_2}{(1 - \varepsilon_2)/\varepsilon_2 A_2} \quad q_1 = \frac{E_{b3} - J_3}{(1 - \varepsilon_3)/\varepsilon_3 A_3} \tag{8, 9}
\]

The surface areas are expressed as

\[
A_1 = \pi D_1^2 / 4 = 0.07069 \, \text{m}^2 \quad A_2 = \pi D_1 L = 0.2827 \tag{10, 11}
\]

\[
A_3 = \pi \left( D_1^2 - D_4^2 \right) = 0.06998 \, \text{m}^2 \quad A_2 = \pi D_4^2 / 4 = 0.0007069 \, \text{m}^2 \tag{12, 13}
\]

Next evaluate the view factors. There are \( N^2 = 4^2 = 16 \) and \( N(N - 1)/2 = 6 \) must be independently evaluated, and the remaining can be determined by summation rules and reciprocity relations. The six independently determined \( F_{ij} \) are:

\textit{By inspection}: (1) \( F_{11} = 0 \) (2) \( F_{33} = 0 \) (3) \( F_{44} = 0 \) (4) \( F_{34} = 0 \)

\textit{Coaxial parallel disks}: from Fig. 13.5 or Table 13.5,

\[
F_{14} = 0.5 \left( S - \left[ S^2 - 4 \left( \frac{r_4}{\eta} \right)^2 \right]^{1/2} \right) \tag{5}
\]

\[
F_{14} = 0.5 \left( 5.01 - \left[ 5.01^2 - 4 \left( \frac{150}{300} \right)^2 \right]^{1/2} \right) = 0.001997
\]

\[
S = 1 + \frac{1 + R_4^2}{R_1^2} = 1 + \frac{1 + 0.05^2}{0.5^2} = 5.010
\]

\[
R_1 = \eta / L = 150 / 300 = 0.5 \quad R_4 = 15 / 300 = 0.05
\]

\textit{Coaxial parallel disks}: from the composite surface rule, Eq. 13.5,

\[
F_{13} = F_{1(3,4)} - F_{14} = 0.17157 - 0.01997 = 0.1696
\]

where \( F_{1(3,4)} \) can be evaluated from the coaxial parallel disk relation, Table 13.5. For these surfaces, \( R_1 = r_1/L = 150/300 = 0.5, R_{(3,4)} = r_3/L = 150/300 = 0.5 \), and \( S = 6.000 \).

\textit{The view factors}: Using summation rules and reciprocity relations, the remaining 10 view factors can be evaluated. Written in matrix form, the \( F_{ij} \) are

Continued .....
The $F_{ij}$ shown with an asterisk were independently determined.

From knowledge of the relevant view factors, the energy balances, Eqs. (3, 4, 5) can be solved simultaneously to obtain the radiosities,

$$
\begin{align*}
J_1 & = 1.514 \times 10^5 \\
J_2 & = 1.097 \times 10^5 \\
J_3 & = 1.087 \times 10^5 \\
J_4 & = 576.8
\end{align*}
$$

From Eqs. (6) and (7), the required lamp irradiation and cooling-coil heat removal rate are

$$
G_{\text{lamp}} = 52.650 \text{ W/m}^2 \quad q_{\text{coil}} = 2.89 \text{ kW}
$$

(b) If the enclosure were perfectly reflecting, the radiosity of the wafer, $J_1$, would be equal to its blackbody emissive power. For the conditions of part (a), $J_1 = 1.514 \times 10^5 \text{ W/m}^2$ and $E_{b1} = 1.619 \times 10^5 \text{ W/m}^2$. As such, the radiosity would be independent of $\varepsilon_w$ thereby minimizing effects due to variation of that property from wafer-to-wafer. Using the foregoing analysis in the IHT workspace (see Comment 1 below), the fractional difference, $(E_{b1} - J_1)/E_{b1}$, was computed and plotted as a function of $L/D$, the aspect ratio of the enclosure.

Note that as the aspect ratio increases, the fractional difference between the wafer blackbody emissive power and the radiosity increases. As the enclosure gets larger, ($L/D$ increases), more power supplied to the wafer is transferred to the water-cooled walls. For any $L/D$ condition, the effect of increasing the wafer emissivity is to reduce the fractional difference. That is, as $\varepsilon_w$ increases, the radiosity increases. The lowest curve on the above plot corresponds to the condition $\varepsilon_2 = \varepsilon_3 = 0.03$, rather than 0.07 as used in the $\varepsilon_w$ parameter study. The effect of reducing $\varepsilon_2$ is substantial, nearly halving the fractional difference. We conclude that the “best” cavity is one with a low aspect ratio and low emissivity (high reflectivity) enclosure walls.

COMMENTS: The IHT model developed to perform the foregoing analysis is shown below. Since the model utilizes several IHT Tools, good practice suggests the code be built in stages. In the first stage, the view factors were evaluated; the bottom portion of the code. Note that you must set the $F_{ij}$ which

Continued ….
are zero to a value such as 1e-20 rather than 0. In the second stage, the enclosure exchange analysis was added to the code to obtain the radiosities and required heat rate. Finally, the equations necessary to obtain the fractional difference and perform the parameter analysis were added.

**PROBLEM 13.90**

**KNOWN:** Observation cabin located in a hot-strip mill directly over the line; cabin floor (f) exposed to steel strip (ss) at \( T_{ss} = 920^\circ C \) and to mill surroundings at \( T_{sur} = 80^\circ C \).

**FIND:** Coolant system heat removal rate required to maintain the cabin floor at \( T_f = 50^\circ C \) for the following conditions: (a) when the floor is directly exposed to the steel strip and (b) when a radiation shield (s) \( \varepsilon_s = 0.10 \) is installed between the floor and the strip.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Cabin floor (f) or shield (s), steel strip (ss), and mill surroundings (sur) form a three-surface, diffuse-gray enclosure, (2) Surfaces with uniform radiosities, (3) Mill surroundings are isothermal, black, (4) Floor-shield configuration treated as infinite parallel planes, and (5) Negligible convection heat transfer to the cabin floor.

**ANALYSIS:** A gray-diffuse, three-surface enclosure is formed by the cabin floor (f) (or radiation shield, s), steel strip (ss), and the mill surroundings (sur). The heat removal rate required to maintain the cabin floor at \( T_f = 50^\circ C \) is equal to \( -q_f \) (or, \( -q_s \)), where \( q_f \) or \( q_s \) is the net radiation leaving the floor or shield. The schematic below represents the details of the surface energy balance on the floor and shield for the conditions without the shield (floor exposed) and with the shield (floor shielded from strip).

(a) **Without shield**

(b) **With shield**

(a) **Without the shield.** Radiation surface energy balances, Eq. 13.21, are written for the floor (f) and steel strip (ss) surfaces to determine their radiosities.

\[
\frac{E_{b,f} - J_f}{(1 - \varepsilon_f) / \varepsilon_f A_f} = \frac{J_f - J_{ss}}{1 / A_f F_{f-ss}} + \frac{J_f - E_{b,sur}}{1 / A_f F_{f-sur}}
\]

\[
\frac{E_{b,ss} - J_{ss}}{(1 - \varepsilon_{ss}) / \varepsilon_{ss} A_{ss}} = \frac{J_{ss} - J_f}{1 / A_{ss} F_{ss-f}} + \frac{J_{ss} - E_{b,sur}}{1 / A_{ss} F_{ss-sur}}
\]

Since the surroundings (sur) are black, \( J_{sur} = E_{b,sur} \). The blackbody emissive powers are expressed as \( E_b = \sigma T^4 \) where \( \sigma = 5.67 \times 10^{-8} \text{ W/m}^2\cdot\text{K}^4 \). The net radiation leaving the floor, Eq. 13.20, is

\[
q_f = A_f F_{f-ss}(J_f - J_{ss}) + A_f F_{f-sur}(J_f - E_{b,sur})
\]

Continued ....
PROBLEM 13.90 (Cont.)

The required view factors for the analysis are contained in the summation rule for the areas $A_f$ and $A_{ss}$.

$$F_{f-ss} + F_{f-sur} = 1 \quad F_{ss-f} + F_{ss-sur} = 1 \quad (4.5)$$

$F_{f-ss}$ can be evaluated from Fig. 13.4 (Table 13.2) for the aligned parallel rectangles geometry. By symmetry, $F_{ss-f} = F_{f-ss}$, and with the summation rule, all the view factors are determined. Using the foregoing relations in the $IHT$ workspace, the following results were obtained:

$$F_{f-ss} = 0.1864 \quad J_f = 7959 \text{ W/m}^2$$

$$F_{f-sur} = 0.8136 \quad J_{ss} = 97.96 \text{ kW/m}^2$$

and the heat removal rate required of the coolant system (cs) is

$$q_{cs} = -q_f = 41.3 \text{ kW}$$

(b) With the shield. Radiation surface energy balances are written for the shield (s) and steel strip (ss) to determine their radiosities.

$$\frac{E_{b,s} - J_s}{(1 - \varepsilon_s)/\varepsilon_s A_s} = \frac{J_s - J_{ss}}{1/A_s F_{s-ss}} + \frac{J_s - E_{b,sur}}{1/A_s F_{s-sur}} \quad (6)$$

$$\frac{E_{b,ss} - J_{ss}}{(1 - \varepsilon_{ss})/\varepsilon_{ss} A_{ss}} = \frac{J_{ss} - J_s}{1/A_{ss} F_{ss-s}} + \frac{J_{ss} - E_{b,sur}}{1/A_{ss} F_{ss-sur}} \quad (7)$$

The net radiation leaving the shield is

$$q_s = A_{ss} F_{ss-s} \left(J_{ss} - J_s\right) + A_{ss} F_{ss-sur} \left(J_{ss} - E_{b,sur}\right) \quad (8)$$

Since the temperature of the shield is unknown, an additional relation is required. The heat transfer from the shield (s) to the floor (f) - the coolant heat removal rate - is

$$-q_s = \frac{\sigma (T_s^4 - T_f^4) A_s}{1 - 1/\varepsilon_s - 1/\varepsilon_f} \quad (9)$$

where the floor-shield configuration is that of infinite parallel planes, Eq. 13.24. Using the foregoing relations in the $IHT$ workspace, with appropriate view factors from part (a), the following results were obtained

$$J_s = 18.13 \text{ kW/m}^2 \quad J_{ss} = 98.20 \text{ kW/m}^2 \quad T_s = 377^\circ C$$

and the heat removal rate required of the coolant system is

$$q_{cs} = -q_s = 6.55 \text{ kW}$$

COMMENTS: The effect of the shield is to reduce the coolant system heat rate by a factor of nearly seven. Maintaining the integrity of the reflecting shield ($\varepsilon_s = 0.10$) operating at nearly $400^\circ C$ in the mill environment to prevent corrosion or oxidation may be necessary.
PROBLEM 13.91

**KNOWN:** Opaque, diffuse-gray plate with $\varepsilon_1 = 0.8$ is at $T_1 = 400$ K at a particular instant. The bottom surface of the plate is subjected to radiative exchange with a furnace. The top surface is subjected to ambient air and large surroundings.

**FIND:** (a) Net radiative heat transfer to the bottom surface of the plate for $T_1 = 400$ K, (b) Change in temperature of the plate with time, $dT_1/dt$, and (c) Compute and plot $dT_1/dt$ as a function of $T_1$ for the range $350 \leq T_1 \leq 900$ K; determine the steady-state temperature of the plate.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Plate is opaque, diffuse-gray and isothermal, (2) Furnace bottom behaves as a blackbody while sides are perfectly insulated, (3) Surroundings are large compared to the plate and behave as a blackbody.

**ANALYSIS:** (a) Recognize that the plate ($A_1$), furnace bottom ($A_2$) and furnace side walls ($A_R$) form a three-surface enclosure with one surface being re-radiating. The net radiative heat transfer leaving $A_1$ follows from Eq. 13.30 written as

$$q_1 = \frac{E_{b1} - E_{b2}}{\varepsilon_1 A_1 + \frac{1}{A_1 F_{12}} + \frac{1}{A_2 F_{1R}}} + \frac{1 - \varepsilon_2}{\varepsilon_2 A_2}$$

From Fig. 13.4 with $X/L = 0.2/0.2 = 1$ and $Y/L = 0.2/0.2 = 1$, it follows that $F_{12} = 0.2$ and $F_{1R} = 1 - F_{12} = 1 - 0.2 = 0.8$. Hence, with $F_{1R} = F_{2R}$ (by symmetry) and $\varepsilon_2 = 1$.

$$q_1 = \frac{5.67 \times 10^{-8} \text{ W} / \text{m}^2 \cdot \text{K}^4 (400^4 - 1000^4) \text{ K}^4}{1 - 0.8 + \frac{1}{0.8 \times 0.4 \text{ m}^2 + 0.4 \text{ m}^2 \times 0.20 + \left( \frac{2}{0.04 \text{ m}^2} \times 0.8 \right)^{-1}}} = -1153 \text{ W}$$

It follows the net radiative exchange to the plate is, $q_{\text{rad,f}} = 1153$ W.

(b) Perform now an energy balance on the plate written as

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \dot{E}_{\text{st}}$$

$$q_{\text{rad,f}} - q_{\text{conv}} - q_{\text{rad, sur}} = Mc_p \frac{dT_1}{dt}$$

$$q_{\text{rad,f}} - hA_s (T_1 - T_\infty) - \varepsilon_1 A_1 \sigma (T_1^4 - T_{\text{sur}}^4) = Mc_p \frac{dT_1}{dt}$$

Substituting numerical values and rearranging to obtain $dT/dt$, find

Continued .....
PROBLEM 13.91 (Cont.)

\[
\frac{dT_1}{dt} = \frac{1}{2 \text{ kg} \times 900 \text{ J/kg} \cdot \text{K}} \left[ +1153 \text{ W} - 25 \text{ W/m}^2 \cdot \text{K} \times 0.04 \text{ m}^2 \times (400 - 300) \text{ K} \\
-0.8 \times 0.04 \text{ m}^2 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left(400^4 - 300^4\right) \text{K}^4 \right]
\]

\[
\frac{dT_1}{dt} = 0.57 \text{ K/s}.
\]

(c) With Eqs. (1) and (2) in the IHT workspace, \(dT_1/dt\) was computed and plotted as a function of \(T_1\).

When \(T_1 = 400 \text{ K}\), the condition of part (b), we found \(dT_1/dt = 0.57 \text{ K/s}\) which indicates the plate temperature is increasing with time. For \(T_1 = 900 \text{ K}\), \(dT_1/dt\) is a negative value indicating the plate temperature will decrease with time. The steady-state condition corresponds to \(dT_1/dt = 0\) for which

\[
T_{1,ss} = 715 \text{ K}
\]

COMMENTS: Using the IHT Radiation Tools – Radiation Exchange Analysis, Three Surface Enclosure with Re-radiating Surface and View Factors, Aligned Parallel Rectangle – the above analysis can be performed. A copy of the workspace follows:

```plaintext
// Energy Balance on the Plate, Equation 2:
M * cp * dTdt = - q1 – h * A1 * (T1 – Tinf) – eps1 * A1 * sigma * (T1^4 – Tsur^4)

/* Radiation Tool – Radiation Exchange Analysis, Three-Surface Enclosure with Reradiating Surface: */
/* For the three-surface enclosure A1, A2 and the reradiating surface AR, the net rate of radiation transfer
from the surface A1 to surface A2 is */
q1 = (Eb1 – Eb2) / ( (1 – eps1) / (eps1 * A1) + 1 / (A1 * F12 + 1/(1/(A1 * F1R) + 1/(A2 * F2R))) + (1 –
eps2) / (eps2 * A2))  // Eq 13.30
/* The net rate of radiation transfer from surface A2 to surface A1 is */
q2 = -q1
/* From a radiation energy balance on AR, */
(JR – J1) / (1/(AR * FR1)) + (JR – J2) / (1/(AR *FR2)) = 0  // Eq 13.31
/* where the radiosities J1 and J2 are determined from the radiation rate equations expressed in terms of
the surface resistances, Eq 13.22 */
q1 = (Eb1 – J1) / ((1 – eps1) / (eps1 * A1))
q2 = (Eb2 – J2) / ((1-eps2) / (eps2 * A2))
// The blackbody emissive powers for A1 and A2 are
Eb1 = sigma * T1^4
Eb2 = sigma * T2^4
// For the reradiating surface,
JR = EbR
```
PROBLEM 13.91 (Cont.)

\[ \text{EbR} = \sigma \cdot T_R^4 \]
\[ \sigma = 5.67 \times 10^{-8} \quad \text{W/m}^2 \cdot \text{K}^4 \]

// Radiation Tool – View Factor:

PROBLEM 13.92

KNOWN: Tool for processing silicon wafer within a vacuum chamber with cooled walls. Thin wafer is radiatively coupled on its back side to a chuck which is electrically heated. The top side is irradiated by an ion beam flux and experiences convection with the process gas and radioactive exchange with the ion-beam grid control surface and the chamber walls.

FIND: (a) Show control surfaces and all relevant processes on a schematic of the wafer, and (b) Perform an energy balance on the wafer and determine the chuck temperature $T_c$ required to maintain the prescribed conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Wafer is diffuse, gray, (3) Separation distance between the wafer and chuck is much smaller than the wafer and chuck diameters, (4) Negligible convection in the gap between the wafer and chuck; convection occurs on the wafer top surface with the process gas, (5) Surfaces forming the three-surface enclosure – wafer ($\varepsilon_w = 0.8$), grid ($\varepsilon_g = 1$), and chamber walls ($\varepsilon_c = 1$) have uniform radiosity and are diffuse, gray, and (6) the chuck surface is black.

ANALYSIS: (a) The wafer is shown schematically above in relation to the key components of the tool: the ion beam generator, the grid which is used to control the ion beam flux, $q_{ib}$, the chuck which aids in controlling the wafer temperature and the process gas flowing over the wafer top surface. The schematic below shows the control surfaces on the top and back surfaces of the wafer along with the relevant thermal processes: $q_{cv}$, convection between the wafer and process gas; $q_a$, applied heat source due to absorption of the ion beam flux, $q_{ib}$; $q_{1,\text{top}}$, net radiation leaving the top surface of the wafer (1) which is part of the three-surface enclosure – grid (2) and chamber walls (3), and; $q_{1,\text{bac}}$, net radiation leaving the backside of the wafer (w) which is part of a two-surface enclosure formed with the chuck (c).

Continued …..
PROBLEM 13.92 (Cont.)

(b) Referring to the schematic and the identified thermal processes, the energy balance on the wafer has the form,

\[ \dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0 \]
\[ -q_{\text{cv}} + q_a - q_{\text{l,bac}} - q_{\text{l, top}} = 0 \]  \hspace{1cm} (1)

where each of the processes are evaluated as follows:

**Convection with the process gas:** with \( A_w = \pi D_w^2 = \pi \left(0.200\text{m}\right)^2 / 4 = 0.03142 \text{ m}^2 \),

\[ q_{\text{cv}} = hA_w (T_w - T_\infty) = 10 \text{ W} / \text{m}^2 \times 0.03142 \text{ m}^2 \times (700 - 500) \text{ K} = 62.84 \text{ W} \]  \hspace{1cm} (2)

**Applied heat source – ion beam:**

\[ q_a = q_{ib} A_w = 600 \text{ W} / \text{m}^2 \times 0.3142 \text{ m}^2 = 18.85 \text{ W} \]  \hspace{1cm} (3)

**Net radiation heat rate, back side; enclosure \((w,c)\):** for the two-surface enclosure comprised of the back side of the wafer \((w)\) and the chuck, \((c)\), Eq. 13.28, yields

\[ q_{\text{l,bac}} = \sigma \left( T_w^4 - T_c^4 \right) \frac{A_w}{(1 - \varepsilon_w) / \varepsilon_w + 1} / \frac{A_w F_{wc} + (1 - \varepsilon_c) / \varepsilon_c A_c}{(1 - \varepsilon_w) / \varepsilon_w + 1} \]

and since the wafer-chuck approximate large parallel plates, \( F_{wc} = 1 \), and since the chuck is black, \( \varepsilon_c = 1 \),

\[ q_{\text{l,bac}} = \sigma \frac{T_w^4 - T_c^4}{T_w^4 - T_c^4} A_w \]
\[ = \frac{0.03142 \text{ m}^2 \times \sigma \left(700^4 - T_c^4\right)K^4}{(1 - 0.6)/0.6 + 1} = 1.069 \times 10^{-9} \left(700^4 - T_c^4\right) \]

**Net radiation heat rate, top surface; enclosure \((1, 2, 3)\):** from the surface energy balance on \( A_1 \), Eq. 13.20.

\[ q_{\text{l, top}} = \frac{E_{b1} - J_1}{(1 - \varepsilon_1) / \varepsilon_1 A_1} \]
\[ = \frac{J_1 - J_2 + J_1 - J_3}{1/A_1 F_{12} + 1/A_1 F_{13}} \]
\[ = \frac{E_{b2} + \sigma T_g^4}{(1 - \varepsilon_1) / \varepsilon_1 A_1} \]
\[ = \frac{E_b3 + \sigma T_{vc}^4}{(1 - \varepsilon_1) / \varepsilon_1 A_1} \]

where \( \varepsilon_1 = \varepsilon_w \), \( A_1 = A_w \), \( E_{b1} = \sigma T_1^4 \) and the radiosity can be evaluated by an enclosure analysis following the methodology of Section 13.2.2. From the energy balance, Eq. 13.21,

\[ \frac{E_{b1} - J_1}{(1 - \varepsilon_1) / \varepsilon_1 A_1} = \frac{J_1 - J_2 + J_1 - J_3}{1/A_1 F_{12} + 1/A_1 F_{13}} \]
\[ = \frac{E_{b2} + \sigma T_g^4}{1/A_1 F_{12} + 1/A_1 F_{13}} \]
\[ = \frac{E_{b3} + \sigma T_{vc}^4}{1/A_1 F_{12} + 1/A_1 F_{13}} \]

where \( J_2 = E_{b2} = \sigma T_g^4 \) and \( J_3 = E_{b3} = \sigma T_{vc}^4 \) since both surfaces are black (\( \varepsilon_g = \varepsilon_{vc} = 1 \)). The view factor \( F_{12} \) can be computed from the relation for coaxial parallel disks, Table 13.5.

\[ F_{12} = 0.5 \left\{ S - \left[ S^2 - 4 \left( r_2 / \eta \right)^2 \right]^{1/2} \right\} = 0.5 \left\{ 6.0 - \left[ 6.0^2 - 4 \left( 1 \right)^2 \right]^{1/2} \right\} = 0.1716 \]

\[ S = 1 + 1 + \frac{R_2^2}{R_1^2} = 1 + \frac{1+0.5^2}{0.5^2} = 6.00 \]

Continued …..
PROBLEM 13.92 (Cont.)

\[ R_1 = \eta / L = 100 / 200 = 0.5 \quad R_4 = r_4 / L = 0.5 \]

The view factor \( F_{13} \) follows from the summation rule applied to \( A_1 \).

\[ F_{13} = 1 - F_{12} = 1 - 0.1716 = 0.8284 \]

Substituting numerical values into Eq. (6), with \( T_1 = T_w = 700 \) K, \( T_2 = T_g = 500 \) K, and \( T_3 = T_{vc} = 300 \) K, find \( J_1 \),

\[
\frac{\sigma T_1^4}{(1 - \varepsilon_1) / \varepsilon_1 A_1} \cdot \frac{1}{F_{12}} - J_1 = \frac{1}{F_{13}} - \sigma T_4^4
\]

\[ J_1 = 8564 \text{ W/m}^2 \]

Using Eq. (5), find \( q_{1,\text{top}} \) with \( E_{b2} = \sigma T_w^4 = 13,614 \text{ W/m}^2 \) and \( A_1 = A_w \),

\[ q_{1,\text{top}} = \frac{(13,614 - 8564) \text{ W/m}^2}{(1 - 0.6) / (0.6 \times 0.03142 \text{m}^2)} = 238 \text{ W} \]

Evaluating \( T_c \) from the energy balance on the wafer, Eq. (1), and substituting appropriate expressions for each of the processes, find

\[-62.84 \text{ W/m}^2 + 18.85 \text{ W} - 1.069 \times 10^{-9} \left( 700^4 - T_c^4 \right) - 238 \text{ W} = 0 \]

\[ T_c = 842.5 \text{ K} \]

From Eq. (4), with \( T_c = 815 \) K, the electrical power required to maintain the chuck is

\[ P_c = -q_{1,\text{bac}} = 1.069 \times 10^{-9} \left( 700^4 - 842.5 \right) = 282 \text{ W} \]

**COMMENTS:** Recognize that the method of analysis is centered about an energy balance on the wafer. Identifying the processes and representing them on the energy balance schematic is a vital step in developing the strategy for a solution. This methodology introduced in Section 1.3.3 becomes important, if not essential, in analyzing complicated physical systems.
PROBLEM 13.93

KNOWN: Ice rink with prescribed ice, rink air, wall, ceiling and outdoor air conditions.

FIND: (a) Temperature of the ceiling, $T_c$, having an emissivity of 0.05 (highly reflective panels) or 0.94 (painted panels); determine whether condensation will occur for either or both ceiling panel types if the relative humidity of the rink air is 70%, and (b) Calculate and plot the ceiling temperature as a function of ceiling insulation thickness for $0.1 \leq t \leq 1$ m, identify conditions for which condensation will occur on the ceiling.

SCHEMATIC:

ASSUMPTIONS: (1) Rink comprised of the ice, walls and ceiling approximates a three-surface, diffuse-gray enclosure, (2) Surfaces have uniform radiosities, (3) Ice surface and walls are black, (4) Panels are diffuse-gray, and (5) Thermal resistance for convection on the outdoor side of the ceiling is negligible compared to the conduction thermal resistance of the ceiling insulation.

PROPERTIES: *Psychometric chart* (Atmospheric pressure; dry bulb temperature, $T_{db} = T_{\infty,i} = 15^\circ C$; relative humidity, $RH = 70\%$): Dew point temperature, $T_{dp} = 9.4^\circ C$.

ANALYSIS: The energy balance on the ceiling illustrated in the schematic below has the form

$$\dot{E}_{in} - \dot{E}_{out} = 0$$

where the rate equations for each process are

$$q_o = \left( T_c - T_{\infty,o} \right) / R_{cond} \quad R_{cond} = t / k A_c$$

$$q_{conv,c} = h A_c \left( T_c - T_{\infty,i} \right)$$

$$q_{rad,c} = \varepsilon E_b \left( T_c \right) A_c - \alpha A_w F_{wc} E_b \left( T_w \right) - \alpha A_i F_{ic} E_b \left( T_i \right)$$

The blackbody emissive powers are $E_b = \sigma T^4$ where $\sigma = 5.67 \times 10^{-8}$ W/m$^2$·K$^4$. Since the ceiling panels are diffuse-gray, $\alpha = \varepsilon$. The view factors required of Eq. (5): determine $F_{ic}$ (ice to ceiling) from Table 13.2 (Fig. 13.5) for parallel, coaxial disks

$$F_{ic} = 0.672$$

and $F_{wc}$ (wall to ceiling) from the summation rule on the ice (i) and the reciprocity rule,

$$F_{ic} + F_{iw} = 1 \quad F_{iw} = F_{cw} \quad (symmetry)$$

$$F_{cw} = 1 - F_{ic}$$

$$F_{wc} = \left( A_c / A_w \right) F_{cw} = \left( A_c / A_w \right) \left( 1 - F_{ic} \right) = 0.410$$

Continued ....
where \( A_c = \pi D^2/4 \) and \( A_w = \pi DL \).

Using the foregoing energy balance, Eq. (1), and the rate equations, Eqs. (2-5), the ceiling temperature is calculated using radiative properties for the two panel types,

\[
\begin{array}{|c|c|c|}
\hline
\text{Ceiling panel} & \varepsilon & T_c \, (^\circ C) \\
\text{Reflective} & 0.05 & 14.0 \\
\text{Paint} & 0.94 & 8.6 \quad T_c < T_{dp} < \\
\hline
\end{array}
\]

The dew point is 9.4\(^\circ\)C corresponding to a relative humidity of 70\% with (dry bulb) air temperature of 15\(^\circ\)C. Condensation will occur on the painted panel since \( T_c < T_{dp} \).

(b) The equations required of the analysis above were solved using \textit{IHT}. The analysis is extended to calculate the ceiling temperatures for a range of insulation thickness and the results plotted below.

![Energy balance on ceiling diagram](image)

For the reflective panel (\( \varepsilon = 0.05 \)), the ceiling surface temperature is considerably above the dew point. Therefore, condensation will not occur for the range of insulation thickness shown. For the painted panel (\( \varepsilon = 0.94 \)), the ceiling surface temperature is always below the dew point. We expect condensation to occur for the range of insulation thickness shown.

\textbf{COMMENTS:} From the analysis, recognize that the radiative exchange between the ice and the ceiling is the dominant process for influencing the ceiling temperature. With the reflective panel, the rate is reduced nearly 20 times that with the painted panel. With the painted panel ceiling, for most of the conditions likely to exist in the rink, condensation will occur.
**PROBLEM 13.94**

**KNOWN:** Diameter, temperature and emissivity of boiler tube. Thermal conductivity and emissivity of ash deposit. Convection coefficient and temperature of gas flow over the tube. Temperature of surroundings.

**FIND:** (a) Rate of heat transfer to tube without ash deposit, (b) Rate of heat transfer with an ash deposit of diameter $D_d = 0.06$ m, (c) Effect of deposit diameter and convection coefficient on heat rate and contributions due to convection and radiation.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Diffuse/gray surface behavior, (2) Surroundings form a large enclosure about the tube and may be approximated as a blackbody, (3) One-dimensional conduction in ash, (4) Steady-state.

**ANALYSIS:** (a) Without an ash deposit, the heat rate per unit tube length may be calculated directly.

$$q' = \frac{\pi D_T (T_{\infty} - T_t)}{\varepsilon_T} + \varepsilon_T \sigma \pi D_T \left(T_{\text{sur}}^4 - T_t^4\right)$$

$$q' = 100 \text{ W} / \text{m} \cdot \text{K} \left(\pi \right)0.05 \text{ m} \left(1800 - 600\right) \text{K} + 0.8 \times 5.67 \times 10^{-8} \text{ W} / \text{m}^2 \cdot \text{K}^4 \left(\pi \right)(0.05 \text{ m}) \left(1500^4 - 600^4\right) \text{K}$$

$$q' = (18,850 + 35,150) \text{ W} / \text{m} = 54,000 \text{ W} / \text{m}$$

(b) Performing an energy balance for a control surface about the outer surface of the ash deposit, $q'_{\text{conv}} + q'_{\text{rad}} = q'_{\text{cond}}$. or

$$\frac{\pi D_d (T_{\infty} - T_d)}{\varepsilon_d} + \varepsilon_d \sigma \pi D_d \left(T_{\text{sur}}^4 - T_d^4\right) = \frac{2\pi k (T_d - T_t)}{\ln (D_d / D_t)}$$

Hence, canceling $\pi$ and considering an ash deposit for which $D_d = 0.06$ m,

$$100 \text{ W} / \text{m}^2 \cdot \text{K} \left(0.06 \text{ m} \right) \left(1800 - T_d\right) \text{K} + 0.9 \times 5.67 \times 10^{-8} \text{ W} / \text{m}^2 \cdot \text{K}^4 \left(0.06 \text{ m} \right) \left(1500^4 - T_d^4\right) \text{K}^4$$

$$= \frac{2 \left(1 \text{ W} / \text{m} \cdot \text{K} \right) \left(T_d - 600\right) \text{K}}{\ln (0.06/0.05)}$$

A trial-and-error solution yields $T_d \approx 1346 \text{ K}$, from which it follows that

$$q' = \frac{\pi D_d (T_{\infty} - T_d)}{\varepsilon_d} + \varepsilon_d \sigma \pi D_d \left(T_{\text{sur}}^4 - T_d^4\right)$$

$$q' = 100 \text{ W} / \text{m}^2 \cdot \text{K} \left(\pi \right)0.06 \text{ m} \left(1800 - 1346\right) \text{K} + 0.9 \times 5.67 \times 10^{-8} \text{ W} / \text{m}^2 \cdot \text{K}^4 \left(\pi \right)0.06 \text{ m} \left(1500^4 - 1346^4\right) \text{K}^4$$

Continued …..
PROBLEM 13.94 (Cont.)

\[ q' = (8560 + 17,140) \, \text{W/m} = 25,700 \, \text{W/m} \]

(c) The foregoing energy balance was entered into the *IHT* workspace and parametric calculations were performed to explore the effects of \( \overline{h} \) and \( D_d \) on the heat rates.

For \( D_d = 0.06 \, \text{m} \) and \( 10 \leq h \leq 1000 \, \text{W/m}^2 \cdot \text{K} \), the heat rate to the tube, \( q_{\text{cond}}' \), as well as the contribution due to convection, \( q_{\text{conv}}' \), increase with increasing \( \overline{h} \). However, because the outer surface temperature \( T_d \) also increases with \( \overline{h} \), the contribution due to radiation decreases and becomes negative (heat transfer from the surface) when \( T_d \) exceeds 1500 K at \( \overline{h} = 540 \, \text{W/m}^2 \cdot \text{K} \). Both the convection and radiation heat rates, and hence the conduction heat rate, increase with decreasing \( D_d \), as \( T_d \) decreases and approaches \( T_t = 600 \, \text{K} \). However, even for \( D_d = 0.051 \, \text{m} \) (a deposit thickness of 0.5 mm), \( T_d = 773 \, \text{K} \) and the ash provides a significant resistance to heat transfer.

**COMMENTS:** Boiler operation in an energy efficient manner dictates that ash deposits be minimized.
**PROBLEM 13.95**

**KNOWN:** Two parallel, large, diffuse-gray surfaces; top one maintained at \( T_1 \) while lower one is insulated and experiences convection.

**FIND:** (a) Temperature of lower surface, \( T_2 \), when \( \varepsilon_1 = \varepsilon_2 = 0.5 \) and (b) Radiant flux leaving the viewing port.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Surfaces are large, diffuse-gray, (2) Lower surface experiences convection and radiation exchange, backside is perfectly insulated.

**ANALYSIS:** (a) Perform an energy balance on the lower surface, giving

\[
q_{\text{conv}} + q_{\text{rad},1} = 0
\]

where the latter term is equal to \( q_1^r \) or \( q_{12}^r \), the net radiant power per unit area exchanged between surfaces 1 and 2. For this two surface enclosure,

\[
q_1^r = \frac{E_b(T_1) - E_b(T_2)}{(1 - \varepsilon_1)/\varepsilon_1 + 1/F_{12} + (1 - \varepsilon_2)/\varepsilon_2} = \frac{\sigma(T_1^4 - T_2^4)}{(1 - \varepsilon_1)/\varepsilon_1 + 1 + (1 - \varepsilon_2)/\varepsilon_2}
\]

with \( F_{12} = 1 \). Combining Eqs. (1) and (2),

\[
h(T_\infty - T_2) + \sigma(T_1^4 - T_2^4)/[(1 - \varepsilon_1)/\varepsilon_1 + 1 + (1 - \varepsilon_2)/\varepsilon_2] = 0
\]

Substituting numerical values with \( \varepsilon_1 = \varepsilon_2 = 0.5 \),

\[
50 \text{ W/m}^2 \cdot \text{K} (300 - T_2) \text{ K} + 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (400^4 - T_2^4) \text{ K}^4 + [1 + 1 + 1] = 0
\]

\( T_2 = 306 \text{ K} \).

(b) The radiant flux leaving the viewing port is \( q_{\text{vp}}^r = G_1 \). From an energy balance on the upper plate

\[
q_1^r = E_1 - \alpha_1 G_1
\]

where \( q_1^r = q_{1-2}^r \), net exchange by radiation. But

\[
q_1^r = (1/3)\sigma(T_1^4 - T_2^4)
\]

\[
E_1 = \varepsilon E_b = 0.5\sigma T_1^4
\]

Hence, the flux is

\[
G_1 = (E_1 - q_1)/\alpha = (1/0.5)\left[0.5\sigma T_1^4 - (1/3)\sigma(T_1^4 - T_2^4)\right]
\]

\[
G_1 = 2\sigma\left[(0.5 - 0.333)T_1^4 + 0.333T_2^4\right] = 816 \text{ W/m}^2.
\]
**PROBLEM 13.96**

**KNOWN:** Dimensions, emissivities and temperatures of heated and cured surfaces at opposite ends of a cylindrical cavity. External conditions.

**FIND:** Required heater power and outside convection coefficient.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Opaque, diffuse-gray surfaces, (3) Negligible convection within cavity, (4) Isothermal disk and heater surfaces, (5) One-dimensional conduction in base, (6) Negligible contact resistance between heater and base, (7) Sidewall is reradiating.

**ANALYSIS:** The equivalent circuit is

From an energy balance on the heater surface, \( q_{1,\text{elec}} = q_{1,\text{cond}} + q_{1,\text{rad}} \),

\[
q_{1,\text{elec}} = k_b \left( \frac{\pi D^2}{4} \right) \frac{T_1 - T_b}{L_b} + \frac{\sigma \left( T_1^4 - T_2^4 \right)}{1 - \varepsilon_1 \varepsilon_1 A_1} + \frac{1}{1 - \varepsilon_2,1 - \varepsilon_2,1 A_2} \left( \frac{1}{A_1 F_1} \right) \left( \frac{1}{A_2 F_2} \right) + \frac{1}{\varepsilon_2,1 A_2}
\]

where \( A_1 = A_2 = \pi D^2/4 = \pi(0.12 \text{ m})^2/4 = 0.0113 \text{ m}^2 \) and from Fig. 13.5, with \( L_e/r_1 = 3.33 \) and \( r_2/L_e = 0.3 \) find \( F_{12} = F_{21} = 0.077 \); hence, \( F_{1R} = F_{2R} = 0.923 \). The required heater power is

\[
q_{1,\text{elec}} = 20 \text{ W/m·K} \times 0.0113 \text{ m}^2 \left( \frac{800 - 300}{0.025} \right) K
\]

\[
= 0.0113 \text{ m}^2 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left( 800^4 - 400^4 \right) \frac{K^4}{0.9} + \frac{1 - 0.9}{0.9} \times \frac{1}{0.077 + \left[ (1/0.923) + (1/0.923) \right]^{-1} + 0.5 \cdot 0.5}
\]

\[
q_{1,\text{elec}} = 4521 \text{ W} + 82.9 \text{ W} = 4604 \text{ W}.
\]

An energy balance for the disk yields, \( q_{\text{rad,2}} = q_{\text{rad,1}} = h_o A_2 (T_2 - T_{\infty}) + \varepsilon_2,0 A_2 \sigma (T_2^4 - T_{\text{sur}}^4) \),

\[
82.9 \text{ W} - 0.9 \times 0.0113 \text{ m}^2 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left( 400^4 - 300^4 \right) \frac{K^4}{h_o} = 64 \text{ W/m}^2 \cdot \text{K}.
\]

**COMMENTS:** Conduction through the ceramic base represents an enormous system loss. The base should be insulated to greatly reduce this loss and hence the electric power input.
PROBLEM 13.97

KNOWN: Electrical conductors in the form of parallel plates having one edge mounted to a ceramic insulated base. Plates exposed to large, isothermal surroundings, $T_{\text{sur}}$. Operating temperature is $T_1 = 500$ K.

FIND: (a) Electrical power dissipated in a conductor plate per unit length, $q_1'$, considering only radiative exchange with the surroundings; temperature of the ceramic insulated base $T_2$; and, (b) $q_1'$ and $T_2$ when the surfaces experience convection with an airstream at $T_\infty = 300$ K and a convection coefficient of $h = 24$ W/m$^2$·K.

SCHEMATIC:

ASSUMPTIONS: (1) Conductor surfaces are diffuse, gray, (2) Conductor and ceramic insulated base surfaces have uniform temperatures and radiosities, (3) Surroundings are large, isothermal.

ANALYSIS: (a) Define the opening between the conductivities as the hypothetical area $A_3$ at the temperature of the surroundings, $T_{\text{sur}}$, with an emissivity $\varepsilon_3 = 1$ since all the radiation incident on the area will be absorbed. The conductor (1)-base (2)-opening (3) form a three surface enclosure with one surface re-radiating (2). From Section 13.3.5 and Eq. 13.30, the net radiation leaving the conductor surface $A_1$ is

$$q_1 = \frac{E_{b1} - E_{b2}}{1 - \varepsilon_1} + \frac{1}{\varepsilon_1 A_1 F_{13} + \left[(1/A_1 F_{12}) + (1/A_3 F_{32})\right]^{-1}} + \frac{1 - \varepsilon_3}{\varepsilon_3 A_3}$$

where $E_{b1} = \sigma T_1^4$ and $E_{b2} = \sigma T_2^4$. The view factors are evaluated as follows:

$F_{32}$: use the relation for two aligned parallel rectangles, Table 13.2 or Fig. 13.4,

$$X = X/L = w/L = 10/40 = 0.25 \quad \bar{Y} = Y/L = \infty$$

$$F_{32} = 0.1231$$

$F_{13}$: applying reciprocity between $A_1$ and $A_3$, where $A_1 = 2L \ell = 2 \times 0.040 \ m \ell = 0.080 \ell$ and $A_3 = w \ell = 0.010 \ell$ and $\ell$ is the length of the conductors normal to the page, $\ell >> L$ or $w$,

$$F_{13} = \frac{A_3 F_{31}}{A_1} = 0.010 \ell \times 0.8769 / 0.080 \ell = 0.1096$$

where $F_{31}$ can be obtained by using the summation rule on $A_3$,

$$F_{31} = 1 - F_{32} = 1 - 0.1231 = 0.8769$$

$F_{12}$: by symmetry

$$F_{12} = F_{13} = 0.1096$$

Continued .....
PROBLEM 13.97 (Cont.)

Substituting numerical values into Eq. (1), the net radiation leaving the conductor is

\[
q_1 = \frac{1 - 0.8}{0.8 \times 0.080 \ell} \cdot \frac{1}{0.80 \ell \times 0.1096 + \left[ (1/0.80 \ell \times 0.1096) + (1/0.010 \ell \times 0.123) \right]^{-1} + 0}
\]

\[
q_1' = q_1 / \ell = \frac{(3544 - 459.3) W}{3.1250 + 101.557 + 0} = 29.5 \text{ W/m}
\]

(b) Consider now convection processes occurring at the conductor (1) and base (2) surfaces, and perform energy balances as illustrated in the schematic below.

**Surface 1**: The heat rate from the conductor includes convection and the net radiation heat rates,

\[
q_{in} = q_{cv,1} + q_1 = h A_1 (T_1 - T_\infty) + \frac{E_{b1} - J_1}{(1 - \varepsilon_1) / \varepsilon_1 A_1}
\]

and the radiosity \( J_1 \) can be determined from the radiation energy balance, Eq. 13.21,

\[
\frac{E_{b1} - J_1}{(1 - \varepsilon_1) / \varepsilon_1 A_1} = \frac{J_1 - J_2}{1 / A_1 F_{12}} + \frac{J_1 - J_3}{1 / A_1 F_{13}}
\]

where \( J_3 = E_{b3} = \sigma T_3^4 \) since A_3 is black.

**Surface 2**: Since the surface is insulated (adiabatic), the energy balance has the form

\[
0 = q_{cv,2} + q_2 = h A_2 (T_2 - T_\infty) + \frac{E_{b2} - J_2}{1 - \varepsilon_2 / \varepsilon_2 A_2}
\]

and the radiosity \( J_2 \) can be determined from the radiation energy balance, Eq. 13.21,

\[
\frac{E_{b2} - J_2}{(1 - \varepsilon_2) / \varepsilon_2 A_2} = \frac{J_2 - J_1}{1 / A_2 F_{21}} + \frac{J_2 - J_3}{1 / A_2 F_{23}}
\]

There are 4 equations, Eqs. (2-5), with 4 unknowns: \( J_1, J_2, T_2 \) and \( q_1 \). Substituting numerical values, the simultaneous solution to the set yields

\[
J_1 = 3417 \text{ W/m}^2 \quad J_2 = 1745 \text{ W/m}^2 \quad T_2 = 352 \text{ K} \quad q_{in}' = 441 \text{ W/m}
\]

**COMMENTS**: (1) The effect of convection is substantial, increasing the heat removal rate from 29.5 W to 441 W for the combined modes.

(2) With the convection process, the current carrying capacity of the conductors can be increased. Another advantage is that, with the presence of convection, the ceramic base operates at a cooler temperature: 352 K vs. 483 K.
PROBLEM 13.98

KNOWN: Surface temperature and spectral radiative properties. Temperature of ambient air. Solar irradiation or temperature of shield.

FIND: (a) Convection heat transfer coefficient when surface is exposed to solar radiation, (b) Temperature of shield needed to maintain prescribed surface temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Surface is diffuse ($\alpha_{\lambda} = \varepsilon_{\lambda}$), (2) Bottom of surface is adiabatic, (3) Atmospheric irradiation is negligible, (4) With shield, convection coefficient is unchanged and radiation losses at ends are negligible (two-surface enclosure).

ANALYSIS: (a) From a surface energy balance,

$$\alpha_S G_S = \varepsilon_s \sigma T_s^4 + h \left( T_s - T_\infty \right).$$

Emission occurs mostly at long wavelengths, hence $\varepsilon_s = \alpha_2 = 0.3$. However,

$$\alpha_s = \frac{\int_0^\infty \alpha_\lambda E_\lambda \left( \lambda, 5800 \text{ K} \right) \lambda d\lambda}{E_b} = \alpha_1 F(0-1\mu m) + \alpha_2 F(1-\infty)$$

and from Table 12.1 at $\lambda T = 5800 \mu m \cdot K$, $F(0-1\mu m) = 0.720$ and hence, $F(1-\infty) = 0.280$ giving $\alpha = 0.9 \times 0.72 + 0.3 \times 0.280 = 0.732$.

Hence

$$h = \frac{\alpha_s G_S - \varepsilon_s \sigma T_s^4}{T_s - T_\infty} = \frac{0.732 \left( 1200 \text{ W/m}^2 \right) - 0.3 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (320 \text{ K})^4}{20 \text{ K}}$$

$$h = 35 \text{ W/m}^2 \cdot \text{K}. \quad \checkmark$$

(b) Since the plate emits mostly at long wavelengths, $\alpha_s = \varepsilon_s = 0.3$. Hence radiation exchange is between two diffuse-gray surfaces.

$$q_{ps} = \frac{\sigma \left( T_p^4 - T_s^4 \right)}{1/\varepsilon_p + 2/\varepsilon_s - 1} = q_{conv} = h \left( T_s - T_\infty \right)$$

$$T_p^4 = \left( h/\sigma \right) \left( T_s - T_\infty \right) \left( 1/\varepsilon_p + 1/\varepsilon_s - 1 \right) + T_s^4$$

$$T_p^4 = \frac{35 \text{ W/m}^2 \cdot \text{K} (20 \text{ K})}{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4} \left( \frac{1}{0.8} + \frac{1}{0.3} - 1 \right) + (320 \text{ K})^4$$

$$T_p = 484 \text{ K}. \quad \checkmark$$

COMMENTS: For $T_p = 484 \text{ K}$ and $\lambda = 1 \mu m$, $\lambda T = 484 \mu m \cdot K$ and $F_{(0, \lambda)} = 0.000$. Hence assumption of $\alpha_s = 0.3$ is excellent.
PROBLEM 13.99

KNOWN: Long uniform rod with volumetric energy generation positioned coaxially within a larger circular tube maintained at 500°C.

FIND: (a) Center $T_1(0)$ and surface $T_{1\text{s}}$ temperatures of the rod for evacuated space, (b) $T_1(0)$ and $T_{1\text{s}}$ for airspace, (c) Effect of tube diameter and emissivity on $T_1(0)$ and $T_{1\text{s}}$.

SCHEMATIC:

ASSUMPTIONS: (1) All surfaces are diffuse-gray.

PROPERTIES: Table A-4. Air ($\bar{T} = 780$ K): $\nu = 81.5 \times 10^{-6}$ m$^2$/s, $k = 0.0563$ W/m·K, $\alpha = 115.6 \times 10^{-6}$ m$^2$/s, $\beta = 0.00128$ K$^{-1}$, Pr = 0.706.

ANALYSIS: (a) The net heat exchange by radiation between the rod and the tube is

$$ q_{12} = \sigma \left( T_1^4 - T_2^4 \right) \frac{(1-\varepsilon_1)/\varepsilon_1 \pi D_1 + (1-\varepsilon_2)/\varepsilon_2 \pi D_2}{1 + [(1-\varepsilon_2)/\varepsilon_2](D_1/D_2)} \tag{1} $$

and, from an energy balance on the rod, $-\dot{E}_{\text{out}} + \dot{E}_{\text{gen}} = 0$, or

$$ q_{12} = \dot{q} \left( \pi D_1^2 / 4 \right) \tag{2} $$

Combining Eqs. (1) and (2) and substituting numerical values, with $F_{12} = 1$, we obtain

$$ \dot{q} = \frac{4}{D_1} \left[ \frac{\sigma \left( T_1^4 - T_2^4 \right)}{(1-\varepsilon_1)/\varepsilon_1 + 1 + [(1-\varepsilon_2)/\varepsilon_2](D_1/D_2)} \right] $$

$$ 20 \times 10^3 \frac{W}{m^3} = \frac{4}{0.050m} \left[ \frac{5.67 \times 10^{-8} W/m^2 \cdot K \cdot K^4 \left(T_{1\text{s}}^4 - 773^4\right)}{(1-0.2)/0.2 + 1 + [(1-0.2)/0.2](0.050/0.060)} \right] $$

$$ = 54.4 \times 10^{-8} \left( T_{1\text{s}}^4 - 773^4 \right) W/m^3 $$

$$ T_{1\text{s}} = 792 \text{ K.} \left< \right. $$

From Eq. 3.53, the rod center temperature is

$$ T_1(0) = \frac{\dot{q} \left(D_1/2\right)^2}{4k} + T_{1\text{s}} $$

$$ T_1(0) = \frac{20 \times 10^3 \frac{W}{m^3} \left(0.050m/2\right)^2}{4 \times 15 \frac{W}{m \cdot K}} + 792 \text{ K} = 0.21 \text{ K} + 792 \text{ K} = 792.2 \text{ K.} \left< \right. $$

(b) The convection heat rate is given by Eqs. 9.58 to 9.60. However, assuming a maximum possible value of $(T_{s1} - T_2) = 19$ K, $Ra_L = g\beta (T_{s1} - T_2) L^3 / \nu \alpha = 9.8 \text{ m/s}^2 \left(0.00128 \text{ K}^{-1}\right)19 \text{ K (0.005 m)}^3 /115.6 \times 81.5 \times 10^{-12} \text{ m}^4 /s^2 = 3.16$ and $Ra_c^* = \left[\ln(D_2/D_1)\right] \left[(D_1)^{-3/5} + (D_2)^{-3/5}\right] \left[\ln(1.2)\right] \left[(0.005 m)^3 [(0.05 m)^{3/5}

Continued …..
PROBLEM 13.99 (Cont.)

\[ + (0.06 \text{ m})^{3/5} \} \ 3.16 = 0.14. \] It follows that buoyancy driven flow is negligible and heat transfer across the airspace is by conduction. Hence, from Eq. 3.27, \( q_{\text{cond}} = 2 \pi k \frac{(T_{1s} - T_{2})}{\ln(r_2 / r_1)} \).

\[ q_{\text{cond}} = \frac{2\pi k (T_{1s} - T_{2})}{\ln (r_2 / r_1)} = \frac{2\pi (0.0563 \ \text{W} / \text{m} \cdot \text{K})(T_{1s} - 773)K}{\ln (30 / 25)} = 1.94 (T_{1s} - 773) \]

The energy balance then becomes

\[ \dot{q} = \frac{\pi D_1^2}{4} (q'_{12} + q'_{\text{cond}}) \quad \text{or} \]

\[ 2 \times 10^4 = \left[ 54.4 \times 10^{-8} (T_{1s}^4 - 773^4) + 988 (T_{1s} - 773) \right] \]

\[ T_{1s} = 783 \ \text{K} \quad \text{and} \quad T_1 (0) = 783.2 \ \text{K} \]

(c) Entering the foregoing model and the prescribed properties of air into the IHT workspace, the parametric calculations were performed for \( D_2 = 0.06 \) m and \( D_2 = 0.10 \) m. For \( D_2 = 1.0 \) m, \( Ra^*_c > 100 \) and heat transfer across the airspace is by free convection, instead of conduction. In this case, convection was evaluated by entering Eqs. 9.58 – 9.60 into the workspace. The results are plotted as follows.

The first graph corresponds to the evacuated space, and the surface temperature decreases with increasing \( \varepsilon_1 = \varepsilon_2 \), as well as with \( D_2 \). The increased emissivities enhance the effectiveness of emission at surface 1 and absorption at surface 2, both which have the effect of reducing \( T_{1s} \). Similarly, with increasing \( D_2 \), more of the radiation emitted from surface 1 is ultimately absorbed at 2 (less of the radiation reflected by surface 2 is intercepted by 1). The second graph reveals the expected effect of a reduction in \( T_{1s} \) with inclusion of heat transfer across the air. For small emissivities \( (\varepsilon_1 = \varepsilon_2 < 0.2) \), conduction across the air is significant relative to radiation, and the small conduction resistance corresponding to \( D_2 = 0.06 \) m yields the smallest value of \( T_{1s} \). However, with increasing \( \varepsilon \), conduction/convection effects diminish relative to radiation and the trend reverts to one of decreasing \( T_{1s} \) with increasing \( D_2 \).

**COMMENTS:** For this situation, the temperature variation *within* the rod is small and independent of surface conditions.
PROBLEM 13.100

FIND: (a) Temperature of intervening wall, (b) Verification of gas temperature on one side.

SCHEMATIC:

ASSUMPTIONS: (1) All duct surfaces may be approximated as blackbodies, (2) Fully developed conditions, (3) Negligible temperature difference across intervening wall, (4) Gases are nonparticipating media.

ANALYSIS: (a) Applying an energy balance to a control surface about the wall yields

\[ \dot{E}_{in} = \dot{E}_{out}. \]

Assuming \( T_{g,1} > T_w > T_{g,2} \), it follows that

\[ q_{\text{rad}}(1 \rightarrow w) + q_{\text{conv}}(g1 \rightarrow w) = q_{\text{rad}}(w \rightarrow 2) + q_{\text{conv}}(w \rightarrow g2) \]

\[
A_1 F_{w1} \sigma (T_1^4 - T_w^4) + h A_w (T_{g,1} - T_w) = A_w F_{w2} \sigma (T_w^4 - T_2^4) + h A_w (T_w - T_{g,2})
\]

and with

\[ A_1 F_{w1} = A_w F_{w1} = A_w F_{w2} = A_w \]

and substituting numerical values,

\[ 2\sigma T_w^4 + 2hT_w = \sigma (T_1^4 + T_2^4) + h (T_{g,1} + T_{g,2}) \]

\[ 2\times10^{-8}T_w^4 + 10T_w = 13,900. \]

Trial-and-error solution yields

\( T_w = 526 \) K.

(b) Applying an energy balance to a control surface about the hot gas (g,1) yields

\[ \dot{E}_{in} = \dot{E}_{out} \]

\[ h A_1 (T_1 - T_{g,1}) = h A_w (T_{g,1} - T_w) \]

or

\[ T_1 - T_{g,1} = \left[ D / (\pi D / 2) \right] (T_{g,1} - T_w) \]

\[ 29^\circ C = 29^\circ C. \]

COMMENTS: Since there is no change in any of the temperatures in the axial direction, this scheme simply provides for energy transfer from side wall 1 to side wall 2.
**PROBLEM 13.101**

**KNOWN:** Temperature, dimensions and arrangement of heating elements between two large parallel plates, one insulated and the other of prescribed temperature. Convection coefficients associated with elements and bottom surface.

**FIND:** (a) Temperature of gas enclosed by plates, (b) Element electric power requirement, (c) Rate of heat transfer to 1 m × 1m section of panel.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Diffuse-gray surfaces, (2) Negligible end effects since the surfaces form an enclosure, (3) Gas is nonparticipating, (4) Surface 3 is reradiating with negligible conduction and convection.

**ANALYSIS:** (a) Performing an energy balance for a unit control surface about the gas space, \( \dot{E}_{in} - \dot{E}_{out} = 0 \).

\[
\frac{h_1 \pi D (T_1 - T_m) - h_2 s (T_m - T_2)}{h_1 \pi D + h_2 s} = 0
\]

\[
T_m = \frac{h_1 \pi D T_1 + h_2 s T_2}{h_1 \pi D + h_2 s} = \frac{10 \text{ W/m}^2 \cdot \text{K} \cdot (0.025 \text{ m})600 \text{ K} + 2 \text{ W/m}^2 \cdot \text{K} \cdot (0.05 \text{ m})400 \text{ K}}{10 \text{ W/m}^2 \cdot \text{K} \cdot (0.025 \text{ m}) + 2 \text{ W/m}^2 \cdot \text{K} \cdot (0.05 \text{ m})} = \frac{577 \text{ K}}{577 \text{ K}}
\]

(b) The equivalent thermal circuit is

The energy balance on surface 1 is

\[
q_{1,elec} = q_{1,conv} + q_{1,rad}
\]

where \( q_{1,rad} \) can be evaluated by considering a unit cell of the form

\[
A_1' = \pi D = \pi (0.025 \text{ m}) = 0.0785 \text{ m}
\]

\[
A_2' = A_3' = s = 0.05 \text{ m}
\]

Continued …..
The view factors are:

\[ F_{21} = 1 - \left[ 1 - (D/s)^2 \right]^{1/2} + (D/s) \tan^{-1} \left[ \left( s^2 - D^2 \right)/D^2 \right]^{1/2} \]

\[ F_{21} = 1 - \left[ 1 - 0.25 \right]^{1/2} + 0.5 \tan^{-1} (4-1)^{1/2} = 0.658 \]

\[ F_{23} = 1 - F_{21} = 0.342 = F_{32}. \]

For the unit cell,

\[ A'_2 F_{21} = 0.05 \times 0.658 = 0.0329 \ m = A'_2 F_{31} = A'_3 F_{13} \]

\[ A'_2 F_{23} = 0.05 \times 0.342 = 0.0171 \ m = A'_3 F_{32}. \]

Hence,

\[ q'_{i,\text{rad}} = \frac{E_{b1} - E_{b2}}{R_{\text{equiv}}' + (1 - \varepsilon_2)/\varepsilon_2 A'_2} \]

\[ R_{\text{equiv}}' = A'_1 F_{12} + \frac{1}{1/A'_1 F_{13} + 1/A'_2 F_{23}} = \left[ 0.0329 + \frac{1}{(0.0329)^{-1} + (0.0171)^{-1}} \right] \ m \]

\[ R_{\text{equiv}}' = 22.6 \ m^{-1}. \]

Hence

\[ q'_{i,\text{rad}} = \frac{5.67 \times 10^{-8} W/\ m^2 \cdot K \cdot (600^4 - 400^4) K^4}{22.6 + (1 - 0.5)/0.5 \times 0.05} m^{-1} = 138.3 \ W/\ m \]

\[ q'_{i,\text{conv}} = \hbar \pi D (T_i - T_m) = 10 \ W/\ m^2 \cdot K \cdot \pi (0.025 \ m) (600 - 577) K = 17.8 \ W/\ m \]

\[ q'_{i,\text{elec}} = (138.3 + 17.8) W/\ m = 156 \ W/\ m. \]

(c) Since all energy added via the heating elements must be transferred to surface 2,

\[ q'_2 = q'_i. \]

Hence, since there are 20 elements in a 1 m wide strip,

\[ q_2(1\text{m} \times 1\text{m}) = 20 \times q'_{i,\text{elec}} = 3120 \ W. \]

**COMMENTS:** The bottom panel would have to be cooled (from below) by a heat sink which could dissipate 3120 W/m².
**PROBLEM 13.102**

**KNOWN:** Flat plate solar collector configuration.

**FIND:** Relevant heat transfer processes.

**SCHEMATIC:**

The incident solar radiation will experience transmission, reflection and absorption at each of the cover plates. However, it is desirable to have plates for which absorption and reflection are minimized and transmission is maximized. Glass of low iron content is a suitable material. Solar radiation incident on the absorber plate may be absorbed and reflected, but it is desirable to have a coating which maximizes absorption at short wavelengths.

Energy losses from the absorber plate are associated with radiation, convection and conduction. Thermal radiation exchange occurs between the absorber and the adjoining cover plate, between the two cover plates, and between the top cover plate and the surroundings. To minimize this loss, it is desirable that the emissivity of the absorber plate be small at long wavelengths. Energy is also transferred by free convection from the absorber plate to the first cover plate and between cover plates. It is transferred by free or forced convection to the atmosphere. Energy is also transferred by conduction from the absorber through the insulation.

The foregoing processes provide for heat loss from the absorber, and it is desirable to minimize these losses. The difference between the solar radiation absorbed by the absorber and the energy loss by radiation, convection and conduction is the energy which is transferred to the working fluid. This transfer occurs by conduction through the absorber and the tube wall and by forced convection from the tube wall to the fluid.
**PROBLEM 13.103**

**KNOWN:** Operating conditions of a flat plate solar collector.

**FIND:** Expressions for determining the rate at which useful energy is collected per unit area.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Uniform surface heat fluxes and temperatures, (3) Opaque, diffuse-gray surface behavior for long-wave thermal radiation, (4) Complete absorption of solar radiation by absorber plate \((\alpha_{ap,S} = 1)\).

**ANALYSIS:** From an energy balance on the absorber plate, \(\dot{E}_{in} = \dot{E}_{out}\),

\[
\alpha_{ap,S} \left( \tau_{cp,S} \right) G_S = q_u + q_{conv,i} + q_{rad,ap-cp}.
\]

Hence with complete absorption of solar radiation by the absorber plate,

\[
q_u = \tau_{cp,S} G_S - h_i \left( T_{ap} - T_{cp} \right) - \frac{\sigma \left( T_{ap}^4 - T_{cp}^4 \right)}{1/\epsilon_{ap} + 1/\epsilon_{cp} - 1}
\]

(1)

where \(F_{ap-cp} = 1\) and Eq. 13.24 is used to obtain \(q_{rad,ap-cp}^*\). To determine \(q_u^*\) from Eq. (1), however, \(T_{cp}\) must be known. From an energy balance on the cover plate,

\[
\alpha_{cp,S} G_S + q_{conv,i} + q_{rad,ap-cp} = q_{conv,o} + q_{rad,sky}
\]

or

\[
\alpha_{cp,S} G_S + h_i \left( T_{ap} - T_{cp} \right) + \frac{\sigma \left( T_{ap}^4 - T_{cp}^4 \right)}{1/\epsilon_{ap} + 1/\epsilon_c - 1}
\]

\[
= h_o \left( T_{cp} - T_{\infty} \right) + \epsilon_{cp} \sigma \left( T_{cp}^4 - T_{sky}^4 \right).
\]

(2)

Eq. (2) may be used to obtain \(T_{cp}\).

**COMMENTS:** With \(T_{ap}\) presumed to be known, \(T_{cp}\) may be evaluated from Eq. (2) and \(q_u^*\) from Eq. (1).
PROBLEM 13.104

KNOWN: Ceiling temperature of furnace. Thickness, thermal conductivity, and/or emissivities of alternative thermal insulation systems. Convection coefficient at outer surface and temperature of surroundings.

FIND: (a) Mathematical model for each system, (b) Temperature of outer surface $T_{s,o}$ and heat loss $q''$ for each system and prescribed conditions, (c) Effect of emissivity on $T_{s,o}$ and $q''$.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Diffuse/gray surfaces, (3) Surroundings form a large enclosure about the furnace, (4) Radiation in air space corresponds to a two-surface enclosure of large parallel plates.

PROPERTIES: Table A-4, air ($T_f = 730$ K): $k = 0.055$ W/m·K, $\alpha = 1.09 \times 10^{-4}$ m$^2$/s, $\nu = 7.62 \times 10^{-5}$ m$^2$/s, $\beta = 0.001335$ K$^{-1}$, Pr = 0.702.

ANALYSIS: (a) To obtain $T_{s,o}$ and $q''$, an energy balance must be performed at the outer surface of the shield.

**Insulation:**

$q''_{\text{cond}} = q''_{\text{conv},o} + q''_{\text{rad},o} = q''$

$k = \frac{(T_{s,i} - T_{s,o})}{L} = h_o \left( T_{s,o} - T_\infty \right) + \varepsilon_o \sigma \left( T_{s,o} - T_{\text{sur}} \right)$

**Air Space:**

$q''_{\text{conv},i} + q''_{\text{rad},i} = q''_{\text{conv},o} + q''_{\text{rad},o} = q''$

$h_i \left( T_{s,i} - T_{s,o} \right) + \frac{\sigma \left( T_{s,i}^4 - T_{s,o}^4 \right)}{1 + \frac{1}{\varepsilon_i} - 1} = h_o \left( T_{s,o} - T_\infty \right) + \varepsilon_o \sigma \left( T_{s,o}^4 - T_{\text{sur}}^4 \right)$

where Eq. 13.24 has been used to evaluate $q''_{\text{rad},i}$ and $h_i$ is given by Eq. 9.49

$$\overline{Nu_L} = \frac{h_i L}{k} = 0.696 Ra_L^{1/3} Pr^{0.074}$$

(b) For the prescribed conditions ($\varepsilon_i = \varepsilon_o = 0.5$), the following results were obtained.

**Insulation:** The energy equation becomes

$$0.09 \frac{\text{W}}{\text{m} \cdot \text{K}} \left( 900 - T_{s,o} \right) K = 25 \frac{\text{W}}{\text{m}^2 \cdot \text{K}} \left( T_{s,o} - 300 \right) K + 0.5 \times 5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} \left( T_{s,o}^4 - 300^4 \right) K$$

Continued …..
and a trial-and-error solution yields

\[ T_{s,o} = 366 \text{ K} \quad q' = 1920 \text{ W/m}^2 \]  

**Air-Space:** The energy equation becomes

\[
h_i \left( 900 - T_{s,o} \right) K + \frac{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left( 900^4 - T_{s,o}^4 \right) K^4}{3} \\
= 25 \text{ W/m}^2 \cdot K \left( T_{s,o} - 300 \right) K + 0.5 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left( T_{s,o}^4 - 300^4 \right) K^4
\]

where

\[
h_i = \frac{0.055 \text{ W/m} \cdot \text{K}}{0.025 \text{ m}} 0.069 \text{Ra}_L^{1/3} \text{Pr}^{0.074}
\]

and Ra\_L = g\beta(T_{s,i} - T_{s,o})L^3/\alpha\nu. A trial-and-error solution, which includes reevaluation of the air properties, yields

\[ T_{s,o} = 598 \text{ K} \quad q' = 10,849 \text{ W/m}^2 \]

The inner and outer heat fluxes are \( q_{\text{conv},i} = 867 \text{ W/m}^2 \), \( q_{\text{rad},i} = 9982 \text{ W/m}^2 \), \( q_{\text{conv},o} = 7452 \text{ W/m}^2 \), and \( q_{\text{rad},o} = 3397 \text{ W/m}^2 \).

(c) Entering the foregoing models into the IHT workspace, the following results were generated.

**Insulation:**

![Graphs showing surface temperature and emissivity](image)
As expected, the outer surface temperature decreases with increasing $\varepsilon_o$. However, the reduction in $T_{s,o}$ is not large since heat transfer from the outer surface is dominated by convection.

In this case $T_{s,o}$ increases with increasing $\varepsilon_o = \varepsilon_i$ and the effect is significant. The effect is due to an increase in radiative transfer from the inner surface, with $q_{\text{rad},i} = q_{\text{conv},i} = 1750 \text{ W/m}^2$ for $\varepsilon_o = \varepsilon_i = 0.1$ and $q_{\text{rad},i} = 20,100 \text{ W/m}^2 \gg q_{\text{conv},i} = 523 \text{ W/m}^2$ for $\varepsilon_o = \varepsilon_i = 0.9$. With the increase in $T_{s,o}$, the total heat flux increases, along with the relative contribution of radiation ($q_{\text{rad},o}$) to heat transfer from the outer surface.

**COMMENTS:**

1. With no insulation or radiation shield and $\varepsilon_i = 0.5$, radiative and convective heat fluxes from the ceiling are 18,370 and 15,000 W/m$^2$, respectively. Hence, a significant reduction in the heat loss results from use of the insulation or the shield, although the insulation is clearly more effective.

2. Rayleigh numbers associated with free convection in the air space are well below the lower limit of applicability of Eq. (1). Hence, the correlation was used outside its designated range, and the error associated with evaluating $h_i$ may be large.

3. The *IHT* solver had difficulty achieving convergence in the first calculation performed for the radiation shield, since the energy balance involves two nonlinear terms due to radiation and one due to convection. To obtain a solution, a fixed value of $Ra_L$ was prescribed for Eq. (1), while a second value of $Ra_{L,2} = g \beta (T_{s,i} - T_{s,o}) L^3 / \alpha \nu$ was computed from the solution. The prescribed value of $Ra_L$ was replaced by the value of $Ra_{L,2}$ and the calculations were repeated until $Ra_{L,2} = Ra_L$. 
PROBLEM 13.105

KNOWN: Dimensions of a composite insulation consisting of honeycomb core sandwiched between solid slabs.

FIND: Total thermal resistance.

SCHEMATIC: Because of the repetitive nature of the honeycomb core, the cell sidewalls will be adiabatic. That is, there is no lateral heat transfer from cell to cell, and it suffices to consider the heat transfer across a single cell.

ASSUMPTIONS: (1) One-dimensional, steady-state conditions, (2) Equivalent conditions for each cell, (3) Constant properties, (4) Diffuse, gray surface behavior.

PROPERTIES: Table A-3, Particle board (low density): \( k_1 = 0.078 \text{ W/m} \cdot \text{K} \); Particle board (high density): \( k_2 = 0.170 \text{ W/m} \cdot \text{K} \); For both board materials, \( \varepsilon = 0.85 \); Table A-4, Air (\( \bar{T} = 7.5^\circ\text{C}, 1 \text{ atm} \)): \( \nu = 14.15 \times 10^{-6} \text{ m}^2/\text{s}, k = 0.0247 \text{ W/m} \cdot \text{K} \), \( \alpha = 19.9 \times 10^{-6} \text{ m}^2/\text{s} \), \( \Pr = 0.71 \), \( \beta = 3.57 \times 10^{-3} \text{ K}^{-1} \).

ANALYSIS: The total resistance of the composite is determined by conduction, convection and radiation processes occurring within the honeycomb and by conduction across the inner and outer slabs. The corresponding thermal circuit is shown.

The total resistance of the composite and equivalent resistance for the honeycomb are

\[
R = R_{\text{cond},i} + R_{\text{eq}} + R_{\text{cond},o} \quad \quad R_{\text{eq}}^{-1} = \left( R_{\text{cond}}^{-1} + R_{\text{conv}}^{-1} + R_{\text{rad}}^{-1} \right)_{\text{hc}}.
\]

The component resistances may be evaluated as follows. The inner and outer slabs are plane walls, for which the thermal resistance is given by Eq. 3.6. Hence, since \( L_1 = L_3 \) and the slabs are constructed from low-density particle board.

\[
R_{\text{cond},i} = R_{\text{cond},o} = \frac{L_1}{k_1 W^2} = \frac{0.0125 \text{ m}}{0.078 \text{ W/m} \cdot \text{K} \cdot (0.01 \text{ m})^2} = 1603 \text{ K/W}.
\]

Continued ….
Similarly, applying Eq. 3.6 to the side walls of the cell

\[ R_{\text{cond, hc}} = \frac{L_2}{k_2 \left( W^2 - (W - t)^2 \right)} = \frac{L_2}{k_2 \left( 2Wt - t^2 \right)} \]

\[ = \frac{0.050 \text{ m}}{0.170 \text{ W} / \text{m} K \times 2 \times 0.01 \text{ m} \times 0.002 \text{ m} - (0.002 \text{ m})^2} = 8170 \text{ K} / \text{W}. \]

From Eq. 3.9 the convection resistance associated with the cellular airspace may be expressed as

\[ R_{\text{conv, hc}} = 1 / h (W - t)^2. \]

The cell forms an enclosure that may be classified as a horizontal cavity heated from below, and the appropriate form of the Rayleigh number is \( \text{Ra}_L = g \beta (T_1 - T_2) L^3_2 / \alpha \nu \). To evaluate this parameter, however, it is necessary to *assume* a value of the cell temperature difference. As a first approximation, \( T_1 - T_2 = 15^\circ \text{C} - (-5^\circ \text{C}) = 20^\circ \text{C}, \)

\[ \text{Ra}_L = \frac{9.8 \text{ m} / \text{s}^2 \left( 3.57 \times 10^{-3} \text{ K}^{-1} \right)(20 \text{ K})(0.05 \text{ m})^3}{19.9 \times 10^{-6} \text{ m}^2 / \text{s} \times 14.15 \times 10^{-6} \text{ m}^2 / \text{s}} = 3.11 \times 10^5. \]

Applying Eq. 9.49 as a first approximation, it follows that

\[ h = (k / L_2) \left[ 0.069 \text{Pr}^{1/3} \right] = \frac{0.0247 \text{ W} / \text{m} \cdot \text{K}}{0.05 \text{ m}} \left[ 0.069 \left( 3.11 \times 10^5 \right)^{1/3} (0.71)^{0.074} \right] = 2.25 \text{ W} / \text{m}^2 \cdot \text{K}. \]

The convection resistance is then

\[ R_{\text{conv, hc}} = \frac{1}{2.25 \text{ W} / \text{m}^2 \cdot \text{K} \times (0.01 \text{ m} - 0.002 \text{ m})^2} = 6944 \text{ K} / \text{W}. \]

The resistance to heat transfer by radiation may be obtained by first noting that the cell forms a three-surface enclosure for which the sidewalls are reradiating. The net radiation heat transfer between the end surfaces of the cell is then given by Eq. 13.30. With \( \varepsilon_1 = \varepsilon_2 = \varepsilon \) and \( A_1 = A_2 = (W - t)^2 \), the equation reduces to

\[ q_{\text{rad}} = \frac{(W - t)^2 \sigma (T_1^4 - T_2^4)}{2(1/\varepsilon - 1) + \left[ F_{12} + \left[ (F_{1R} + F_{2R}) / F_{1R} F_{2R} \right]^{-1} \right]^{-1}}. \]

However, with \( F_{1R} = F_{2R} = (1 - F_{12}) \), it follows that

\[ q_{\text{rad}} = \frac{(W - t)^2 \sigma (T_1^4 - T_2^4)}{2(1/\varepsilon - 1) + \left[ F_{12} + \left( (1-F_{12})^2 / 2(1-F_{12}) \right)^{-1} \right]^{-1}} = \frac{(W - t)^2 \sigma (T_1^4 - T_2^4)}{2(1/\varepsilon - 1) + \frac{2}{1+F_{12}}}. \]

The view factor \( F_{12} \) may be obtained from Fig. 13.4, where

\[ \frac{X}{L} = \frac{Y}{L} = \frac{W - t}{L_2} = \frac{10 \text{ mm} - 2 \text{ mm}}{50 \text{ mm}} = 0.16. \]

Hence, \( F_{12} = 0.01 \). Defining the radiation resistance as

\[ R_{\text{rad, hc}} = \frac{T_1 - T_2}{q_{\text{rad}}} \]

it follows that

Continued ….
PROBLEM 13.105 (Cont.)

\[ R_{\text{rad, hc}} = \frac{2(1/\varepsilon - 1) + 2/(1 + T_1/T_2)}{(W - t)^2 \sigma \left((T_1^2 + T_2^2)(T_1 + T_2)\right)} \]

where \( \left(T_1^4 - T_2^4\right) = \left(T_1^2 + T_2^2\right)(T_1 + T_2)(T_1 - T_2) \). Accordingly,

\[ R_{\text{rad, hc}} = \frac{2\left(\begin{array}{c} 1 \\ 0.85 \\ -1 \end{array}\right) + \frac{2}{1 + 0.01}}{(0.01 \text{ m} - 0.002 \text{ m})^2 \times 5.67 \times 10^{-8} \text{ W} / \text{m}^2 \cdot \text{K}^4 \left[(288 \text{ K})^2 + (268 \text{ K})^2\right]} \times (288 + 268) \text{ K} \]

where, again, it is assumed that \( T_1 = 15^\circ \text{C} \) and \( T_2 = -5^\circ \text{C} \). From the above expression, it follows that

\[ R_{\text{rad, hc}} = \frac{0.353 + 1.980}{3.123 \times 10^{-4}} = 7471 \text{ K} / \text{W}. \]

In summary the component resistances are

\[ R_{\text{cond, i}} = R_{\text{cond, o}} = 1603 \text{ K} / \text{W} \]
\[ R_{\text{cond, hc}} = 8170 \text{ K} / \text{W} \quad R_{\text{conv, hc}} = 6944 \text{ K} / \text{W} \quad R_{\text{rad, hc}} = 7471 \text{ K} / \text{W}. \]

The equivalent resistance is then

\[ R_{\text{eq}} = \left(\begin{array}{c} \frac{1}{8170} + \frac{1}{6944} + \frac{1}{7471} \end{array}\right)^{-1} = 2498 \text{ K} / \text{W} \]

and the total resistance is

\[ R = 1603 + 2498 + 1603 = 5704 \text{ K} / \text{W}. \]

COMMENTS: (1) The problem is iterative, since values of \( T_1 \) and \( T_2 \) were assumed to calculate \( R_{\text{conv, hc}} \) and \( R_{\text{rad, hc}} \). To check the validity of the assumed values, we first obtain the heat transfer rate \( q \) from the expression

\[ q = \frac{T_{s,1} - T_{s,2}}{R} = \frac{25^\circ \text{C} - (-10^\circ \text{C})}{5704 \text{ K} / \text{W}} = 6.14 \times 10^{-3} \text{ W}. \]

Hence

\[ T_1 = T_{s,1} - qR_{\text{cond, i}} = 25^\circ \text{C} - 6.14 \times 10^{-3} \text{ W} \times 1603 \text{ K} / \text{W} = 15.2^\circ \text{C} \]
\[ T_2 = T_{s,0} + qR_{\text{cond, o}} = -10^\circ \text{C} + 6.14 \times 10^{-3} \text{ W} \times 1603 \text{ K} / \text{W} = -0.2^\circ \text{C}. \]

Using these values of \( T_1 \) and \( T_2 \), \( R_{\text{conv, hc}} \) and \( R_{\text{rad, hc}} \) should be recomputed and the process repeated until satisfactory agreement is obtained between the initial and computed values of \( T_1 \) and \( T_2 \).

(2) The resistance of a section of low density particle board 75 mm thick \( (L_1 + L_2 + L_3) \) of area \( W^2 \) is 9615 K/W, which exceeds the total resistance of the composite by approximately 70%. Accordingly, use of the honeycomb structure offers no advantages as an insulating material. Its effectiveness as an insulator could be improved \( (R_{\text{eq}} \text{ increased}) \) by reducing the wall thickness \( t \) to increase \( R_{\text{cond}} \), evacuating the cell to increase \( R_{\text{conv}} \), and/or decreasing \( \varepsilon \) to increase \( R_{\text{rad}} \). A significant increase in \( R_{\text{rad, hc}} \) could be achieved by aluminizing the top and bottom surfaces of the cell.
PROBLEM 13.106

KNOWN: Dimensions and surface conditions of a cylindrical thermos bottle filled with hot coffee and lying horizontally.

FIND: Heat loss.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible heat loss from ends (long infinite cylinders), (3) Diffuse-gray surface behavior.

PROPERTIES: Table A-4, Air \((T_f = (T_1 + T_2)/2 = 328 \text{ K}, 1 \text{ atm})\): \(k = 0.0284 \text{ W/m-K}, \nu = 23.74 \times 10^{-6} \text{ m}^2/\text{s}, \alpha = 26.6 \times 10^{-6} \text{ m}^2/\text{s}, \text{Pr} = 0.0703, \beta = 3.05 \times 10^{-3} \text{ K}^{-1}\).

ANALYSIS: The heat transfer across the air space is

\[
q = q_{\text{rad}} + q_{\text{conv}}.
\]

From Eq. 13.25 for concentric cylinders

\[
q_{\text{rad}} = \frac{\sigma (\pi D_L) \left(T_1^4 - T_2^4\right)}{1 + 1 - \varepsilon_2 \left(\frac{\bar{n}}{\bar{r}_2}\right)} = \frac{4.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}}{4 + 3 (0.035/0.04)} = 3.20 \text{ W}.
\]

From Eq. 9.25,

\[
\text{Ra}_L = \frac{g \beta (T_1 - T_2)L^3}{\alpha \nu} = \frac{9.8 \text{ m/s}^2 \left(3.05 \times 10^{-3} \text{ K}^{-1}\right) \left(40 \text{ K}\right) \left(0.005 \text{ m}\right)^3}{26.6 \times 10^{-6} \text{ m}^2/\text{s} \times 23.74 \times 10^{-6} \text{ m}^2/\text{s}} = 236.7.
\]

Hence from Eq. 9.60

\[
\text{Ra}_c^* = \frac{\left[\ln \left(\frac{D_2}{D_1}\right)\right]^4 \text{Ra}_L}{L^3 \left(\frac{D_1^{-0.6} + D_2^{-0.6}}{2}\right)^5} = \frac{\left[\ln (0.08/0.07)\right]^4 236.7}{(0.005 \text{ m})^3 \left(0.07^{-0.6} + 0.08^{-0.6}\right)^5} = 7.85.
\]

However, the implication of such a small value of \(\text{Ra}_c^*\) is that free convection effects are negligible.

Heat transfer across the airspace is therefore by conduction \((k_{\text{eff}} = k)\). From Eq. 3.27

\[
q_{\text{conv}} = \frac{2\pi Lk (T_1 - T_2)}{\ln \left(\frac{r_2}{\eta}\right)} = \frac{2\pi \times 0.3 \text{ m} 	imes 0.0284 \text{ W/m-K} \times (75 - 35) \text{ K}}{\ln (0.04/0.035)} = 16.04 \text{ W}.
\]

Hence the total heat loss is

\[
q = q_{\text{rad}} + q_{\text{conv}} = 19.24 \text{ W}.
\]

COMMENTS: (1) End effects could be considered in a more detailed analysis, (2) Conduction losses could be eliminated by evacuating the annulus.
**PROBLEM 13.107**

**KNOWN:** Thickness and height of a vertical air space. Emissivity and temperature of adjoining surfaces.

**FIND:** (a) Heat loss per unit area across the space, (b) Heat loss per unit area if space is filled with urethane foam.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Diffuse-gray surface behavior, (3) Air space is a vertical cavity, (4) Constant properties, (5) One-dimensional conduction across foam.

**PROPERTIES:** *Table A-4*, Air ($T_f = 4^\circ C, 1\ atm$): $\nu = 13.84 \times 10^{-6} $ m$^2$/s, $k = 0.0245$ W/m$\cdot$K, $\alpha = 19.5 \times 10^{-6} $ m$^2$/s, $Pr = 0.71$, $\beta = 3.61 \times 10^{-3} $ K$^{-1}$; *Table A-3*, Urethane foam: $k = 0.026$ W/m$\cdot$K.

**ANALYSIS:** (a) With the air space, heat loss is by radiation and free convection or conduction. From Eq. 13.24,

$$ q_{\text{rad}} = \frac{\sigma (T_1^4 - T_2^4)}{1/\varepsilon_1 + 1/\varepsilon_2 - 1} = \frac{5.67 \times 10^{-8} W/m^2 \cdot K^4 (291^4 - 263^4) K^4}{1.222} = 110.7 W/m^2. $$

With

$$ Ra_L = \frac{g \beta (T_1 - T_2) L^3}{\nu \alpha} = \frac{9.8 m^2/s (3.61 \times 10^{-3} K^{-1}) (18+10) K (0.1 m)^3}{13.84 \times 10^{-6} m^2/s \times 19.5 \times 10^{-6} m^2/s} = 3.67 \times 10^6 $$

and $H/L = 30$, Eq. 9.53 may be used as a first approximation to obtain

$$ \overline{Nu}_L = 0.046 Ra_L^{1/3} = 0.046 \left(3.67 \times 10^6\right)^{1/3} = 7.10 $$

$$ h = \frac{k}{\overline{Nu}_L} = 0.0245 W/m \cdot K/0.1 m = 1.74 W/m^2 \cdot K. $$

The convection heat flux is

$$ q_{\text{conv}}^* = \frac{h}{L} (T_1 - T_2) = 1.74 W/m^2 \cdot K (18+10) K = 48.7 W/m^2. $$

The heat loss is then

$$ q^* = q_{\text{rad}}^* + q_{\text{conv}}^* = 110.7 + 48.7 = 159 W/m^2. $$

(b) With the foam, heat loss is by conduction and

$$ q^* = q_{\text{cond}}^* = \frac{k}{L} (T_1 - T_2) = \frac{0.026 W/m \cdot K/0.1 m}{(18+10) K} = 7.3 W/m^2. $$

**COMMENTS:** Use of the foam insulation reduces the heat loss considerably. Note the significant effect of radiation.
**PROBLEM 13.108**

**KNOWN:** Temperatures and emissivity of window panes and critical Rayleigh number for onset of convection in air space.

**FIND:** (a) The conduction heat flux across the air gap for the optimal spacing, (b) The total heat flux for uncoated panes, (c) The total heat flux if one or both of the panes has a low-emissivity coating.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Critical Rayleigh number is $Ra_{L,c} = 2000$, (2) Constant properties, (3) Radiation exchange between large (infinite), parallel, diffuse-gray surfaces.

**PROPERTIES:** Table A-4, air $[T = (T_1 + T_2)/2 = 1^\circ C = 274 \text{ K}]$: $\nu = 13.6 \times 10^{-6} \text{ m}^2/\text{s}, k = 0.0242 \text{ W/m-K}, \alpha = 19.1 \times 10^{-6} \text{ m}^2/\text{s}, \beta = 0.00365 \text{ K}^{-1}$.

**ANALYSIS:** (a) With $Ra_{L,c} = g \beta (T_1 - T_2) L_{op}^3 / \alpha \nu$

$$L_{op} = \left[ \frac{\alpha \nu Ra_{L,c}}{g \beta (T_1 - T_2)} \right]^{1/3} = \left[ \frac{19.1 \times 13.6 \times 10^{-12} \text{ m}^4/\text{s}^2 \times 2000}{9.8 \text{ m/s}^2 \left(0.00365 \text{ K}^{-1}\right)42^\circ \text{C}} \right]^{1/3} = 0.0070 \text{ m}$$

The conduction heat flux is then

$$q_{cond}^\ast = k(T_1 - T_2) / L_{op} = 0.0242 \text{ W/m} \cdot \text{K (42}^\circ \text{C})/0.0070 \text{ m} = 145.2 \text{ W/m}^2$$

(b) For conventional glass ($\varepsilon_g = 0.90$), Eq. (13.24) yields,

$$q_{rad}^\ast = \frac{\sigma (T_1^4 - T_2^4)}{2 \left(\frac{1}{\varepsilon_g} - 1\right)} = \frac{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left(295^4 - 253^4\right)}{1.222} = 161.3 \text{ W/m}^2$$

and the total heat flux is

$$q_{tot}^\ast = q_{cond}^\ast + q_{rad}^\ast = 306.5 \text{ W/m}^2$$

(c) With only one surface coated,

$$q_{rad}^\ast = \frac{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left(295^4 - 253^4\right)}{\frac{1}{0.90} + \frac{1}{0.10} - 1} = 19.5 \text{ W/m}^2$$

Continued …..
PROBLEM 13.108 (Cont.)

\[ q_{\text{tot}} = 164.7 \text{ W/m}^2 \]

With both surfaces coated,

\[ q_{\text{rad}} = \frac{5.67 \times 10^{-8} \text{ W/m}^2 \cdot K^4 \left(295^4 - 253^4\right)}{\frac{1}{0.10} + \frac{1}{0.10} - 1} = 10.4 \text{ W/m}^2 \]

\[ q_{\text{tot}} = 155.6 \text{ W/m}^2 \]

**COMMENTS:** Without any coating, radiation makes a large contribution (53\%) to the total heat loss. With one coated pane, there is a significant reduction (46\%) in the total heat loss. However, the benefit of coating both panes is marginal, with only an additional 3\% reduction in the total heat loss.
PROBLEM 13.109

KNOWN: Dimensions and emissivity of double pane window. Thickness of air gap. Temperatures of room and ambient air and the related surroundings.

FIND: (a) Temperatures of glass panes and rate of heat transfer through window, (b) Heat rate if gap is evacuated. Heat rate if special coating is applied to window.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Negligible glass pane thermal resistance, (3) Constant properties, (4) Diffuse-gray surface behavior, (5) Radiation exchange between interior window surfaces may be approximated as exchange between infinite parallel plates, (6) Interior and exterior surroundings are very large.

PROPERTIES: Table A-4, Air (p = 1 atm). Obtained from using IHT to solve for conditions of Part (a): \( T_{f,i} = 287.4 \) K; \( v_i = 14.8 \times 10^{-6} \) m\(^2\)/s, \( k_i = 0.0253 \) W/m\( \cdot \)K, \( \alpha_i = 20.8 \times 10^{-6} \) m\(^2\)/s, \( P_i = 0.71, \beta_i = 0.00348 \) K\(^{-1}\). \( T_\infty = (T_{s,i} + T_{s,o}) / 2 = 273.7 \) K; \( v = 13.6 \times 10^{-6} \) m\(^2\)/s, \( k = 0.0242 \) W/m\( \cdot \)K, \( \alpha = 19.0 \times 10^{-6} \) m\(^2\)/s, \( P = 0.71, \beta = 0.00365 \) K\(^{-1}\). \( T_{f,o} = 259.3 \) K; \( v_o = 12.3 \times 10^{-6} \) m\(^2\)/s, \( k_o = 0.023 \) W/m\( \cdot \)K, \( \alpha_o = 17.1 \times 10^{-6} \) m\(^2\)/s, \( P_o = 0.72, \beta_o = 0.00386 \) K\(^{-1}\).

ANALYSIS: (a) The heat flux through the window may be expressed as

\[
q^* = q_{\text{rad},i} + q_{\text{conv},i} = \varepsilon_g \sigma \left( T_{\text{sur},i}^4 - T_{s,i}^4 \right) + \bar{h}_i \left( T_{\infty,i} - T_{s,i} \right) 
\]

(1)

\[
q^* = q_{\text{rad},\text{gap}} + q_{\text{conv},\text{gap}} = \frac{\sigma \left( T_{s,i}^4 - T_{s,o}^4 \right)}{1 + \frac{1}{\varepsilon_g} - 1} + \bar{h}_{\text{gap}} \left( T_{s,i} - T_{s,o} \right) 
\]

(2)

\[
q^* = q_{\text{rad},o} + q_{\text{conv},o} = \varepsilon_g \sigma \left( T_{s,o}^4 - T_{\text{sur},o}^4 \right) + \bar{h}_o \left( T_{s,o} - T_{\infty,o} \right) 
\]

(3)

where radiation exchange between the window panes is determined from Eq. (13.24) and radiation exchange with the surroundings is determined from Eq. (13.27). The inner and outer convection coefficients, \( \bar{h}_i \) and \( \bar{h}_o \), are determined from Eq. (9.26), and \( \bar{h}_{\text{gap}} \) is obtained from Eq. (9.52).

The foregoing equations may be solved for the three unknowns \( \{q^*, T_{s,i}, T_{s,o}\} \). Using the IHT software to effect the solution, we obtain

\[ T_{s,i} = 281.8 \text{ K} = 8.8^\circ \text{C} \]

Continued ….
PROBLEM 13.109 (Cont.)

\[ T_{s,o} = 265.6 \text{ K} = -7.4^\circ\text{C} \]

\[ q = 91.3 \text{ W} \]

(b) If the air space is evacuated \((\bar{h}_g = 0)\), we obtain

\[ T_{s,i} = 283.6 \text{ K} = 10.6^\circ\text{C} \]

\[ T_{s,o} = 263.8 \text{ K} = 9.2^\circ\text{C} \]

\[ q = 75.5 \text{ W} \]

If the space is not evacuated but the coating is applied to inner surfaces of the window panes,

\[ T_{s,i} = 285.9 \text{ K} = 12.9^\circ\text{C} \]

\[ T_{s,o} = 261.3 \text{ K} = -11.7^\circ\text{C} \]

\[ q = 55.9 \text{ W} \]

If the space is evacuated and the coating is applied,

\[ T_{s,i} = 291.7 \text{ K} = 18.7^\circ\text{C} \]

\[ T_{s,o} = 254.7 \text{ K} = -18.3^\circ\text{C} \]

\[ q = 9.0 \text{ W} \]

COMMENTS:  (1) For the conditions of part (a), the convection and radiation heat fluxes are comparable at the inner and outer surfaces of the window, but because of the comparatively small convection coefficient, the radiation flux is approximately twice the convection flux across the air gap.  (2) As the resistance across the air gap is progressively increased (evacuated, coated, evacuated and coated), the temperatures of the inner and outer panes increase and decrease, respectively, and the heat loss decreases.  (3) Clearly, there are significant energy savings associated with evacuation of the gap and application of the coating.  (4) In all cases, solutions were obtained using the temperature-dependent properties of air provided by the software.  The property values listed in the PROPERTIES section of this solution pertain to the conditions of part (a).
PROBLEM 13.110

KNOWN: Absorber and cover plate temperatures and spectral absorptivities for a flat plate solar collector. Collector orientation and solar flux.

FIND: (a) Rate of solar radiation absorption per unit area, (b) Heat loss per unit area.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Adiabatic sides and bottom, (3) Cover is transparent to solar radiation, (4) Sun emits as a blackbody at 5800 K, (5) Cover and absorber plates are diffuse-gray to long wave radiation, (6) Negligible end effects, (7) L << width and length.

PROPERTIES: Table A-4, Air (T = T_a + T_c)/2 = 321.5 K, 1 atm): v = 18.05 × 10^{-6} \text{ m}^2/\text{s}, k = 0.0279 \text{ W/m} \cdot \text{K}, \alpha = 25.7 \times 10^{-6} \text{ m}^2/\text{s}.

ANALYSIS: (a) The absorbed solar irradiation is

\[ G_{S,\text{abs}} = \alpha_{S,a} G_S \]

where

\[ G_S = q_s \cos 30^\circ = 900 \times 0.866 = 779.4 \text{ W/m}^2 \]

\[ \alpha_{S,a} = \int_0^\infty \alpha_{\lambda,a} G_{\lambda,S} d\lambda = \int_0^\infty \alpha_{\lambda,a} E_{\lambda,b} \left(5800 \text{ K}\right) d\lambda \]

\[ \alpha_{S,a} = \alpha_{\lambda,a,1}\left(F_{0\rightarrow2 \mu m}\right) + \alpha_{\lambda,a,2}\left(F_{2\rightarrow\infty}\right) \]

For \( \lambda T = 2 \mu m \times 5800 \text{ K} = 11,600 \mu m \cdot \text{K} \) from Table 12.1, \( F_{0\rightarrow2 \lambda T} = 0.941 \), find

\[ \alpha_{S,a} = 0.9 \times 0.941 + 0.2 \times (1 - 0.941) = 0.859. \]

Hence

\[ G_{S,\text{abs}} = 0.859 \times 779.4 = 669 \text{ W/m}^2. \]

(b) The heat loss per unit area from the collector is

\[ q^{\text{loss}} = q^{\text{conv}} + q^{\text{rad}}. \]

The convection heat flux is

\[ q^{\text{conv}} = h (T_a - T_c) \]

Continued …..
and with
\[ \text{Ra}_L = \frac{g \beta (T_a - T_c) L^3}{\alpha \nu} \]
\[ \text{Ra}_L = \frac{9.8 \text{ m/s}^2 \times (321.5 \text{ K})^{-1} (343 - 300) \text{K} (0.02 \text{ m})^3}{18.05 \times 10^{-6} \text{ m}^2 / \text{s} \times 25.7 \times 10^{-6} \text{ m}^2 / \text{s}} = 22,604 \]

find from Eq. 9.54 with
\[ \frac{H}{L} > 12, \quad \tau < \tau^*, \quad \cos \tau = 0.5, \quad \text{Ra}_L \cos \tau = 11,302 \]
\[ \bar{\text{Nu}}_L = 1 + 1.44 \left[ 1 - \frac{1708}{11,302} \right] \left[ 1 - \frac{1708 \left( \sin 108^\circ \right)^{1.6}}{11,302} \right] + \left[ \frac{11,302}{5830} \right]^{1/3} - 1 \]
\[ \bar{h} = \frac{\text{Nu}_L}{L} \frac{k}{L} = 2.30 \times \frac{0.0279 \text{ W/m} \cdot \text{K}}{0.02 \text{ m}} = 3.21 \text{ W/m}^2 \cdot \text{K}. \]

Hence, the convective heat flux is
\[ q_{\text{conv}}^* = 3.21 \text{ W/m}^2 \cdot \text{K} \times (343 - 300) \text{K} = 138.0 \text{ W/m}^2. \]

The radiative exchange can be determined from Eq. 13.24 treating the cover and absorber plates as a two-surface enclosure,
\[ q_{\text{rad}}^* = \frac{\sigma T_a^4 - T_c^4}{1/\varepsilon_a + 1/\varepsilon_c - 1} = \frac{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left[ (343 \text{ K})^4 - (300 \text{ K})^4 \right]}{1/0.2 + 1/0.75 - 1} \]
\[ q_{\text{rad}}^* = 61.1 \text{ W/m}^2. \]

Hence, the total heat loss per unit area from the collector
\[ q_{\text{loss}}^* = (138.0 + 61.1) = 199 \text{ W/m}^2. \]

**COMMENTS:**

1. Non-solar components of radiation transfer are concentrated at long wavelength for which \( \alpha_a = \varepsilon_a = 0.2 \) and \( \alpha_c = \varepsilon_c = 0.75. \)

2. The collector efficiency is
\[ \eta = \frac{669.3 - 199.1}{669.3} \times 100 = 70\%. \]

This value is uncharacteristically high due to specification of nearly optimum \( \alpha_a(\lambda) \) for absorber.
PROBLEM 13.111

KNOWN: Diameters and temperatures of a heated tube and a radiation shield.

FIND: (a) Total heat loss per unit length of tube, (b) Effect of shield diameter on heat rate.

SCHEMATIC:

ASSUMPTIONS: (1) Opaque, diffuse-gray surfaces, (2) Negligible end effects.

PROPERTIES: Table A-4, Air (\(T_f = 77.5^\circ\text{C} = 350\text{ K}\)): \(k = 0.030\text{ W/m-K}, \text{Pr} = 0.70, \nu = 20.92 \times 10^{-6}\text{ m}^2/\text{s}, \alpha = 29.9 \times 10^{-6}\text{ m}^2/\text{s}, \beta = 0.00286\text{ K}^{-1}\).

ANALYSIS: (a) Heat loss from the tube is by radiation and free convection

\[
q' = q_{\text{rad}} + q_{\text{conv}}
\]

From Eq. (13.25)

\[
q_{\text{rad}} = \frac{\sigma (\pi D_t) \left(T_i^4 - T_o^4\right)}{1 + \frac{1 - \varepsilon_o}{\varepsilon_i} \left(\frac{r_i}{r_o}\right)}
\]

or

\[
q_{\text{rad}} = \frac{5.67 \times 10^{-8}\text{ W/m\cdot K}^4 (\pi \times 0.1\text{m}) (393^4 - 308^4) \text{ K}^4}{1 + \frac{1 - 0.05}{0.9} \left(\frac{0.05}{0.06}\right)} = 30.2 \frac{\text{W}}{\text{m}}
\]

\[
Ra_L = \frac{g \beta (T_i - T_o) L^3}{\nu \alpha} = \frac{9.8\text{ m/s}^2 \times 0.00286\text{ K}^{-1} (85\text{ K})(0.01\text{m})^3}{(20.92 \times 10^{-6}\text{ m}^2/\text{s})(29.9 \times 10^{-6}\text{ m}^2/\text{s})} = 3809
\]

Hence from Eq. (9.60)

\[
Ra_c^* = \left[\frac{\ell n \left(D_o/D_t\right)}{\ell n \left(D_t^4/D_r^4\right)} \right]^4 \frac{Ra_L}{L^3 \left(D_t^{-3/5} + D_r^{-3/5}\right)^5} = \left[\frac{\ell n \left(0.12/0.10\right)}{\ell n \left(0.10\right)} \right]^4 \frac{3809}{(0.01\text{m})^3 \left((0.1\text{m})^{-0.6} + (0.12\text{m})^{-0.6}\right)^5} = 171.6
\]

and from Eq. (9.59)

\[
k_{\text{eff}} = 0.386 k \left(\frac{\text{Pr}}{0.861 + \text{Pr}}\right)^{1/4} \left(Ra_c^*\right)^{1/4}
\]

Continued …..
PROBLEM 13.111 (Cont.)

\[ k_{\text{eff}} = 0.386 \left( \frac{0.03}{0.861+0.7} \right)^{1/4} (171.6)^{1/4} = 0.0343 \frac{W}{m \cdot K} \]

Hence from Eq. (9.58)

\[ q'_{\text{conv}} = \frac{2\pi k_{\text{eff}}}{\ln \left( \frac{D_0}{D_i} \right)} (T_i - T_o) = \frac{2\pi \left( \frac{0.0343}{m \cdot K} \right)}{\ln \left( \frac{0.12}{0.10} \right)} (120 - 35)K = 100.5 \frac{W}{m} \]

\[ q' = (30.2 + 100.5) \frac{W}{m} = 130.7 \frac{W}{m} \]

(b) As shown below, both convection and radiation, and hence the total heat rate, increase with increasing shield diameter. In the limit as \( D_o \to \infty \), the radiation rate approaches that corresponding to net transfer between a small surface and large surroundings at \( T_o \). The rate is independent of \( \varepsilon \).

**COMMENTS:** Designation of a shield temperature is arbitrary. The temperature depends on the nature of the environment external to the shield.
PROBLEM 13.112

KNOWN: Diameters of heated tube and radiation shield. Tube surface temperature and temperature of ambient air and surroundings.

FIND: Temperature of radiation shield and heat loss per unit length of tube.

SCHEMATIC:

ASSUMPTIONS: (1) Opaque, diffuse-gray surfaces, (2) Negligible end effects, (3) Large surroundings, (4) Quiescent air, (5) Steady-state.

PROPERTIES: Determined from use of IHT software for iterative solution. Air, \((T_i + T_o)/2 = 362.7\) K: \(v_i = 2.23 \times 10^{-5}\) m²/s, \(k_i = 0.031\) W/m·K, \(\alpha_i = 3.20 \times 10^{-5}\) m²/s, \(\beta_i = 0.00276\) K⁻¹, \(Pr_i = 0.698\). Air, \(T_f = 312.7\) K: \(v_o = 1.72 \times 10^{-5}\) m²/s, \(k_o = 0.027\) W/m·K, \(\alpha_o = 2.44 \times 10^{-5}\) m²/s, \(\beta_o = 0.0032\) K⁻¹, \(Pr_o = 0.705\).

ANALYSIS: From an energy balance on the radiation shield, \(q_i' = q_i' = q_i' + q_{\text{rad},i} + q_{\text{conv},i} = q_{\text{rad},o} + q_{\text{conv},o}\). Evaluating the inner and outer radiation rates from Eqs. (13.25) and (13.27), respectively, and the convection heat rate in the air gap from Eq. (9.58),

\[
\frac{\sigma \pi D_i \left(T_i^4 - T_o^4\right)}{1 - \varepsilon_i} + \frac{2\pi k_{\text{eff}} (T_i - T_o)}{\ln(D_o/D_i)} = \sigma \pi D_o \varepsilon_o \left(T_o^4 - T_{\text{sur}}^4\right) + \pi D_o \overline{h}_o (T_o - T_\infty)
\]

From Eqs. (9.59) and (9.60)

\[
k_{\text{eff}} = 0.386 k_i \left(\frac{Pr_i}{0.861 + Pr_i}\right)^{1/4} \left(\frac{Ra_c^*}{Ra_c^*}\right)^{1/4}
\]

\[
Ra_c^* = \frac{\left[\ln(D_o/D_i)\right]^4 Ra_L}{L^3 \left(D_i^{-3/5} + D_o^{-3/5}\right)^5}
\]

where \(Ra_L = g \beta_i (T_i - T_o) L^3 / v_i \alpha_i\) and \(L = (D_o - D_i)/2\). From Eq. (9.34), the convection coefficient on the outer surface of the shield is

\[
\overline{h}_o = \frac{k_o}{D_o} \left[0.60 + \left(\frac{0.387 Ra_{D}^{1/6}}{1 + (0.559/Pr)^{9/16}}\right)^{8/27}\right]^2
\]

Continued …..
The solution to the energy balance is obtained using the *IHT* software, and the result is

\[ T_0 = 332.5 \text{ K} = 59.5^\circ \text{C} \]

The corresponding value of the heat loss is

\[ q' = 88.7 \text{ W/m} \]

**COMMENTS:**

1. The radiation and convection heat rates are \( q'_{\text{rad,i}} = 23.7 \text{ W/m}, \quad q'_{\text{rad,o}} = 10.4 \text{ W/m}, \quad q'_{\text{conv,i}} = 65.0 \text{ W/m}, \quad \text{and} \quad q'_{\text{conv,o}} = 78.3 \text{ W/m}. \) Convection is clearly the dominant mode of heat transfer.

2. With a value of \( T_0 = 59.5^\circ \text{C} > 35^\circ \text{C}, \) the heat loss is reduced (88.7 W/m compared to 130.7 W/m if the shield is at 35°C).
**PROBLEM 13.113**

**KNOWN:** Dimensions and inclination angle of a flat-plate solar collector. Absorber and cover plate temperatures and emissivities.

**FIND:** (a) Rate of heat transfer by free convection and radiation, (b) Effect of the absorber plate temperature on the heat rates.

**SCHEMATIC:**

![Diagram of a flat-plate solar collector with dimensions and temperatures labeled]

**ASSUMPTIONS:** (1) Diffuse-gray, opaque surface behavior.

**PROPERTIES:** Table A-4, air ($\bar{T} = (T_1 + T_2) / 2 = 323$ K): $v = 18.2 \times 10^{-6}$ m$^2$/s, $k = 0.028$ W/m-K, $\alpha = 25.9 \times 10^{-6}$ m$^2$/s, $Pr = 704$, $\beta = 0.0031$ K$^{-1}$.

**ANALYSIS:**

(a) The convection heat rate is

$$q_{\text{conv}} = \bar{h} A \left( T_1 - T_2 \right)$$

where $A = wH = 4$ m$^2$ and, with $H/L > 12$ and $\tau < \tau^* = 70$ deg, $\bar{h}$ is given by Eq. 9.54. With a Rayleigh number of

$$Ra_L = \frac{g \beta (T_1 - T_2) L^3}{\alpha v} = \frac{9.8 \text{ m/s}^2 \left(0.0031 \text{ K}^{-1}\right)(40^\circ \text{C})(0.03 \text{ m})^3}{25.9 \times 10^{-6} \text{ m}^2/\text{s} \times 18.2 \times 10^{-6} \text{ m}^2/\text{s}} = 69,600$$

$$\bar{Nu}_L = 1 + 1.44 \left[ 1 - \frac{1708}{0.5 (69,600)} \right] \left[ 1 - \frac{1708 (0.923)}{0.5 (69,600)} \right] + \left[ \frac{0.5 \times 69,600}{5830} \right]^{1/3} - 1$$

$$\bar{Nu}_L = 11.44 \times 0.955 \times 0.814 = 3.12$$

$$\bar{h} = \left( \frac{k}{L} \right) \bar{Nu}_L = \left( 0.028 \text{ W/m-K} / 0.03 \text{ m} \right) 3.12 = 2.91 \text{ W/m}^2\cdot\text{K}$$

$$q_{\text{conv}} = 2.91 \text{ W/m}^2\cdot\text{K} \left( 4 \text{ m}^2 \right) (70 - 30)^\circ \text{C} = 466 \text{ W}$$

The net rate of radiation exchange is given by Eq. 13.24.

$$q = \frac{A \sigma (T_1^4 - T_2^4)}{\frac{1}{\varepsilon_1} + \frac{1}{\varepsilon_2} - 1} = \frac{1}{0.96} \frac{1}{0.92} = 1088 \text{ W}$$

(b) The effect of the absorber plate temperature was determined by entering Eq. 9.54 into the IHT workspace and using the Properties and Radiation Toolpads.

Continued ....
As expected, the convection and radiation losses increase with increasing $T_i$, with the $T^4$ dependence providing a more pronounced increase for the radiation.

**COMMENTS:** To minimize heat losses, it is obviously desirable to operate the absorber plate at the lowest possible temperature. However, requirements for the outlet temperature of the working fluid may dictate operation at a low flow rate and hence an elevated plate temperature.
**PROBLEM 13.114**

**KNOWN:** Disk heated by an electric furnace on its lower surface and exposed to an environment on its upper surface.

**FIND:** (a) Net heat transfer to (or from) the disk $q_{net,d}$ when $T_d = 400$ K and (b) Compute and plot $q_{net,d}$ as a function of disk temperature for the range $300 \leq T_d \leq 500$ K; determine steady-state temperature of the disk.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Disk is isothermal; negligible thermal resistance, (3) Surroundings are isothermal and large compared to the disk, (4) Non-black surfaces are gray-diffuse, (5) Furnace-disk forms a 3-surface enclosure, (6) Negligible convection in furnace, (7) Ambient air is quiescent.

**PROPERTIES:** Table A-4, Air ($T_f = (T_d + T_\infty)/2 = 350$ K, 1 atm): $\nu = 20.92 \times 10^{-6}$ m²/s, $k = 0.30$ W/m·K, $\alpha = 29.9 \times 10^{-6}$ m²/s.

**ANALYSIS:** (a) Perform an energy balance on the disk identifying: $q_{rad}$ as the net radiation exchange between the disk and surroundings; $q_{conv}$ as the convection heat transfer; and $q_3$ as the net radiation leaving the disk within the 3-surface enclosure.

\[
q_{net,d} = q_{in} - q_{out} = -q_{rad} - q_{conv} - q_3
\]  

Radiation exchange with surroundings: The rate equation is of the form

\[
q_{rad} = \varepsilon_{d,2} A_d \sigma (T_d^4 - T_{sur}^4)
\]  

\[
q_{rad} = 0.8 \pi^4 (0.400 m)^2 5.67 \times 10^{-8} W/m^2 \cdot K^4 \left(400^4 - 300^4\right) K^4 = 99.8 W.
\]

Free convection: The rate equation is of the form

\[
q_{conv} = \overline{h} A_d (T_d - T_\infty)
\]

where $\overline{h}$ can be estimated by an appropriate convection correlation. Find first,

\[
Ra_L = g \beta \Delta T L^3 / \nu \alpha
\]

\[
Ra_L = 9.8 m/s^2 (1/350 K)(400 - 300)(0.400 m / 4)^3 / 20.92 \times 10^{-6} m^2/s^2 \times 29.9 \times 10^{-6} m^2/s
\]

\[
Ra_L = 4.476 \times 10^6
\]

where $L = A/\pi = D/4$. For the upper surface of a heated plate for which $10^4 \leq Ra_L \leq 10^7$, Eq. 9.30 is the appropriate correlation, 

Continued ….
PROBLEM 13.114 (Cont.)

\[ \overline{Nu_L} = \frac{\overline{h} L}{k} = 0.54 \text{Ra}^{1/4} \tag{5} \]
\[ \overline{h} = 0.030 \text{ W} / \text{m} \cdot \text{K} \left( \frac{0.400 \text{ m}}{4} \right) \times 0.54 \left( 4.476 \times 10^6 \right)^{1/4} = 7.45 \text{ W} / \text{m}^2 \cdot \text{K} \]

Hence, from Eq. (3),
\[ q_{\text{conv}} = 7.45 \text{ W} / \text{m}^2 \cdot \text{K} \left( \frac{\pi}{4} \right) \left( 0.400 \text{ m} \right)^2 \left( 400 - 300 \right) \text{K} = 93.6 \text{ W}. \]

**Furnace-disk enclosure:** From Eq. 13.20, the net radiation leaving the disk is
\[ q_3 = \frac{J_3 - J_1}{\left( A_3 F_{31} \right)^{-1}} + \frac{J_3 - J_2}{\left( A_3 F_{32} \right)^{-1}} = A_3 \left[ F_{31} (J_3 - J_1) + F_{32} (J_3 - J_2) \right]. \tag{6} \]

The view factor \( F_{32} \) can be evaluated from the *coaxial parallel disks* relation of Table 13.1 or from Fig. 13.5.

\[ R_i = \frac{r_i}{L} = 200 \text{ mm} / 200 \text{ mm} = 1, \]
\[ R_j = \frac{r_j}{L} = 1, \]
\[ S = 1 + \left( 1 + R_j^2 \right) / R_j^2 = 1 + \left( 1 + 1^2 \right) = 3 \]
\[ F_{31} = 1 / 2 \left[ S - \left( 3^2 - 4 \left( r_j / r_i \right)^2 \right)^{1/2} \right] = 1 / 2 \left[ 3 - \left( 3^2 - 4 \left( 1^2 \right)^{1/2} \right) \right] = 0.382. \tag{7} \]

From summation rule, \( F_{32} = 1 - F_{33} - F_{31} = 0.618 \) with \( F_{33} = 0 \). Since surfaces \( A_2 \) and \( A_3 \) are black,
\[ J_2 = E_{b2} = \sigma T_2^4 \text{ W} / \text{m}^2 \]
\[ J_3 = E_{b3} = \sigma T_3^4 \text{ W} / \text{m}^2. \]

To determine \( J_1 \), use Eq. 13.21, the radiation balance equation for \( A_1 \), noting that \( F_{12} = F_{32} \) and \( F_{13} = F_{31} \),
\[
\frac{E_{b1} - J_1}{(1 - \varepsilon_1) / \varepsilon_1 A_1} = \frac{J_1 - J_2}{\left( A_1 F_{12} \right)^{-1}} + \frac{J_1 - J_3}{\left( A_1 F_{13} \right)^{-1}} \\
\frac{3544 - J_1}{(1 - 0.6) / 0.6} = \frac{J_1 - 3544}{(0.180)^{-1}} + \frac{J_1 - 1452}{(0.382)^{-1}} \\
J_1 = 3226 \text{ W} / \text{m}^2. \tag{8} \]

Substituting numerical values in Eq. (6), find
\[ q_3 = \left( \frac{\pi}{4} \right) \left( 0.400 \text{ m} \right)^2 \left[ 0.382 \left( 1452 - 3226 \right) \text{ W} / \text{m}^2 + 0.618 \left( 1452 - 3544 \right) \text{ W} / \text{m}^2 \right] = -248 \text{ W}. \]

Returning to the overall energy balance, Eq. (1), the net heat transfer to the disk is
\[ q_{\text{net,d}} = -99.8 \text{ W} - 93.6 \text{ W} - (-248 \text{ W}) = +54.6 \text{ W}. \]

That is, there is a net heat transfer rate *into* the disk.

(b) Using the energy balance, Eq. (1), and the rate equation, Eqs. (2) and (3) with the *IHT Radiation Tool, Radiation, Exchange Analysis, Radiation surface energy balances* and the *Correlation Tool, Free Convection, Horizontal Plate (Hot surface up)*, the analysis was performed to obtain \( q_{\text{net,d}} \) as a function of \( T_d \). The results are plotted below.

The steady-state condition occurs when \( q_{\text{net,d}} = 0 \) for which
\[ T_d = 413 \text{ K} \]

Continued …..

**PROBLEM 13.115**

**KNOWN:** Radiation shield facing hot wall at $T_w = 400$ K is backed by an insulating material of known thermal conductivity and thickness which is exposed to ambient air and surroundings at 300 K.

**FIND:** (a) Heat loss per unit area from the hot wall, (b) Radiosity of the shield, and (c) Perform a parameter sensitivity analysis on the insulation system considering effects of shield reflectivity $\rho_s$, insulation thermal conductivity $k$, overall coefficient $h$, on the heat loss from the hot wall.

**SCHEMATIC:**

![Schematic diagram of the problem](image)

**ASSUMPTIONS:** (1) Wall is black surface of uniform temperature, (2) Shield and wall behave as parallel infinite plates, (3) Negligible convection in region between shield and wall, (4) Shield is diffuse-gray and very thin, (5) Prescribed coefficient $h = 10$ W/m$^2$·K is for convection and radiation.

**ANALYSIS:** (a) Perform an energy balance on the shield to obtain

$$q_{w-s}^{\text{cond}} = \frac{\sigma(400^4 - T_s^4)}{1 + 1/0.05 - 1} \left(\frac{T_s - 300}{0.025/0.016 + 1/10}\right)\text{m}^2\cdot\text{K}/\text{W}$$

$$T_s = 350 \text{ K}.$$

where $\varepsilon_s = 1 - \rho_s$. Hence,

$$q_{w-s}^{\text{cond}} = \frac{(350 - 300)\text{K}}{(0.025/0.016 + 1/10)\text{m}^2\cdot\text{K}/\text{W}} = 30 \text{ W/m}^2.$$

(b) The radiosity of the shield follows form the definition,

$$J_s = \rho_s G_s + \varepsilon_s E_b(T_s) = \rho_s \left(\sigma T_w^4\right) + (1 - \rho_s) \left(\sigma T_s^4\right),$$

$$J_s = 0.95\sigma(400^4) + (1 - 0.95)\sigma(350^4) = 1421 \text{ W/m}^2.$$

with $\sigma = 5.67 \times 10^{-8}$ W/m$^2$·K$^4$.

Continued…..
(c) Using the Eqs. (1) and (2) in the IHT workspace, $q_{W-s}''$ can be computed and plotted for selected ranges of the insulation system variables, $\rho_s$, $k$, and $h$. Intuitively we know that $q_{W-s}''$ will decrease with increasing $\rho_s$, decreasing $k$ and decreasing $h$. We chose to generate the following family of curves plotting $q_{W-s}''$ vs. $k$ for selected values of $\rho_s$ and $h$.

![Graph showing heat loss vs. thermal conductivity for different values of $\rho_s$ and $h$.]

Considering the base condition with variable $k$, reducing $k$ by a factor of 3, the heat loss is reduced by a factor of 2. The effect of changing $h$ (4 to 24 W/m$^2$·K) has little influence on the heat loss. However, the effect of shield reflectivity change is very significant. With $\rho_s = 0.98$, probably the upper limit of a practical reflector-type shield, the heat loss is reduced by a factor of two. To improve the performance of the insulation system, it is most advantageous to increase $\rho_s$ and decrease $k$. 

PROBLEM 13.116

KNOWN: Diameter and surface temperature of a fire tube. Gas low rate and temperature. Emissivity of tube and partition.

FIND: (a) Heat transfer per unit tube length, \( q' \), without the partition, (b) Partition temperature, \( T_p \), and heat rate with the partition, (c) Effect of flow rate and emissivity on \( q' \) and \( T_p \). Effect of emissivity on radiative and convective contributions to \( q' \).

SCHEMATIC:

ASSUMPTIONS: (1) Fully-developed flow in duct, (2) Diffuse/gray surface behavior, (3) Negligible gas radiation.

PROPERTIES: Table A-4, air (\( T_{m,g} = 900 \) K): \( \mu = 398 \times 10^{-7} \text{ N} \cdot \text{s} / \text{m}^2, k = 0.062 \text{ W} / \text{m} \cdot \text{K}, Pr = 0.72; \) air (\( T_s = 385 \) K): \( \mu = 224 \times 10^{-7} \text{ N} \cdot \text{s} / \text{m}^2. \)

ANALYSIS: (a) Without the partition, heat transfer to the tube wall is only by convection. With \( \dot{m} = 0.05 \text{ kg/s} \) and \( Re_D = 4 \frac{m_g}{\pi D} \mu = 4 \left( \frac{0.05 \text{ kg/s}}{\pi (0.07 \text{ m})} \right) 398 \times 10^{-7} \text{ N} \cdot \text{s} / \text{m}^2 = 22,850 \), the flow is turbulent. From Eq. (8.61),

\[
Nu_D = 0.027 Re_D^{4/5} Pr^{1/3} \left( \frac{\mu_s}{\mu_g} \right)^{0.14} = 0.027 \left( 22,850 \right)^{4/5} \left( \frac{0.72}{398} \right)^{1/3} \left( \frac{224}{398} \right)^{0.14} = 80.5
\]

\[
h = \frac{k}{D} Nu_D = \frac{0.062 \text{ W} / \text{m} \cdot \text{K}}{0.07 \text{ m}} = 80.5 = 71.3 \text{ W} / \text{m}^2 \cdot \text{K}
\]

\[
q' = h \pi D (T_{m,g} - T_s) = 71.3 \text{ W} / \text{m}^2 \cdot \text{K} (\pi) 0.07 \text{ m} (900 - 385) = 8075 \text{ W} / \text{m}
\]

(b) The temperature of the partition is determined from an energy balance which equates net radiation exchange with the tube wall to convection from the gas. Hence, \( q'_{\text{rad}} = q'_{\text{conv}} \), where from Eq. 13.23,

\[
q'_{\text{rad}} = \frac{\sigma}{1 - \epsilon_p} \left( T_p^4 - T_s^4 \right)
\]

where \( F_{12} = 1 \) and \( A_p / A_s = D / (\pi D/2) = 2 / \pi = 0.637 \). The flow is now in a noncircular duct for which \( D_h = 4A_c / P = 4(\pi D^2/8) / (\pi D/2 + D) = \pi D / (\pi + 2) = 0.611 \text{ D} = 0.0428 \text{ m} \) and \( \dot{m}_{1/2} = \dot{m}_g / 2 = 0.025 \text{ kg/s} \). Hence, \( Re_D = \dot{m}_{1/2} D_h / A_c \mu = \dot{m}_{1/2} D_h / (\pi D^2/8) \mu = 8(0.025 \text{ kg/s}) (0.0428 \text{ m}) / (\pi (0.07 \text{ m})^2 398 \times 10^{-7} \text{ N} \cdot \text{s} / \text{m}^2 = 13,970 \) and

\[
Nu_D = 0.027 \left( 13,970 \right)^{4/5} \left( \frac{0.72}{398} \right)^{1/3} \left( \frac{224}{398} \right)^{0.14} = 54.3
\]

\[
h = \frac{k}{D_h} Nu_D = \frac{0.062 \text{ W} / \text{m} \cdot \text{K}}{0.0428 \text{ m}} = 54.3 = 78.7 \text{ W} / \text{m}^2 \cdot \text{K}
\]

Continued .....
PROBLEM 13.116 (Cont.)

Hence, with \( \varepsilon_s = \varepsilon_p = 0.5 \) and \( q_{\text{conv}}^* = h\left(T_{m,g} - T_p\right) \),

\[
\frac{5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left(T_p^4 - 385^4\right) K^4}{1 + 1 + 0.637} = 78.7 \text{ W/m}^2 \cdot \text{K} \left(900 - T_p\right) K
\]

\[
21.5 \times 10^{-8} T_p^4 + 78.7 T_p - 71,302 = 0
\]

A trial-and-error solution yields

\( T_p = 796 \text{ K} \)

The heat rate to one-half of the tube is then

\[
q_{1/2} = q_{ps} + q_{\text{conv}} = \frac{D \sigma \left(T_p^4 - T_s^4\right)}{1 - \varepsilon_p + \frac{1}{F_{ps}}} + h\left(\pi D/2\right) \left(T_{m,g} - T_s\right) + \frac{\varepsilon_s A_p}{A_s} + \frac{\varepsilon_s A_p}{A_s}
\]

\[
q_{1/2} = 0.07 \text{ m} \left(5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4\right) \left(796.4^4 - 385^4\right) K^4 + 78.7 \text{ W/m}^2 \cdot \text{K} \left(0.110 \text{ m}\right) \left(900 - 385\right) K
\]

\( q_{1/2} = 572 \text{ W/m} + 4458 \text{ W/m} = 5030 \text{ W/m} \)

The heat rate for the entire tube is

\( q' = 2q_{1/2} = 10,060 \text{ W/m} \)

(c) The foregoing model was entered into the IHT workspace, and parametric calculations were performed to obtain the following results.

Radiation transfer from the partition increases with increasing \( \varepsilon_p = \varepsilon_s \), thereby reducing \( T_p \) while increasing \( q' \). Since \( h \) increases with increasing \( m \), \( T_p \) and \( q' \) also increase with \( m \).

Continued .....
Although the radiative contribution to the heat rate increases with increasing $\varepsilon_p = \varepsilon_s$, it still remains small relative to convection.

**COMMENTS:** Contrasting the heat rate predicted for part (b) with that for part (a), it is clear that use of the partition enhances heat transfer to the tube. However, the effect is due primarily to an increase in $h$ and secondarily to the addition of radiation.
PROBLEM 13.117

KNOWN: Height and width of a two-dimensional cavity filled with helium. Temperatures and emissivities of opposing vertical plates.

FIND: (a) Heat rate per unit length, (b) Effect of L on heat rate.

SCHEMATIC:

![Diagram of the cavity with dimensions and temperatures](image)

ASSUMPTIONS: (1) Steady-state conditions, (2) Isothermal plates, (3) Diffuse-gray surfaces, (4) Reradiating cavity sidewalls.

PROPERTIES: Table A-4, Helium (T = 318 K, 1 atm): ν = 136 × 10^{-6} m^2/s, k = 0.158 W/m·K, α = 201 × 10^{-6} m^2/s, Pr = 0.679, β = 0.00314 K^{-1}.

ANALYSIS: (a) The power generated by the electronics leaving the surface A_1 is q' = q'_conv + q'_rad, or

\[ q' = \bar{h}H(T_1 - T_2) + \frac{H\sigma\left(T_1^4 - T_2^4\right)}{1 - \varepsilon_1 + \frac{1}{\varepsilon_1 F_{12} + \left(1/F_{1R} + 1/F_{2R}\right)^{-1}} + \frac{1 - \varepsilon_2}{\varepsilon_2}} \]

The free convection coefficient can be estimated using Eq. 9.50 with

\[ Ra_L = \frac{g\beta(T_1 - T_2)L^3}{\alpha \nu} = \frac{9.8 \text{ m/s}^2 \left(0.00314 \text{ K}^{-1}\right) 60 \text{ K} (0.02 \text{ m})^3}{201 \times 10^{-6} \times 136 \times 10^{-6} \text{ m}^4 / \text{s}^2} = 540 \]

However, since Ra_L < 1000, free convection effects can be neglected, in which case heat transfer is by conduction and \( \bar{h}_L = 1 \). Hence,

\[ \bar{h} = \bar{h}_L (k/L) = 1.0 \left(0.158 \text{ W/m·K} / 0.02 \text{ m}\right) = 7.9 \text{ W/m}^2 \cdot \text{K}. \]

The view factor can be found from Fig. 13.4 with X/L = 8 and Y/L = ∞. Hence, F_{12} = 0.9 and F_{1R} = F_{2R} = 0.1. It follows that

\[ q' = 7.9 \text{ W/m}^2 \cdot \text{K} (0.16 \text{ m}) (60^\circ\text{C}) + \frac{0.16 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K} \left(348^4 - 288^4\right) K^4}{0.25 + \frac{1}{0.9 + \left[10 + 10^{-1}\right] + 0.25} + 0.25} \]

\[ q' = 75.8 \text{ W/m} + 45.5 \text{ W/m} = 121 \text{ W/m}. \]

Continued …..
(b) To assess the effect of plate spacing on convection heat transfer, \( q'_{\text{conv}} = \overline{h}H(T_1 - T_2) \) was computed by using both Eq. 9.50 and the conduction limit \( \left( \overline{Nu}_L = 1 \right) \) to determine \( \overline{h} \). These expressions were entered into the IHT workspace, and the Radiation Toolpad was used to obtain the appropriate radiation rate equation and view factor.

The cross-over at \( L = 28 \text{ mm} \) marks the plate spacing below and above which, respectively, the conduction limit and Eq. 9.50 are applicable. Although there is a slight increase in \( q'_{\text{conv}} \) with increasing \( L \) for \( L > 28 \text{ mm} \), the increase pales by comparison with that corresponding to a reduction in \( L \) for \( L < 28 \text{ mm} \). As the two plates are brought closer to each other in the conduction limit, the reduction in the corresponding thermal resistance significantly increases the heat rate. The total heat rate and the conduction and radiative components are also plotted for \( 5 \leq L \leq 25 \text{ mm} \). There is an increase in \( q'_{\text{rad}} \) with decreasing \( L \), due to an increase in \( F_{12} \) (\( F_{12} = 0.97 \) for \( L = 5 \text{ mm} \)). However, the increase is small, and conduction is the dominant heat transfer mode.

**COMMENTS:** Even for small values of \( L \), the total heat rate is small and the scheme is poorly suited for electronic cooling. Note that helium is preferred over air on the basis of its larger thermal conductivity.
Problem 13.118

**Known:** Diameters, temperatures, and emissivities of concentric spheres.

**Find:** Rate at which nitrogen is vented from the inner sphere. Effect of radiative properties on evaporation rate.

**Schematic:**

- **D_o = 1.10 m**
- **D_i = 1 m**
- **T_i = 77 K, ε_i = 0.3**
- **T_o = 283 K, ε_o = 0.3**
- **Liquid nitrogen**
- **Helium, ρ = 1 atm**

**Assumptions:** Diffuse-gray surfaces.

**Properties:** Liquid nitrogen (given): \( h_{fg} = 2 \times 10^5 \text{ J/kg} \); Table A-4, Helium \( (\bar{T} = (T_i + T_o)/2 = 180 \text{ K}, 1 \text{ atm}): v = 51.3 \times 10^{-6} \text{ m}^2/\text{s}, k = 0.107 \text{ W/m-K}, \alpha = 76.2 \times 10^{-6} \text{ m}^2/\text{s}, \text{Pr} = 0.673, \beta = 0.00556 \text{ K}^{-1}. \)

**Analysis:** (a) Performing an energy balance for a control surface about the liquid nitrogen, it follows that \( q = q_{\text{conv}} + q_{\text{rad}} = \dot{m}h_{fg}. \) From the Raithby-Hollands expressions for free convection between concentric spheres, \( q_{\text{conv}} = k_{\text{eff}}\pi(D_oD_o/L)(T_o - T_i), \) where

\[
k_{\text{eff}} = 0.74k \left( \frac{Pr}{0.861 + Pr} \right)^{1/4} \left[ \frac{L}{(D_oD_i)^4(D_i^{-7/5} + D_o^{-7/5})^{5/4}} \right]^{1/4}
\]

\[
Ra_L = \frac{g\beta(T_o - T_i)L^3}{\nu\alpha} = \frac{9.8 \text{ m}/\text{s}^2 \left(0.00556 \text{ K}^{-1}\right)(206 \text{ K})(0.05 \text{ m})^3}{\left(51.3 \times 10^{-6} \text{ m}^2/\text{s}\right)(76.2 \times 10^{-6} \text{ m}^2/\text{s})} = 3.589 \times 10^5.
\]

Hence,

\[
k_{\text{eff}} = 0.74 \left(\frac{0.107 \text{ W/m-K}}{0.861 + 0.673}\right)^{1/4} \left[ \frac{0.05 \times 3.589 \times 10^5}{1.1^4(1 + 0.875)^5} \right]^{1/4} = 0.309 \text{ W/m-K}.
\]

The heat rate by convection is

\[
q_{\text{conv}} = 0.309 \text{ W/m-K} \pi \left(1.10 \text{ m}^2 / 0.05 \text{ m}\right)206 \text{ K} = 4399 \text{ W}.
\]

From Table 13.3,

\[
q_{\text{rad}} = \frac{\sigma\pi D_i^2(T_o^4 - T_i^4)}{1/\varepsilon_i + \left((1 - \varepsilon_i)/\varepsilon_o\right)(D_i/D_o)^2}
\]

\[
= \frac{\left(5.67 \times 10^{-8} \text{ W/m}^2\cdot\text{K}^4\right)\pi(1 \text{ m})^2(283^4 - 77^4)K^4}{1/0.3 + (0.7/0.3)(1/1.1)^2} = 216 \text{ W}.
\]

Continued ….
PROBLEM 13.118 (Cont.)

Hence, \[ \dot{m} = q / h_{fg} = \frac{(4399 + 216) W}{2 \times 10^5 J/kg} = 0.023 \text{ kg/s}. \]

With the cavity evacuated, \( IHT \) was used to compute the radiation heat rate as a function of \( \varepsilon_i = \varepsilon_o \).

![Graph showing the radiation heat rate as a function of emissivity]

Clearly, significant advantage is associated with reducing the emissivities and \( q_{rad} = 31.8 \text{ W} \) for \( \varepsilon_i = \varepsilon_o = 0.05 \).

**COMMENTS:** The convection heat rate is too large. It could be reduced by replacing He with a gas of smaller k, a cryogenic insulator (Table A.3), or a vacuum. Radiation effects are second order for small values of the emissivity.
PROBLEM 13.119

KNOWN: Dimensions, emissivity and upper temperature limit of coated panel. Arrangement and power dissipation of a radiant heater. Temperature of surroundings.

FIND: (a) Minimum panel-heater separation, neglecting convection, (b) Minimum panel-heater separation, including convection.

SCHEMATIC:

ASSUMPTIONS: (1) Top and bottom surfaces of heater and panel, respectively, are adiabatic, (2) Bottom and top surfaces of heater and panel, respectively are diffuse-gray, (3) Surroundings form a large enclosure about the heater-panel arrangement, (4) Steady-state conditions, (5) Heater power is dissipated entirely as radiation (negligible convection), (6) Air is quiescent and convection from panel may be approximated as free convection from a horizontal surface, (7) Air is at atmospheric pressure.

PROPERTIES: Table A-4, Air (T_f = (400 + 298)/2 ≈ 350 K, 1 atm): ν = 20.9 × 10^{-6} m^2/s, k = 0.03 W/m·K, Pr = 0.700, α = 29.9 × 10^{-6} m^2/s, β = 2.86 × 10^{-3} K^{-1}.

ANALYSIS: (a) Neglecting convection effects, the panel constitutes a floating potential for which the net radiative transfer must be zero. That is, the panel behaves as a re-radiating surface for which $E_{b2} = J_2$. Hence

$$q_1 = \frac{J_1 - E_{b2}}{1/A_1 F_{12}} + \frac{J_1 - E_{b3}}{1/A_1 F_{13}}$$

and evaluating terms

$$E_{b2} = \sigma T_2^4 = 5.67 \times 10^{-8} \text{W/m}^2\text{·K}^4 (400 \text{ K})^4 = 1452 \text{ W/m}^2$$

$$E_{b3} = \sigma T_3^4 = 5.67 \times 10^{-8} \text{W/m}^2\text{·K}^4 (298 \text{ K})^4 = 447 \text{ W/m}^2$$

$$F_{13} = 1 - F_{12} \quad A_1 = 25 \text{ m}^2$$

find that

$$\frac{75,000 \text{ W}}{25 \text{ m}^2} = \frac{J_1 - 1452}{1/F_{12}} + \frac{J_1 - 447}{1/(1-F_{12})}$$

$$3000 \text{ W/m}^2 = F_{12} (J_1 - 1452) + (J_1 - 447) - F_{12} (J_1 - 447)$$

$$J_1 = 3447 + 1005 F_{12}.$$  \hspace{1cm} (2)

Performing a radiation balance on the panel yields

$$\frac{J_1 - E_{b2}}{1/A_1 F_{12}} = \frac{E_{b2} - E_{b3}}{1/A_2 F_{23}}$$

Continued ….
PROBLEM 13.119 (Cont.)

With $A_1 = A_2$ and $F_{23} = 1 - F_{12}$

$$F_1 (J_1 - 1452) = (1 - F_{12}) (1452 - 447)$$

or

$$447F_{12} = F_{12}J_1 - 1005.$$  \(\text{(3)}\)

Substituting for $J_1$ from Eq. (2), find

$$447F_{12} = F_{12} (3447 + 1005F_{12}) - 1005$$

$$1005F_{12}^2 + 3000F_{12} - 1005 = 0$$

$$F_{12} = 0.30.$$  

Hence from Fig. 13.4, with $X/L = Y/L$ and $F_{ij} = 0.3$,

$$X/L = 1.45$$

$$L \approx 5 \text{ m}/1.45 = 3.45 \text{ m}.$$  \(<\)

(b) Accounting for convection from the panel, the net radiation transfer is no longer zero at this surface and $E_{b2} \neq J_2$. It then follows that

$$q_1 = \frac{J_1 - J_2}{1/A_1F_{12}} + \frac{J_1 - E_{b3}}{1/A_1F_{13}}$$  \(\text{(4)}\)

where, from an energy balance on the panel,

$$\frac{J_2 - E_{b2}}{(1 - \varepsilon_2) / \varepsilon_2 A_2} = q_{\text{conv},2} = \bar{h}A_2 (T_2 - T_\infty).$$  \(\text{(5)}\)

With $L \equiv A_s/P = 25 \text{ m}^2/20 \text{ m} = 1.25 \text{ m}$,

$$Ra_L = \frac{g\beta (T_s - T_\infty) L^3}{\nu \alpha} = \frac{9.8 \text{ m/s}^2 \left(2.86 \times 10^{-3} \text{ K}^{-1}\right) (102 \text{ K}) (1.25 \text{ m})^3}{(20.9 \times 29.9) 10^{-12} \text{ m}^4/\text{s}^2} = 8.94 \times 10^9.$$  

Hence

$$Nu_L = 0.15Ra_L^{1/3} = 0.15 \left(8.94 \times 10^9\right)^{1/3} = 311$$

$$\bar{h} = 311 \text{ k}/L = 311 \frac{0.03 \text{ W/m-K}}{1.25 \text{ m}} = 7.46 \text{ W/m}^2 \cdot \text{K}$$

$$q_{\text{conv},2} = 7.46 \text{ W/m}^2 \cdot \text{K} (102 \text{ K}) = 761 \text{ W/m}^2.$$

From Eq. (5)

$$J_2 = E_{b2} + \frac{1 - \varepsilon_2}{\varepsilon_2} q_{\text{conv},2} = 1452 + \frac{0.7}{0.3} \times 761 = 3228 \text{ W/m}^2.$$  

Continued .....

PROBLEM 13.119 (Cont.)

From Eq. (4),
\[ \frac{75,000}{25} = \frac{J_1 - 3228}{1/F_1} + \frac{J_1 - 447}{1/(1-F_1)} \]
\[ 3000 = F_1 (J_1 - 3228) + J_1 - 447 - F_1 (J_1 - 447) \]
\[ J_1 = 3447 + 2781F_1. \]  \hspace{1cm} (6)

From an energy balance on the panel,
\[ \frac{J_1 - J_2}{1/A_1F_1} + \frac{E_{b3} - J_2}{1/A_2F_{23}} = \frac{J_2 - E_{b2}}{(1 - \epsilon_2)/\epsilon_2A_2} = q_{\text{conv},2} \]
\[ F_1 (J_1 - 3228) + (1 - F_1)(447 - 3228) = 761 \]
\[ F_1 J_1 - 447F_1 = 3542. \]

Substituting from Eq. (6),
\[ F_1 (3447 + 2781F_2) - 447F_1 = 3542 \]
\[ 2781F_2^2 + 3000F_2 - 3542 = 0 \]
\[ F_2 = 0.71. \]

Hence from Fig. 13.4, with \( X/L = Y/L \) and \( F_{ij} = 0.71 \),
\[ \frac{X}{L} = 5.7 \]
\[ L = \frac{5 \text{ m}}{5.7} = 0.88 \text{ m.} \]

**COMMENTS:**

(1) The results are independent of the heater surface radiative properties.

(2) Convection at the heater surface would reduce the heat rate \( q_1 \) available for radiation exchange and hence reduce the value of \( L \).
**PROBLEM 13.120**

**KNOWN:** Diameter and emissivity of rod heater. Diameter and position of reflector. Width, emissivity, temperature and position of coated panel. Temperature of air and large surroundings.

**FIND:** (a) Equivalent thermal circuit, (b) System of equations for determining heater and reflector temperatures. Values of temperatures for prescribed conditions, (c) Electrical power needed to operate heater.

**SCHEMATIC:**

![Schematic Diagram](image)

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Diffuse-gray surfaces, (3) Large surroundings act as blackbody, (4) Surfaces are infinitely long (negligible end effects), (5) Air is quiescent, (6) Negligible convection at reflector, (7) Reflector and panel are perfectly insulated.

**PROPERTIES:** Table A-4, Air (T_f = 350 K, 1 atm): k = 0.03 W/m·K, v = 20.9 × 10^{-6} m^2/s, α = 29.9 × 10^{-6} m^2/s, Pr = 0.70; (T_f = (1295 + 300)/2 = 800 K): k = 0.0573 W/m·K, v = 84.9 × 10^{-6} m^2/s, α = 120 × 10^{-6} m^2/s.

**ANALYSIS:** (a) We have assumed blackbody behavior for A_1 and A_4; hence, J = E_b. Also, A_2 is insulated and has negligible convection; hence q = 0 and J_2 = E_{b_2}. The equivalent thermal circuit is:

![Equivalent Thermal Circuit](image)

(b) Performing surface energy balances at 1, 2 and 3:

\[
q_1 - q_{\text{conv,1}} = \frac{E_{b_1} - E_{b_2}}{1/A_1F_{12}} + \frac{E_{b_1} - J_3}{1/A_1F_{13}} + \frac{E_{b_1} - E_{b_4}}{1/A_1F_{14}}
\]

(1)

\[
0 = \frac{E_{b_1} - E_{b_2}}{1/A_2F_{21}} + \frac{J_3 - E_{b_2}}{1/A_2F_{23}} + \frac{E_{b_4} - E_{b_2}}{1/A_2F_{24}}
\]

(2)

\[
\frac{J_3 - E_{b_3}}{(1-\varepsilon_3)/\varepsilon_3A_3} = \frac{E_{b_1} - J_3}{1/A_3F_{31}} + \frac{E_{b_2} - J_3}{1/A_3F_{32}} + \frac{E_{b_4} - J_3}{1/A_3F_{34}}
\]

(3a)

where

\[
\frac{J_3 - E_{b_3}}{(1-\varepsilon_3)/\varepsilon_3A_3} = q_{\text{conv,3}}.
\]

(3b)

Continued ….
PROBLEM 13.120 (Cont.)

Solution procedure with $E_{b3}$ and $E_{b4}$ known: Evaluate $q_{\text{conv,3}}$ and use Eq. (3b) to obtain $J_3$; Solve Eqs. (2) and (3a) simultaneously for $E_{b1}$ and $E_{b2}$ and hence $T_1$ and $T_2$; Evaluate $q_{\text{conv,1}}$ and use Eq. (1) to obtain $q_1$.

For free convection from a heated, horizontal plate:

$$L_c = \frac{A_s}{P} = \frac{(W \times L)}{(2L + 2W)} \approx \frac{W}{2} = 0.5 \text{ m}$$

$$Ra_L = \frac{g \beta (T_3 - T_\infty) L_c^3}{\alpha v} = \frac{9.8 \text{ m/s}^2 (350 \text{ K})^{-1} (100 \text{ K})(0.5 \text{ m})^3}{20.9 \times 10^{-12} \text{ m}^4 / \text{s}^2} = \frac{5.6 \times 10^8}{1}$$

$$\text{Nu}_L = 0.15Ra_L^{1/3} = 0.15 \left(5.6 \times 10^8\right)^{1/3} = 123.6$$

$$\overline{h}_3 = \frac{k}{\text{Nu}_L} \approx \frac{0.03 \text{ W/mK} \times 123.6}{0.5 \text{ m}} = 7.42 \text{ W/m}^2\cdot\text{K}.$$ 

$q_{\text{conv,3}} = \overline{h}_3 (T_3 - T_\infty) = 742 \text{ W/m}^2.$

Hence, with

$$E_{b3} = \sigma T_3^4 = 5.67 \times 10^{-8} \text{ W/m}^2\cdot\text{K}^4 (400 \text{ K})^4 = 1451 \text{ W/m}^2$$

using Eq. (3b) find

$$J_3 = E_{b3} + \frac{1 - \varepsilon_3}{\varepsilon_3 A_3} q_{\text{conv,3}} = (1451 + [0.3/0.7] \times 742) = 1769 \text{ W/m}^2.$$  

View Factors: From symmetry, it follows that $F_{12} = 0.5$. With $\theta = \tan^{-1}(W/2)/H = \tan^{-1}(0.5) = 26.57^\circ$, it follows that $F_{13} = 2\theta / 360 = 0.148$.

From summation and reciprocity relations,

$$F_{14} = 1 - F_{12} - F_{13} = 0.352$$

$$F_{21} = (A_1 / A_2) F_{12} = (2D_1 / D_2) F_{12} = 0.02 \times 0.5 = 0.01$$

$$F_{23} = (A_3 / A_2) F_{32} = (2/\pi)(F_{32} - F_{31}).$$

For $X/L = 1, Y/L \approx \infty$, find from Fig. 13.4 that $F_{32'} = 0.42$. Also find,

$$F_{31} = (A_1 / A_3) F_{13} = (\pi \times 0.01 / 1)0.148 = 0.00465 \approx 0.005$$

$$F_{23} = (2/\pi)(0.42 - 0.005) = 0.264$$

$$F_{22} = 1 - F_{22'} = 1 - (A_2 / A_2) F_{22'} = 1 - (2/\pi) = 0.363$$

$$F_{24} = 1 - F_{21} - F_{22} - F_{23} = 0.363$$

Continued .....
PROBLEM 13.120 (Cont.)

\[ F_{31} = 0.005, \quad F_{32} = 0.415 \]
\[ F_{34} = 1 - F_{32}' = 1 - 0.42 = 0.58. \]

With \( E_{b4} = \sigma T_4^4 = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \) \((300 \text{ K})^4 = 459 \text{ W/m}^2\),

\[ \text{Eq. (3a)} \to 0.005(E_{b1} - 1769) + 0.415(E_{b2} - 1769) + 0.58(459 - 1769) = 742 \]
\[ 0.005E_{b1} + 0.415E_{b2} = 2245 \] \hspace{1cm} \hspace{1cm} (4)

\[ \text{Eq. (2)} \to 0.01(E_{b1} - E_{b2}) + 0.264(1769 - E_{b2}) + 0.363(459 - E_{b2}) = 0 \]
\[ 0.01E_{b1} - 0.637E_{b2} + 633.6 = 0. \] \hspace{1cm} \hspace{1cm} (5)

Hence, manipulating Eqs. (4) and (5), find

\[ E_{b2} = 0.0157E_{b1} + 994.7 \]
\[ 0.005E_{b1} + (0.415)(0.0157E_{b1} + 994.7) = 2245. \]

\[ E_{b1} = 159.322 \text{ W/m}^2 \quad T_1 = (E_{b1} / \sigma)^{1/4} = 1295 \text{ K} \]
\[ E_{b2} = 0.0157(159.322) + 994.7 = 3496 \text{ W/m}^2 \quad T_2 = (E_{b2} / \sigma)^{1/4} = 498 \text{ K}. \]

(c) With \( T_1 = 1295 \text{ K}, \) then \( T_f = (1295 + 300)/2 \approx 800 \text{ K}, \) and using

\[ \text{Ra}_D = \frac{g \beta (T_1 - T_\infty) D_1^3}{\alpha v} = \frac{9.8 \text{ m/s}^2 (1/800 \text{ K})(1295 - 300)K(0.01 \text{ m})^3}{120 \times 84.9 \times 10^{-12} \text{ m}^4 / \text{s}^2} = 1196 \]
\[ \text{Nu}_D = 0.85 \text{Ra}_D^{0.188} = 0.85(1196)^{0.188} = 3.22 \]
\[ \bar{h}_1 = (k / D_1) \text{Nu}_D = (0.0573 / 0.01) \times 3.22 = 18.5 \text{ W/m}^2 \cdot \text{K}. \]

The convection heat flux is

\[ q_{\text{conv},1} = \bar{h}_1 (T_1 - T_\infty) = 18.5(1295 - 300) = 18,407 \text{ W/m}^2, \]

Using Eq. (1), find

\[ q_1 = q_{\text{conv},1} + F_{12} (E_{b1} - E_{b2}) + F_{13} (E_{b1} - J_3) + F_{14} (E_{b1} - E_{b4}) \]
\[ q_1^* = 18,407 + 0.5(159,322 - 3496) \]
\[ + 0.148(159,322 - 1769) + 0.352(159,322 - 459) \]
\[ q_1^* = 18,407 + (77,913 + 23,314 + 55,920) \]
\[ q_1^* = 18,407 + 236,381 = 254,788 \text{ W/m}^2 \]
\[ q_1^* = \pi D_1 q_1^* = \pi (0.01) 254,788 = 8000 \text{ W/m}. \]

**COMMENTS:** Although convection represents less than 8% of the net radiant transfer from the heater, it is equal to the net radiant transfer to the panel. Since the reflector is a re-radiating surface, results are independent of its emissivity.
PROBLEM 13.121

KNOWN: Temperature, power dissipation and emissivity of a cylindrical heat source. Surface emissivities of a parabolic reflector. Temperature of air and surroundings.

FIND: (a) Radiation circuit, (b) Net radiation transfer from the heater, (c) Net radiation transfer from the heater to the surroundings, (d) Temperature of reflector.

SCHEMATIC: 

ASSUMPTIONS: (1) Steady-state conditions, (2) Heater and reflector are in quiescent and infinite air, (3) Surroundings are infinitely large, (4) Reflector is thin (isothermal), (5) Diffuse-gray surfaces.

PROPERTIES: Table A-4, Air (T_f = 750 K, 1 atm): ν = 76.37 × 10^{-6} m^2/s, k = 0.0549 W/m·K, α = 109 × 10^{-6} m^2/s, Pr = 0.702.

ANALYSIS: (a) The thermal circuit is 

(b) Energy transfer from the heater is by radiation and free convection. Hence,

\[ P_1' = q_1' + q_{1, \text{conv}} \]

where

\[ q_{1, \text{conv}} = \overline{h} \pi D 1 (T_1 - T_\infty) \]

and

\[ \text{Ra}_D = \frac{g \beta (T_1 - T_\infty) D^3}{\nu \alpha} = \frac{9.8 \text{ m/s}^2 (750 \text{ K})^{-1} (900 \text{ K}) (0.005 \text{ m})^3}{76.37 \times 109 \times 10^{-12} \text{ m}^4 / \text{s}^2} = 176.6. \]

Using the Churchill and Chu correlation, find

\[ \overline{Nu}_D = \left\{ \frac{0.6 + \frac{0.387 \text{Ra}_D^{1/6}}{1 + (0.559 / \text{Pr})^{9/16}}^{8/27}}{2} \right\}^2 \]

\[ \overline{h} = \overline{Nu}_D (k / D) = 1.85 (0.0549 \text{ W/m} \cdot \text{K}) (0.005 \text{ m}) = 20.3 \text{ W/m}^2 \cdot \text{K}. \]

Continued ....
Hence,
\[ q_{i,\text{conv}} = 20.3 \text{ W/m}^2 \cdot K \pi (0.005 \text{ m})(1200-300) \text{ K} = 287 \text{ W/m} \]
\[ q_i' = 1500 \text{ W/m} - 287 \text{ W/m} = 1213 \text{ W/m}. \]

(c) The net radiative heat transfer from the heater to the surroundings is
\[ q_i'(\text{sur}) = A_1 F_{\text{sur}} (J_i - J_{\text{sur}}). \]
The view factor is
\[ F_{\text{sur}} = (135/360) = 0.375 \]
and the radiosities are
\[ J_{\text{sur}} = \sigma T_{\text{sur}}^4 = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot K^4 (300 \text{ K})^4 = 459 \text{ W/m}^2 \]
\[ J_i = E_{b1} - q_i' (1-\varepsilon_i)\varepsilon_i A_i' = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot K^4 (1200 \text{ K})^4 \]
\[ -1213 \text{ W/m} [0.2/0.8 \pi (0.005 \text{ m})] \]
\[ J_i = 98,268 \text{ W/m}^2. \]
Hence
\[ q_i'(\text{sur}) = \pi (0.005 \text{ m})0.375(98,268-459) \text{ W/m}^2 = 576 \text{ W/m}. \]

(d) Perform an energy balance on the reflector,
\[ q_{2i} = q_{2o} + q_{2,\text{conv}} \]
\[ \frac{J_{2i} - E_{b2}}{(1-\varepsilon_{2o})/\varepsilon_{2i} A_i'_{2}} = \frac{E_{b2} - J_{\text{sur}}}{(1-\varepsilon_{2o})/\varepsilon_{2o} A_2' + 1/A_2' F_{\text{sur}}(\text{sur})} + 2h_2 A_2' (T_2 - T_{\infty}). \]
The radiosity of the reflector is
\[ J_{2i} = J_1 - \frac{q_i'(2i)}{A_1 F_{2i}(2i)} = 98,268 \text{ W/m}^2 - \frac{(1213-576) \text{ W/m}}{\pi (0.005 \text{ m})(225/360)} \]
\[ J_{2i} = 33,384 \text{ W/m}^2. \]
Hence
\[ 33,384 - 5.67 \times 10^{-8} \left(\frac{T_2^4}{0.9/0.1 \times 0.2 \text{ m}}\right) = 5.67 \times 10^{-8} \left(\frac{T_2^4}{0.2/0.8 \times 0.2 \text{ m}}\right) - 459 \]
\[ -2 \times 0.4 (T_2 - 300) \]
\[ 741.9 - 0.126 \times 10^{-8} T_2^4 = 0.907 \times 10^{-8} T_2^4 - 73.4 + 0.8 T_2 - 240 \]
\[ 1.033 \times 10^{-8} T_2^4 + 0.8 T_2 = 1005 \]
and from a trial and error solution, find
\[ T_2 = 502 \text{ K}. \]

**COMMENTS:** Choice of small \(\varepsilon_{2i}\) and large \(\varepsilon_{2o}\) insures that most of the radiation from heater is reflected to surroundings and reflector temperature remains low.
PROBLEM 13.122

KNOWN: Geometrical conditions associated with tube array. Tube wall temperature and pressure of water flowing through tubes. Gas inlet velocity and temperature when heat is transferred from products of combustion in cross-flow, or temperature of electrically heated plates when heat is transferred by radiation from the plates.

FIND: (a) Steam production rate for gas flow without heated plates, (b) Steam production rate with heated plates and no gas flow, (c) Effects of inserting unheated plates with gas flow.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible gas radiation, (3) Tube and plate surfaces may be approximated as blackbodies, (4) Gas outlet temperature is 600 K.

PROPERTIES: Table A-4, Air ($\overline{T} = 900$ K, 1 atm): $\rho = 0.387$ kg/m$^3$, $c_p = 1121$ J/kg$\cdot$K, $\nu = 102.9 \times 10^{-6}$ m$^2$/s, $k = 0.062$ W/m$\cdot$K, Pr = 0.720; (T = 400 K): Pr = 0.686; (T = 1200 K): $\rho = 0.29$ kg/m$^3$; Table A-6, Sat. water (2.5 bars): $h_{fg} = 2.18 \times 10^6$ J/kg.

ANALYSIS: (a) With $V_{\text{max}} = [S_T/(S_T - D)]V = 20$ m/s

$\text{Re}_D = \frac{V_{\text{max}}D}{\nu} = \frac{20 \text{ m/s} \times (0.01 \text{ m})}{102.9 \times 10^{-6} \text{ m}^2/\text{s}} = 1944$

and from the Zhukauskas correlation with $C = 0.27$ and $m = 0.63$,

$\text{Nu}_D = 0.27 (1944)^{0.63} (0.720)^{0.36} (0.720/0.686)^{1/4} = 28.7$

$\bar{h} = 0.062$ W/m$\cdot$K$\times 28.7/0.01 \text{ m} = 178$ W/m$^2$$\cdot$K.

The outlet temperature may be evaluated from

$\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp \left( -\frac{\bar{h}A}{mc_p} \right) = \exp \left( -\frac{\bar{h}N\pi DL}{\rho VN_T S_T L c_p} \right)$

$\frac{400 - T_{m,o}}{400 - 1200} = \exp \left( -\frac{178 \text{ W/m}^2\cdot\text{K} \times 100 \pi \times 0.01 \text{ m}}{0.29 \text{ kg/m}^3 \times 10 \text{ m/s} \times 5 \times 0.02 \text{ m} \times 1121 \text{ J/kg} \cdot \text{K}} \right)$

$T_{m,o} = 543$ K.

Continued …..
PROBLEM 13.122 (Cont.)

With

\[ \Delta T_{\text{f/m}} = \frac{(T_s - T_{m,i}) - (T_s - T_{m,o})}{\ln (T_s - T_{m,i})/(T_s - T_{m,o})} = \frac{-800 - (-143)}{\ln (800/143)} = -382 \text{ K} \]

find

\[ q = \bar{h}A\Delta T_{\text{f/m}} = 178 \text{ W/m}^2 \cdot \text{K} (100)\pi (0.01 \text{ m})1 \text{ m} (-382 \text{ K}) \]
\[ q = -214 \text{ kW}. \]

If the water enters and leaves as saturated liquid and vapor, respectively, it follows that \( -q = \dot{m} h_{fg} \).

\[ \dot{m} = \frac{214,000 \text{ W}}{2.18 \times 10^6 \text{ J/kg}} = 0.098 \text{ kg/s}. \]

(b) The radiation exchange between the plates and tube walls is

\[ q = \left[ A_p F_{ps} \sigma (T^4_p - T^4_s) \right] \cdot 2 \cdot N_T \]

where the factor of 2 is due to radiation transfer from two plates. The view factor and area are

\[ F_{ps} = 1 - \left[ 1 - (D/S)^2 \right]^{1/2} + (D/S)\tan^{-1}\left[ \left( S^2 - D^2 \right)/D^2 \right]^{1/2} \]
\[ F_{ps} = 1 - 0.866 + 0.5\tan^{-1}1.732 = 1 - 0.866 + 0.524 \]
\[ F_{ps} = 0.658 \]
\[ A_p = N_L \cdot S_L \cdot 1 \text{ m} = 20 \times 0.02 \text{ m} \times 1 \text{ m} = 0.40 \text{ m}^2. \]

Hence,

\[ q = 5 \times \left[ 0.80 \text{ m}^2 \times 0.658 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (1200^4 - 400^4) \right] \]
\[ q = 305,440 \text{ W} \]

and the steam production rate is

\[ \dot{m} = \frac{305,440 \text{ W}}{2.18 \times 10^6 \text{ J/kg}} = 0.140 \text{ kg/s}. \]

(c) The plate temperature is determined by an energy balance for which convection to the plate from the gas is equal to net radiation transfer from the plate to the tube. Conditions are complicated by the fact that the gas transfers energy to both the plate and the tubes, and its decay is not governed by a simple exponential. Insertion of the plates enhances heat transfer to the tubes and thereby increases the steam generation rate. However, for the prescribed conditions, the effect would be small, since in case (a), the heat transfer is already \( \approx 80\% \) of the maximum possible transfer.
**PROBLEM 13.123**

**KNOWN:** Gas-fired radiant tube located within a furnace having quiescent gas at 950 K. At a particular axial location, inner wall and gas temperature measured by thermocouples.

**FIND:** Temperature of the outer tube wall at the axial location where the thermocouple measurements are being made.

**SCHEMATIC:**

![Diagram of gas-fired radiant tube](image)

**ASSUMPTIONS:** (1) Silicon carbide tube walls have negligible thermal resistance and are diffuse-gray, (2) Tubes are positioned horizontally, (3) Gas is radiatively non-participating and quiescent, (4) Furnace gas behaves as ideal gas, $\beta = 1/T$.

**PROPERTIES:** Gas (given): $\rho = 0.32$ kg/m$^3$, $\nu = 130 \times 10^{-6}$ m$^2$/s, $k = 0.070$ W/m·K, $Pr = 0.72$, $\alpha = \nu/Pr = 1.806 \times 10^{-4}$ m$^2$/s.

**ANALYSIS:** Consider a segment of the outer tube at the Prescribed axial location and perform an energy balance,

$$\dot{E}_{in} - \dot{E}_{out} = 0$$

$$q_{rad,i} + q_{conv,i} - q_{rad,o} - q_{conv,o} = 0 \quad (1)$$

The heat rates by radiative transfer are:

**Inside:** For long concentric cylinders, Eq. 13.25,

$$q_{rad,i} = \frac{\sigma \pi D_i \left( T_{s,i}^4 - T_{s,o}^4 \right)}{1/\varepsilon_1 + (1-\varepsilon_2)/\varepsilon_2 \left( D_i / D_o \right)}$$

$$q_{rad,i} = \frac{5.67 \times 10^{-8} \text{W/m}^2 \cdot \text{K}^4 \left( 0.10 \text{ m} \right) \left( 1200^4 - T_{s,o}^4 \right) \text{K}^4}{1/0.6 + (1-0.6)/0.6 (0.10/0.20)}$$

$$q_{rad,i} = 8.906 \times 10^{-9} \left( 1200^4 - T_{s,o}^4 \right). \quad (2)$$

**Outside:** For the outer tube surface to large surroundings,

$$q_{rad,o} = \varepsilon \pi D_o \sigma \left( T_{s,o}^4 - T_{sur}^4 \right) = 0.6 \pi \left( 0.20 \text{ m} \right) 5.67 \times 10^{-8} \text{W/m}^2 \cdot \text{K}^4 \left( T_{s,o}^4 - 950^4 \right) \text{K}^4$$

$$q_{rad,o} = 2.138 \times 10^{-8} \left( T_{s,o}^4 - 950^4 \right). \quad (3)$$

The heat rates by convection processes are:

Continued …..
PROBLEM 13.123 (Cont.)

Inside: The rate equation is

\[ q_{\text{conv},i} = h_i \pi D_0 \left( T_{m,g} - T_{s,o} \right). \] (4)

Find the Reynolds number with \( A_c = \pi \left( D_o^2 - D_i^2 \right) / 4 \) and \( D_h = 4 A_c / P, \)

\[ \text{Re}_D = \frac{u_m D_h}{\nu} \quad u_m = \frac{m}{\rho A_c} = 0.13 \text{ kg} / \text{s} / \left[ 0.32 \text{ kg} / \text{m}^3 \times \pi / 4 \left( 0.2^2 - 0.1^2 \right) \text{ m}^2 \right] = 17.2 \text{ m/s} \]

\[ D_h = \frac{4 \left( \pi / 4 \right) \left( D_o^4 - D_i^2 \right)}{\pi \left( D_o + D_i \right)} = \frac{\pi \left( 0.2^2 - 0.1^2 \right) \text{m}^2}{(0.2+0.1) \text{m}} = 0.100 \text{ m} \quad \text{Re}_D = \frac{17.2 \text{ m/s} \times 0.100 \text{ m}}{130 \times 10^{-6} \text{ m}^2 / \text{s}} = 13,231. \]

The flow is turbulent and assumed to be fully developed; from the Dittus-Boelter correlation,

\[ N_u D = h D / k = 0.023 \text{ Re}^{0.8} \text{ Pr}^{0.3} \]

\[ h_i = \frac{0.070 \text{ W/m} \cdot \text{K}}{0.100 \text{ m}} \times 0.023 (13,231)^{0.8} (0.720)^{0.3} = 28.9 \text{ W/m}^2 \cdot \text{K} \]

Substituting into Eq. (4),

\[ q_{\text{conv},i} = 28.9 \text{ W/m}^2 \cdot \text{K} \times \pi \left( 0.20 \text{ m} \right) \left( 1050 - T_{s,o} \right) \text{K} = 18.16 \left( 1050 - T_{s,o} \right). \] (5)

Outside: The rate equation is

\[ q_{\text{conv},o} = h_o \pi D_0 \left( T_{s,o} - T_{\infty} \right). \]

Evaluate the Rayleigh number assuming \( T_{s,o} = 1025 \text{ K} \) so that \( T_f = 987 \text{ K}, \)

\[ \text{Ra}_D = \frac{g \beta \Delta T \rho_0^3}{\nu \alpha} = \frac{9.8 \text{ m}^2 \cdot \text{s}^2 \left( 1/987 \text{ K} \right) \left( 1025 - 950 \right) \text{K} \left( 0.20 \text{ m} \right)^3}{130 \times 10^{-6} \text{ m}^2 / \text{s} \times 1.806 \times 10^{-4} \text{ m}^2 / \text{s}} = 2.537 \times 10^5. \]

For a horizontal tube, using Eq. 9.33 and Table 9.1,

\[ \text{Nu}_D = h_o D_0 / k = \text{CRa}_D^{0.48} \left[ 2.537 \times 10^5 \right]^{1/4} = 10.77 \]

\[ h_o = \frac{0.070 \text{ W/m} \cdot \text{K}}{0.20 \text{ m} \times 10.77} = 3.77 \text{ W/m}^2 \cdot \text{K} \]

Substituting into Eq. (6),

\[ q_{\text{conv},o} = 3.77 \text{ W/m}^2 \cdot \text{K} \times \pi \left( 0.20 \text{ m} \right) \left( T_{s,o} - 950 \right) \text{K} = 2.369 \left( T_{s,o} - 950 \right). \] (7)

Returning to the energy balance relation on the outer tube, Eq. (1), substitute for the individual rates from Eqs. (2, 5, 3, 7),

\[ 8.906 \times 10^{-9} \left( 1200^4 - T_{s,o}^4 \right) + 18.16 \left( 1050 - T_{s,o} \right) - 2.138 \times 10^{-8} \left( T_{s,o}^4 - 950^4 \right) - 2.369 \left( T_{s,o} - 950 \right) = 0 \] (8)

By trial-and-error, find \( T_{s,o} = 1040 \text{ K}. \)

COMMENTS: (1) Recall that in estimating \( h_o \) we assumed \( T_{s,o} = 1025 \text{ K}, \) such that \( \Delta T = 75 \text{ K} \) (vs. 92 K using \( T_{s,o} = 1042 \text{ K} \)) for use in evaluating the Rayleigh number. For an improved estimate of \( T_{s,o}, \) it would be advisable to recalculate \( h_o. \)

(2) Note from Eq. (8) that the radiation processes dominate the heat transfer rate:

PROBLEM 13.124

KNOWN: Temperature and emissivity of ceramic plate which is separated from a glass plate of equivalent height and width by an air space. Temperature of air and surroundings on opposite side of glass. Spectral radiative properties of glass.

FIND: (a) Transmissivity of glass, (b) Glass temperature \( T_g \) and total heat rate \( q_h \), (c) Effect of external forced convection on \( T_g \) and \( q_h \).

SCHEMATIC:

![Schematic diagram of the problem setup.](image)

ASSUMPTIONS: (1) Spectral distribution of emission from ceramic approximates that of a blackbody, (2) Glass surface is diffuse, (3) Atmospheric air in cavity and ambient, (4) Cavity may be approximated as a two-surface enclosure with infinite parallel plates, (5) Glass is isothermal.

PROPERTIES: Table A-4, air \((p = 1 \text{ atm})\): Evaluated at \( \bar{T} = (T_c + T_g)/2 \) and \( T_f = (T_g + T_\infty)/2 \) using IHT Properties Toolpad.

ANALYSIS: (a) The total transmissivity of the glass is

\[
\tau = \frac{\int_0^{\infty} \tau_\lambda \lambda^2 E_\lambda b d\lambda}{\int_0^{\infty} E_\lambda b d\lambda} = \frac{\int_{\lambda_1}^{\lambda_2} \left( E_{\lambda, b} / E_b \right) d\lambda}{\int_{\lambda_1}^{\lambda_2} \left( E_{\lambda, b} / E_b \right) d\lambda} = \frac{F(0 \rightarrow \lambda_2) - F(0 \rightarrow \lambda_1)}{F(0 \rightarrow \lambda_1)}
\]

With \( \lambda_2 T = 1600 \mu\text{m} \cdot \text{K} \) and \( \lambda_1 T = 400 \mu\text{m} \cdot \text{K} \), respectively, Table 12.1 yields \( F(0 \rightarrow \lambda_2) = 0.0197 \) and \( F(0 \rightarrow \lambda_1) = 0.0 \). Hence,

\[
\tau = 0.0197 < \tau_0
\]

With so little transmission of radiation from the ceramic, the glass plate may be assumed to be opaque to a good approximation. Since more than 98% of the incident radiation is at wavelengths exceeding 1.6 \( \mu\text{m} \), for which \( \alpha_\lambda = 0.9, \alpha_\lambda = 0.9 \). Also, since \( T_g < T_c \), nearly 100% of emission from the glass is at \( \lambda > 1.6 \mu\text{m} \), for which \( \epsilon_\lambda = \alpha_\lambda = 0.9, \epsilon_g = 0.9 \) and the glass may be approximated as a gray surface.

(b) The glass temperature may be obtained from an energy balance of the form \( q_{\text{conv},i}^* + q_{\text{rad},i}^* = q_{\text{conv},o}^* + q_{\text{rad},o}^* \). Using Eqs. 13.24 and 13.27 to evaluate \( q_{\text{rad},i}^* \) and \( q_{\text{rad},o}^* \), respectively, it follows that

\[
\bar{h}_1 (T_c - T_g) + \frac{\sigma (T_c^4 - T_g^4)}{1 + T_c^4 - T_g^4} = \bar{h}_0 (T_g - T_\infty) + \epsilon_g \sigma (T_g^4 - T_{\text{sur}}^4)
\]

Continued …..
PROBLEM 13.124 (Cont.)

where, assuming $10^4 \leq Ra_L \leq 10^7$, $\overline{h_i}$ and $\overline{h_o}$ are given by Eqs. 9.52 and 9.26, respectively,

$$\overline{h_i} = \frac{k_i}{L} Ra_L^{1/4} Pr_i^{0.012} (H/L)^{-0.3}$$

$$\overline{h_o} = \frac{k_o}{H} \left\{ 0.825 + \frac{0.387 Ra_H^{1/6}}{1 + (0.492 / Pr_o)^{9/16}} \right\}^2$$

with $Ra_L = g \beta_i (T_c - T_g) L^3 / \nu_i \alpha_i$ and $Ra_H = g \beta_o (T_g - T_\infty) H^3 / \nu_o \alpha_o$. Entering the energy balance into the IHT workspace and using the Correlations, Properties and Radiation Toolpads to evaluate the convection and radiation terms, the following result is obtained.

$$T_g = 825 \text{ K}$$

The corresponding value of $q_h$ is

$$q_h = 108 \text{ kW}$$

where $q_{\text{conv},i} = 3216 \text{ W}$, $q_{\text{rad},i} = 104.7 \text{ kW}$, $q_{\text{conv},o} = 15,190 \text{ W}$ and $q_{\text{rad},o} = 92.8 \text{ kW}$. The convection coefficients are $\overline{h_i} = 4.6 \text{ W/m}^2 \cdot \text{K}$ and $\overline{h_o} = 7.2 \text{ W/m}^2 \cdot \text{K}$.

(c) For the prescribed range of $\overline{h_o}$, IHT was used to generate the following results.

With increasing $\overline{h_o}$, the glass is cooled more effectively and $T_g$ must decrease. With decreasing $T_g$, $q_{\text{conv},i}$, $q_{\text{rad},i}$ and hence $q_h$ must increase. Note that radiation makes the dominant contribution to heat transfer across the airspace. Although $q_{\text{rad},o}$ decreases with decreasing $T_g$, the increase in $q_{\text{conv},o}$ exceeds the reduction in $q_{\text{rad},o}$. 
PROBLEM 13.125

KNOWN: Conditions associated with a spherical furnace cavity.

FIND: Cooling rate needed to maintain furnace wall at a prescribed temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Blackbody behavior for furnace wall, (3) \( N_2 \) is non-radiating.

ANALYSIS: From an energy balance on a unit surface area of the furnace wall, the cooling rate per unit area must equal the absorbed irradiation from the gas \( \left( E_g \right) \) minus the portion of the wall’s emissive power absorbed by the gas

\[
q_c' = E_g - \alpha_g E_b \left( T_s \right)
\]

\[
q_c' = E_g \sigma T_g^4 - \alpha_g \sigma T_s^4.
\]

Hence, for the entire furnace wall,

\[
q_c = A_s \sigma \left( E_g T_g^4 - \alpha_g T_s^4 \right).
\]

The gas emissivity, \( \varepsilon_g \), follows from Table 13.4 with

\[
L_e = 0.65D = 0.65 \times 0.5 \ m = 0.325 \ m = 1.066 \ ft.
\]

\[
p_e L_e = 0.25 \ \text{atm} \times 1.066 \ ft = 0.267 \ \text{ft} - \text{atm}
\]

and from Fig. 13.18, find \( \varepsilon_g = \varepsilon_c = 0.09 \). From Eq. 13.42,

\[
\alpha_g = \alpha_c = C_c \left( \frac{T_g}{T_s} \right)^{0.45} \times \varepsilon_c \left( T_s, p_c L_e \left[ T_s / T_g \right] \right).
\]

With \( C_c = 1 \) from Fig. 13.19,

\[
\alpha_g = 1 (1400 / 50)^{0.45} \times \varepsilon_c \left( 500K, 0.095 \ \text{ft} - \text{atm} \right)
\]

where, from Fig. 13.18,

\[
\varepsilon_c \left( 500K, 0.095 \ \text{ft} - \text{atm} \right) = 0.067.
\]

Hence

\[
\alpha_g = 1 (1400 / 500)^{0.45} \times 0.067 = 0.106
\]

and the heat rate is

\[
q_c = \pi \left( 0.5 \ m \right)^2 5.67 \times 10^{-8} \ W / \ m^2 \cdot K^4 \left[ 0.09 (1400 \ K)^4 - 0.106 (500 \ K)^4 \right]
\]

\[
q_c = 15.1 \ kW.
\]
**PROBLEM 13.126**

**KNOWN:** Diameter and gas pressure, temperature and composition associated with a gas turbine combustion chamber.

**FIND:** Net radiative heat flux between the gas and the chamber surface.

**SCHEMATIC:**

![Schematic Diagram](image)

**ASSUMPTIONS:** (1) Steady-state conditions, (2) Blackbody behavior for chamber surface, (3) Remaining species are non-radiating, (4) Chamber may be approximated as an infinitely long tube.

**ANALYSIS:** From Eq. 13.40 the net rate of radiation transfer to the surface is

\[
q_{\text{net}} = A_s \sigma \left( T_g^4 - \alpha_g T_s^4 \right)
\]

or

\[
\dot{q}_{\text{net}} = \pi D \sigma \left( T_g^4 - \alpha_g T_s^4 \right)
\]

with \( A_s = \pi DL \). From Table 13.4, \( L_c = 0.95D = 0.95 \times 0.4 \) m = 0.380 m = 1.25 ft. Hence, \( p_w L_c = p_c L_c = 0.152 \) atm \( \times 1.25 \) ft = 0.187 atm-ft. From Fig. 13.16 (\( T_g = 1273 \) K), \( \varepsilon_w \approx 0.069 \).

From Fig. 13.18 (\( T_g = 1273 \) K), \( \varepsilon_c = 0.085 \).

From Fig. 13.20 (\( p_w / (p_c + p_w) = 0.5, L_c (p_w + p_c) = 0.375 \) ft-atm, \( T_g \geq 930^\circ \text{C} \)), \( \Delta \varepsilon \geq 0.01 \).

From Eq. 13.38,

\[
\varepsilon_g = \varepsilon_w + \varepsilon_c - \Delta \varepsilon = 0.069 + 0.085 - 0.01 = 0.144.
\]

From Eq. 13.41 for the water vapor,

\[
\alpha_w = C_w \left( \frac{T_g}{T_s} \right)^{0.45} \times \varepsilon_w \left( T_s, p_w L_c \left[ \frac{T_s}{T_g} \right] \right)
\]

where from Fig. 13.16 (773 K, 0.114 ft-atm), \( \varepsilon_w \approx 0.083 \),

\[
\alpha_w = 1 \left( \frac{1273}{773} \right)^{0.45} \times 0.083 = 0.104.
\]

From Eq. 13.42, using Fig. 13.18 (773 K, 0.114 ft-atm), \( \varepsilon_c \approx 0.08 \),

\[
\alpha_c = 1 \left( \frac{1273}{773} \right)^{0.45} \times 0.08 = 0.100.
\]

From Fig. 13.20, the correction factor for water vapor at carbon dioxide mixture,

\[
\left( p_w / (p_c + p_w) = 0.1, L_c (p_w + p_c) = 0.375, T_g = 540^\circ \text{C} \right), \Delta \alpha = 0.004
\]

and using Eq. 13.43

\[
\alpha_g = \alpha_w + \alpha_c - \Delta \alpha = 0.104 + 0.100 - 0.004 = 0.200.
\]

Hence, the heat rate is

\[
\dot{q}_{\text{net}} = \pi (0.4 \text{ m}) 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left[ 0.144 (1273)^4 - 0.200 (773)^4 \right] = 21.9 \text{ kW/m}.
\]
PROBLEM 13.127

KNOWN: Pressure, temperature and composition of flue gas in a long duct of prescribed diameter.

FIND: Net radiative flux to the duct surface.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Duct surface behaves as a blackbody, (3) Other gases are non-radiating, (4) Flue may be approximated as an infinitely long tube.

ANALYSIS: With \( A_s = \pi DL \), it follows from Eq. 13.40 that

\[
q'_{\text{net}} = \pi D \sigma \left( T_g^4 - \alpha_s T_s^4 \right)
\]

From Table 13.4, \( L_e = 0.95D = 0.95 \times 1 \text{ m} = 0.95 \text{ m} = 3.12 \text{ ft} \). Hence

\[
p_w L_e = 0.12 \text{ atm} \times 3.12 \text{ m} = 0.312 \text{ atm-ft}
\]

\[
p_c L_e = 0.05 \text{ atm} \times 3.12 \text{ m} = 0.156 \text{ atm-ft}
\]

With \( T_g = 1400 \text{ K} \), Fig. 13.16 \( \rightarrow \varepsilon_w = 0.083 \); Fig. 13.18 \( \rightarrow \varepsilon_c = 0.072 \). With \( p_w/(p_c + p_w) = 0.67 \), \( L_e(p_w + p_c) = 0.468 \text{ atm-ft} \), \( T_g \geq 930^\circ \text{C} \), Fig. 13.20 \( \rightarrow \Delta \varepsilon = 0.01 \). Hence from Eq. 13.38,

\[
\varepsilon_g = \varepsilon_w + \varepsilon_c - \Delta \varepsilon = 0.083 + 0.072 - 0.01 = 0.145.
\]

From Eq. 13.41,

\[
\alpha_w = C_w \left( T_g / T_s \right)^{0.45} \times \varepsilon_w \left( T_s, p_w L_e \left[ T_s / T_g \right] \right)
\]

\[
\alpha_w = 1 \left( 1400 / 400 \right)^{0.45} \times \varepsilon_w \text{ Fig. 13.16 } \rightarrow \varepsilon_w \left( 400 \text{ K}, 0.0891 \text{ atm-ft} \right) = 0.1
\]

\[
\alpha_w = 0.176.
\]

From Eq. 13.42,

\[
\alpha_c = C_c \left( T_g / T_s \right)^{0.45} \times \varepsilon_c \left( T_s, p_c L_e T_s / T_g \right)
\]

\[
\alpha_c = 1 \left( 1400 / 400 \right)^{0.45} \times \varepsilon_c \text{ Fig. 13.18 } \rightarrow \varepsilon_c \left( 400 \text{ K}, 0.0891 \text{ atm-ft} \right) = 0.053
\]

\[
\alpha_c = 0.093.
\]

With \( p_w/(p_c + p_w) = 0.67 \), \( L_e(p_w + p_c) = 0.468 \text{ atm-ft} \), \( T_g \approx 125^\circ \text{C} \), Fig. 13.20 gives

\( \Delta \alpha = 0.003 \).

Hence from Eq. 13.43,

\[
\alpha_g = \alpha_w + \alpha_c - \Delta \alpha = 0.176 + 0.093 - 0.003 = 0.266.
\]

The heat rate per unit length is

\[
q'_{\text{net}} = \pi (1 \text{ m}) 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left[ 0.145 (1400 \text{ K})^4 - 0.266 (400 \text{ K})^4 \right]
\]

\[
q'_{\text{net}} = 98 \text{ kW/m}.
\]
PROBLEM 13.128

KNOWN: Gas mixture of prescribed temperature, pressure and composition between large parallel plates of prescribed separation.

FIND: Net radiation flux to the plates.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Furnace wall behaves as a blackbody, (3) O₂ and N₂ are non-radiating, (4) Negligible end effects.

ANALYSIS: The net radiative flux to a plate is

\[ q_s^* = G_s - E_s = \varepsilon_g \sigma T_g^4 - (1 - \tau_g) \sigma T_s^4 \]

where \( G_s = \varepsilon_g \sigma T_g^4 + \tau_g E_s \), \( E_s = \sigma T_s^4 \) and \( \tau_g = 1 - \alpha_g (T_s) \). From Table 13.4, \( L_e = 1.8L = 1.8 \times 0.75 \text{ m} = 1.35 \text{ m} = 4.43 \text{ ft} \). Hence \( p_w L_e = p_c L_e = 1.33 \text{ atm-ft} \). From Figs. 3.16 and 3.18 find \( \varepsilon_w = 0.22 \) and \( \varepsilon_c = 0.16 \) for \( p = 1 \text{ atm} \). With \( (p_w + p)/2 = 1.15 \text{ atm} \), Fig. 13.17 yields \( C_w = 1.40 \) and from Fig. 13.19, \( C_c = 1.08 \). Hence, the gas emissivities are

\[ \varepsilon_w = C_w \varepsilon_w (1 \text{ atm}) = 1.40 \times 0.22 = 0.31 \quad \text{and} \quad \varepsilon_c = C_c \varepsilon_c (1 \text{ atm}) = 1.08 \times 0.16 = 0.17. \]

From Fig. 13.20 with \( p_w/(p_c + p_w) = 0.5 \), \( L_e(p_c + p_w) = 2.66 \text{ atm-ft} \) and \( T_g > 930^\circ \text{C}, \Delta \varepsilon \approx 0.047. \)

Hence, from Eq. 13.38,

\[ \varepsilon_g = \varepsilon_w + \varepsilon_c - \Delta \varepsilon = 0.31 + 0.17 - 0.047 = 0.43. \]

To evaluate \( \alpha_g \) at \( T_s \), use Eq. 13.43 with

\[ \alpha_w = C_w \left( \frac{T_g}{T_s} \right)^{0.45} \varepsilon_w \left( T_s, p_w L_2 T_s / T_g \right) = C_w \left( \frac{1300}{500} \right)^{0.45} \varepsilon_w (500, 0.51) \]

\[ \alpha_w = 1.40 \left( \frac{1300}{500} \right)^{0.45} 0.22 = 0.47 \]

\[ \alpha_c = C_c \left( \frac{1300}{500} \right)^{0.45} \varepsilon_c (500, 0.51) = 1.08 \left( \frac{1300}{500} \right)^{0.45} 0.11 = 0.18. \]

From Fig. 13.20, with \( T_g = 125^\circ \text{C} \) and \( L_e(p_c + p_w) = 2.66 \text{ atm-ft} \), \( \Delta \alpha = \Delta \varepsilon = 0.024 \). Hence

\[ \alpha_g = \alpha_w + \alpha_c - \Delta \alpha = 0.47 + 0.18 - 0.024 = 0.63 \quad \text{and} \quad \tau_g = 1 - \alpha_g = 0.37. \]

Hence, the heat flux from Eq. (1) is

\[ q_s^* = 0.43 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left( 1300 \text{ K} \right)^4 - 0.63 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left( 500 \text{ K} \right)^4 \]

\[ q_s^* \approx 67.4 \text{ kW/m}^2. \]

The net radiative flux to both plates is then \( q_s^{*2} = 134.8 \text{ kW/m}^2. \)
PROBLEM 13.129

**KNOWN:** Flow rate, temperature, pressure and composition of exhaust gas in pipe of prescribed diameter. Velocity and temperature of external coolant.

**FIND:** Pipe wall temperature and heat flux.

**SCHEMATIC:**

![Schematic Diagram](image)

**ASSUMPTIONS:** (1) L/D >> 1 (infinitely long pipe), (2) Negligible axial gradient for gas temperature, (3) Gas is in fully developed flow, (4) Gas thermophysical properties are those of air, (5) Negligible pipe wall thermal resistance, (6) Negligible pipe wall emission.

**PROPERTIES:** Table A-4: Air (T_m = 2000 K, 1 atm): \( \rho = 0.174 \text{ kg/m}^3, \mu = 689 \times 10^{-7} \text{ kg/m.s}, k = 0.137 \text{ W/m-K}, \text{Pr} = 0.672; \) Table A-6: Water (T_\infty = 300 K): \( \rho = 997 \text{ kg/m}^3, \mu = 855 \times 10^{-6} \text{ kg/s.m}, k = 0.613 \text{ W/m-K}, \text{Pr} = 5.83. \)

**ANALYSIS:** Performing an energy balance for a control surface about the pipe wall,

\[ q_e^r + q_c^r = q_c^o \]

\[ \varepsilon_g \sigma T_g^4 + h_i (T_m - T_s) = \bar{h}_0 (T_s - T_\infty) \]

The gas emissivity is

\[ \varepsilon_g = \varepsilon_w + \varepsilon_c + \Delta \varepsilon \]

where

\[ L_e = 0.95D = 0.238 \text{ m} = 0.799 \text{ ft} \]

\[ p_e L_e = p_w L_e = 0.1 \text{ atm} \times 0.238 \text{ m} = 0.0238 \text{ atm·m} = 0.0779 \text{ atm·ft} \]

and from Fig. 13.16 \( \varepsilon_w = 0.017; \) Fig. 13.18 \( \varepsilon_c = 0.031; \) Fig. 13.20 \( \Delta \varepsilon = 0.001. \) Hence \( \varepsilon_g = 0.047. \) Estimating the internal flow convection coefficient, find

\[ \text{Re}_{D} = \frac{\frac{4}{17} \times 0.25 \text{ kg/s}}{\pi \times (0.25 \text{ m})689 \times 10^{-7} \text{ kg/m.s}} = 18,480 \]

and for turbulent flow,

\[ \text{Nu}_{D} = 0.023 \text{Re}_{D}^{4/5} \text{Pr}^{0.3} = 0.023(18,480)^{4/5}(0.672)^{0.3} = 52.9 \]

\[ h_i = \frac{\text{Nu}_{D} k}{D} = \frac{52.9 \times 0.137 \text{ W/m-K}}{0.25 \text{ m}} = 29.0 \text{ W/m}^2\cdot\text{K}. \]

Continued …..
PROBLEM 13.129 (Cont.)

Estimating the *external convection coefficient*, find

\[
\text{Re}_D = \frac{\rho v D}{\mu} = \frac{997 \text{ kg} / \text{m}^3 \times 0.3 \text{ m/s} \times 0.25 \text{ m}}{855 \times 10^{-6} \text{ kg/s} \cdot \text{m}} = 87,456.
\]

Hence

\[
\overline{\text{Nu}}_D = 0.26 \text{ Re}_D^{0.6} \text{ Pr}^{0.37} (\text{Pr}/\text{Pr}_s)^{1/4}.
\]

Assuming \(\text{Pr}/\text{Pr}_s \approx 1\),

\[
\overline{\text{Nu}}_D = 0.26(87,456)^{0.6}(5.83)^{0.37} = 461
\]

\[
\overline{\text{h}}_o = \overline{\text{Nu}}_D \left(\frac{k}{D}\right) = 461 \left(\frac{0.613}{0.25} \text{ W} / \text{m} \cdot \text{K} / 0.25 \text{ m}\right) = 1129 \text{ W} / \text{m}^2 \cdot \text{K}.
\]

Substituting numerical values in the energy balance, find

\[
0.047 \times 5.67 \times 10^{-8} \text{ W} / \text{m}^2 \cdot \text{K}^4 (2000 \text{ K})^4 + 29 \text{ W} / \text{m}^2 \cdot \text{K} (2000 - T_s) \text{K}
\]

\[
= 1129 \text{ W} / \text{m}^2 \cdot \text{K} (T_s - 300) \text{K}
\]

\(T_s = 380 \text{ K}.
\)

The heat flux due to convection is

\[
q_{c,i} = h_i (T_m - T_s) = 29 \text{ W} / \text{m}^2 \cdot \text{K} (2000 - 379.4) \text{K} = 46,997 \text{ W} / \text{m}^2
\]

and the total heat flux is

\[
q_s = q_i + q_{c,i} = 42,638 + 46,997 = 89,640 \text{ W} / \text{m}^2.
\]

**COMMENTS:** Contributions of gas radiation and convection to the wall heat flux are approximately the same. Small value of \(T_s\) justifies neglecting emission from the pipe wall to the gas. \(\text{Pr}_s = 1.62\) for \(T_s = 380 \rightarrow (\text{Pr}/\text{Pr}_s)^{1/4} = 1.38\). Hence the value of \(\overline{\text{h}}_o\) should be corrected. The value would \(\uparrow\), and \(T_s\) would \(\downarrow\).
PROBLEM 13.130

FIND: Rate at which saturated liquid can be converted to saturated vapor, $\dot{m}_s$.

SCHEMATIC:

ASSUMPTIONS: (1) Inner wall is thin and steam side convection coefficient is very large; hence $T_s = T_{sat}(2.455\text{ bar})$, (2) For calculation of gas radiation, inner tube is assumed infinitely long and gas is approximated as isothermal at $T_g$.

PROPERTIES: Flue gas (given): $\mu = 530 \times 10^{-7}\text{ kg/s m, k = 0.091 W/m K, Pr = 0.70; Table A-6}$, Saturated water (2.455 bar): $T_s = 400\text{ K, } h_{fg} = 2183\text{ kJ/kg}$.

ANALYSIS: The steam generation rate is

$$\dot{m}_s = \frac{q}{h_{fg}} = \left(\frac{q_{conv} + q_{rad}}{h_{fg}}\right)$$

where

$$q_{rad} = A_s \sigma \left(\varepsilon_g T_g^4 - \alpha_g T_s^4\right)$$

with

$$\varepsilon_g = \varepsilon_w + \varepsilon_c - \Delta \varepsilon \quad \alpha_g = \alpha_w + \alpha_c - \Delta \alpha.$$ 

From Table 13.4, find $L_e = 0.95D = 0.95\text{ m} = 3.117\text{ ft}$. Hence

$$p_w L_e = 0.2\text{ atm} \times 3.117\text{ ft} = 0.623\text{ ft-atm}$$

$$p_c L_e = 0.1\text{ atm} \times 3.117\text{ ft} = 0.312\text{ ft-atm}.$$ 

From Fig. 13.16, find $\varepsilon_w \approx 0.13$ and Fig. 13.18 find $\varepsilon_c = 0.095$. With $p_w/(p_c + p_w) = 0.67$ and $L_e(p_w + p_c) = 0.935\text{ ft-atm}$, from Fig. 13.20 find $\Delta \varepsilon = 0.036 = \Delta \alpha$. Hence $\alpha_w = 0.13 + 0.095 - 0.036 = 0.189$.

Also, with $p_w L_e(T_g/T_s) = 0.2\text{ atm} \times 0.95\text{ m(400/1400)} = 0.178\text{ ft-atm}$ and $T_s = 400\text{ K}, Fig. 13.16$ yields $\varepsilon_w = 0.14$. With $p_c L_e(T_s/T_g) = 0.1\text{ atm} \times 0.95\text{ m(400/1400)} = 0.089\text{ ft-atm}$ and $T_s = 400\text{ K}, Fig. 13.18$ yields $\varepsilon_c = 0.067$. Hence

$$\alpha_w = \left(\frac{T_g}{T_s}\right)^{0.45} \varepsilon_w \left(T_s, p_w L_e T_s / T_g\right)$$

$$\alpha_w = \left(\frac{1400}{400}\right)^{0.45} 0.14 = 0.246$$

and

$$\alpha_c = \left(\frac{T_g}{T_s}\right)^{0.65} \varepsilon_c \left(T_s, p_c L_e T_s / T_g\right)$$

Continued .....
\[ \alpha_c = \left( \frac{1400}{400} \right)^{0.65} 0.067 = 0.151 \]
\[ \alpha_g = 0.246 + 0.151 - 0.036 = 0.361. \]

Hence
\[ q_{\text{rad}} = \pi (1 \text{ m})^2 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \left[ 0.189 (1400 \text{ K})^4 - 0.361 (400 \text{ K})^4 \right] \]
\[ q_{\text{rad}} = (905.3 - 11.5) \text{ kW} = 893.8 \text{ kW}. \]

For convection,
\[ q_{\text{conv}} = h \pi D L (T_g - T_s) \]
with
\[ \text{Re}_D = \frac{4 m}{\pi D \mu} = \frac{4 \times 2 \text{ kg/s}}{\pi \times 1 \text{ m} \times 530 \times 10^{-7} \text{ kg/s} \cdot \text{m}} = 48,047 \]

and assuming fully developed turbulent flow throughout the tube, the Dittus-Boelter correlation gives
\[ \overline{\text{Nu}}_D = 0.023 \text{Re}_D^{4/5} \text{Pr}^{0.3} = 0.023 (48,047)^{4/5} (0.70)^{0.3} = 115 \]
\[ h = (k / D) \overline{\text{Nu}}_D = (0.091 \text{ W/m} \cdot \text{K}/1 \text{ m}) 115 = 10.5 \text{ W/m}^2 \cdot \text{K}. \]

Hence
\[ q_{\text{conv}} = 10.5 \text{ W/m}^2 \cdot \text{K} (1 \text{ m})^2 (1400 - 400) \text{ K} = 230.1 \text{ kW} \]

and the vapor production rate is
\[ \dot{m}_s = \frac{q}{h_{fg}} = \frac{893.8 + 230.1) \text{ kW}}{2183 \text{ kJ/kg}} = \frac{1123.9 \text{ kW}}{2183 \text{ kJ/kg}} \]
\[ \dot{m}_s = 0.515 \text{ kg/s}. \]

**COMMENTS:**

(1) Heat transfer is dominated by radiation, which is typical of heat recovery devices having a large gas volume.

(2) A more detailed analysis would account for radiation exchange involving the ends (upstream and downstream) of the inner tube.

(3) Using a representative specific heat of \( c_p = 1.2 \text{ kJ/kg-K} \), the temperature drop of the gas passing through the tube would be \( \Delta T_g = 1123.9 \text{ kW}/(2 \text{ kg/s} \times 1.2 \text{ kJ/kg-K}) = 468 \text{ K}. \)
PROBLEM 13.131

KNOWN: Wet newsprint moving through a drying oven.

FIND: Required evaporation rate, air velocity and oven temperature.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible freestream turbulence, (3) Heat and mass transfer analogy applicable, (4) Oven and newsprint surfaces are diffuse gray, (5) Oven end effects negligible.

PROPERTIES: Table A-6, Water vapor (300 K, 1 atm): \( \rho_{\text{sat}} = \frac{1}{v_g} = 0.0256 \text{ kg/m}^3 \), \( h_{fg} = 2438 \text{ kJ/kg} \); Table A-4, Air (300 K, 1 atm): \( \eta = 15.89 \times 10^{-6} \text{ m}^2/\text{s} \); Table A-8, Water vapor-air (300 K, 1 atm): \( D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s} \), \( S_c = \eta/D_{AB} = 0.611 \).

ANALYSIS: The evaporation rate required to completely dry the newsprint having a water content of \( m_A^* = 0.02 \text{ kg/m}^2 \) as it enters the oven \((x = L)\) follows from a species balance on the newsprint.

\[
\dot{M}_{A,\text{in}} - \dot{M}_{A,\text{out}} = \dot{M}_{\text{st}}
\]

The rate at which moisture enters in the newsprint is

\[
\dot{M}_{L} - \dot{M}_{0} - \dot{M}_{A,s} = 0.
\]

The rate at which moisture enters in the newsprint is

\[
\dot{M}_{L} = m_A^* V W
\]

hence,

\[
\dot{M}_{A,s} = m_A^* V W = 0.02 \text{ kg/m}^2 \times 0.2 \text{ m/s} \times 1 \text{ m} = 4 \times 10^{-3} \text{ kg/s}. \quad <
\]

The required velocity of the airstream through the oven, \( u_{\infty} \), can be determined from a convection analysis. From the rate equation,

\[
\dot{M}_{A,s} = \bar{h}_m W L (\rho_{A,s} - \rho_{A,\infty}) = \bar{h}_m W L \rho_{A,\text{sat}} (1 - \phi_{\infty})
\]

\[
\bar{h}_m = \dot{M}_{A,s} / W L \rho_{A,\text{sat}} (1 - \phi_{\infty})
\]

\[
\bar{h}_m = 4 \times 10^{-3} \text{ kg/s} / 1 \text{ m} \times 20 \text{ m} \times 0.0256 \text{ kg/m}^3 (1 - 0.2) = 9.77 \times 10^{-3} \text{ m/s}.
\]

Now determine what flow velocity is required to produce such a coefficient. Assume flow over a flat plate with

\[
\bar{Sh}_L = \bar{h}_m L / D_{AB} = 9.77 \times 10^{-3} \text{ m/s} \times 20 \text{ m} / 0.26 \times 10^{-4} \text{ m}^2/\text{s} = 7515
\]

Continued ......
PROBLEM 13.131 (Cont.)

\[ \text{Re}_L = \left[ \frac{\text{Sh}_L}{0.664 \text{Sc}^{1/3}} \right]^2 = \left[ \frac{7515}{0.664 (0.611)^{1/3}} \right]^2 = 1.78 \times 10^8. \]

Since \( \text{Re}_L > \text{Re}_{Lc} = 5 \times 10^5 \), the flow must be turbulent. Using the correlation for mixed laminar and turbulent flow conditions, find

\[ \text{Re}_{L}^{4/5} = \left[ \frac{\text{Sh}_L}{\text{Sc}^{1/3}} + 871 \right] / 0.037 \]

\[ \text{Re}_{L}^{4/5} = \left[ 7515 / (0.611)^{1/3} + 871 \right] / 0.037 \]

\[ \text{Re}_L = 5.95 \times 10^6 \]

noting \( \text{Re}_L > \text{Re}_{Lc} \). Recognize that \( u^*_\infty \) is the velocity relative to the newsprint,

\[ u^*_\infty = \text{Re}_L \frac{v}{L} = 5.95 \times 10^6 \times 15.89 \times 10^{-6} \text{ m}^2 / \text{s} / 20 \text{ m} = 4.73 \text{ m} / \text{s}. \]

The air velocity relative to the oven will be,

\[ u_\infty = u^*_\infty - V = (4.73 - 0.2) \text{ m} / \text{s} = 4.53 \text{ m} / \text{s}. \]

The temperature required of the oven surface follows from an energy balance on the newsprint. Find

\[ \dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0 \]

\[ q_{\text{rad}} - q_{\text{evap}} = 0 \]

where

\[ q_{\text{evap}} = \dot{M}_{A,s} h_{fg} = 4.0 \times 10^{-3} \text{ kg} / \text{s} \times 2438 \times 10^3 \text{ J/kg} = 9752 \text{ W} \]

and the radiation exchange is that for a two surface enclosure, Eq. 13.23,

\[ q_{\text{rad}} = \frac{\sigma \left( T_1^4 - T_2^4 \right)}{(1 - \varepsilon_1) / \varepsilon_1 A_1 + 1 / A_1 F_1 + (1 - \varepsilon_2) / \varepsilon_2 A_2}. \]

Evaluate,

\[ A_1 = \pi / 2 \text{ WL}, \quad A_2 = \text{WL}, \quad F_2_1 = 1, \quad \text{ and } A_1 F_1_2 = A_2 F_2_1 = \text{WL} \]

hence, with \( \varepsilon_1 = 0.8 \),

\[ q_{\text{rad}} = \sigma \text{WL} \left( T_1^4 - T_2^4 \right) / \left[ (1/2\pi) + 1 \right] \]

\[ T_1^4 = T_2^4 + q_{\text{rad}} \left[ (1/2\pi) + 1 \right] / \sigma \text{WL} \]

\[ T_1^4 = (300 \text{ K})^4 + 9752 \text{ W} \left[ (1/2\pi + 1) \right] / 5.67 \times 10^{-8} \text{ W} / \text{m}^2 \cdot \text{K}^4 \times 1 \text{ m} \times 20 \text{ m} \]

\[ T_1 = 367 \text{ K}. \]

COMMENTS: Note that there is no convection heat transfer since \( T_\infty = T_s = 300 \text{ K} \).
PROBLEM 13.132

KNOWN: Configuration of grain dryer. Emissivities of grain bed and heater surface. Temperature of grain.

FIND: (a) Temperature of heater required for specified drying rate, (b) Convection mass transfer coefficient required to sustain evaporation, (c) Validity of assuming negligible convection heat transfer.

SCHEMATIC:

ASSUMPTIONS: (1) Diffuse/gray surfaces, (2) Oven wall is a reradiating surface, (3) Negligible convection heat transfer, (4) Applicability of heat/mass transfer analogy, (5) Air is dry.

PROPERTIES: Table A-6, saturated water (T = 330 K): \( v_g = 8.82 \text{ m}^3/\text{kg}, h_{fg} = 2.366 \times 10^6 \text{ J/kg}. \) Table A-4, air (assume T \( \approx \) 300 K): \( \rho = 1.614 \text{ kg/m}^3, c_p = 1007 \text{ J/kg} \cdot \text{K}, \alpha = 22.5 \times 10^{-6} \text{ m}^2/\text{s}. \) Table A-8, H\(_2\)O(v) – air (T = 298 K): \( D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}. \)

ANALYSIS: (a) Neglecting convection, the energy required for evaporation must be supplied by net radiation transfer from the heater plate to the grain bed. Hence,

\[
q'_\text{rad} = \dot{m}'_{\text{evap}} h_{fg} = (2.5 \text{ kg/h} \cdot \text{m}) \left(2.366 \times 10^6 \text{ J/kg}\right)/3600 \text{s/h} = 1643 \text{ W/m}
\]

where \( q'_\text{rad} \) is given by Eq. 13.30. With \( A'_p = A'_g \equiv A' \),

\[
q'_\text{rad} = \frac{A' \left(E_{bp} - E_{bg}\right)}{1 - \varepsilon_p + \frac{1}{\varepsilon_p}} + \frac{\varepsilon_g}{1 - \varepsilon_g}
\]

where \( A' = R = 1 \text{ m}, F_{pg} = 0 \text{ and } F_{pR} = F_{gR} = 1 \). Hence,

\[
q'_\text{rad} = \frac{\sigma \left(T_p^4 - 320^4\right)}{0.25 + 2 + 0.111} = 2.40 \times 10^{-8} \left(T_p^4 - 320^4\right) = 1643 \text{ W/m}
\]

\[
2.40 \times 10^{-8} T_p^4 - 2518 = 1643
\]

\[ T_p = 530 \text{ K} \]

(b) The evaporation rate is given by Eq. 6.12, and with \( A'_s = 1 \text{ m}, n'_A = m'_\text{evap}, \text{ and } \rho_{A,\infty} = 0. \)

Continued …..
PROBLEM 13.132 (Cont.)

\[ h_m = \frac{n_A'}{A_s' \rho_{A,s}} = \frac{n_A' v_g}{A_s'} = \frac{2.5 \text{ kg/h m}}{1 \text{ m}} \times \frac{1}{3600 \text{ s}} \times 8.82 \frac{\text{m}^3}{\text{kg}} = 6.13 \times 10^{-3} \text{ m/s} \]

(c) From the heat and mass transfer analogy, Eq. 6.92,

\[ h = h_m \rho_c p L_e^{2/3} \]

where \( L_e = \alpha / D_{AB} = 22.5 / 26.0 = 0.865. \) Hence

\[ h = 6.13 \times 10^{-3} \text{ m/s} \left( 1.161 \text{ kg/m}^3 \right) \left( 1007 \text{ J/kg K} \right) \left( 0.865 \right)^{2/3} = 6.5 \text{ W/m}^2 \cdot \text{K} \]

The corresponding convection heat transfer rate is

\[ q_{\text{conv}}' = h A' (T_g - T_\infty) = 6.5 \text{ W/m}^2 \cdot \text{K} \left( 330 - 300 \right) \text{K} = 195 \text{ W/m} \]

Since \( q_{\text{conv}}' << q_{\text{rad}}' \), the assumption of negligible convection heat transfer is reasonable.
PROBLEM 13.133

KNOWN: Diameters of coaxial cylindrical drum and heater. Heater emissivity. Temperature and emissivity of pellets covering bottom half of drum. Convection mass transfer coefficient associated with flow of dry air over the pellets.

FIND: (a) Evaporation rate per unit length of drum, (b) Surface temperatures of heater and top half of drum.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) Negligible heat transfer from ends of drum, (3) Diffuse-gray surface behavior, (4) Negligible heat loss from the drum to the surroundings, (5) Negligible convection heat transfer from interior surfaces of the drum, (6) Pellet surface area corresponds to that of bottom half of drum.

PROPERTIES Table A-6, sat. water (T = 325 K): $\rho_{A,\text{sat}} = \nu_g^{-1} = 0.0904$ kg/m$^3$, $h_f = 2378$ kJ/kg.

ANALYSIS: (a) The evaporation rate is

$$n_A' = h_m \left( \pi D_d / 2 \right) \left[ \rho_{A,\text{sat}} (T_p) - \rho_{A,\infty} \right]$$

$$n_A' = 0.024 \text{ m/s} \left( \pi \times 1 \text{ m} / 2 \right) \times 0.0904 \text{ kg/m}^3 / \text{s} = 0.00341 \text{ kg/s/m}$$

(b) From an energy balance on the surface of the pellets,

$$q_p' = q_{\text{evap}}' = n_A' h_f g = 0.00341 \text{ kg/s/m} \times 2.378 \times 10^6 \text{ J/kg} = 8109 \text{ W/m}$$

where $q_p'$ may be determined from analysis of radiation transfer in a three surface enclosure. Since the top half of the enclosure may be treated as reradiating, net radiation transfer to the pellets may be obtained from Eq. 13.30, which takes the form

$$q_p' = \frac{E_{bh} - E_{bp}}{1 - \varepsilon_h} + \frac{1}{\varepsilon_h A_h} A_h F_{hp} + \left[ (1 / A_h F_{hd}) + (1 / A_p F_{pd}) \right]^{-1} + \frac{1 - \varepsilon_p}{\varepsilon_p A_p'}$$

where $F_{hp} = F_{hd} = 0.5$, $A_h = \pi D_h$ and $A_p' = \pi D_d / 2$.

The view factor $F_{pd}$ may be obtained from the summation rule,

$$F_{pd} = 1 - F_{ph} - F_{pp}$$

Continued …..
where \( F_{ph} = A_h F_{hp} / A_p = (\pi D_h \times 0.5) / (\pi D_d / 2) = 0.10 \) and

\[
F_{pp} = 1 - \left( \frac{2}{\pi} \right) \left[ 1 - (0.1)^2 \right]^{1/2} + 0.1 \sin^{-1}(0.1) = 0.360
\]

Hence, \( F_{pd} = 1 - 0.10 - 0.360 = 0.540 \), and the expression for the heat rate yields

\[
8109 \text{ W/m} = \frac{E_{bh} - \sigma (325 \text{ K})^4}{\frac{0.25}{\pi \times 0.1m} + \frac{1}{\pi \left( 0.1m \times 0.5 + \left( (0.1m \times 0.5)^{-1} + (0.5m \times 0.54)^{-1} \right)^{-1} \right)} + \frac{0.053}{\pi \times 0.5m}}
\]

\[
E_{bh} = \sigma T_h^4 = 35,359 \text{ W/m}^2
\]

\[
T_h = 889 \text{ K}
\]

Applying Eq. (13.19) to surfaces h and p,

\[
J_h = E_{bh} - q_h \left( 1 - \epsilon_h \right) / \epsilon_h A_h' = 35,359 \text{ W/m}^2 - 6,453 \text{ W/m}^2 = 28,906 \text{ W/m}^2
\]

\[
J_p = E_{bp} + q_p \left( 1 - \epsilon_p \right) / \epsilon_p A_p' = 633 \text{ W/m}^2 + 272 \text{ W/m}^2 = 905 \text{ W/m}^2
\]

Hence, from

\[
\frac{J_h - J_d}{(A_h' F_{hd})^{-1}} - \frac{J_d - J_p}{(A_p' F_{pd})^{-1}} = 0
\]

\[
\frac{28,906 \text{ W/m}^2 - J_d}{(\pi \times 0.1m \times 0.5)^{-1}} - \frac{J_d - 905 \text{ W/m}^2}{(\pi \times 0.5m \times 0.54)^{-1}} = 0
\]

\[
J_d = \sigma T_d^4 = 24,530 \text{ W/m}^2
\]

\[
T_d = 811 \text{ K}
\]

**COMMENTS:** The required value of \( T_h \) could be reduced by increasing \( D_h \), although care must be taken to prevent contact of the plastic with the heater.
**PROBLEM 14.1**

**KNOWN:** Mixture of O\(_2\) and N\(_2\) with partial pressures in the ratio 0.21 to 0.79.

**FIND:** Mass fraction of each species in the mixture.

**SCHEMATIC:**

\[
\begin{align*}
\text{O}_2, \text{N}_2 \\
\frac{\text{P}_{\text{O}_2}}{\text{P}_{\text{N}_2}} &= \frac{0.21}{0.79} \\
\text{m}_{\text{O}_2} &= 32 \text{ kg/kmol} \\
\text{m}_{\text{N}_2} &= 28 \text{ kg/kmol}
\end{align*}
\]

**ASSUMPTIONS:** (1) Perfect gas behavior.

**ANALYSIS:** From the definition of the mass fraction,

\[
m_i = \frac{\rho_i}{\rho} = \frac{\rho_i}{\sum \rho_i}
\]

Hence, with

\[
\rho_i = \frac{P_i}{R_i T} = \frac{P_i}{(\mathbb{R}/M_i)T} = \frac{M_i P_i}{\mathbb{R} T}.
\]

Hence

\[
m_i = \frac{M_i P_i / \mathbb{R} T}{\sum M_i P_i / \mathbb{R} T}
\]

or, cancelling terms and dividing numerator and denominator by the total pressure \(p\),

\[
m_i = \frac{M_i x_i}{\sum M_i x_i}.
\]

With the mole fractions as

\[
x_{\text{O}_2} = \frac{\text{P}_{\text{O}_2}}{p} = \frac{0.21}{0.21 + 0.79} = 0.21
\]

\[
x_{\text{N}_2} = \frac{\text{P}_{\text{N}_2}}{p} = 0.79,
\]

find the mass fractions as

\[
m_{\text{O}_2} = \frac{32 \times 0.21}{32 \times 0.21 + 28 \times 0.79} = 0.233
\]

\[
m_{\text{N}_2} = 1 - m_{\text{O}_2} = 0.767.
\]
PROBLEM 14.2

KNOWN: Partial pressures and temperature for a mixture of CO\textsubscript{2} and N\textsubscript{2}.

FIND: Molar concentration, mass density, mole fraction and mass fraction of each species.

SCHEMATIC:

\[
\begin{aligned}
\rho_A &= \rho_B = 1 \text{bar} \\
T &= 298 \text{K}
\end{aligned}
\]

A \rightarrow CO_2, m_A = 44 \text{ kg/kmol} \\
B \rightarrow N_2, m_B = 28 \text{ kg/kmol}

ASSUMPTIONS: (1) Perfect gas behavior.

ANALYSIS: From the equation of state for an ideal gas,

\[
C_i = \frac{p_i}{\rho_i R T}
\]

Hence, with \( p_A = p_B \),

\[
C_A = C_B = \frac{1 \text{ bar}}{8.314 \times 10^{-2} \text{ m}^3 \cdot \text{bar/kmol} \cdot \text{K} \times 298 \text{K}}
\]

\[
C_A = C_B = 0.040 \text{ kmol/m}^3.
\]

With \( \rho_i = m_i C_i \), it follows that

\[
\rho_A = 44 \text{ kg/kmol} \times 0.04 \text{ kmol/m}^3 = 1.78 \text{ kg/m}^3
\]

\[
\rho_B = 28 \text{ kg/kmol} \times 0.04 \text{ kmol/m}^3 = 1.13 \text{ kg/m}^3.
\]

Also, with

\[
x_i = C_i / \Sigma_i C_i
\]

find

\[
x_A = x_B = 0.04/0.08 = 0.5
\]

and with

\[
m_i = \rho_i / \Sigma \rho_i
\]

find

\[
m_A = 1.78/(1.78 + 1.13) = 0.61
\]

\[
m_B = 1.13/(1.78 + 1.13) = 0.39.
\]
PROBLEM 14.3

KNOWN: Mole fraction (or mass fraction) and molecular weight of each species in a mixture of \( n \) species. Equal mole fractions (or mass fractions) of \( \text{O}_2, \text{N}_2 \) and \( \text{CO}_2 \) in a mixture.

FIND:

SCHEMATIC:

ASSUMPTIONS: (1) Perfect gas behavior.

ANALYSIS: (a) With

\[
m_i = \frac{p_i}{\rho} = \frac{\rho_i}{\sum \rho_i} = \sum \frac{p_i}{R_i T} = \sum \frac{p_i M_i / RT}{RT}
\]

and dividing numerator and denominator by the total pressure \( p \),

\[
m_i = \frac{M_i x_i}{\sum M_i x_i}.
\]

Similarly,

\[
x_i = \frac{p_i}{\rho} = \frac{\rho_i R_i T}{\sum \rho_i R_i T} = \sum \frac{(\rho_i / M_i) RT}{RT}
\]

or, dividing numerator and denominator by the total density \( \rho \)

\[
x_i = \frac{m_i / M_i}{\sum m_i / M_i}.
\]

(b) With

\[
M_{\text{O}_2} x_{\text{O}_2} + M_{\text{N}_2} x_{\text{N}_2} + M_{\text{CO}_2} x_{\text{CO}_2} = 32 \times 0.333 + 28 \times 0.33 + 44 \times 0.333 = 34.6
\]

\[
m_{\text{O}_2} = 0.31, \quad m_{\text{N}_2} = 0.27, \quad m_{\text{CO}_2} = 0.42.
\]

With

\[
m_{\text{O}_2} / M_{\text{O}_2} + m_{\text{N}_2} / M_{\text{N}_2} + m_{\text{CO}_2} / M_{\text{CO}_2} = 0.333/32 + 0.333/28 + 0.333/44
\]

\[
m_{\text{O}_2} = 2.987 \times 10^{-2}.
\]

find

\[
x_{\text{O}_2} = 0.35, \quad x_{\text{N}_2} = 0.40, \quad x_{\text{CO}_2} = 0.25.
\]
PROBLEM 14.4

KNOWN: Temperature of atmospheric air and water. Percentage by volume of oxygen in the air.

FIND: (a) Mole and mass fractions of water at the air and water sides of the interface, (b) Mole and mass fractions of oxygen in the air and water.

SCHEMATIC:

ASSUMPTIONS: (1) Perfect gas behavior for air and water vapor, (2) Thermodynamic equilibrium at liquid/vapor interface, (3) Dilute concentration of oxygen and other gases in water, (4) Molecular weight of air is independent of vapor concentration.

PROPERTIES: Table A-6, Saturated water (T = 290 K): $p_{vap} = 0.01917$ bars. Table A-9, O$_2$/water, $H = 37,600$ bars.

ANALYSIS: (a) Assuming ideal gas behavior, $p_{w,vap} = (N_{w,vap}/V) \cdot T$ and $p = (N/V) \cdot T$, in which case

$$x_{w,vap} = \left( \frac{p_{w,vap}}{p_{air}} \right) = \left( \frac{0.01917}{1.0133} \right) = 0.0194$$

With $m_{w,vap} = (\rho_{w,vap}/\rho_{air}) = (C_{w,vap} M_w/C_{air} M_{air}) = x_{w,vap} (M_w/M_{air})$. Hence,

$$m_{w,vap} = 0.0194 \times \left( \frac{18}{29} \right) = 0.0120$$

Assuming negligible gas phase concentrations in the liquid,

$$x_{w,liq} = m_{w,liq} = 1$$

(b) Since the partial volume of a gaseous species is proportional to the number of moles of the species, its mole fraction is equivalent to its volume fraction. Hence on the air side of the interface

$$x_{O_2,air} = 0.205$$

$$m_{O_2,air} = x_{O_2,air} \left( \frac{M_{O_2}}{M_{air}} \right) = 0.205 \times \left( \frac{32}{29} \right) = 0.226$$

The mole fraction of O$_2$ in the water is

$$x_{O_2,liq} = \frac{p_{O_2,air}}{H} = \frac{0.208 \text{ bars}}{37,600 \text{ bars}} = 5.53 \times 10^{-6}$$

where $p_{O_2,air} = x_{O_2,air} \cdot p_{atm} = 0.205 \times 1.0133 \text{ bars} = 0.208 \text{ bars}$. The mass fraction of O$_2$ in the water is

$$m_{O_2,liq} = x_{O_2,liq} \left( \frac{M_{O_2}}{M_w} \right) = 5.53 \times 10^{-6} \times \left( \frac{32}{18} \right) = 9.83 \times 10^{-6}$$

COMMENTS: There is a large discontinuity in the oxygen content between the air and water sides of the interface. Despite the low concentration of oxygen in the water, it is sufficient to support the life of aquatic organisms.
PROBLEM 14.5

KNOWN: Air is enclosed at uniform pressure in a vertical, cylindrical container whose top and bottom surfaces are maintained at different temperatures.

FIND: (a) Conditions in air when bottom surface is colder than top surface, (b) Conditions when bottom surface is hotter than top surface.

SCHEMATIC:

ASSUMPTIONS: (1) Uniform pressure, (2) Perfect gas behavior.

ANALYSIS: (a) If $T_1 > T_2$, the axial temperature gradient $(dT/dx)$ will result in an axial density gradient. However, since $d\rho / dx < 0$ there will be no buoyancy driven, convective motion of the mixture.

There will also be axial species density gradients, $d\rho_{O_2} / dx$ and $d\rho_{N_2} / dx$. However, there is no gradient associated with the mass fractions $(dm_{O_2} / dx = 0, dm_{N_2} / dx = 0)$. Hence, from Fick’s law, Eq. 14.1, there is no mass transfer by diffusion.

(b) If $T_1 < T_2$, $d\rho / dx > 0$ and there will be a buoyancy driven, convective motion of the mixture. However, $dm_{O_2} / dx = 0$ and $dm_{N_2} / dx = 0$, and there is still no mass transfer. Hence, although there is motion of each species with the convective motion of the mixture, there is no relative motion between species.

COMMENTS: The commonly used special case of Fick’s law,

$$j_A = -D_{AB} \frac{d\rho_A}{dx}$$

would be inappropriate for this problem since $\rho$ is not uniform. If applied, this special case indicates that mass transfer would occur, thereby providing an incorrect result.
PROBLEM 14.6

KNOWN: Pressure and temperature of hydrogen stored in a spherical steel tank of prescribed diameter and thickness.

FIND: (a) Initial rate of hydrogen mass loss from the tank, (b) Initial rate of pressure drop in the tank.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional species diffusion in a stationary medium, (2) Uniform total molar concentration, C, (3) No chemical reactions.

ANALYSIS: (a) From Table 14.1

\[ N_{A,r} = \frac{C_{A,o} - C_{A,L}}{R_m \text{diff}} = \frac{C_{A,o}}{(1/4 \pi D_{AB})(\frac{1}{r_i} - \frac{1}{r_o})} \]

\[ = \frac{4\pi (0.3 \times 10^{-12} \text{ m}^2 / \text{s}) \times 1.5 \text{ kmol/m}^3}{(1/0.05 \text{ m} - 1/0.052 \text{ m})} = 7.35 \times 10^{-12} \text{ kmol/s} \]

or

\[ n_{A,r} = m_A N_{A,r} = 2 \text{ kg/kmol} \times 7.35 \times 10^{-12} \text{ kmol/s} = 14.7 \times 10^{-12} \text{ kg/s}. \]

(b) Applying a species balance to a control volume about the hydrogen,

\[ \dot{M}_{A,st} = -\dot{M}_{A,\text{out}} = -n_{A,r} \]

\[ \dot{M}_{A,st} = \frac{d(\rho_A V)}{dt} = \frac{\pi D^3}{6} \frac{dp_A}{dt} = \frac{\pi D^3}{6R_A T \frac{dp_A}{dt}} = \frac{\pi D^3 m_A}{6\rho T} \frac{dp_A}{dt} \]

Hence

\[ \frac{dp_A}{dt} = -\frac{6\rho T}{\pi D^3 m_A} n_{A,r} = -\frac{6\left(0.08314 \text{ m}^3 \cdot \text{bar/kmol} \cdot \text{K}\right)(300 \text{ K})}{\pi \left(0.1 \text{ m}^3\right)2 \text{ kg/kmol}} \times 14.7 \times 10^{-12} \text{ kg/s} \]

\[ \frac{dp_A}{dt} = -3.50 \times 10^{-7} \text{ bar/s}. \]

COMMENTS: If the spherical shell is approximated as a plane wall, \( N_{a,x} = D_{AB}(C_{A,o}) \pi D^2/L = 7.07 \times 10^{12} \text{ kmol/s}. \) This result is 4% lower than that associated with the spherical shell calculation.
PROBLEM 14.7

KNOWN: Molar concentrations of helium at the inner and outer surfaces of a plastic membrane. Diffusion coefficient and membrane thickness.

FIND: Molar diffusion flux.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional diffusion in a plane wall, (3) Stationary medium, (4) Uniform \( C = C_A + C_B \).

ANALYSIS: The molar flux may be obtained from Eq. 14.50,

\[
N_{A,x}^\prime = \frac{D_{AB}}{L} (C_{A,1} - C_{A,2}) = \frac{10^{-9} \text{ m}^2/\text{s}}{0.001 \text{ m}} (0.02 - 0.005) \text{ kmol/m}^3
\]

\[
N_{A,x}^\prime = 1.5 \times 10^{-8} \text{ kmol/s \cdot m}^2.
\]

COMMENTS: The mass flux is

\[
n_{A,x}^\prime = M_A N_{A,x}^\prime = 4 \text{ kg/kmol} \times 1.5 \times 10^{-8} \text{ kmol/s \cdot m}^2 = 6 \times 10^{-8} \text{ kg/s \cdot m}^2.
\]
PROBLEM 14.8

KNOWN: Mass diffusion coefficients of two binary mixtures at a given temperature, 298 K.

FIND: Mass diffusion coefficients at a different temperature, T = 350 K.

ASSUMPTIONS: (a) Ideal gas behavior, (b) Mixtures at 1 atm total pressure.

PROPERTIES: Table A-8, Ammonia-air binary mixture (298 K), $D_{AB} = 0.28 \times 10^{-4} \text{ m}^2/\text{s}$; Hydrogen-air binary mixture (298 K), $D_{AB} = 0.41 \times 10^{-4} \text{ m}^2/\text{s}$.

ANALYSIS: According to treatment of Section 14.1.5, assuming ideal gas behavior,

$$D_{AB} \sim T^{3/2}$$

where T is in kelvin units. It follows then, that for

$$\begin{align*}
\text{NH}_3 - \text{Air: } & \quad D_{AB}(350 \text{ K}) = 0.28 \times 10^{-4} \text{ m}^2/\text{s} (350 \text{ K} / 298 \text{ K})^{3/2} \\
& \quad D_{AB}(350 \text{ K}) = 0.36 \times 10^{-4} \text{ m}^2/\text{s} < \\
\text{H}_2 - \text{Air: } & \quad D_{AB}(350 \text{ K}) = 0.41 \times 10^{-4} \text{ m}^2/\text{s} (350/298)^{3/2} \\
& \quad D_{AB}(350 \text{ K}) = 0.52 \times 10^{-4} \text{ m}^2/\text{s} <
\end{align*}$$

COMMENTS: Since the H$_2$ molecule is smaller than the NH$_3$ molecule, it follows that

$$D_{H_2-Air} > D_{NH_3-Air}$$

as indeed the numerical data indicate.
PROBLEM 14.9

KNOWN: The inner and outer surfaces of an iron cylinder of 100-mm length are exposed to a carburizing gas (mixtures of CO and CO\textsubscript{2}). Observed experimental data on the variation of the carbon composition (weight carbon, %) in the iron at 1000°C as a function of radius. Carbon flow rate under steady-state conditions.

FIND: (a) Beginning with Fick’s law, show that $\frac{d\rho_c}{d\ln(r)}$ is a constant if the diffusion coefficient, $D_{\text{C-Fe}}$, is a constant; sketch of the carbon mass density, $\rho_c(r)$, as function of $\ln(r)$ for such a diffusion process; (b) Create a graph for the experimental data and determine whether $D_{\text{C-Fe}}$ for this diffusion process is constant, increases or decreases with increasing mass density; and (c) Using the experimental data, calculate and tabulate $D_{\text{C-Fe}}$ for selected carbon compositions over the range of the experiment.

SCHEMATIC:

PROPERTIES: Iron (1000°C). $\rho = 7730 \text{ kg/m}^3$. Experimental observations of carbon composition

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional, radial diffusion in a stationary medium, and (3) Uniform total concentration.

ANALYSIS: (a) For the one-dimensional, radial (cylindrical) coordinate system, Fick’s law is

$$j_A = -D_{\text{AB}} A_r \frac{d\rho_A}{dr}$$

where $A_r = 2\pi r L$. For steady-state conditions, $j_A$ is constant, and if $D_{\text{AB}}$ is constant, the product

$$r \frac{d\rho_A}{dr} = C_1$$

must be a constant. Using the differential relation $dr/r = d(\ln r)$, it follows that

$$\frac{d\rho_A}{d \ln r} = C_1$$

so that on a ln(r) plot, $\rho_A$ is a straight line. See the graph below for this behavior.
PROBLEM 14.9 (Cont.)

(b) To determine whether $D_{C-Fe}$ is a constant for the experimental diffusion process, the data are represented on a $\ln(r)$ coordinate.

Since the plot is not linear, $D_{C-Fe}$ is not a constant. From the treatment of part (a), if $D_{AB}$ is not a constant, then

$$D_{AB} \frac{d\rho_A}{d(ln r)} = C_2$$

must be constant. We conclude that $D_{C-Fe}$ will be lower at the radial position where the gradient is higher. Hence, we expect $D_{C-Fe}$ to increase with increasing carbon content.

(c) From a plot of Wt - %C vs. $r$ (not shown), the mass fraction gradient is determined at three locations and Fick’s law is used to calculate the diffusion coefficient,

$$j_c = -\rho \cdot A_r \cdot D_{C-Fe} \frac{\Delta (Wt - \% C)}{\Delta r}$$

where the mass flow rate is

$$j_c = 3.6 \times 10^{-3} \text{ kg / 100 h} (3600 \text{ s / h}) = 1 \times 10^{-8} \text{ kg / s}$$

and $\rho = 7730 \text{ kg/m}^3$, density of iron. The results of this analysis yield,

PROBLEM 14.10

KNOWN: Three-dimensional diffusion of species A in a stationary medium with chemical reactions.

FIND: Derive molar form of diffusion equation.

SCHEMATIC:

ASSUMPTIONS: (1) Uniform total molar concentration, (2) Stationary medium.

ANALYSIS: The derivation parallels that of Section 14.2.2, except that Eq. 14.33 is applied on a molar basis. That is,

\[ N_{A,x} + N_{A,y} + N_{A,z} + \dot{N}_{A,g} - N_{A,x+dx} - N_{A,y+dy} - N_{A,z+dz} = \dot{N}_{A,\text{st}}. \]

With

\[ N_{A,x+dx} = N_{A,x} + \frac{\partial N_{A,x}}{\partial x} dx, \]
\[ N_{A,y+dy} = \ldots \]
\[ N_{A,x} = -D_{AB} (dydz) \frac{\partial C_A}{\partial x}, \]
\[ N_{A,y} = \ldots \]
\[ \dot{N}_{A,g} = \dot{N}_A (dxdydz), \]
\[ \dot{N}_{A,\text{st}} = \frac{\partial C_A}{\partial t} dxdydz \]

It follows that

\[ \frac{\partial}{\partial x} \left( D_{AB} \frac{\partial C_A}{\partial x} \right) + \frac{\partial}{\partial y} \left( D_{AB} \frac{\partial C_A}{\partial y} \right) + \frac{\partial}{\partial z} \left( D_{AB} \frac{\partial C_A}{\partial z} \right) + \dot{N}_A = \frac{\partial C_A}{\partial t}. \]

COMMENTS: If \( D_{AB} \) is constant, the foregoing result reduces to Eq. 14.38b.
PROBLEM 14.11

KNOWN: Gas (A) diffuses through a cylindrical tube wall (B) and experiences chemical reactions at a volumetric rate, $\dot{N}_A$.

FIND: Differential equation which governs molar concentration of gas in plastic.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional radial diffusion, (2) Uniform total molar concentration, (3) Stationary medium.

ANALYSIS: Dividing the species conservation requirement, Eq. 14.33, by the molecular weight, $A$, and applying it to a differential control volume of unit length normal to the page,

$$\dot{N}_{A,r} + \dot{N}_{A,g} - \dot{N}_{A,s} = \dot{N}_{A,st}$$

where

$$\dot{N}_{A,r} = (2\pi r \cdot 1) N_A^* \cdot r = -2\pi r D_{AB} \frac{\partial C_A}{\partial r}$$

$$\dot{N}_{A,r+dr} = \dot{N}_{A,r} + \frac{\partial N_{A,r}}{\partial r} dr$$

$$\dot{N}_{A,g} = -\dot{N}_A \left( 2\pi r \cdot dr \cdot 1 \right)$$

Thus

$$\dot{N}_{A, st} = \frac{\partial}{\partial t} \left[ C_A \left( 2\pi r dr \cdot 1 \right) \right].$$

Hence

$$-\dot{N}_A \left( 2\pi r dr \right) + 2\pi D_{AB} \frac{\partial}{\partial r} \left( r \frac{\partial C_A}{\partial r} \right) dr = 2\pi r dr \frac{\partial C_A}{\partial t}$$

or

$$D_{AB} \frac{\partial}{\partial r} \left( r \frac{\partial C_A}{\partial r} \right) - \dot{N}_A = \frac{\partial C_A}{\partial t}.$$

COMMENTS: (1) The minus sign in the generation term is necessitated by the fact that the reactions deplete the concentration of species A.

(2) From knowledge of $\dot{N}_A \left( r, t \right)$, the foregoing equation could be solved for $C_A \left( r, t \right)$.

(3) Note the agreement between the above result and the one-dimensional form of Eq. 14.39 for uniform C.
**PROBLEM 14.12**

**KNOWN:** One-dimensional, radial diffusion of species A in a stationary, spherical medium with chemical reactions.

**FIND:** Derive appropriate form of diffusion equation.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional, radial diffusion, (2) Uniform total molar concentration, (3) Stationary medium.

**ANALYSIS:** Dividing the species conservation requirement, Eq. 14.33, by the molecular weight, \( A \), and applying it to the differential control volume, it follows that

\[
N_{A,r} + \dot{N}_{A,g} - N_{A,r+dr} = \dot{N}_{A,st}
\]

where

\[
N_{A,r} = -D_{AB}4\pi r^2 \frac{\partial C_A}{\partial r}
\]

\[
N_{A,r+dr} = N_{A,r} + \frac{\partial N_{A,r}}{\partial r} dr
\]

\[
\dot{N}_{A,g} = \dot{N}_A \left( 4\pi r^2 dr \right), \quad \dot{N}_{A,st} = -\left[ \frac{\partial}{\partial t} \left( \frac{C_A \left( 4\pi r^2 dr \right)}{dr} \right) \right].
\]

Hence

\[
\dot{N}_A \left( 4\pi r^2 dr \right) + 4\pi \frac{\partial}{\partial r} \left( D_{AB}r^2 \frac{\partial C_A}{\partial r} \right) dr = 4\pi r^2 \frac{\partial C_A}{\partial t} dr
\]

or

\[
\frac{1}{r^2} \frac{\partial}{\partial r} \left( D_{AB}r^2 \frac{\partial C_A}{\partial r} \right) + \dot{N}_A = \frac{\partial C_A}{\partial t}.
\]

**COMMENTS:** Equation 14.40 reduces to the foregoing result if C is independent of \( r \) and variations in \( \phi \) and \( \theta \) are negligible.
PROBLEM 14.13

KNOWN: Oxygen pressures on opposite sides of a rubber membrane.

FIND: (a) Molar diffusion flux of O₂, (b) Molar concentrations of O₂ outside the rubber.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, steady-state conditions, (2) Stationary medium of uniform total molar concentration, \( C = C_A + C_B \), (3) Perfect gas behavior.

PROPERTIES: Table A-8, Oxygen-rubber (298 K): \( D_{AB} = 0.21 \times 10^{-9} \text{ m}^2/\text{s} \); Table A-10, Oxygen-rubber (298 K): \( S = 3.12 \times 10^{-3} \text{ kmol/m}^3 \cdot \text{bar} \).

ANALYSIS: (a) For the assumed conditions

\[
N_{A,x}^* = j_{A,x}^* = -D_{AB} \frac{dC_A}{dx} = D_{AB} \frac{C_A(0) - C_A(L)}{L}.
\]

From Eq. 14.33,

\[
C_A(0) = S_p A_1 = 6.24 \times 10^{-3} \text{ kmol/m}^3
\]

\[
C_A(L) = S_p A_2 = 3.12 \times 10^{-3} \text{ kmol/m}^3.
\]

Hence

\[
N_{A,x}^* = 0.21 \times 10^{-9} \text{ m}^2/\text{s} \left( \frac{6.24 \times 10^{-3} - 3.12 \times 10^{-3}}{0.0005 \text{ m}} \right) \text{kmol/m}^3 \]

\[
N_{A,x}^* = 1.31 \times 10^{-9} \text{ kmol/s} \cdot \text{m}^2.
\]

(b) From the perfect gas law

\[
C_{A,1} = \frac{p_{A,1}}{\gamma R T} = \frac{2 \text{ bar}}{\left( 0.08314 \text{ m}^3 \cdot \text{bar/kmol} \cdot \text{K} \right) 298 \text{ K}} = 0.0807 \text{ kmol/m}^3
\]

\[
C_{A,2} = 0.5C_{A,1} = 0.0404 \text{ kmol/m}^3.
\]

COMMENTS: Recognize that the molar concentrations outside the membrane differ from those within the membrane; that is, \( C_{A,1} \neq C_A(0) \) and \( C_{A,2} \neq C_A(L) \).
PROBLEM 14.14

KNOWN: Water vapor is transferred through dry wall by diffusion.

FIND: The mass diffusion rate through a $0.01 \times 3 \times 5$ m wall.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional species diffusion, (3) Homogeneous medium, (4) Constant properties, (5) Uniform total molar concentration, (6) Stationary medium with $x_A << 1$, (7) Negligible condensation in the dry wall.

ANALYSIS: From Eq. 14.46,

$$N_A^x = -CD_{AB}\frac{dx_A}{dx} = -D_{AB}\frac{dC_A}{dx} = D_{AB}\frac{C_{A,1} - C_{A,2}}{L}.$$  

From Eq. 14.33

$$C_{A,1} = Sp_{A,1} = 0.15 \times 10^{-3} \text{kmol/m}^3$$

$$C_{A,2} = Sp_{A,2} = 0 \text{ kmol/m}^3.$$

Hence

$$N_A^x = 10^{-9} \text{ m}^2/\text{s} \times \frac{0.15 \times 10^{-3} \text{ kmol/m}^3}{0.01 \text{ m}} = 0.15 \times 10^{-10} \text{ kmol/s \cdot m}^2.$$

Therefore

$$n_A = M_A \left( A \cdot N_A^x \right) = 18 \text{ kg/kmol} \times 15 \text{ m}^2 \times 0.15 \times 10^{-10} \text{ kmol/s \cdot m}^2$$

or

$$n_A = 4.05 \times 10^{-9} \text{ kg/s}.$$
**PROBLEM 14.15**

**KNOWN:** Pressure and temperature of CO$_2$ in a container of prescribed volume. Thickness and surface area of rubber plug.

**FIND:** (a) Mass rate of CO$_2$ loss from container, (b) Reduction in pressure over a 24 h period.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Loss of CO$_2$ is only by diffusion through the rubber plug, (2) One-dimensional diffusion through a stationary medium, (3) Diffusion rate is constant over the 24 h period, (4) Perfect gas behavior, (5) Negligible CO$_2$ pressure outside the plug.

**PROPERTIES:** Table A-8, CO$_2$-rubber (298 K, 1 atm): $D_{AB} = 0.11 \times 10^{-9}$ m$^2$/s; Table A-10, CO$_2$-rubber (298 K, 1 atm): $S = 40.15 \times 10^{-3}$ kmol/m$^3$·bar.

**ANALYSIS:** (a) For diffusion through a stationary medium,

$$N_A = AD_{AB} \frac{C_{A,1} - C_{A,2}}{L}$$

where $C_{A,1} = S p_{A,1} = 40.15 \times 10^{-3}$ kmol/m$^3$·bar $\times$ 5 bar = 0.200 kmol/m$^3$

$C_{A,2} = S p_{A,2} = 0.$

Hence

$$N_A = 3 \times 10^{-4} \text{ m}^2 \left(0.11 \times 10^{-9} \text{ m}^2/\text{s}\right) \frac{(0.200 - 0) \text{ kmol/m}^3}{0.02 \text{ m}} = 3.30 \times 10^{-13} \text{ kmol/s}$$

and

$$n_A = M_A N_A = 44 \text{ kg/kmol} \times 3.30 \times 10^{-13} \text{ kmol/s} = 1.45 \times 10^{-11} \text{ kg/s}. \quad \checkmark$$

(b) Applying conservation of mass to a control volume about the container

$$\frac{d (p_A V)}{dt} = -n_A \quad \text{or} \quad \frac{d (C_A V)}{dt} = -N_A.$$

Hence, with $C_A = p_A/\mathcal{RT}$,

$$\frac{dp_A}{dt} = - \frac{N_A \mathcal{RT}}{V} = - \frac{3.3 \times 10^{-13} \text{ kmol/s} \times 8.314 \times 10^{-2} \text{ m}^3/\text{kmol} \cdot \text{K} \left(298 \text{ K}\right)}{10^{-2} \text{ m}^3} = -8.18 \times 10^{-10} \text{ bar/s}.$$

Hence

$$\Delta p_A = \left(\frac{dp_A}{dt}\right)\Delta t = -8.18 \times 10^{-10} \text{ bar/s} \times 24 \text{ h} \times 3600 \text{ s/h} = 7.06 \times 10^{-5} \text{ bar}. \quad \checkmark$$
PROBLEM 14.16

KNOWN: Pressure and temperature of helium in a glass cylinder of 100 mm inside diameter and 5 mm thickness.

FIND: Mass rate of helium loss per unit length.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional radial diffusion through cylinder wall, (3) Negligible end losses, (4) Stationary medium, (5) Uniform total molar concentration, (6) Negligible helium concentration outside cylinder.

PROPERTIES: Table A-8, He-SiO₂ (298 K): \( D_{AB} \approx 0.4 \times 10^{-13} \text{ m}^2/\text{s} \); Table A-10, He-SiO₂ (298 K): \( S \approx 0.45 \times 10^{-3} \text{ kmol/m}^3 \cdot \text{bar} \).

ANALYSIS: From Table 14.1,

\[
N'_{A,r} = \frac{C_{A,S1} - C_{A,S2}}{\ln \left( \frac{r_2}{\eta} \right) / 2\pi D_{AB}}
\]

where, from Eq. 14.44, \( C_{A,S} = S \rho A \). Hence

\[
C_{A,S1} = S \rho A,1 = 0.45 \times 10^{-3} \text{ kmol/m}^3 \cdot \text{bar} \times 4 \text{ bar} = 1.8 \times 10^{-3} \text{ kmol/m}^3
\]

\[
C_{A,S2} = S \rho A,2 = 0.
\]

Hence

\[
N'_{A,r} = \frac{1.8 \times 10^{-3} \text{ kmol/m}^3}{\ln \left( \frac{0.055}{0.050} \right) / 2\pi \left( 0.4 \times 10^{-13} \text{ m}^2/\text{s} \right)}
\]

\[
N'_{A,r} = 4.75 \times 10^{-15} \text{ kmol/s} \cdot \text{m}.
\]

The mass loss is then

\[
n'_{A,r} = M_A N'_{A,r} = 4 \text{ kg/kmol} \times 4.75 \times 10^{-15} \text{ kmol/s} \cdot \text{m}
\]

\[
n'_{A,r} = 1.90 \times 10^{-14} \text{ kg/s} \cdot \text{m}.
\]
PROBLEM 14.17

KNOWN: Temperature and pressure of helium stored in a spherical pyrex container of prescribed diameter and wall thickness.

FIND: Mass rate of helium loss.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Helium loss by one-dimensional diffusion in radial direction through the pyrex, (3) \( C = C_A + C_B \) is independent of \( r \), and \( x_A << 1 \), (4) Stationary medium.

PROPERTIES: Table A-8, He-SiO\(_2\) (293 K): \( D_{AB} = 0.4 \times 10^{-13} \text{ m }^2/\text{s} \); Table A-10, He-SiO\(_2\) (293 K): \( S = 0.45 \times 10^{-3} \text{ kmol/m}^3\cdot\text{bar} \).

ANALYSIS: From Table 14.1, the molar diffusion rate may be expressed as

\[
N_A, r = \frac{C_{A,S1} - C_{A,S2}}{R_{m,dif}}
\]

where

\[
R_{m,dif} = \frac{1}{4\pi D_{AB}} \left( \frac{1}{r_1} - \frac{1}{r_2} \right) = \frac{1}{4\pi} \left( \frac{1}{0.4 \times 10^{-13} \text{ m}^2/\text{s}} \right) \left( \frac{1}{0.1 \text{ m}} - \frac{1}{0.01 \text{ m}} \right) = 1.81 \times 10^{12} \text{ s}/\text{m}^3
\]

with

\[
C_{A,S1} = 0.45 \times 10^{-3} \text{ kmol/m}^3\cdot\text{bar} \times 4 \text{ bar} = 1.80 \times 10^{-3} \text{ kmol/m}^3
\]

\[C_{A,S2} = 0\]

find

\[
N_A, r = \frac{1.80 \times 10^{-3} \text{ kmol/m}^3}{1.81 \times 10^{12} \text{ s}/\text{m}^3} = 10^{-15} \text{ kmol/s.}
\]

Hence

\[
n_A, r = M_A N_A, r = 4 \text{ kg/mol} \times 10^{-15} \text{ kmol/s} = 4 \times 10^{-15} \text{ kg/s.}
\]

COMMENTS: Since \( r_1 \approx r_2 \), the spherical shell could have been approximated as a plane wall with \( L = 0.01 \text{ m} \) and \( A = 4\pi r_m^2 = 0.139 \text{ m}^2 \). From Table 14.1,

\[
R_{m,dif} = \frac{L}{D_{AB} A} = \frac{0.01 \text{ m}}{0.4 \times 10^{-13} \text{ m}^2/\text{s}} \left( \frac{0.139 \text{ m}^2}{0.137 \text{ m}^2} \right) = 1.8 \times 10^{12} \text{ s}/\text{m}^3
\]

and

\[
N_A, x = \frac{C_{A,S1} - C_{A,S2}}{R_{m,dif}} = \frac{1.80 \times 10^{-3} \text{ kmol/m}^3}{1.8 \times 10^{12} \text{ s}/\text{m}^3} = 10^{-15} \text{ kmol/s.}
\]

Hence the approximation is excellent.
**PROBLEM 14.18**

**KNOWN:** Pressure and temperature of hydrogen inside and outside of a circular tube. Diffusivity and solubility of hydrogen in tube wall of prescribed thickness and diameter.

**FIND:** Rate of hydrogen transfer through tube per unit length.

**SCHEMATIC:**

![Schematic of hydrogen transfer through a tube](image)

**ASSUMPTIONS:** (1) Steady diffusion in radial direction, (2) Uniform total molar concentration in wall, (3) No chemical reactions.

**ANALYSIS:** The mass transfer rate per unit tube length is

$$N_{A,r}^{'} = \frac{C_A(\eta) - C_A(r_2)}{\ln(r_2/\eta)/2\pi D_{AB}}$$

where from Eq. 14.44, $C_A, s = S_p a$,

$$C_A(\eta) = S_p A,1 = 160 \text{ kmol/m}^3 \cdot \text{atm} \times 2 \text{ atm} = 320 \text{ kmol/m}^3$$

$$C_A(r_2) = S_p A,2 = 160 \text{ kmol/m}^3 \cdot \text{atm} \times 0.1 \text{ atm} = 16 \text{ kmol/m}^3.$$

Hence,

$$N_{A,r}^{'} = \frac{(320 - 16) \text{ kmol/m}^3}{\ln(20.5/20)/2\pi \times 1.8 \times 10^{-11} \text{ m}^2/\text{s}} = 304 \text{ kmol/m}^3 \div 2.18 \times 10^8 \text{ s/m}^2$$

$$N_{A,r}^{'} = 1.39 \times 10^{-6} \text{ kmol/s \cdot m.}$$

**COMMENTS:** If the wall were assumed to be plane,

$$R_{m, \text{dif}}^{'} = \frac{L}{D_{AB} \pi D} = \frac{5 \times 10^{-4} \text{ m}}{1.8 \times 10^{-11} \text{ m}^2/\text{s} \pi (0.04 \text{ m})} = 2.21 \times 10^8 \text{ s/m}^2$$

which is close to the value of $2.18 \times 10^8 \text{ s/m}^2$ for the cylindrical wall.
PROBLEM 14.19

KNOWN: Dimensions of nickel tube and pressure of hydrogen flow through the tube. Diffusion coefficient.

FIND: Mass rate of hydrogen diffusion per unit tube length.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, (2) One-dimensional diffusion through tube wall, (3) Negligible pressure of H₂ in ambient air, (4) Tube wall is a stationary medium of uniform total molar concentration, (5) Constant properties.

PROPERTIES: Table A-10 (H₂ – Ni): \( S = 9.01 \times 10^{-3} \text{ kmol/m}^3\cdot\text{bar} \).

ANALYSIS: From Table 14.1, the resistance to diffusion per unit tube length is
\[
R_{m, \text{dir}} = \ln \left(\frac{D_o}{D_i}\right)/2\pi D_{AB},
\]
and the molar rate of hydrogen diffusion per unit length is
\[
N_{A,r} = \frac{2\pi D_{AB} (C_{A,si} - C_{A,so})}{\ln \left(\frac{D_o}{D_i}\right)}
\]

From Eq. (14.44), the tube wall molar concentrations are
\[
C_{A,si} = S p_{A,i} = 9.01 \times 10^{-3} \text{ kmol/m}^3\cdot\text{bar} \times 4 \text{ bar} = 0.036 \text{ kmol/m}^3
\]
\[
C_{A,so} = S p_{A,o} = 0
\]
\[
N_{A,r} = \frac{2\pi \times 10^{-12} \text{ m}^2/\text{s} \times 0.036 \text{ kmol/m}^3}{\ln (0.028/0.025)} = 2.00 \times 10^{-12} \text{ kmol/s}\cdot\text{m}
\]

With \( M_A = 2 \text{ kg/kmol for H}_2 \),
\[
n_{A,r} = M_A N_{A,r} = 2 \text{ kg/kmol} \times 2.00 \times 10^{-12} \text{ kmol/s}\cdot\text{m} = 4.00 \times 10^{-12} \text{ kg/s}\cdot\text{m}
\]

COMMENTS: The hydrogen loss is miniscule.
PROBLEM 14.20

KNOWN: Conditions of the exhaust gas passing over a catalytic surface for the removal of NO.

FIND: (a) Mole fraction of NO at the catalytic surface, (b) NO removal rate.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional species diffusion through the film, (3) Effects of bulk motion on NO transfer in the film are negligible, (4) No homogeneous reactions of NO within the film, (5) Constant properties, including the total molar concentration, C, throughout the film.

ANALYSIS: Subject to the above assumptions, the transfer of species A (NO) is governed by diffusion in a stationary medium, and the desired results are obtained from Eqs. 14.60 and 14.61. Hence

\[ \frac{x_{A,s}}{x_{A,L}} = \frac{1}{1 + \left( \frac{Lk_f}{D_{AB}} \right)} \]

\[ x_{A,s} = \frac{0.15}{1 + 0.001 \times 0.05 \ m/s \times 10^{-4} \ m^2/s} = 0.10. \]

Also

\[ N_{A,s}^* = -\frac{k_i^* C x_{A,L}}{1 + \left( \frac{Lk_f}{D_{AB}} \right)} \]

where, from the equation of state for a perfect gas,

\[ C = \frac{p}{\rho T} = \frac{1.2 \ bar}{8.314 \times 10^{-2} \ m^3 \cdot bar/kmol \cdot K \times 773 \ K} = 0.0187 \ kmol/m^3. \]

Hence

\[ N_{A,s}^* = -\frac{0.05 \ m/s \times 0.0187 \ kmol/m^3 \times 0.15}{1 + \left( 0.001 \times 0.05 \ m/s \times 10^{-4} \ m^2/s \right)} = -9.35 \times 10^{-5} \ kmol/s \cdot m^2 \]

or

\[ n_{A,s}^* = M A N_{A,s}^* = 30 \ kg/kmol \left( -9.35 \times 10^{-5} \ kmol/s \cdot m^2 \right) = -2.80 \times 10^{-3} \ kg/s \cdot m^2. \]

The molar rate of NO removal for the entire surface is then

\[ N_{A,s} = N_{A,s}^* A = -9.35 \times 10^{-5} \ kmol/s \cdot m^2 \times 0.02 \ m^2 = -1.87 \times 10^{-6} \ kmol/s \]

or

\[ n_{A,S} = -5.61 \times 10^{-5} \ kg/s. \]

COMMENTS: Because bulk motion is likely to contribute significantly to NO transfer within the film, the above results should be viewed as a first approximation.
PROBLEM 14.21

KNOWN: Radius of coal pellets burning in oxygen atmosphere of prescribed pressure and temperature.

FIND: Oxygen molar consumption rate.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional diffusion in r, (2) Steady-state conditions, (3) Constant properties, (4) Perfect gas behavior, (5) Uniform C and T.

ANALYSIS: From Equation 14.53,

\[
\frac{d}{dr} \left( r^2 \frac{dC_A}{dr} \right) = 0
\]

\[
dC_A/dr = C_1/r^2 \quad \text{or} \quad C_A = -C_1/r + C_2.
\]

The boundary conditions at \( r \to \infty \) and \( r = r_o \) are, respectively,

\[
C_A(\infty) = C \quad \to \quad C_2 = C
\]

\[
\dot{N}_A = N_A^* (r_0) = -C_{AB} \frac{dx_A}{dr} \bigg|_{r_0} = -D_{AB} \frac{dC_A}{dr} \bigg|_{r_0}
\]

Hence

\[
-k_f (-C_1/r_0 + C) = -D_{AB} C_1/r_0^2
\]

\[
k_f (C_1/r_0) + D_{AB} \left( C_1/r_0^2 \right) = k_f C \quad \text{or} \quad C_1 = \frac{k_f C}{(k_f/r_0) + \left( D_{AB}/r_0^2 \right)}.
\]

The oxygen molar consumption rate is

\[
N_A^* (r_0) = -D_{AB} \frac{dC_A}{dr} \bigg|_{r_0} = -D_{AB} \frac{k_f C}{k_f r_0 + D_{AB}}
\]

where

\[
C = \frac{p}{RT} = \frac{1 \text{ atm}}{\left( 8.205 \times 10^{-2} \text{ m}^3 \cdot \text{atm/kmol} \cdot \text{K} \right) 1450 \text{ K}} = 8.405 \times 10^{-3} \text{ kmol/m}^3.
\]

Hence,

\[
N_A^* (r_0) = -1.71 \times 10^{-4} \text{ m}^2 / s \cdot 0.1 \text{ m/s} \times 8.405 \times 10^{-3} \text{ kmol/m}^3 = -5.30 \times 10^{-4} \text{ kmol/m}^2 \cdot \text{s}
\]

\[
N_A (r_0) = 4\pi r_0^2 N_A^* (r_0) = 4\pi (0.001 \text{ m})^2 \times 5.30 \times 10^{-4} \text{ kmol/s} \cdot \text{m}^2
\]

\[
N_A (r_0) = 6.66 \times 10^{-9} \text{ kmol/s}.
\]

COMMENTS: The \( O_2 \) consumption rate would increase with increasing \( k_f \) and approach a limiting finite value as \( k_f \) approaches infinity.
PROBLEM 14.22

KNOWN: Radius of coal particles burning in oxygen atmosphere of prescribed pressure and temperature.

FIND: (a) Radial distributions of O$_2$ and CO$_2$, (b) O$_2$ molar consumption rate.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, steady-state conditions, (2) Uniform total molar concentration, (3) No homogeneous chemical reactions, (4) Coal is pure carbon, (5) Surface reaction rate is infinite (hence concentration of O$_2$ at surface, C$_A$, is zero), (6) Constant D$_{AB}$, (7) Perfect gas behavior.

PROPERTIES: Table A-8, CO$_2$ → O$_2$; D$_{AB}$ (273 K) = 0.14 × 10$^{-4}$ m$^2$/s; D$_{AB}$ (1450 K) = D$_{AB}$ (273 K) (1450/273)$^{3/2}$ = 1.71 × 10$^{-4}$ m$^2$/s.

ANALYSIS: (a) For the assumed conditions, Eq. 14.53 reduces to

\[
\frac{d}{dr} \left( r^2 \frac{dC_A}{dr} \right) = 0
\]

\[
r^2 \left( \frac{dC_A}{dr} \right) = C_1 \quad \text{or} \quad C_A = -\left( \frac{C_1}{r} \right) + C_2.
\]

From the boundary conditions:
\[
C_A(\infty) = C \rightarrow C_2 = C
\]
\[
C_A(r_0) = 0 \rightarrow 0 = -\frac{C_1}{r_0} + C \quad \quad C_1 = C r_0.
\]

Hence, recognizing that C = C$_A$ + C$_B$,
\[
C_A = C - C \left( \frac{r_0}{r} \right) = C(1 - \frac{r_0}{r}) \quad \quad C_B = C - C_A = C \left( \frac{r_0}{r} \right).
\]

(b) The conditions correspond to equimolar, counter diffusion (N$_A^r$ = -N$_B^r$), with
\[
N_{A,r} = N_{A,r}^* 4\pi r^2 = -CD_{AB} 4\pi r^2 \frac{dx_A}{dr} = -D_{AB} 4\pi r^2 \frac{dC_A}{dr} = -4\pi D_{AB} r^2 \left( \frac{C r_0}{r^2} \right) = -4\pi D_{AB} C r_0.
\]

With
\[
C = \frac{p}{\gamma T} = \frac{1 \text{ atm}}{8.205 \times 10^{-2} \text{ m}^3 \cdot \text{atm/kmol} \cdot \text{K} \times 1450 \text{ K}} = 8.405 \times 10^{-3} \text{ kmol/m}^3
\]

find
\[
N_{A,r} = -1.71 \times 10^{-4} \text{ m}^2 / \text{s} \times 4\pi \times 8.405 \times 10^{-3} \text{ kmol/m}^3 \left( 10^{-3} \text{ m} \right)
\]
\[
N_{A,r} = 1.81 \times 10^{-8} \text{ kmol/s}.
\]
PROBLEM 14.23

KNOWN: Pore geometry in a catalytic reactor. Concentration of reacting species at pore opening and order of catalytic reaction.

FIND: (a) Differential equation which determines concentration of reacting species, (b) Distribution of reacting species concentration along the pore.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional diffusion in x direction, (3) Stationary medium, (4) Uniform total molar concentration.

ANALYSIS: (a) Apply the species conservation requirement to the differential control volume, 

\[ N_{A,x} - k_i C_A \left( \pi D \right) dx - N_{A,x+dx} = 0, \]

where

\[ N_{A,x+dx} = N_{A,x} + \left( \frac{dN_{A,x}}{dx} \right) dx \]

and from Fick’s law

\[ N_{A,x} = \left( -CD_{AB} \frac{dx_A}{dx} \right) \frac{\pi D^2}{4} = -\frac{\pi D^2}{4} D_{AB} \frac{dC_A}{dx}. \]

Hence

\[ -\frac{dN_A}{dx} dx - k_i C_A \left( \pi D \right) dx = \frac{\pi D^2}{4} D_{AB} \frac{d^2C_A}{dx^2} - k_i C_A \left( \pi D \right) dx = 0 \]

\[ \frac{d^2C_A}{dx^2} - \frac{4 k_i}{D D_{AB}} C_A = 0. \]

(b) A solution to the above equation is readily obtained by recognizing that it is of exactly the same form as the energy equation for an extended surface of uniform cross section. Hence for boundary conditions of the form

\[ C_A \left( 0 \right) = C_{A,0}, \]

\[ -D_{AB} \left( \frac{dC_A}{dx} \right)_{x=L} = k_i C_A \left( L \right) \]

the solution must be analogous to that obtained for a fin with a convection tip condition. With the analogous quantities

\[ C_A \leftrightarrow \theta \equiv T - T_\infty, \]

\[ m \equiv \left( 4 k_i / D D_{AB} \right)^{1/2} \leftrightarrow \left( 4 h / D k \right)^{1/2} \]

\[ D_{AB} \leftrightarrow k, \]

\[ k_i \leftrightarrow h \]

the solution is, by analogy to Eq. 3.70

\[ C_A \left( x \right) = \frac{\cosh m \left( L - x \right) + \left( k_i / m D_{AB} \right) \sinh m \left( L - x \right)}{\cosh mL + \left( k_i / m D_{AB} \right) \sinh mL}. \]

COMMENTS: The total pore reaction rate is \(- D_{AB} (\pi D^2 / 4) \left( \frac{dC_A}{dx} \right)_{x=0}\), which can be inferred by applying the analogy to Eq. 3.72.
**PROBLEM 14.24**

**KNOWN:** Pressure, temperature and mole fraction of CO in auto exhaust. Diffusion coefficient for CO in gas mixture. Film thickness and reaction rate coefficient for catalytic surface.

**FIND:** (a) Mole fraction of CO at catalytic surface and CO removal rate, (b) Effect of reaction rate coefficient on removal rate.

**SCHEMATIC:**

![Schematic](image)

**ASSUMPTIONS:** (1) Steady-state, (2) One-dimensional species diffusion in film, (3) Negligible effect of advection in film, (4) Constant total molar concentration and diffusion coefficient in film.

**ANALYSIS:** From Eq. (14.60) the surface molar concentration is

$$x_A(0) = \frac{x_{A,L}}{1 + \left( \frac{Lk_1^*/D_{AB}}{1 + \left( \frac{0.01m \times 0.005 m/s}{10^{-4} m^2/s} \right) \right)} = 0.0008$$

With $C = \frac{p \times T}{R \times T} = 1.2 \text{ bar}/(8.314 \times 10^{-2} \text{ m}^3 \cdot \text{bar/kmol} \times 773 \text{ K}) = 0.0187 \text{ kmol/m}^3$, Eq. (14.61) yields a CO molar flux, and hence a CO removal rate, of

$$N_{A,s}^* = -N_A^* (0) = \frac{k_1^* C x_{A,L}}{1 + \left( \frac{Lk_1^*/D_{AB}}{1 + \left( \frac{0.01m \times 0.005 m/s}{10^{-4} m^2/s} \right) \right)} = 7.48 \times 10^{-8} \text{ kmol/s} \cdot \text{m}^2$$

If the process is diffusion limited, $Lk_1^*/D_{AB} >> 1$ and

$$N_{A,s}^* = \frac{C D_{AB} x_{A,L}}{L} = \frac{0.0187 \text{ kmol/m}^3 \times 10^{-4} \text{ m}^2/s \times 0.0012}{0.01m} = 2.24 \times 10^{-7} \text{ kmol/s} \cdot \text{m}^2$$

**COMMENTS:** If the process is reaction limited, $N_{A,s}^* \to 0$ as $k_1^* \to 0$. 
**PROBLEM 14.25**

**KNOWN:** Partial pressures and temperatures of CO\textsubscript{2} at opposite ends of a circular tube which also contains nitrogen.

**FIND:** Mass transfer rate of CO\textsubscript{2} through the tube.

**SCHEMATIC:**

![Diagram](image)

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional diffusion, (3) Uniform temperature and total pressure.

**PROPERTIES:** *Table A-8*, CO\textsubscript{2} – N\textsubscript{2} (T \approx 298 K, 1 atm): $D_{AB} = 0.16 \times 10^{-4}$ m\textsuperscript{2}/s.

**ANALYSIS:** From Eq. 14.70 the CO\textsubscript{2} molar transfer rate is

$$N_A = \frac{D_{AB} \left( \frac{\pi D^2}{4} \right) p_{A,0} - p_{A,L}}{9 \pi T L}$$

$$N_A = \frac{0.16 \times 10^{-4} \text{ m}^2/\text{s} \left( \frac{\pi}{4} \right) (0.05 \text{ m})^2 (100 - 50) \text{ mmHg}}{0.08205 \text{ m}^3 \cdot \text{atm/kmol} \cdot \text{K} \times 298 \text{ K} \times 1 \text{ m} \times 760 \text{ mmHg/atm}}$$

$$N_A = 8.45 \times 10^{-11} \text{ kmol/s}.$$  

The mass transfer rate is then

$$n_A = m_A n_A = 44 \text{ kg/kmol} \times 8.45 \times 10^{-11} \text{ kmol/s}$$

$$n_A = 3.72 \times 10^{-9} \text{ kg/s}. <$$

**COMMENTS:** Although the molar transfer rate of N\textsubscript{2} in the opposite direction is $N_B = 8.45 \times 10^{-11}$ kmol/s, the mass transfer rate is

$$n_B = m_B n_B = 28 \text{ kg/kmol} \times 8.45 \times 10^{-11} \text{ kmol/s} = 2.37 \times 10^{-9} \text{ kg/s}.$$
PROBLEM 14.26

KNOWN: Conditions associated with evaporation from a liquid in a column, with vapor (A) transfer occurring in a gas (B). In one case B has unlimited solubility in the liquid; in the other case it is insoluble.

FIND: Case characterized by the largest evaporation rate and ratio of evaporation rates if $p_A = 0$ at the top of the column and $p_A = p/10$ at the liquid interface.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional species transfer, (3) Uniform temperature and total pressure in the column, (4) Constant properties.

ANALYSIS: If gas B has unlimited solubility in the liquid, the solution corresponds to equimolar counter diffusion of A and B. From Eqs. 14.63 and 14.68, it follows that

$$N_{A,x}^* = -CD_{AB} \frac{dx_A}{dx} = CD_{AB} \frac{x_{A,0} - x_{A,L}}{L}. \quad (1)$$

If gas B is completely insoluble in the liquid, the diffusion of A is augmented by convection and from Eqs. 14.73 and 14.77

$$N_{A,x}^* = -CD_{AB} \frac{dx_A}{dx} + C_A v^* = CD_{AB} \frac{\ln \frac{1-x_{A,L}}{1-x_{A,0}}}{L}. \quad (2)$$

Comparing Eqs. (1) and (2), it is obvious that the evaporation rate for the second case exceeds that for the first case. Also

$$\frac{N_{A,x}^*(sol)}{N_{A,x}^*(insol)} = \frac{(CD_{AB} / L)(x_{A,0} - x_{A,L})}{(CD_{AB} / L) \ln \left(\frac{1-x_{A,L}}{1-x_{A,0}}\right)} = \frac{0.1 - 0}{\ln \left(\frac{1-0}{1-0.1}\right)}$$

$$= 0.949.$$ <

COMMENTS: The above result suggests that, since the mole fraction of the saturated vapor is typically small, the rate of evaporation in a column is well approximated by the result corresponding to equimolar counter diffusion.
**PROBLEM 14.27**

**KNOWN:** Water in an open pan exposed to prescribed ambient conditions.

**FIND:** Evaporation rate considering (a) diffusion only and (b) convective effects.

**SCHEMATIC:**

![Schematic diagram showing water in an open pan with air flow and ambient conditions.]

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional diffusion, (3) Constant properties, (4) Uniform T and p, (5) Perfect gas behavior.

**PROPERTIES:** *Table A-8*, Water vapor-air (T = 300 K, 1 atm), $D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}$; *Table A-6*, Water vapor (T = 300 K, 1 atm), $p_{\text{sat}} = 0.03513 \text{ bar}$, $v_g = 39.13 \text{ m}^3/\text{kg}$.

**ANALYSIS:** (a) The evaporation rate considering only diffusion follows from Eq. 14.63 simplified for a stationary medium. That is,

$$N_{A,x} = N_{A,x}^* \cdot A = -D_{AB}A \frac{dC_A}{dx}.$$  

Recognizing that $\phi \equiv p_A/p_{A,\text{sat}} = C_A/C_{A,\text{sat}}$, the rate is expressed as

$$N_{A,x} = -D_{AB}A \frac{C_{A,\infty} - C_{A,s}}{L} = \frac{D_{AB}A}{L} C_{A,\text{sat}} \left(1 - \phi_{\infty}\right)$$

$$N_{A,x} = \frac{0.26 \times 10^{-4} \text{ m}^2/\text{s} \left(\pi / 4\right) (0.2 \text{ m})^2}{80 \times 10^{-3} \text{ m}} \frac{1}{39.13 \text{ m}^3/\text{kg} \times 18 \text{ kg/kmol}} (1 - 0.25) = 1.087 \times 10^{-8} \text{ kmol/s}$$

where $C_{A,s} = 1/(v_g \cdot M_A)$ with $M_A = 18 \text{ kg/kmol}$.

(b) The evaporation rate considering convective effects using Eq. 14.77 is

$$N_{A,x} = N_{A,x}^* \cdot A = \frac{CD_{AB}A}{L} \ln \frac{1 - x_{A,L}}{1 - x_{A,0}}.$$  

Using the perfect gas law, the total concentration of the mixture is

$$C = \frac{p}{RT} = 1.0133 \text{ bar} \left(8.314 \times 10^{-2} \text{ m}^3 \cdot \text{bar/kmol} \cdot \text{K} \times 300 \text{K}\right) = 0.04063 \text{ kJmol/m}^3$$

where $p = 1 \text{ atm} = 1.0133 \text{ bar}$. The mole fractions at $x = 0$ and $x = L$ are

$$x_{A,0} = \frac{p_{A,s}}{p} = 0.03531 \text{ bar} = 0.0348 \quad x_{A,L} = \phi_{\infty}x_{A,0} = 0.0087.$$  

Hence

$$N_{A,x} = \frac{0.04063 \text{ kJmol/m}^3 \times 0.26 \times 10^{-4} \text{ m}^2/\text{s} \left(\pi / 4\right) (0.2 \text{ m})^2}{80 \times 10^{-3} \text{ m}} \ln \frac{1 - 0.0087}{1 - 0.0348} = 1.107 \times 10^{-8} \text{ kmol/s.}$$  

**COMMENTS:** For this situation, the convective effect is very small but does tend to increase (by 1.5%) the evaporation rate as expected.
**PROBLEM 14.28**

**KNOWN:** Vapor concentrations at ends of a tube used to grow crystals. Presence of an inert gas. Ends are impermeable to the gas. Constant temperature.

**FIND:** Vapor molar flux and spatial distribution of vapor molar concentration. Location of maximum concentration gradient.

**SCHEMATIC:**

![Diagram](image)

**ASSUMPTIONS:** (1) One-dimensional, steady-state conditions, (2) Constant properties, (3) Constant pressure, hence C is constant.

**ANALYSIS:** Physical conditions are analogous to those of the evaporation problem considered in Section 14.4.4 with

\[ C_{A,0} > C_{A,L} \rightarrow \text{diffusion of vapor from source to crystal,} \]

\[ C_{B,L} > C_{B,0} \rightarrow \text{diffusion of inert gas from crystal to source,} \]

Impermeable ends \( \rightarrow \) absolute flux of species B is zero \( (N_{B,x} = 0) \); hence \( v_{B,x} = 0 \).

Diffusion of B from crystal to source must be balanced by advection from source to crystal. The advective velocity is \( v^*_{A,x} = N_{A,x}'' / C \). The vapor molar flux is therefore determined by Eq. 14.77,

\[
N_{A,x}'' = \frac{CD_{AB}}{L} \ln \left( \frac{1-x_{A,L}}{1-x_{A,0}} \right) <
\]

and the vapor molar concentration is given by Eq. 14.75,

\[
x_A = \frac{C_A}{C} = 1 - \left( 1 - x_{A,0} \right) \left( \frac{1-x_{A,L}}{1-x_{A,0}} \right)^{x/L} <
\]

From Eq. 14.72,

\[
\frac{dx_A}{dx} = -N_{A,x}'' (1-x_A) / CD_{AB}
\]

\[
\frac{dC_A}{dx} = -N_{A,x}'' (1-x_A) / D_{AB}
\]

Hence maximum concentration gradient corresponds to minimum \( x_A \) and occurs at \( x = L \).

**COMMENTS:** Vapor transfer is enhanced by the advection, which is induced by presence of the inert gas.
PROBLEM 14.29

KNOWN: Spherical droplet of liquid A and radius \( r_0 \) evaporating into stagnant gas B.

FIND: Evaporation rate of species A in terms of \( p_{A,\text{sat}} \), partial pressure \( p_A(r) \), the total pressure \( p \) and other pertinent parameters.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional, radial, species diffusion, (3) Constant properties, including total concentration, (4) Droplet and mixture air at uniform pressure and temperature, (5) Perfect gas behavior.

ANALYSIS: From Eq. 14.31 for a radial spherical coordinate system, the evaporation rate of liquid A into a binary gas mixture A + B is

\[
N_{A,r} = -D_{AB} A_r \frac{dC_A}{dr} + \frac{C_A}{C} N_{A,r}
\]

where \( A_r = 4\pi r^2 \) and \( N_{A,r} = N_A \), a constant,

\[
N_A \left(1 - \frac{C_A}{C}\right) = -D_{AB} \cdot 4\pi r^2 \cdot \frac{dC_A}{dr}.
\]

From perfect gas behavior, \( C_A = p_A / \gamma T \) and \( C = p / \gamma T \),

\[
N_A \left(p - p_A\right) = -D_{AB} \cdot 4\pi r^2 \cdot \frac{p}{\gamma T} \frac{dp_A}{dr}
\]

Separating variables, setting definite limits, and integrating

\[
-N_A \frac{\gamma T}{p} \frac{1}{4\pi D_{AB}} \int_{r_0}^{r} dr \frac{dp_A}{p-p_A} = \int_{p_{A,r_0}}^{p_{A,r}} \frac{dp_A}{p-p_A}
\]

find that

\[
N_A = \frac{4\pi r_0 D_{AB}}{\gamma T} \frac{1}{1-r_0/r} \ln \frac{p-p_A(r)}{p-p_{A,o}}
\]

where \( p_{A,o} = p_A(r_0) = p_{A,\text{sat}} \), the saturation pressure of liquid A at temperature T.

COMMENTS: Compare the method of solution and result with the content of Section 14.4.4, Evaporation in a Column.
PROBLEM 14.30

KNOWN: Vent pipe on a methanol distillation system condenser discharges to atmosphere at 1 bar. Cooler and vent at 21°C. Vapor volume of cooler is 0.005 m³.

FIND: (a) Weekly loss of methanol vapor due to diffusion out the vent pipe and (b) Weekly loss due to expulsion of methanol vapor in the cooler once per hour caused by process heat rate change.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional species transport, (3) Uniform temperature and total pressure in vent pipe, (4) Constant properties, (5) Perfect gas behavior.

PROPERTIES: Methanol-air mixture (given, 273 K): $D_{AB} = 0.13 \times 10^{-4} \text{ m}^2/\text{s}$.

ANALYSIS: (a) The methanol transfer rate through the vent follows from Eq. 14.77:

$$N_{A,X} = N_{A,X}^* \cdot A_C = \frac{\pi D^2}{4} \frac{C D_{AB}}{L} \ln \frac{1 - p_{A,2}/p}{1 - p_{A,1}/p}$$

where $p_{A,2} = 0$ and $p_{A,1} = p_A = 100 \text{ mmHg} = 0.1333 \text{ bar} = 13.3 \text{ kPa},$

$$C = \frac{p}{\gamma T} = \frac{1 \text{ bar}}{8.314 \times 10^{-2} \text{ m}^3/\text{kmol} \cdot \text{K}(21 + 273) \text{ K}} = 4.093 \times 10^{-2} \text{ kmol/m}^3$$

$$D_{AB} (294 \text{ K}) = D_{AB} (273) (294/273)^{3/2} = 0.13 \times 10^{-4} \text{ m}^2/\text{s} (294/273)^{3/2} = 0.145 \times 10^{-4} \text{ m}^2/\text{s}.$$ 

Substituting numerical values, find the rate on a weekly basis as

$$N_A = \frac{\pi (0.035 \text{ m})^2}{4} \times 4.093 \times 10^{-2} \text{ kmol/m}^3 \times \frac{0.145 \times 10^{-4} \text{ m}^2/\text{s}}{0.5 \text{ m}} \ln \frac{1 - 1}{1 - 0.1333/1} \times 3600 \text{ s/h} \times 24 \text{ h/day} \times 7 \text{ day/week} = 9.883 \times 10^{-5} \text{ kmol/week}$$

$$m_A = N_A M_A = 9.883 \times 10^{-5} \text{ kmol/week} \times 32 \text{ kg/kmol} = 0.00316 \text{ kg/week}. \quad \checkmark$$

(b) The methanol vapor in the cooler of volume 0.005 m³ is expelled once per hour, so that the additional mass loss is $m_A = n_A M_A$, where $n_A$ is

$$n_A = \frac{p_A V}{\gamma RT} = \frac{0.1333 \text{ bar} \times 0.005 \text{ m}^3}{8.314 \times 10^{-2} \text{ m}^3/\text{kmol} \cdot \text{bar} \cdot \text{K} \times 294 \text{ K}} = 2.728 \times 10^{-5} \text{ kmol}$$

from which it follows that

$$m_A = 2.728 \times 10^{-5} \text{ kmol/week} \times 24 \times 7 \times 32 \text{ kg/kmol} = 0.1467 \text{ kg/week}. \quad \checkmark$$

COMMENTS: Note that the loss through the vent is approximately 2% that lost by expulsion when the process heat rate is varied.
PROBLEM 14.31

KNOWN: Clean surface with pure steam has condensate rate of 0.020 kg/m$^2$⋅s for the prescribed conditions. With the presence of stagnant air in the steam, the condensate surface drops from 28°C to 24°C and the condensate rate is halved.

FIND: Partial pressure of air in the air-steam mixture as a function of distance from the condensate film.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties including pressure in air-steam mixture, (3) Perfect gas behavior.

PROPERTIES: Table A-6, Water vapor: $p_{\text{sat}}$ (28°C = 301 K) = 0.03767 bar; $p_{\text{sat}}$ (24°C = 297 K) = 0.02983 bar; Table A-8, Water-air (298 K, 1 bar): $D_{AB} = 0.26 \times 10^{-4}$ m$^2$/s.

ANALYSIS: The partial pressure distribution of the air as a function of distance $y$ can be found from the species (A) rate expression, Eq. 14.77,

$$N_A, y = (CD_{AB} / y) \ln \left(1 - x_{A,y}\right)/\left(1 - x_{A,0}\right).$$

With $C = p/R{T}$, $x_{B,y} = 1 - x_{A,y}$ and $x_{B,0} = 1 - x_{A,0}$, recognizing that $x_B = p_B/p$, find

$$p_B(y) = p_{B,0} \exp \left(\frac{N_A, y}{pD_{AB}} \frac{RT}{y}\right)$$

$$p_{B,0} = p - p_{A,0} = p_{\text{sat}} (28°C) - p_{\text{sat}} (24°C) = (0.03767 - 0.02983) \text{bar} = 0.00784 \text{ bar}.$$

With $N_A, y = -(0.020/2) \text{ kg/m}^2\cdot\text{s}/28 \text{ kg/kgmol} = 3.57 \times 10^{-4} \text{ kmol/m}^2\cdot\text{s},

$$p_B(y) = 0.0784 \text{ bar} \times \exp \left(3.57 \times 10^{-4} \text{ kmol/m}^2\cdot\text{s} \times \frac{8.314 \times 10^{-2} \text{ m}^3\cdot\text{bar/kmol}\cdot\text{K} \times 299 \text{ K}}{0.03767 \text{ bar} \times 6.902 \times 10^{-4} \text{ m}^2/\text{s}}\right)$$

$$p_B(y) = 784 \text{ kPa} \times \exp (-0.3415y)$$

with $p_B$ in [kPa] and $y$ in [mm], where $T = 26°C = 299 \text{ K}$, the average temperature of the air-steam mixture, and $D_{AB} \approx p^{-1} T^{3/2} = 0.26 \times 10^{-4} \text{ m}^2/\text{s} (1/0.03767) (299/298)^{3/2} = 6.902 \times 10^{-4} \text{ m}^2/\text{s}$. Selected values for the pressure are shown below and the distribution is shown above:

<table>

COMMENTS: To minimize inert gas effects, the usual practice is to pass vapor over the surfaces so that the inert gases are eventually collected near the outlet region of the condenser. Our estimate shows that the effective region to be swept is approximately 10 mm thick.
PROBLEM 14.32

KNOWN: Column containing liquid phase of water (A) evaporates into the air (B) flowing over the mouth of the column.

FIND: Evaporation rate of water (kg/h.m²) using the known value of the binary diffusion coefficient for the water vapor - air mixture.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, one-dimensional diffusion in the column, (2) Constant properties, (3) Uniform temperature and pressure throughout the column, (4) Water vapor exhibits ideal gas behavior, and (5) Negligible water vapor in the chamber air.

PROPERTIES: Table A-6, water (T = 320 K): \( p_{\text{sat}} = 0.1053 \text{ bar} \); Table A-8, water vapor-air (0.25 atm, 320 K): Since \( D_{AB} \sim p^{-1} T^{3/2} \), find

\[ D_{AB} = \frac{0.26 \times 10^{-4}}{(0.1053 / 0.25)} \left( \frac{320}{298} \right)^{3/2} = 1.157 \times 10^{-4} \text{ m}^2 / \text{s} \]

ANALYSIS: Equimolar counter diffusion occurs in the vertical column as water vapor, evaporating at the liquid-vapor interface (\( x = 0 \)), diffuses up the column through air out into the chamber. From Eq. 14.7, the molar flow rate per unit area is

\[ N_{A,x}'' = \frac{C D_{AB} L}{L} \ln \frac{1 - x_{A,L}}{1 - x_{A,0}} \]

where \( C \) is the mixture concentration determined from the ideal gas law as

\[ C = \frac{p}{R_T} = \frac{0.25 \text{ atm}}{8.205 \times 10^{-2} \text{ m}^3 \cdot \text{atm/kmol} \cdot \text{K} \times 320 \text{ K}} = 0.009397 \text{ kmol/m}^3 \]

where \( R_T = 8.205 \times 10^{-2} \text{ m}^3 \cdot \text{atm/kmol} \cdot \text{K} \). The mole fractions at \( x = 0 \) and \( x = L \) are

\[ x_{A,L} = 0 \quad \text{(no water vapor in air above column)} \]

\[ x_{A,0} = \frac{p_A}{p} = 0.1053 / 0.25 = 0.4212 \]

where \( p_A \) is the saturation pressure for water at \( T = 320 \text{ K} \). Substituting numerical values

\[ N_{A,x}'' = \frac{0.009397 \text{ kmol/m}^3 \times 1.157 \times 10^{-4} \text{ m}^2 / \text{s}}{0.150 \text{ m}} \ln \frac{(1 - 0)}{(1 - 0.4212)} \]

\[ N_{A,x}'' = 3.964 \times 10^{-6} \text{ kmol/m}^2 \cdot \text{s} \]

or, on a mass basis,

\[ m_{A,x}'' = N_{A,x}'' M_A \]

\[ m_{A,x}'' = 3.964 \times 10^{-6} \text{ kmol/m}^2 \cdot \text{s} \times 3600 \text{ s/h} \times 18 \text{ kg/kmol} \]

\[ m_{A,x}'' = 0.257 \text{ kg/m}^2 \cdot \text{h} \]
PROBLEM 14.33

KNOWN: Ground level flux of NO\textsubscript{2} in a stagnant urban atmosphere.

FIND: (a) Vertical distribution of NO\textsubscript{2} molar concentration, (b) Critical ground level flux of NO\textsubscript{2}, \(N_{A,0,\text{crit}}\).

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional diffusion in a stationary medium, (3) Total molar concentration \(C\) is uniform, (4) Perfect gas behavior.

ANALYSIS: (a) For the prescribed conditions the molar concentration of NO\textsubscript{2} is given by Eq. 14.80, subject to the following boundary conditions.

\[
C_{A}(\infty) = 0, \quad \frac{dC_{A}}{dx}\bigg|_{x=0} = -\frac{N_{A,0}}{D_{AB}}.
\]

From the first condition, \(C_{1} = 0\). From the second condition, \(-mC_{2} = -\frac{N_{A,0}}{D_{AB}}\).

Hence

\[
C_{A}(x) = \frac{N_{A,0}}{mD_{AB}} e^{-mx}
\]

where \(m = (k_{1}/D_{AB})^{1/2}\).

(b) At ground level, \(C_{A}(0) = \frac{N_{A,0}}{mD_{AB}}\). Hence, from the perfect gas law,

\[
P_{A}(0) = C_{A}(0)RT = \frac{3RTN_{A,0}}{mD_{AB}}.
\]

Hence, with \(m = (0.03/0.15 \times 10^{-4})^{1/2} \text{ m}^{-1} = 44.7 \text{ m}^{-1}\).

\[
N_{A,0,\text{crit}} = \frac{mD_{AB}P_{A}(0)_{\text{crit}}}{RT} = \frac{44.7 \text{ m}^{-1} \times 0.15 \times 10^{-4} \text{ m}^{2}/\text{s} \times 2 \times 10^{-6} \text{ bar}}{8.314 \times 10^{-2} \text{ m}^{3} \cdot \text{bar/kmol} \cdot \text{K} \times 300 \text{ K}}
\]

\[
N_{A,0,\text{crit}} = 5.38 \times 10^{-11} \text{ kmol/s} \cdot \text{m}^{2}
\]

COMMENTS: Because the dispersion of pollutants in the atmosphere is governed strongly by convection effects, the above model should be viewed as a first approximation which describes a worst case condition.
PROBLEM 14.34

KNOWN: Radius of a spherical organism and molar concentration of oxygen at surface. Diffusion and reaction rate coefficients.

FIND: (a) Radial distribution of O₂ concentration, (b) Rate of O₂ consumption, (c) Molar concentration at r = 0.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state, one-dimensional diffusion, (2) Stationary medium, (3) Uniform total molar concentration, (4) Constant properties (k₀, D_AB).

ANALYSIS: (a) For the prescribed conditions and assumptions, Eq. (14.40) reduces to

\[
\frac{D_{AB}}{r^2} \frac{d}{dr} \left( r^2 \frac{dC_A}{dr} \right) - k_0 = 0
\]

\[
r^2 \frac{dC_A}{dr} = \frac{k_0 r^3}{3D_{AB}} + C_1
\]

\[
C_A = \frac{k_0 r^2}{6D_{AB}} - \frac{C_1}{r} + C_2
\]

With the requirement that C_A(r) remain finite at r = 0, C₁ = 0. With C_A(r₀) = C_A,₀

\[
C_2 = C_A,₀ - \frac{k_0 r_0^2}{6D_{AB}}
\]

\[
C_A = C_A,₀ - \left( \frac{k_0}{6D_{AB}} \right) \left( r_0^2 - r^2 \right)
\]

Because C_A cannot be less than zero at any location within the organism, the right-hand side of the foregoing equation must always exceed zero, thereby placing limits on the value of C_A,₀. The smallest possible value of C_A,₀ is determined from the requirement that C_A(0) ≥ 0, in which case

\[
C_A,₀ ≥ \left( \frac{k_0 r_0^2}{6D_{AB}} \right)
\]

(b) Since oxygen consumption occurs at a uniform volumetric rate of k₀, the total respiration rate is \( \dot{R} = \forall k_0 \), or

\[
\dot{R} = (4/3)\pi r_0^3 k_0
\]

Continued ….
PROBLEM 14.34 (Cont.)

(c) With \( r = 0 \),

\[
C_A(0) = C_{A,o} - k_0 r_0^2 / 6D_{AB}
\]

\[
C_A(0) = 5 \times 10^{-5} \, \text{kmol/m}^3 - 1.2 \times 10^{-4} \, \text{kmol/s} \cdot \text{m}^3 \left(10^{-4} \, \text{m}\right)^2 / 6 \times 10^{-8} \, \text{m}^2 / \text{s}
\]

\[
C_A(0) = 3 \times 10^{-5} \, \text{kmol/m}^3
\]

**COMMENTS:**

1. The minimum value of \( C_{A,o} \) for which a physically realistic solution is possible is

\[
C_{A,o} = k_0 r_0^2 / 6D_{AB} = 2 \times 10^{-5} \, \text{kmol/m}^3.
\]

2. The total respiration rate may also be obtained by applying Fick’s law at \( r = r_o \), in which case

\[
\dot{R} = -N_A (r_o) = +D_{AB} \left( 4\pi r_o^2 \right) \frac{dC_A}{dr} \bigg|_{r=r_o} = D_{AB} \left( 4\pi r_o^2 \right) \left( k_o / 6D_{AB} \right) 2r_o = \left( 4/3 \right) \pi r_o^3 k_0.
\]

The result agrees with that of part (b).
PROBLEM 14.35

KNOWN: Radius of a spherical organism and molar concentration of oxygen at its surface. Diffusion and reaction rate coefficients.

FIND: (a) Radial distribution of O₂ concentration, (b) Expression for rate of O₂ consumption, (c) Molar concentration at r = 0 and rate of oxygen consumption for prescribed conditions.

SCHEMATIC:

**ASSUMPTIONS:** (1) Steady-state, one-dimensional diffusion, (2) Stationary medium, (3) Uniform total molar concentration, (4) Constant properties (k₁, D_AB).

**ANALYSIS:** (a) For the prescribed conditions and assumptions, Eq. (14.40) reduces to

\[ \frac{1}{r^2} \frac{d}{dr} \left( D_{AB} r^2 \frac{dC_A}{dr} \right) - k_1 C_A = 0 \]

With \( y \equiv r C_A \), \( \frac{dC_A}{dr} = (1/r) \frac{dy}{dr} - y/r^2 \) and

\[ \frac{1}{r^2} \frac{d}{dr} \left( D_{AB} r^2 \frac{dC_A}{dr} \right) = \frac{D_{AB}}{r^2} \frac{d}{dr} \left( r \frac{dy}{dr} - y \right) = \frac{D_{AB}}{r^2} \left( r \frac{d^2y}{dr^2} \right) \]

The species equation is then

\[ \frac{d^2y}{dr^2} - \frac{k_1}{D_{AB}} y = 0 \]

The general solution is of the form

\[ y = C_1 \sinh \left( \frac{k_1}{D_{AB}} \right)^{1/2} r + C_2 \cosh \left( \frac{k_1}{D_{AB}} \right)^{1/2} r \]

or

\[ C_A = \frac{C_1}{r} \sinh \left( \frac{k_1}{D_{AB}} \right)^{1/2} r + \frac{C_2}{r} \cosh \left( \frac{k_1}{D_{AB}} \right)^{1/2} r \]

Because \( C_A \) must remain finite at \( r = 0 \), \( C_2 = 0 \). Hence, with \( C_A (r_0) = C_{A,0} \),

\[ C_1 = \frac{C_{A,0} r_0}{\sinh \left( \frac{k_1}{D_{AB}} \right)^{1/2} r_0} \]

and

Continued .....
PROBLEM 14.35 (Cont.)

\[ C_A = C_{A,0} \left( \frac{r_0}{r} \right) \frac{\sinh \left( \frac{k_1}{D_{AB}} \right)^{1/2} r}{\sinh \left( \frac{k_1}{D_{AB}} \right)^{1/2} r_0} \]

(b) The total O\textsubscript{2} consumption rate corresponds to the rate of diffusion at the surface of the organism.

\[ \dot{R} = -N_A (r_0) = +D_{AB} \left( 4\pi r_0^2 \right) \frac{dC_A}{dr} \bigg|_{r_0} \]

\[ \dot{R} = 4\pi r_0^2 D_{AB} C_{A,0} r_0 \left[ -\frac{1}{r_0^2} + \frac{1}{r_0^2} \left( \frac{k_1}{D_{AB}} \right)^{1/2} \cot \left( \frac{k_1}{D_{AB}} \right)^{1/2} \right] \]

\[ \dot{R} = 4\pi r_0^2 D_{AB} C_{A,0} (\alpha \coth \alpha - 1) \]

where \( \alpha \equiv \left( \frac{k_1^2}{D_{AB}} \right)^{1/2} \).

(c) For the prescribed conditions, \( \left( \frac{k_1}{D_{AB}} \right)^{1/2} = (20 \text{ s}^{-1} \div 10^{-8} \text{ m}^2/\text{s})^{1/2} \) = 44,720 m\textsuperscript{-1} and \( \alpha = 4.472 \).

\[ C_A = \frac{5 \times 10^{-5} \text{ kmol/m}^3 \times 10^{-4} \text{ m}}{\sinh (4.472)} \times \frac{\sinh \left( \frac{k_1}{D_{AB}} \right)^{1/2} r}{r} = 1.136 \times 10^{-10} \text{ kmol/m}^3 \times \frac{\sinh \left( \frac{k_1}{D_{AB}} \right)^{1/2} r}{r} \]

In the limit of \( r \to 0 \), the foregoing expression yields

\[ C_A (r \to 0) = 5.11 \times 10^{-6} \text{ kmol/m}^3 \]

\[ \dot{R} = 4\pi \times 10^{-4} \text{ m} \times 10^{-8} \text{ m}^2/\text{s} \times 5 \times 10^{-5} \text{ kmol/m}^3 (4.472 \coth 4.472 - 1) = 2.18 \times 10^{-15} \text{ kmol/s} \]

COMMENTS: The total respiration rate may also be obtained by integrating the volumetric rate of consumption over the volume of the organism. That is, \( \dot{R} = -\int N_A d\mathcal{V} = \int_0^{r_0} k_1 C_A (r) 4\pi r^2 dr \).
PROBLEM 14.36

KNOWN: Radius and catalytic reaction rate of a porous spherical pellet. Surface mole fraction of reactant and effective diffusion coefficient.

FIND: (a) Radial distribution of reactant concentration in pellet, total reactant consumption rate, and pellet effectiveness, (b) CO consumption rate and effectiveness for prescribed conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional radial diffusion, (3) Constant properties, (4) Homogeneous chemical reactions, (5) Isothermal, constant pressure conditions within pellet, (6) Stationary medium.

ANALYSIS: (a) In spherical coordinates, the mass diffusion equation is given by

\[
\frac{1}{r^2} \frac{\partial}{\partial r} \left( r^2 D_{AB} \frac{\partial x_A}{\partial r} \right) + \dot{N}_A = 0
\]

where \( C, D_{AB} \) are constant and \( \dot{N}_A = -k^\prime I A_v C_A \). Hence

\[
\frac{1}{r^2} \frac{d}{dr} \left( r^2 \frac{dx_A}{dr} \right) - \frac{k^\prime I A_v C_A}{D_{eff}} x_A = 0.
\]

The boundary conditions are \( x_A(r_o) = x_{A,s} \) and \( x_A(0) \) is finite. Transform the dependent variable, \( y \equiv r x_A \), with

\[
\frac{d x_A}{dr} = \frac{1}{r} \frac{d y}{dr} - \frac{y}{r^2}
\]

or

\[
\frac{1}{r^2} \frac{d}{dr} \left( r^2 \frac{dx_A}{dr} \right) = \frac{1}{r^2} \frac{d}{dr} \left( r \frac{dy}{dr} \right) = \frac{1}{r^2} \frac{d^2 y}{dr^2}.
\]

Hence

\[
\frac{d^2 y}{dr^2} - \frac{k^\prime I A_v C_A}{D_{eff}} y = 0.
\]

The general solution is of the form

\[ y = C_1 \sinh \left( ar \right) + C_2 \cosh \left( ar \right) \]

where \( a = \left( k^\prime I A_v C_A / D_{eff} \right)^{1/2} \) giving

\[ x_A = \frac{C_1}{r} \sinh \left( ar \right) + \frac{C_2}{r} \cosh \left( ar \right) \]

and using the boundary conditions,

\[ x_A(0) \text{ finite} \rightarrow C_2 = 0 \quad x_A \left( r_o \right) = x_{A,s} \rightarrow C_1 = x_{A,s} / \sinh \left( ar_o \right). \]

Continued …..
PROBLEM 14.36 (Cont.)

Hence

\[
x_A(r) = x_{A,s}(r_o/r) \frac{\sinh(\frac{ar}{r_o})}{\sinh(\frac{ar}{r_o})}.
\]

Applying conservation of species to a control volume about the pellet, \( \dot{N}_{A,in} + \dot{N}_{A,g} = 0 \), the total rate of consumption of A in the pellet is

\[
-\dot{N}_{A,g} = \dot{N}_{A,in} = N_{A,r}(r_o) = 4\pi r_o^2 j_A^*(r_o).
\]

Hence

\[
N_{A,r}(r_o) = \left(4\pi r_o^2\right) \left(-CD_{eff} \frac{dx_A}{dr}\right)_{r=r_o} = \frac{4\pi r_o^3}{\sinh(\frac{ar}{r_o})} CD_{eff} x_{A,s} \left[\frac{\sinh(\frac{ar}{r_o})}{r^2} - \frac{\cosh(\frac{ar}{r_o})}{r^2}\right]_{r=r_o}
\]

\[
N_{A,r}(r_o) = 4\pi r_o CD_{eff} x_{A,s} \left[1 - \frac{ar}{\tanh(ar)}\right].
\]

The pellet effectiveness \( \varepsilon \) is defined as \( \varepsilon = \frac{N_{A,r}(r_o)}{[N_{A,r}(r_o)]_{max}} \) and the maximum consumption occurs if \( x_A(r) = x_{A,s} \) for all \( 0 \leq r \leq r_o \). Hence

\[
\left[N_{A,r}(r_o)\right]_{max} = N_A V_p = -k^*_A v_C x_{A,s} \frac{4}{3} \pi r_o^3
\]

\[
\varepsilon = -\frac{3}{2} \left[1 - \frac{ar}{\tanh(ar)}\right].
\]

(b) To evaluate the rate, first determine values for these parameters:

\[
C = \frac{p}{RT} = \frac{1.2 \text{ atm}}{0.08205 \text{ m}^3/\text{atm/kmol} \times 823 \text{ K}} = 0.0178 \text{ kmol/m}^3
\]

\[
a = \left(\frac{k^*_A v}{D_{eff}}\right)^{1/2} = \left(\frac{10^{-3} \text{ m/s} \times 10^8 \text{ m}^2/\text{m}^3}{2 \times 10^{-5} \text{ m}^2/\text{s}}\right)^{1/2} = 7.07 \times 10^4 \text{ m}^{-1}
\]

\[
ar_o = 176.8 \quad \tanh(ar_o) = 1.
\]

Hence the consumption rate is

\[
N_{A,r}(r_o) = 4\pi (0.0025 \text{ m}) 0.0178 \text{ kmol/m}^3 \times 2 \times 10^{-5} \text{ m}^2/\text{s} \times 0.04 (1 - 176.8)
\]

\[
N_{A,r}(r_o) = -7.86 \times 10^{-8} \text{ kmol/s}
\]

and the effectiveness is

\[
\varepsilon = -\frac{3}{\left(7.07 \times 10^4 \text{ m}^{-1}\right)^2 (0.0025 \text{ m})^2} [1 - 176.8] = 0.0169
\]

COMMENTS: For the range of conditions of interest, \( \varepsilon \approx 3/ar_o \). Hence \( \varepsilon \) may be increased by \( \downarrow r_o \), \( \downarrow k^*_A \), \( \downarrow A_v \) and \( \uparrow D_{eff} \). However, \( N_{A,r}(r_o) \) would decrease with \( \downarrow r_o \), \( \downarrow k^*_A \) and \( \downarrow A_v \).
PROBLEM 14.37

KNOWN: Molar concentrations of oxygen at inner and outer surfaces of lung tissue. Volumetric rate of oxygen consumption within the tissue.

FIND: (a) Variation of oxygen molar concentration with position in the tissue, (b) Rate of oxygen transfer to the blood per unit tissue surface area.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional species transfer by diffusion through a plane wall, (3) Homogeneous, stationary medium with uniform total molar concentration and constant diffusion coefficient.

ANALYSIS: (a) From Eq. 14.78 the appropriate form of the species diffusion equation is

\[ D_{AB} \frac{d^2 C_A}{dx^2} - k_o = 0. \]

Integrating,

\[ \frac{dC_A}{dx} = \left( \frac{k_o}{D_{AB}} \right) x + C_1 \]

\[ C_A = \frac{k_o}{2D_{AB}} x^2 + C_1 x + C_2. \]

With \( C_A = C_A(0) \) at \( x = 0 \) and \( C_A = C_A(L) \) at \( x = L \),

\[ C_2 = C_A(0) \]

\[ C_1 = \frac{C_A(L) - C_A(0)}{L} - \frac{k_o L}{2D_{AB}}. \]

Hence

\[ C_A(x) = \frac{k_o}{2D_{AB}} x(x - L) + \left[ C_A(L) - C_A(0) \right] \frac{x}{L} + C_A(0). \]

(b) The oxygen assimilation rate per unit area is

\[ N^*_{A,x}(L) = -D_{AB} \left( \frac{dC_A}{dx} \right)_{x=L} \]

\[ N^*_{A,x}(L) = -D_{AB} \left( \frac{k_o L}{D_{AB}} - \frac{k_o L}{2D_{AB}} \right) - D_{AB} \left( \frac{C_A(L) - C_A(0)}{L} \right) \]

\[ N^*_{A,x} = -\frac{k_o L}{2} + \frac{D_{AB}}{L} \left[ C_A(0) - C_A(L) \right]. \]

COMMENTS: The above model provides a highly approximate and simplified treatment of a complicated problem. The lung tissue is actually heterogeneous and conditions are transient.
**PROBLEM 14.38**

**KNOWN:** Combustion at constant temperature and pressure of a hydrogen-oxygen mixture adjacent to a metal wall according to the reaction $2\text{H}_2 + \text{O}_2 \rightarrow 2\text{H}_2\text{O}$. Molar concentrations of hydrogen, oxygen, and water vapor are 0.10, 0.10 and 0.20 kmol/m$^3$, respectively. Generation rate of water vapor is $0.96 \times 10^{-2}$ kmol/m$^3 \cdot$ s.

**FIND:** (a) Expression for $C_{\text{H}_2}$ as function of distance from wall, plot qualitatively, (b) $C_{\text{H}_2}$ at the wall, (c) Sketch also curves for $C_{\text{O}_2}(x)$ and $C_{\text{H}_2\text{O}}(x)$, and (d) Molar flux of water at $x = 10$ mm.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) Steady-state conditions, (2) One-dimensional diffusion, (3) Stationary mixture, (4) Constant properties including pressure and temperature.

**PROPERTIES:** Species binary diffusion coefficient (given, for H$_2$, O$_2$ and H$_2$O): $D_{AB} = 0.6 \times 10^{-5}$ m$^2$/s.

**ANALYSIS:** (a) The species conservation equation, Eq. 14.38b, and its general solution are

$$\frac{d^2C_A}{dx^2} + \frac{\dot{N}_A}{D_{AB}} = 0 \quad C_A(x) = -\frac{\dot{N}_A}{2D_{AB}} x + C_1x + C_2. \quad (1,2)$$

The boundary condition at the wall must be $dC_A(0)/dx = 0$, such that $C_1 = 0$. For the species hydrogen, evaluate $C_2$ from knowledge of $C_{\text{H}_2}(10 \text{ mm}) = 0.10 \text{ kmol/m}^3$ and $\dot{N}_{\text{H}_2} = -\dot{N}_{\text{H}_2\text{O}}$, according to the chemical reaction. Hence,

$$0.10 \text{ kmol/m}^3 = \frac{-0.96 \times 10^{-2} \text{ kmol/m}^3 \cdot \text{s}}{2 \times 0.6 \times 10^{-5} \text{ m}^2 \cdot \text{s}} (0.010 \text{ m})^2 + 0 + C_2$$

$$C_2 = 0.02 \text{ kmol/m}^3.$$

Hence, the hydrogen species concentration distribution is

$$C_{\text{H}_2}(x) = -\frac{\dot{N}_{\text{H}_2}}{2D_{AB}} x^2 + 0.02 = 800x^2 + 0.02$$

which is parabolic with zero slope at the wall; see sketch above.

(b) The value of $C_{\text{H}_2}$ at the wall is,

$$C_{\text{H}_2}(0) = (0 + 0.02) \text{ kmol/m}^3 = 0.02 \text{ kmol/m}^3.$$

Continued …..
PROBLEM 14.38 (Cont.)

(c) The concentration distribution for water vapor species will be of the same form,

\[ \text{CH}_2\text{O} (x) = - \frac{\dot{\text{N}}_{\text{H}_2\text{O}}}{2D_{\text{AB}}} x^2 + C_1x + C_2 \]

(3)

With \( C_1 = 0 \) for the wall condition, find \( C_2 \) from \( \text{CH}_2\text{O} (10 \text{ mm}) \),

\[ 0.20 \text{ kmol/m}^3 = - \left( \frac{0.96 \times 10^{-2} \text{ kmol/m}^3}{2 \times 0.6 \times 10^{-5} \text{ m}^2 / \text{s}} \right) (0.010 \text{ m})^2 + C_2 \quad C_2 = 0.28 \text{ kmol/m}^3. \]

Hence, \( \text{CH}_2\text{O} \) at the wall is,

\[ \text{CH}_2\text{O} (0) = 0 + 0 + C_2 = 0.28 \text{ kmol/m}^3 \]

and its distribution appears as above. Recognizing that \( \dot{\text{N}}_{\text{O}_2} = -0.5 \dot{\text{N}}_{\text{H}_2\text{O}} \), by the same analysis, find \( \text{CO}_2 (0) = 0.06 \text{ kmol/m}^3 \)

and its shape, also parabolic with zero slope at the wall is shown above.

(d) The molar flux of water vapor at \( x = 10 \text{ mm} \) is given by Fick’s law

\[ \dot{\text{N}}_{\text{H}_2\text{O},x} = -D_{\text{AB}} \frac{d\text{CH}_2\text{O}}{dx} \]

and using the concentration distribution of Eq. (3), find

\[ \dot{\text{N}}_{\text{H}_2\text{O},x} = -D_{\text{AB}} \frac{d}{dx} \left( - \frac{\dot{\text{N}}_{\text{H}_2\text{O}}}{2D_{\text{AB}}} x^2 \right) = +\dot{\text{N}}_{\text{H}_2\text{O},x} \]

and evaluation at the location \( x = 10 \text{ mm} \), the species flux is

\[ \dot{\text{N}}_{\text{H}_2\text{O},x} (10 \text{ mm}) = + \left( 0.96 \times 10^{-2} \text{ kmol/m}^3 \cdot \text{s} \right) \times 0.010 \text{ m} = 9.60 \times 10^{-5} \text{ kmol/m}^2 \cdot \text{s}. \]

COMMENTS: Note that the generation rate of water vapor is a positive quantity. Whereas for \( \text{H}_2 \) and \( \text{O}_2 \), species are consumed and hence \( \dot{\text{N}}_{\text{H}_2} \) and \( \dot{\text{N}}_{\text{O}_2} \) are negative. According to the chemical reaction one mole of \( \text{H}_2 \) and 0.5 mole of \( \text{O}_2 \) are consumed to generate one mole of \( \text{H}_2\text{O} \). Therefore, \( \dot{\text{N}}_{\text{H}_2} = -\dot{\text{N}}_{\text{H}_2\text{O}} \) and \( \dot{\text{N}}_{\text{O}_2} = -0.5 \dot{\text{N}}_{\text{H}_2\text{O}} \).
PROBLEM 14.39

KNOWN: Ground level flux of NO\textsubscript{2} in a stagnant urban atmosphere.

FIND: (a) Governing differential equation and boundary conditions for the molar concentration of NO\textsubscript{2}, (b) Concentration of NO\textsubscript{2} at ground level three hours after the beginning of emissions.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional diffusion in a stationary medium, (2) Uniform total molar concentration, (3) Constant properties.

ANALYSIS: (a) Applying the species conservation requirement, Eq. 14.33, on a molar basis to a unit area of the control volume,

\[ N_{A,x}'' - (k_{\text{i}} C_{A}) dx - N_{A,x+dx}'' = \frac{\partial C_{A}}{\partial t} \times \frac{dx}{\partial t} \]

With \( N_{A,x+dx}'' = N_{A,x}'' + (\partial N_{A,x}'' / \partial x) dx \) and \( N_{A,x}'' = -D_{AB} (\partial C_{A} / \partial x) \), it follows that

\[ D_{AB} \frac{\partial^2 C_{A}}{\partial x^2} - k_{\text{i}} C_{A} = \frac{\partial C_{A}}{\partial t} \]

Initial Condition: \( C_{A} (x,0) = 0 \).

Boundary Conditions: \( -D_{AB} \frac{\partial C_{A}}{\partial x} |_{x=0} = N_{A,0}'' \), \( C_{A} (\infty, t) = 0 \).

(b) The present problem is analogous to Case (2) of Fig. 5.7 for heat conduction in a semi-infinite medium. Hence by analogy to Eq. 5.59, with \( k \leftrightarrow D_{AB} \) and \( \alpha \leftrightarrow D_{AB} \),

\[ C_{A} (x,t) = 2N_{A,0}'' \left( \frac{t}{\pi D_{AB}} \right)^{1/2} \exp \left( -\frac{x^2}{4D_{AB}t} \right) - \frac{N_{A,0}''}{D_{AB}} \text{erfc} \left( \frac{x}{2(D_{AB} t)^{1/2}} \right) \]

At ground level \( (x = 0) \) and 3h,

\[ C_{A} (0,3h) = 2N_{A,0}'' \left( \frac{t}{\pi D_{AB}} \right)^{1/2} \]

\[ C_{A} (0,3h) = 2 \left( 3 \times 10^{-11} \text{ kmol/s} \cdot \text{m}^2 \right) \left( 10,800 \text{s/} \pi \times 0.15 \times 10^{-4} \text{ m}^2 / \text{s} \right)^{1/2} = 9.08 \times 10^{-7} \text{ kmol/m}^3. \]

COMMENTS: The concentration decays rapidly to zero with increasing \( x \), and at \( x = 100 \text{ m} \) it is, for all practical purposes, equal to zero.
PROBLEM 14.40

KNOWN: Carbon dioxide concentration at water surface and reaction rate constant.

FIND: (a) Differential equation which governs variation with position and time of CO\textsubscript{2} concentration in water, (b) Appropriate boundary conditions and solution for a deep body of water with negligible chemical reactions.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional diffusion in x, (2) Constant properties, including total density \( \rho \), (3) Water is stagnant.

ANALYSIS: (a) From Eq. 14.37b, it follows that, for the prescribed conditions,

\[
D_{AB} \frac{\partial^2 \rho_A}{\partial x^2} - k_1 \rho_A = \frac{\partial \rho_A}{\partial t}.
\]

The first term on the left-hand side represents the net transport of CO\textsubscript{2} into a differential control volume by diffusion. The second term represents the rate of CO\textsubscript{2} consumption due to chemical reactions. The term on the right-hand side represents the rate of increase of CO\textsubscript{2} storage within the control volume.

(b) For a deep body of water, appropriate boundary conditions are

\[
\rho_A(0,t) = \rho_A,0
\]

\[
\rho_A(\infty,t) = 0
\]

and, with negligible chemical reactions, the species diffusion equation reduces to

\[
\frac{\partial^2 \rho_A}{\partial x^2} = \frac{1}{D_{AB}} \frac{\partial \rho_A}{\partial t}.
\]

With an initial condition, \( \rho_A(x,0) = \rho_{A,i} = 0 \), the problem is analogous to that involving heat transfer in a semi-infinite medium with constant surface temperature. By analogy to Eq. 5.57, the species concentration is then

\[
\frac{\rho_A(x,t) - \rho_A,0}{-\rho_A,0} = \text{erf}\left(\frac{x}{2(D_{AB}t)^{1/2}}\right)
\]

\[
\rho_A(x,t) = \rho_A,0 \text{erfc}\left(\frac{x}{2(D_{AB}t)^{1/2}}\right).
\]
PROBLEM 14.41

KNOWN: Initial concentration of hydrogen in a sheet of prescribed thickness. Surface concentrations for time \( t > 0 \).

FIND: Time required for density of hydrogen to reach prescribed value at midplane of sheet.

SCHEMATIC:

\[
(A) \rightarrow H_2 \rightarrow \text{Solid} \quad D_{AB} = 9 \times 10^{-7} \text{m}^2/\text{s}
\]

\[
\text{L} = 20 \text{mm}
\]

C\(_A(x,0) = 3 \text{ kmol/m}^3 = C_{A,i}\)

C\(_A(0,t_f) = 1.2 \text{ kg/m}^3 / 2 \text{ kg/kmol}\)

C\(_A(0,t_f) = 0.6 \text{ kmol/m}^3 = C_A\)

C\(_A(20 \text{ mm},t) = 0 = C_{A,s}\)

ASSUMPTIONS: (1) One-dimensional diffusion in \( x \), (2) Constant \( D_{AB} \), (3) No internal chemical reactions, (4) Uniform total molar concentration.

ANALYSIS: Using Heisler chart with heat and mass transfer analogy

\[
\gamma^* = \frac{C_A - C_{A,s}}{C_{A,i} - C_{A,s}} = \frac{0.6 - 0}{3.0 - 0} = 0.2 = \gamma_0^*
\]

With \( B_{im} = \infty \), Fig. D.1 may be used with

\[
\theta_0^* = 0.2, \quad Bi^{-1} = 0 \quad \text{Fo} = 0.75.
\]

Hence

\[
\text{Fo}_m = \frac{D_{AB} t_f}{L^2} = 0.75
\]

\[
t_f = 0.75(0.02 \text{ m})^2 / 9 \times 10^{-7} \text{ m}^2 / \text{s}
\]

\[
t_f = 333 \text{ s}.
\]

COMMENTS: If the one-term approximation to the infinite series solution

\[
\theta^* = \sum_{n=1}^{\infty} C_n \exp\left(-\zeta_n^2 \text{Fo}\right) \cos\left(\zeta_n x^*\right)
\]

is used, it follows that

\[
\gamma_0^* = C_1 \exp\left(-\zeta_1^2 \text{Fo}_m\right) = 0.2
\]

Using values of \( \zeta_1 = 1.56 \) and \( C_1 = 1.27 \), it follows that

\[
\exp\left[-(1.56)^2 \text{Fo}_m\right] = 0.157
\]

\[
\text{Fo}_m = 0.76
\]

which is in excellent agreement with the result from the chart.
**PROBLEM 14.42**

**KNOWN:** Sheet material has high, uniform concentration of hydrogen at the end of a process, and is then subjected to an air stream with a specified, low concentration of hydrogen. Mass transfer parameters specified include: convection mass transfer coefficient, \( h_m \), and the mass diffusivity and solubility of hydrogen (A) in the sheet material (B), \( D_{AB} \) and \( S_{AB} \), respectively.

**FIND:**
(a) The final mass density of hydrogen in the material if the sheet is exposed to the air stream for a very long time, \( \rho_{A,f} \).
(b) Identify and evaluate the parameter that can be used to determine whether the transient mass diffusion process in the sheet can be characterized by a uniform concentration at any time; *Hint:* this situation is analogous to the lumped capacitance method for a transient heat transfer process.
(c) Determine the time required to reduce the hydrogen concentration to twice the limiting value calculated in part (a).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional diffusion, (2) Material B is stationary medium, (3) Constant properties, (4) Uniform temperature in air stream and material, and (5) Ideal gas behavior.

**ANALYSIS:**
(a) The final content of \( \text{H}_2 \) in the material will depend upon the solubility of \( \text{H}_2 \) (A) in the material (B) and its partial pressure in the free stream. From Eq. 14.44,

\[
C_{A,f} = S_{AB} \rho_{A,\infty} = 160 \text{ kmol} / \text{m}^3 \cdot \text{atm} \times 0.1 \text{ atm} = 16 \text{ kmol} / \text{m}^3
\]

\[
\rho_f = M_A C_{A,f} = 2 \text{ kg} / \text{kmol} 	imes 16 \text{ kmol} / \text{m}^3 = 32 \text{ kg} / \text{m}^3
\]

(b) The parameters associated with transient diffusion in the material follow from the analogous treatment of Section 5.2 (Fig. 5.3) and are represented in the schematic.

In the material, from Fick’s law, the diffusive flux is

\[
N_{A,dif} = D_{AB} \left( C_{A,1} - C_{A,2} \right) / L
\]

At the surface, \( x = L \), the rate equation, Eq. 6.8, convective flux of species A is

\[
N_{A,conv} = h_m \left( C_{A,s} - C_{A,\infty} \right)
\]

Continued ….
and substituting the ideal gas law, Eq. 14.9, and introducing the solubility relation, Eq. 14.44,

\[
N'_{A,\text{conv}} = \frac{h_m}{S_{AB} \ R_u \ T_\infty} \left( S_{AB} \ P_{A,s} - S_{AB} \ P_{A,\infty} \right)
\]

\[
N''_{A,\text{conv}} = \frac{h_m}{S_{AB} \ R_u \ T_\infty} \left( C_{2,s} - C_{A,\infty} \right)
\]

(2)

where \( C_{A,\infty} = C_{A,f} \), the final concentration in the material after exposure to the air stream a long time.

Considering a surface species flux balance, as shown in the schematic above, with the rate equations (1) and (2),

\[
\frac{D_{AB} \ (C_{A,1} - C_{A,2})}{L} = \frac{h_m}{S_{AB} \ R_u \ T_\infty} \left( C_{A,s} - C_{A,f} \right)
\]

\[
\frac{C_{A,1} - C_{A,2}}{C_{A,s} - C_{A,f}} = \frac{h_m / S_{AB} \ R_u \ T_\infty}{D_{AB} / L} = \frac{R''_{m,\text{dif}}}{R''_{m,\text{conv}}} = Bi_m
\]

(3)

and introducing resistances to species transfer by diffusion, Eq. 14.51, and convection. Recognize from the analogy to heat transfer, Eq. 5.10 and Table 14.2, that when \( Bi_m < 0.1 \), the concentration can be characterized as uniform during the transient process. That is, the diffusion resistance is negligible compared to the convection resistance,

\[
Bi_m = \frac{h_m L}{S_{AB} \ R_u \ T_\infty \ D_{AB}} < 0.1
\]

(4)

\[
Bi_m = \frac{(15 \ m/h \times 3600 \ s/h) \times 0.003 \ m}{160 \ \text{kmol/m}^3 \cdot \text{atm} \times 8.205 \times 10^{-2} \ \text{m}^3 \cdot \text{atm}/\text{kmol} \cdot \text{K} \times 555 \ \text{K} \times 2.68 \times 10^{-8} \ \text{m}^2 / \text{s}}
\]

\[
Bi_m = 6.60 \times 10^{-3} < 0.1
\]

Hence, the mass transfer process can be treated as a nearly uniform concentration situation. From conservation of species on the material with uniform concentration,

\[
-N''_{A,\text{conv}} = \dot{N}'_{A,\text{st}}
\]

\[
-\frac{h_m}{S_{AB} \ R_u \ T_\infty} \left( C_A - C_{A,f} \right) = L \ \frac{dC_A}{dt}
\]

Integrating, with the initial condition \( C_A(0) = C_{A,i} \), find

\[
\frac{C_A - C_{A,f}}{C_{A,i} - C_{A,f}} = \exp \left( -\frac{h_m \ t}{L \ S_{AB} \ R_u \ T_\infty} \right)
\]

(5) <

Continued ....
which is similar to the analogous heat transfer relation for the lumped capacitance analysis, Eq. 5.6.

\[
\frac{(2-1) \times 16 \text{ kmol/m}^3}{(320-16) \text{ kmol/m}^3} = \exp \left( - \frac{1.5 \text{ m/h} \times t_0}{0.003 \times 160 \text{ kmol/m}^3 \cdot \text{atm} \times 8.205 \times 10^{-2} \text{ m}^3 \cdot \text{atm} / \text{kmol} \cdot \text{K} \times 555 \text{ K}} \right)
\]

\[t_0 = 42.9 \text{ hour}\]
**PROBLEM 14.43**

**KNOWN:** Hydrogen-removal process described in Problem 14.3 (S), but under conditions for which the mass diffusivity of hydrogen gas (A) in the sheet (B) is \( D_{AB} = 1.8 \times 10^{-11} \text{ m}^2/\text{s} \) (instead of \( 2.6 \times 10^{-8} \text{ m}^2/\text{s} \)). With a smaller \( D_{AB} \), a uniform concentration condition may no longer be assumed to exist in the material during the removal process.

**FIND:** (a) The final mass density of hydrogen in the material if the sheet is exposed to the air stream for a very long time, \( \rho_{A,f} \), (b) Identify and evaluate the parameters that describe the transient mass transfer process in the sheet; *Hint:* this situation is analogous to that of transient heat conduction in a plane wall; (c) Assuming a uniform concentration in the sheet at any time during the removal process, determine the time required to reach twice the limiting mass density calculated in part (a); (d) Using the analogy developed in part (b), determine the time required to reduce the hydrogen concentration to twice the limiting value calculated in part (a); Compare the result with that from part (c).

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional diffusion, (2) Material B is a stationary medium, (3) Constant properties, (4) Uniform temperature in air stream and material, and (5) Ideal gas behavior.

**ANALYSIS:** (a) The final content of \( \text{H}_2 \) in the material will depend upon the solubility of \( \text{H}_2 \) (A) in the material (B) at its partial pressure in the free stream. From Eq. 14.44,

\[
C_{A,f} = S_{AB} p_{A,\infty} = 160 \text{ kmol/m}^3 \cdot \text{atm} \times 0.1 \text{ atm} = 16 \text{ kmol/m}^3
\]

\[
\rho_f = M_A C_{A,f} = 2 \text{ kg/kmol} \times 16 \text{ kmol/m}^3 = 32 \text{ kg/m}^3
\]

(b) For the plane wall shown in the schematic below, the heat and mass transfer conservation equations and their initial and boundary conditions are

Heat transfer: \[
\frac{\partial T}{\partial t} = \alpha \frac{\partial^2 T}{\partial x^2}
\]

\( T(x,0) = T_i \)

\( \frac{\partial T}{\partial x}(0,t) = 0 \)

\( -k \frac{\partial T}{\partial x}(L,t) = h[T(L,t) - T_\infty] \)

Mass (Species A) transfer: \[
\frac{\partial C_A}{\partial t} = D_{AB} \frac{\partial^2 C_A}{\partial x^2}
\]

\( C_A(x,0) = C_{A,i} \)

\( \frac{\partial C_A}{\partial x}(0,t) = 0 \)

\( -D_{AB} \frac{\partial C_A}{\partial x}(L,t) = \frac{h_m}{S_{AB} R_u} T[C_A(x,t) - C_f] \)

Continued …..
The derivation for the species transport surface boundary condition is developed in the solution for Problem 14.3 (S). The solution to the mass transfer problem is identical to the analogous heat transfer problem provided the transport coefficients are represented as

\[
\frac{h}{k} \leftrightarrow \frac{h_m}{S_{AB}} \frac{R_u T}{D_{AB}}
\]  

(1)

(c) The uniform concentration transient diffusion process is analogous to the heat transfer lumped-capacitance process. From the solution of Problem 14.3 (S), the time to reach twice the limiting concentration, \( C_A(t_0) = 2C_{A,f} \), can be calculated as

\[
\frac{C_A(t_0) - C_{A,f}}{C_{A,i} - C_{A,f}} = \exp \left( -\frac{h_m t_0}{L S_{AB} R_u T} \right)
\]  

(2)

\[ t_0 = 42.9 \text{ hour} \]

For the present situation, the mass transfer Biot number is

\[
\text{Bi}_m = \frac{h_m L}{S_{AB} R_u T D_{AB}}
\]

\[
\text{Bi}_m = \frac{(15 \text{ m/h} / 3600 \text{ s/h}) \times 0.003 \text{ m}}{160 \text{ kmol/m}^3 \cdot \text{atm} \times 8.205 \times 10^{-2} \text{ m}^3 \cdot \text{atm} / \text{kmol} \cdot \text{K} \times 555 \text{ K} \times 1.8 \times 10^{-11} \text{ m}^2 / \text{s}}
\]

\[ \text{Bi}_m = 9.5 \gg 0.1 \]

and hence the concentration of A within B is not uniform

(d) Invoking the analogy with the heat transfer situation, we can use the one-term series solution, Eq. 5.40, with \( \text{Bi}_m \leftrightarrow \text{Bi} \) and

\[
\text{Fo}_m \leftrightarrow \text{Fo} \quad \text{Fo}_m = \frac{D_{AB} t}{L^2}
\]  

(3)
PROBLEM 14.43 (Cont.)

With $\text{Bi}_m = 9.5$, find $\zeta_1 = 1.4219\text{ rad}$ and $C_1 = 1.2609$ from Table 5.1, so that Eq. 5.41 becomes

$$\frac{C_A(t_o) - C_{A,f}}{C_{A,i} - C_{A,f}} = C_1 \exp\left(-\zeta_1^2 \text{ Fo}_m\right)$$

$$\frac{(2-1) \times 16 \text{ kmol} / m^3}{(320 - 16) \text{ kmol} / m^3} = 1.2609 \exp\left(-1.4219^2 \text{ Fo}_m\right)$$

$$\text{Fo}_m = \frac{1.8 \times 10^{-11} \text{ m}^2 / s \times t_o}{(0.003 \text{ m})^2} = 1.571$$

$$t_o = 218 \text{ hour}$$

COMMENTS:  (1) Since $\text{Bi}_m = 9.5$, the uniform concentration assumption is not valid, and we expect the analysis to provide a longer time estimate to reach $C_A(t_o) = 2C_{A,f}$.

(2) Note that the uniform concentration analysis model of part (c) does not include $D_{AB}$. Why is this so?
PROBLEM 14.44

KNOWN: Radius and temperature of air bubble in water.

FIND: Time to reach 99% of saturated vapor concentration at center.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional radial diffusion of vapor in air, (2) Constant properties, (3) Air is initially dry.

PROPERTIES: Table A-8, Water vapor-air (300 K): $D_{AB} = 0.26 \times 10^{-4} \text{ m}^2/\text{s}$.

ANALYSIS: Use Heisler charts with heat and mass transfer analogy,

$$\gamma^* = \frac{C_A - C_{A,s}}{C_{A,i} - C_{A,s}} = 1 - \frac{C_A}{C_{A,s}}$$

For $\gamma_0^* = 1 - 0.99 = 0.01$ and $B_i m^1 = 0$, from Fig. D.7 find $F_0 = 0.52$. Hence with

$$F_0 = \frac{D_{AB} t}{r_0^2} = 0.52$$

$$t = 0.52 \left( 10^{-6} \text{ m}^2 \right) / 0.26 \times 10^{-4} \text{ m}^2/\text{s} = 0.02 \text{s.}$$

COMMENTS: (1) This estimate is likely to be conservative, since shear driven motion of air within the bubble would enhance vapor transport from the surface to the center.

(2) If the one-term approximation to the infinite series solution,

$$\theta^* = \sum_{n=1}^{\infty} C_n \exp \left( -\varsigma_n^2 F_0 \right) \sin \left( \varsigma_n r^* \right)$$

is used, it follows that with $\sin 0/0 = 1$,

$$\gamma_0^* = C_1 \exp \left( -\varsigma_1^2 F_0 \right) = 0.1.$$ 

Using values of $C_1 = 2.0$ and $\varsigma_1 = 3.11$ for $B_i m = 100$, it follows that

$$0.01 = 2.0 \exp \left[ - (3.11)^2 F_0 \right]$$

or

$$F_0 = 0.55$$

which is in reasonable agreement with the Heisler chart result.
**PROBLEM 14.45**

**KNOWN:** Initial carbon content and prescribed surface content for heated steel.

**FIND:** Time required for carbon mole fraction to reach 0.01 at a distance of 1 mm from the surface.

**SCHEMATIC:**

- **Carbon (A)**
  - \( x_{A,s} = 0.02 \)
  - \( D_{AB} = D_{c,s} = 2 \times 10^{-5} \exp \left[ -17,000/T(K) \right] \)

- **Steel (B),** \( x_A(x,0) = x_{A,i} = 0.001 \)
  - \( x_A(0.001 m, t) = 0.01 \)

**ASSUMPTIONS:**
1. Steel may be approximated as a semi-infinite medium,
2. One-dimensional diffusion in \( x \),
3. Isothermal conditions,
4. No internal chemical reactions,
5. Uniform total molar concentration.

**ANALYSIS:** Conditions within the steel are governed by the species diffusion equation of the form

\[
\frac{\partial^2 C_A}{\partial x^2} = \frac{1}{D_{AB}} \frac{\partial C_A}{\partial t}
\]

or, in molar form,

\[
\frac{\partial^2 x_A}{\partial x^2} = \frac{1}{D_{AB}} \frac{\partial x_A}{\partial t}.
\]

The initial and boundary conditions are of the form

\[
x_A(x,0) = 0.001
\]

\[
x_A(0,t) = x_{A,s} = 0.02, \quad x_A(\infty, t) = 0.001.
\]

The problem is analogous to that of heat transfer in a semi-infinite medium with constant surface temperature, and by analogy to Eq. 5.57, the solution is

\[
\frac{x_A(x,t) - x_{A,s}}{x_{A,i} - x_{A,s}} = \text{erf} \left( \frac{x}{2(D_{AB}t)^{1/2}} \right)
\]

where

\[
D_{AB} = 2 \times 10^{-5} \exp \left[ -17,000/1273 \right] = 3.17 \times 10^{-11} \text{ m}^2/\text{s}.
\]

Hence

\[
\frac{0.01 - 0.02}{0.001 - 0.02} = 0.526 = \text{erf} \left( \frac{0.001}{2 \left( 3.17 \times 10^{-11} \right)^{1/2}} \right)
\]

where \( \text{erf} \ w = 0.526 \rightarrow w = 0.51, \)

\[
0.51 = 0.001/2 \left( 3.17 \times 10^{-11} t \right)^{1/2} \quad \text{or} \quad t = 30,321 \text{ s} = 8.42 \text{ h}.
\]
**PROBLEM 14.46**

**KNOWN:** Thick plate of pure iron at 1000°C subjected to a carburizing process with sudden exposure to a carbon concentration $C_{C,s}$ at the surface.

**FIND:** (a) Consider the heat transfer analog to the carburization process; sketch the mass and heat transfer systems; explain correspondence between variables; provide analytical solutions to the mass and heat transfer situation; (b) Determine the carbon concentration ratio, $C_C(x, t)/C_{C,s}$, at a depth of 1 mm after 1 hour of carburization; and (c) From the analogy, show that the time dependence of the mass flux of carbon into the plate can be expressed as $n_C = \rho_{C,s} \left( D_{C-Fe} / \pi \right)^{1/2}$; also, obtain an expression for the mass of carbon per unit area entering the iron plate over the time period $t$.

**SCHEMATIC:**

**ASSUMPTIONS:** (1) One-dimensional transient diffusion, (2) Thick plate approximates a semi-infinite medium for the transient mass and heat transfer processes, and (3) Constant properties.

**ANALYSIS:** (a) The analogy between the carburizing mass transfer process in the plate and the heat transfer process is illustrated in the schematic above. The basis for the mass - heat transfer analogy stems from the similarity of the conservation of species and energy equations, the general solution to the equations, and their initial and boundary conditions. For both processes, the plate is a semi-infinite medium with initial distributions, $C_C(x, t \leq 0) = C_{C,i} = 0$ and $T(x, t \leq 0) = T_i$, suddenly subjected to a surface potential, $C_C(0, t > 0) = C_{C,s}$ and $T(0, t > 0) = T_s$. The heat transfer situation corresponds to Case 1, Section 5.7, from which the following relations were obtained.

**Mass transfer**

*Rate equation*

$$j_C = -D_{AB} \frac{\partial C_C}{\partial x}$$

*Diffusion equation*

$$\frac{\partial}{\partial x} \left( \frac{\partial C_C}{\partial x} \right) = \frac{1}{D_{AB}} \frac{\partial C_C}{\partial t} \quad [14.84]$$

*Potential distribution*

$$\frac{C_C(x, t) - C_{C,s}}{0 - C_{C,s}} = \text{erfc} \left( \frac{x}{2(D_{AB} t)^{1/2}} \right)$$

**Heat transfer**

*Rate equation*

$$q_x = -k \frac{\partial T}{\partial x}$$

*Diffusion equation*

$$\frac{\partial}{\partial x} \left( \frac{\partial T}{\partial x} \right) = \frac{1}{\alpha} \frac{\partial T}{\partial t} \quad [2.15]$$

*Potential distribution*

$$\frac{T(x, t) - T_s}{T_i - T_s} = \text{erf} \left( \frac{x}{2(\alpha t)^{1/2}} \right) \quad [5.58]$$

Continued …..
PROBLEM 14.46 (Cont.)

Flux

See Part (c)

\[
q_s'(t) = \frac{k(T_s - T_i)}{(\pi\alpha)^{1/2}} \quad [5.58]
\]

(b) Using the concentration distribution expression above, with \(L = 1\) mm, \(t = 1\) h and \(D_{AB} = 3 \times 10^{-11}\) m²/s, find the concentration ratio,

\[
\frac{C_C(1\ \text{mm, } 1\ \text{h})}{C_{c,s}} = \text{erfc}\left(\frac{0.001\ \text{m}}{\sqrt{2(3 \times 10^{-11}\ \text{m}^2/\text{s} \times 3600\ \text{s})}}\right) = 0.0314
\]

(c) From the heat flux expression above, the mass flux of carbon can be written as

\[
n_{c,s} = \frac{D_{C-Fe} (\rho_{C,s} - 0)}{\left(\pi D_{C-Fe} \ t\right)^{1/2}} = \rho_{c,s} \left(D_{C-Fe} / \pi t\right)^{1/2}
\]

The mass per unit area entering the plate over the time period follows from the integration of the rate expression

\[
m_C(t) = \int_0^t n_{c,s} \ dt = \rho_{c,s} \left(D_{AB} / \pi \right)^{1/2} \int_0^t t^{-1/2} \ dt = 2 \rho_{c,s} \left(D_{C-Fe} / t\pi\right)^{1/2}
\]
Problem 14.47

Known: Thickness, initial condition and bottom surface condition of a water layer.

Find: (a) Time to reach 25% of saturation at top, (b) Amount of salt transfer in that time, (c) Final concentration of salt solution at top and bottom.

Schematic:

Assumptions: (1) One-dimensional diffusion, (2) Uniform total mass density, (3) Constant $D_{AB}$.

Analysis: (a) With constant $\rho$ and $D_{AB}$ and no homogeneous chemical reactions, Eq. 14.37b reduces to

$$\frac{\partial^2 \rho_A}{\partial x^2} = \frac{1}{D_{AB}} \frac{\partial \rho_A}{\partial t}$$

with the origin of coordinates placed at the top of the layer, the dimensionless mass density is

$$\gamma^*(x^*, Fo_m) = \gamma = \frac{\rho_A - \rho_{A,s}}{\rho_{A,i} - \rho_{A,s}} = 1 - \frac{\rho_A}{\rho_{A,s}}$$

Hence, $\gamma^*(0, Fo_{m,1}) = 1 - 0.25 = 0.75$. The initial condition is $\gamma^*(x^*, 0) = 1$, and the boundary conditions are

$$\frac{\partial \gamma^*}{\partial x^*} \bigg|_{x^* = 0} = 0 \quad \gamma^*(1, Fo_m) = 0$$

where the condition at $x^* = 1$ corresponds to $Bi_m = \infty$. Hence, the mass transfer problem is analogous to the heat transfer problem governed by Eq. 5.34 to 5.37. Assuming applicability of a one-term approximation ($Fo_m > 0.2$), the solution is analogous to Eq. 5.40.

$$\gamma^* = C_1 \exp \left( -\zeta_1^2 Fo_m \right) \cos \left( \zeta_1 x^* \right)$$

With $Bi_m = \infty, \zeta_1 = \pi / 2 = 1.571$ rad and, from Table 5.1, $C_1 = 1.274$. Hence, for $x^* = 0$,

$$0.75 = 1.274 \exp \left[ -\left(1.571\right)^2 Fo_{m,1} \right]$$

$$Fo_{m,1} = -\ln \left(0.75/1.274\right)/\left(1.571\right)^2 = 0.215.$$  

Hence,

$$t_1 = \frac{L^2}{D_{AB} Fo_{m,1}} = \frac{(1 \text{ m})^2}{1.2 \times 10^{-9} \text{ m}^2/\text{s}} \times 0.215 = 1.79 \times 10^8 \text{ s} = 2071 \text{ days}.$$  

Continued …..
PROBLEM 14.47 (Cont.)

(b) The change in the salt mass within the water is
\[
\Delta M_A = M_A(t_1) - M_{A,i} = \int \left( \rho_A - \rho_{A,i} \right) dV = A \int_0^L \rho_A dx
\]

Hence,
\[
\Delta M^*_A = \rho_{A,s} \int_0^L \left( \frac{\rho_A}{\rho_{A,s}} \right) dx
\]
\[
\Delta M^*_A = \rho_{A,s} L \int_0^L \left( 1 - \gamma^* \right) dx^*
\]
\[
\Delta M_A^* = \rho_{A,s} L \left[ 1 - C_1 \exp\left( -\zeta_1^2 F_{o_m} \cos\left( \zeta_1 x^* \right) \right) \right] dx^*
\]
\[
\Delta M_A^* = \rho_{A,s} L \left[ 1 - C_1 \exp\left( -\zeta_1^2 F_{o_m} \sin\zeta_1 / \zeta_1 \right) \right].
\]

Substituting numerical values,
\[
\Delta M_A^* = 380 \text{ kg/m}^3 (1 \text{ m}) \left[ 1 - \frac{1.274 \exp\left( -{(1.571)^2} / 2 \times 0.215 \right)}{1.571 \text{ rad}} \right]
\]
\[
\Delta M_A^* = 198.7 \text{ kg/m}^2.
\]

(c) Steady-state conditions correspond to a uniform mass density in the water. Hence,
\[
\rho_A(0, \infty) = \rho_A(L, \infty) = \Delta M_A^* / L = 198.7 \text{ kg/m}^3.
\]

COMMENTS: (1) The assumption of constant \( \rho \) is weak, since the density of salt water depends strongly on the salt composition.

(2) The requirement of \( F_{o_m} > 0.2 \) for the one-term approximation to be valid is barely satisfied.
PROBLEM 14.48

KNOWN: Temperature distribution expression for a semi-infinite medium, initially at a uniform temperature, that is suddenly exposed to an instantaneous amount of energy, \( Q''_0 \) (J/m\(^2\)).

Analogous situation of a silicon (Si) wafer with a 1-µm layer of phosphorous (P) that is placed in a furnace suddenly initiating diffusion of P into Si.

FIND: (a) Explain the correspondence between the variables in the analogous temperature and concentration distribution expressions, and (b) Determine the mole fraction of P at a depth of 0.1 mm in the Si after 30 s.

SCHEMATIC:

ASSUMPTIONS: (1) One-dimensional, transient diffusion, (2) Wafer approximates a semi-infinite medium, (3) Uniform properties, and (4) Diffusion process for Si and P is initiated when the wafer reaches the elevated temperature as a consequence of the large temperature dependence of the diffusion coefficient.

PROPERTIES: Given in statement: \( D_{P-Si} = 1.2 \times 10^{-17} \text{ m}^2/\text{s} \); Mass densities of Si and P: 2000 and 2300 kg/m\(^3\); Molecular weights of Si and P: 30.97 and 28.09 kg/kmol.

ANALYSIS: (a) For the thermal process illustrated in the schematic, the temperature distribution is

\[
T(x, t) - T_i = \frac{Q''_0}{\rho c (\pi \alpha t)^{1/2}} \exp\left(-\frac{x^2}{4\alpha t}\right)
\]

where \( T_i \) is the initial, uniform temperature of the medium. For the mass transfer process, the P concentration has the form

\[
C_P(x, t) = \frac{M_P^{P, o}}{(\pi D_{P-Si} t)^{1/2}} \exp\left(-\frac{x^2}{4 D_{P-Si} t}\right)
\]

where \( M_P^{P, o} \) is the molar area density (kmol/m\(^2\)) of P represented by the film of concentration \( C_P \) and thickness \( d_o \).

The correspondence between mass and heat transfer variables in the equations HT and MT involves the following conditions. The LHS represents the increase with time of the temperature or concentration above the initial uniform distribution. The initial concentration is zero, so only the \( C_P \) (x, t) appears. On the RHS note the correspondence of the terms in the exponential parenthesis and in the denominator. The thermal diffusivity and diffusion coefficient are directly analogous; this can be seen by comparing the MT and HT diffusion equations, Eq. 2.15 and 14.84. The terms \( Q''_0 / \rho c \) and \( M_P^{P, o} \) for HT and MT represent the energy and mass instantaneously appearing at the surface. The product \( \rho c \) is the thermal capacity per unit area and appears in the storage term of the HT diffusion equation. For MT, the “capacity” term is the volume itself.

Continued …..
(b) The molar area density \( \text{kmol/m}^2 \) of P associated with the film of thickness \( d_o = 1 \mu\text{m} \) and concentration \( C_{P,o} \) is

\[
M^\prime_{P,o} = C_{P,o} \cdot d_o = \left( \rho_P / M_P \right) d_o
\]

\[
M^\prime_{P,o} = \left( 2000 \text{ kg/m}^3 / 30.97 \text{ kmol/kg} \right) \times 1 \times 10^{-6} \text{ m}
\]

\[
M^\prime_{P,o} = 6.458 \times 10^{-5} \text{ kmol/m}^2
\]

Substituting numerical values into the MT equation, find

\[
C_p(0.1 \text{ mm, 30 s}) = \frac{6.458 \times 10^{-5} \text{ kmol/m}^2}{\left( \pi \times 1.2 \times 10^{-17} \text{ m}^2 / \text{s} \times 30 \text{ s} \right)} \exp \left( (0.0001 \text{ m})^2 / \left( 4 \times 1.2 \times 10^{-7} \text{ m}^2 / \text{s} \times 30 \text{ s} \right) \right)
\]

\[
C_p = 0.08188 \text{ kmol/m}^3
\]

The mole fraction of P in the Si wafer is

\[
x_P = C_P / C_{Si} = C_P / \left( \rho_{Si} / M_{Si} \right)
\]

\[
x_P = 0.08188 \text{ kmol/m}^3 / \left( 2300 \text{ kg/m}^3 / 28.09 \text{ kmol/kg} \right)
\]

\[
x_P = 2.435 \times 10^{-5}
\]
