## THERMODYNAMICS FOR ENGINEERS

## MERLE C. POTIER GBAIG W. SOMERTON

The perfect aid for better grades!
Covers all course fundamentalssupplements any class text

Teaches effective problem solving
222 problems solved step-by-step

Ideal for independent study!

Use with these courses: $\checkmark$ Thernodynamies $\checkmark$ Engineering Thermodynamics
$\checkmark$ Principles of Thermodynamies $\checkmark$ Fundamental of Thermodynamies $\checkmark$ Thermodynamics I

# THERMOD NAMICS FOR ENCINEERS 

## M.C. Potter c.W. Somerton

THE ORIGINAL AND MOST POPULAR COLLEGE COURSE SERIES AROUND THE WORLD

- Helps you learn and understand the complete course: basic theory and concepts, definitions, problems ... and more
- Teaches you how to solve a wide variety of problems in step-by-step detail
- Gives you an effective way to prepare for exams, save time, and learn more from homework problems
- Can be used independently or with your class text
- Includes 222 Solved Problems with complete solutions and 911 additional problems with answers
Also available ... powerful interactive software for learning course content and solving numerical problems based on Mathcad ${ }^{\text { }}$. See back cover and Appendix K.

MERLE C. POTTER has a B.S. degree in Mechanical Engineering from Michigan Technological University; his M.S. in Aerospace Engineering and Ph.D. in Engineering Mechanics were received from The University of Michigan. He is the author or coauthor of The Mechanics of Fluids, Mathematical Methods, Fundamentals of Engineering, and numerous papers in fluid mechanics and energy. Currently he is Professor of Mechanical Engineering at Michigan State University.

CRAIG W. SOMERTON studied Engineering at UCLA, where he was awarded the B.S., M.S., and Ph.D. degrees. He is currently Associate Professor of Mechanical Engineering at Michigan State University. He has published in the International Journal of Mechanical Engineering Education and is a past recipient of the SAE Ralph R. Teetor Educational Award.

## Preface

This book is intended for the first course in thermodynamics required by most, if not all, engineering departments. It is designed to supplement the required text selected for the course; it provides a succinct presentation of the material so that the student can more easily determine the major objective of each section of the textbook. If proofs of theorems are not of primary importance in this first course, the present Schaum's Outline could itself serve as the required text.

The basic thermodynamic principles are liberally illustrated with numerous examples and solved problems that demonstrate how the principles are applied to actual or simulated engineering situations. Supplementary problems that provide students an opportunity to test their problem-solving skills are included at the ends of all chapters. Answers are provided for all these problems.

The material presented in a first course in thermodynamics is more or less the same in most engineering schools. Under a quarter system both the first and second laws are covered, with little time left for applications. Under a semester system it is possible to cover some application areas, such as vapor and gas cycles, nonreactive mixtures, and combustion. This book allows such flexibility. In fact, there is sufficient material for a full year of study.

As U.S. industry continues to avoid the use of SI units, we have written about 25 percent of the examples, solved problems, and supplementary problems in English units. Tables are presented in both systems of units.

The authors wish to thank Mrs. Michelle Gruender for her careful review of the manuscript, Ms. Kelly Bartholemew for her excellent word processing, Mr. B. J. Clark for his friendly and insightful advice, and Ms. Maureen Walker for her efficient production of this book.

## Contents

Chapter 1 CONCEPTS, DEFINITIONS, AND BASIC PRINCIPLES ..... 1
1.1 Introduction ..... 1
1.2 Thermodynamic Systems and Control Volumes ..... 1
1.3 Macroscopic Description ..... 1
1.4 Properties and State of a System ..... 3
1.5 Thermodynamic Equilibrium; Processes ..... 3
1.6 Units ..... 5
1.7 Density, Specific Volume, Specific Weight ..... 6
1.8 Pressure ..... 7
1.9 Temperature ..... 9
1.10 Energy ..... 10
Chapter 2 PROPERTIES OF PURE SUBSTANCES ..... 19
2.1 Introduction ..... 19
2.2 The $P-t-T$ Surface ..... 19
2.3 The Liquid-Vapor Region ..... 20
2.4 Steam Tables ..... 22
2.5 The Ideal-Gas Equation of State ..... 23
2.6 Equations of State for a Nonideal Gas ..... 25
Chapter 3 WORK AND HEAT ..... 33
3.1 Introduction ..... 33
3.2 Definition of Work ..... 33
3.3 Quasiequilibrium Work Due to a Moving Boundary ..... 33
3.4 Nonequilibrium Work ..... 37
3.5 Other Work Modes ..... 38
3.6 Heat ..... 40
Chapter 4 THE FIRST LAW OF THERMODYNAMICS ..... 49
4.1 Introduction ..... 49
4.2 The First Law of Thermodynamics Applied to a Cycle ..... 49
4.3 The First Law Applied to a Process ..... 49
4.4 Enthalpy ..... 52
4.5 Latent Heat ..... 53
4.6 Specific Heats ..... 53
4.7 The First Law Applied to Various Processes ..... 57
4.8 General Formulation for Control Volumes ..... 61
4.9 Applications of the Energy Equation ..... 64
Chapter 5 THE SECOND LAW OF THERMODYNAMICS ..... 98
5.1 Introduction ..... 98
5.2 Heat Engines, Heat Pumps, and Refrigerators ..... 98
5.3 Statements of the Sccond Law of Thermodynamics ..... 99
5.4 Reversibility ..... 100
5.5 The Carnot Engine ..... 101
5.6 Carnot Efficiency ..... 104
Chapter 6 ENTROPY ..... 112
6.1 Introduction ..... 112
6.2 Definition ..... 112
6.3 Entropy for an Ideal Gas with Constant Specific Heats ..... 113
6.4 Entropy for an Ideal Gas with Variable Specific Heats ..... 115
6.5 Entropy for Substances Such as Steam, Solids, and Liquids ..... 116
6.6 The Inequality of Clausius ..... 118
6.7 Entropy Change for an Irreversible Process ..... 119
6.8 The Second Law Applied to a Control Volume ..... 121
Chapter 7 REVERSIBLE WORK, IRREVERSIBILITY, AND AVAILABILITY ..... 137
7.1 Basic Concepts ..... 137
7.2 Reversible Work and Irreversibility ..... 138
7.3 Availability and Exergy ..... 140
7.4 Second-Law Analysis of a Cycle ..... 141
Chapter 8 POWER AND REFRIGERATION VAPOR CYCLES ..... 149
8.1 Introduction ..... 149
8.2 The Rankinc Cycle ..... 149
8.3 Rankine Cycle Efficiency ..... 151
8.4 The Reheat Cycle ..... 154
8.5 The Regenerative Cycle ..... 154
8.6 The Supercritical Rankine Cycle ..... 158
8.7 Effect of Losses on Power Cycle Efficiency ..... 160
8.8 The Vapor Refrigeration Cycle ..... 161
8.9 The Multistage Vapor Refrigeration Cycle ..... 165
8.10 The Heat Pump ..... 167
8.11 The Absorption Refrigeration Cycle ..... 169

# Concepts, Definitions, and Basic Principles 

### 1.1 INTRODUCTION

Thermodynamics is a science in which the storage, the transformation, and the transfer of energy are studied. Energy is stored as internal energy (associated with temperature), kinetic energy (due to motion), potential energy (due to elevation) and chemical energy (due to chemical composition); it is transformed from one of these forms to another; and it is transferred across a boundary as either heat or work. In thermodynamics we will develop mathematical equations that relate the transformations and transfers of energy to material properties such as temperature, pressure, or enthalpy. Substances and their properties thus become an important secondary theme. Much of our work will be based on experimental observations that have been organized into mathematical statements, or laws; the first and second laws of thermodynamics are the most widely used.

The engineer's objective in studying thermodynamics is most often the analysis or design of a large-scale system-anything from an air-conditioner to a nuclear power plant. Such a system may be regarded as a continuum in which the activity of the constituent molecules is averaged into measurable quantities such as pressure, temperature, and velocity. This outline, then, will be restricted to macroscopic or engineering thermodynamics. If the behavior of individual molecules is important, a text in statistical thermodynamics must be consulted.

### 1.2 THERMODYNAMIC SYSTEMS AND CONTROL VOLUMES

A thermodynamic system is a definite quantity of matter most often contained within some closed surface. The surface is usually an obvious one like that enclosing the gas in the cylinder of Fig. 1-1; however, it may be an imagined boundary like the deforming boundary of a certain amount of mass as it flows through a pump. In Fig. 1-1 the system is the compressed gas, the working fluid, and the system boundary is shown by the dotted line.

All matter external to a system is collectively called its surroundings. Thermodynamics is concerned with the interactions of a system and its surroundings, or one system interacting with another. A system interacts with its surroundings by transferring energy across its boundary. No material crosses the boundary of a given system. If the system does not exchange energy with the surroundings, it is an isolated system.

In many cases, an analysis is simplified if attention is focused on a volume in space into which, and or from which, a substance flows. Such a volume is a control volume. A pump, a turbine, an inflating balloon, are examples of control volumes. The surface that completely surrounds the control volume is called a control surface. An example is sketched in Fig. 1-2.

We thus must choose, in a particular problem, whether a system is to be considered or whether a control volume is more useful. If there is mass flux across a boundary of the region, then a control volume is required; otherwise, a system is identified. We will present the analysis of a system first and follow that with a study using the control volume.

### 1.3 MACROSCOPIC DESCRIPTION

In engineering thermodynamics we postulate that the material in our system or control volume is a continuum; that is, it is continuously distributed throughout the region of interest. Such a postulate allows us to describe a system or control volume using only a few measurable properties.

Fig. 1-1

Fig. 1-2
Consider the definition of density given by

$$
\begin{equation*}
\rho=\lim _{\Delta V \rightarrow 0} \frac{\Delta m}{\Delta V} \tag{1.1}
\end{equation*}
$$

where $\Delta m$ is the mass contained in the volume $\Delta V$, shown in Fig. 1-3. Physically, $\Delta V$ cannot be allowed to shrink to zero since, if $\Delta V$ became extremely small, $\Delta m$ would vary discontinuously, depending on the number of molecules in $\Delta V$. So, the zero in the definition of $\rho$ should be replaced by some quantity $\varepsilon$, small, but large enough to eliminate molecular effects. Noting that there are about $3 \times 10^{16}$ molecules in a cubic millimeter of air at standard conditions, $\varepsilon$ need not be very large to contain billions and billions of molecules. For most engineering applications $\varepsilon$ is sufficiently small that we can let it be zero, as in (1.1).

Fig. 1-3
There are, however, situations where the continuum assumption is not valid; for example, the re-entry of satellites. At an elevation of 100 km the mean free path, the average distance a molecule travels before it collides with another molecule, is about 30 mm ; the macroscopic approach is already questionable. At 150 km the mean free path exceeds 3 m , which is comparable to the dimensions of the satellite! Under these conditions statistical methods based on molecular activity must be used.

### 1.4 PROPERTIES AND STATE OF A SYSTEM

The matter in a system may exist in several phases: as a solid, a liquid, or a gas. A phase is a quantity of matter that has the same chemical composition throughout; that is, it is homogeneous. Phase boundaries separate the phases, in what, when taken as a whole, is called a mixture.

A property is any quantity which serves to describe a system. The state of a system is its condition as described by giving values to its properties at a particular instant. The common properties are pressure, temperature, volume, velocity, and position; but others must occasionally be considered. Shape is important when surface effects are significant; color is important when radiation heat transfer is being investigated.

The essential feature of a property is that it has a unique value when a system is in a particular state, and this value does not depend on the previous states that the system passed through; that is, it is not a path function. Since a property is not dependent on the path, any change depends only on the initial and final states of the system. Using the symbol $\phi$ to represent a property, that is stated mathematically as

$$
\begin{equation*}
\int_{\phi_{1}}^{\phi_{2}} d \phi=\phi_{2}-\phi_{1} \tag{1.2}
\end{equation*}
$$

This requires that $d \phi$ be an exact differential; $\phi_{2}-\phi_{1}$ represents the change in the property as the system changes from state 1 to state 2 . There are quantities which we will encounter, such as work, that are path functions for which an exact differential does not exist.

A relatively small number of independent properties suffice to fix all other properties and thus the state of the system. If the system is composed of a single phase, free from magnetic, electrical and surface effects, the state is fixed when any two properties are fixed; this simple system receives most attention in engineering thermodynamics.

Thermodynamic properties are divided into two general types, intensive and extensive. An intensive property is one which does not depend on the mass of the system; temperature, pressure, density and velocity are examples since they are the same for the entire system, or for parts of the system. If we bring two systems together, intensive properties are not summed.

An extensive property is one which depends on the mass of the system; volume, momentum, and kinetic energy, are examples. If two systems are brought together the extensive property of the new system is the sum of the extensive properties of the original two systems.

If we divide an extensive property by the mass a specific property results. The specific volume is thus defined to be

$$
\begin{equation*}
v=\frac{V}{m} \tag{1.3}
\end{equation*}
$$

We will generally use an uppercase letter to represent an extensive property [exception: $m$ for mass] and a lowercase letter to denote the associated intensive property.

### 1.5 THERMODYNAMIC EQUILIBRIUM; PROCESSES

When the temperature or the pressure of a system is referred to, it is assumed that all points of the system have the same, or essentially the same, temperature or pressure. When the properties are assumed constant from point to point and when there is no tendency for change with time, a condition of thermodynamic equilibrium exists. If the temperature, say, is suddenly increased at some part of the system boundary, spontaneous redistribution is assumed to occur until all parts of the system are at the same temperature.

If a system would undergo a large change in its properties when subjected to some small disturbance, it is said to be in metastable equilibrium. A mixture of gasoline and air, or a large bowl on a small table, is such a system.

When a system changes from one equilibrium state to another the path of successive states through which the system passes is called a process. If, in the passing from one state to the next, the deviation from equilibrium is infinitesimal, a quasiequilibrium process occurs and each state in the process may be idealized as an equilibrium state. Many processes, such as the compression and expansion of gases in an internal combustion engine, can be approximated by quasiequilibrium processes with no significant loss of accuracy. If a system undergoes a quasiequilibrium process (such as the slow compression of air in a cylinder) it may be sketched on appropriate coordinates by using a solid line, as shown in Fig. 1-4(a). If the system, however, goes from one equilibrium state to another through a series of nonequilibrium states (as in combustion) a nonequilibrium process occurs. In Fig. $1-4(b)$ the dashed curve represents such a process; between ( $V_{1}, P_{1}$ ) and ( $V_{2}, P_{2}$ ) properties are not uniform throughout the system and thus the state of the system cannot be well defined.

Fig. 1-4

EXAMPLE 1.1 Whether a particular process may be considered quasiequilibrium or nonequilibrium depends on how the process is carried out. Let us add the weight $W$ to the piston of Fig. 1-5. If it is added suddenly as one large weight, as in part ( $a$ ), a nonequilibrium process will occur in the gas, the system. If we divide the weight into a large number of small weights and add them one at a time, as in part (b), a quasiequilibrium process will occur.

Fig. 1-5

Note that the surroundings play no part in the notion of equilibrium. It is possible that the surroundings do work on the system via friction; for quasiequilibrium it is only required that the properties of the system be uniform at any instant during a process.

When a system in a given initial state experiences a series of quasiequilibrium processes and returns to the initial state, the system undergoes a cycle. At the end of the cycle the properties of the system have the same values they had at the beginning; see Fig. 1-6.

The prefix iso- is attached to the name of any property that remains unchanged in a process. An isothermal process is one in which the temperature is held constant; in an isobaric process the pressure remains constant; an isometric process is a constant-volume process. Note the isobaric and the isometric legs in Fig. 1-6.

Fig. 1-6

### 1.6 UNITS

While the student is undoubtedly most at home with SI (Système International) units, much of the data gathered in the United States is in English units. Therefore, a certain number of examples and problems will be presented in English units. Table 1-1 lists units of the principal thermodynamic

Table 1-1

| Quantity | Symbol | SI Units | English Units | To Convert from English to SI Units Multiply by |
| :---: | :---: | :---: | :---: | :---: |
| Length | $L$ | m | ft | 0.3048 |
| Mass | m | kg | lbm | 0.4536 |
| Time | $t$ | s | sec | - |
| Area | A | $\mathrm{m}^{2}$ | $\mathrm{ft}^{2}$ | 0.09290 |
| Volume | V | $\mathrm{m}^{3}$ | $\mathrm{ft}^{3}$ | 0.02832 |
| Velocity | $V$ | m/s | $\mathrm{ft} / \mathrm{sec}$ | 0.3048 |
| Acceleration | $a$ | $\mathrm{m} / \mathrm{s}^{2}$ | $\mathrm{ft} / \mathrm{sec}^{2}$ | 0.3048 |
| Angular velocity | ${ }^{\omega}$ | $\mathrm{rad} / \mathrm{s}$ | $\mathrm{sec}^{-1}$ | - |
| Force, Weight | F, W | N | lbf | 4.448 |
| Density | $\rho$ | $\mathrm{kg} / \mathrm{m}^{3}$ | $\mathrm{lbm} / \mathrm{ft}^{3}$ | 16.02 |
| Specific weight | $\gamma$ | $\mathrm{N} / \mathrm{m}^{3}$ | $\mathrm{lbf} / \mathrm{ft}^{3}$ | 157.1 |
| Pressure, Stress | $P$, $\tau$ | kPa | $\mathrm{lbf} / \mathrm{ft}^{2}$ | 0.04788 |
| Work, Energy | $W, E, U$ | J | ft -lbf | 1.356 |
| Heat transfer | $Q$ | J | Btu | 1055 |

| $10^{9}$ | giga | G |
| $10^{6}$ | mega | M |
| $10^{3}$ | kilo | k |
| $10^{-2}$ | centi* | c |
| $10^{-3}$ | milli | m |
| $10^{-6}$ | micro | $\mu$ |
| $10^{-9}$ | nano | n |
| $10^{-12}$ | pico | p |

* Discouraged except in $\mathrm{cm} . \mathrm{cm}^{2}$, or $\mathrm{cm}^{3}$.
quantities. Observe the dual use of $V$ for volume and velocity; the context and the units will make clear which quantity is intended.

When expressing a quantity in SI units certain letter prefixes may be used to represent multiplication by a power of 10 ; see Table 1-2.

The units of various quantities are interrelated via the physical laws obeyed by the quantities. It follows that, in either system, all units may be expressed as algebraic combinations of a selected set of base units. There are seven base units in the $\mathrm{SI}: \mathrm{m}, \mathrm{kg}, \mathrm{s}, \mathrm{K}, \mathrm{mol}$ (mole), A (ampere), cd (candela). The last two are rarely encountered in engineering thermodynamics.

EXAMPLE 1.2 Newton's second law, $F=m a$, relates a net force acting on a body to its mass and acceleration. Thus, a force of one newton accelerates a mass of one kilogram at one $\mathrm{m} / \mathrm{s}^{2}$; or, a force of one lbf accelerates 32.2 lbm ( 1 slug ) at a rate of one $\mathrm{ft} / \mathrm{sec}^{2}$. Hence, the units are related as

$$
1 \mathrm{~N}=1 \mathrm{~kg} \cdot \mathrm{~m} / \mathrm{s}^{2} \quad \text { or } \quad 1 \mathrm{lbf}=32.2 \mathrm{lbm}-\mathrm{ft} / \mathrm{sec}^{2}
$$

EXAMPLE 1.3 Weight is the force of gravity; by Newton's second law, $W=m g$. As mass remains constant, the variation of $W$ with elevation is due to changes in the acceleration of gravity $g$ (from about $9.77 \mathrm{~m} / \mathrm{s}^{2}$ on the highest mountain to $9.83 \mathrm{~m} / \mathrm{s}^{2}$ in the deepest ocean trench). We will use the standard value $9.81 \mathrm{~m} / \mathrm{s}^{2}$ ( 32.2 $\mathrm{ft} / \mathrm{sec}^{2}$ ), unless otherwise stated.

EXAMPLE 1.4 To express the energy unit $J$ (joule) in terms of SI base units, recall that energy or work is force times distance. Hence, by Example 1.2,

$$
1 \mathrm{~J}=(1 \mathrm{~N})(1 \mathrm{~m})=\left(1 \mathrm{~kg} \cdot \mathrm{~m} / \mathrm{s}^{2}\right)(1 \mathrm{~m})=1 \mathrm{~kg} \cdot \mathrm{~m}^{2} / \mathrm{s}^{2}
$$

In the English system both the lbf and the lbm are base units. As indicated in Table 1-1, the primary energy unit is the $\mathrm{ft}-\mathrm{lbf}$. By Example 1.2,

$$
1 \mathrm{ft}-\mathrm{lbf}=32.2 \mathrm{lbm}-\mathrm{ft}^{2} / \mathrm{sec}^{2}=1 \mathrm{slug}-\mathrm{ft}^{2} / \mathrm{sec}^{2}
$$

analogous to the SI relation found above.

### 1.7 DENSITY, SPECIFIC VOLUME, SPECIFIC WEIGHT

By ( 1.1 ), density is mass per unit volume; by (1.3), specific volume is volume per unit mass. Therefore,

$$
\begin{equation*}
\iota^{\prime}=\frac{1}{\rho} \tag{1.4}
\end{equation*}
$$

Associated with (mass) density is weight density or specific weight $\gamma$ :

$$
\begin{equation*}
\gamma=\frac{W}{V} \tag{1.5}
\end{equation*}
$$

with units $\mathrm{N} / \mathrm{m}^{3}\left(\mathrm{lbf} / \mathrm{ft}^{3}\right)$. [Note that $\gamma$ is volume-specific, not mass-specific.] Specific weight is related to density through $W=m g$ :

$$
\begin{equation*}
\gamma=\rho g \tag{1.6}
\end{equation*}
$$

For water, nominal values of $\rho$ and $\gamma$ are, respectively, $1000 \mathrm{~kg} / \mathrm{m}^{3}\left(62.4 \mathrm{lbm} / \mathrm{ft}^{3}\right)$ and $9810 \mathrm{~N} / \mathrm{m}^{3}$ $\left(62.4 \mathrm{lbf} / \mathrm{ft}^{3}\right)$. For air the nominal values are $1.21 \mathrm{~kg} / \mathrm{m}^{3}\left(0.0755 \mathrm{lbm} / \mathrm{ft}^{3}\right)$ and $11.86 \mathrm{~N} / \mathrm{m}^{3}(0.0755$ $\mathrm{lbf} / \mathrm{ft}^{3}$ ).

EXAMPLE 1.5 The mass of air in a room $3 \times 5 \times 20 \mathrm{~m}$ is known to be 350 kg . Determine the density, specific volume, and specific weight.

$$
\begin{aligned}
\rho & =\frac{m}{\mathrm{~V}}=\frac{350}{(3)(5)(20)}=1.167 \mathrm{~kg} / \mathrm{m}^{3} \quad v=\frac{1}{\rho}=\frac{1}{1.167}=0.857 \mathrm{~m}^{3} / \mathrm{kg} \\
\gamma & =\rho g=(1.167)(9.81)=11.45 \mathrm{~N} / \mathrm{m}^{3}
\end{aligned}
$$

### 1.8 PRESSURE

## Definition

In gases and liquids it is common to call the effect of a normal force acting on an area the pressure. If a force $\Delta F$ acts at an angle to an area $\Delta A$ (Fig. 1-7), only the normal component $\Delta F_{n}$

Fig. 1-7
enters into the definition of pressure:

$$
\begin{equation*}
P=\lim _{\Delta A \rightarrow 0} \frac{\Delta F_{n}}{\Delta A} \tag{1.7}
\end{equation*}
$$

The SI unit of pressure is the pascal $(\mathrm{Pa})$, where

$$
1 \mathrm{~Pa}=1 \mathrm{~N} / \mathrm{m}^{2}=1 \mathrm{~kg} / \mathrm{m} \cdot \mathrm{~s}^{2}
$$

The corresponding English unit is $\mathrm{lbf} / \mathrm{ft}^{2}$, although $\mathrm{lbf} / \mathrm{in}^{2}$ ( psi ) is commonly used.
By considering the pressure forces acting on a triangular fluid element of constant depth we can show that the pressure at a point in a fluid in equilibrium (no motion) is the same in all directions; it is a scalar quantity. For gases and liquids in relative motion the pressure may vary with direction at a point; however, this variation is extremely small and can be ignored in most gases and in liquids with low viscosity (e.g., water). We have not assumed in the above discussion that pressure does not vary from point to point, only that at a particular point it does not vary with direction.

## Pressure Variation with Elevation

In the atmosphere pressure varies with elevation. This variation can be expressed mathematically by considering the equilibrium of the element of air shown in Fig. 1-8. Summing forces on the element

Fig. 1-8
in the vertical direction (up is positive) gives

$$
\begin{equation*}
d P=-\rho g d z \tag{1.8}
\end{equation*}
$$

Now if $P$ is a known function of $z$, the above equation can be integrated to give $P(z)$ :

$$
\begin{equation*}
P(z)-P_{0}=-\int_{0}^{2} \rho g d z \tag{1.9}
\end{equation*}
$$

For a liquid, $\rho$ is constant. If we write (1.8) using $d h=-d z$, we have

$$
\begin{equation*}
d P=\gamma d h \tag{1.10}
\end{equation*}
$$

where $h$ is measured positive downward. Integrating this equation, starting at a liquid surface where $P=0$, results in

$$
\begin{equation*}
P=\gamma h \tag{1.11}
\end{equation*}
$$

This equation can be used to convert to Pa a pressure measured in meters of water or millimeters of mercury.

In most thermodynamic relations absolute pressure must be used. Absolute pressure is gage pressure plus the local atmospheric pressure:

$$
\begin{equation*}
P_{\mathrm{abs}}=P_{\mathrm{gage}}+P_{\mathrm{atm}} \tag{1.12}
\end{equation*}
$$

A negative gage pressure is often called a vacuum, and gages capable of reading negative pressures are cacuum gages. A gage pressure of -50 kPa would be referred to as a vacuum of 50 kPa , with the sign omitted.

Figure 1-9 shows the relationships between absolute and gage pressure.

Fig. 1-9

The word "gage" is generally used in statements of gage pressure; e.g., $P=200 \mathrm{kPa}$ gage. If "gage" is not present, the pressure will, in general, be an absolute pressure. Atmospheric pressure is an absolute pressure, and will be taken as 100 kPa (at sea level), unless otherwise stated. It should be noted that atmospheric pressure is highly dependent on elevation; in Denver, Colorado, it is about 84 kPa , and in a mountain city with elevation 3000 m it is only 70 kPa .

EXAMPLE 1.6 Express a pressure gage reading of 35 psi in absolute pascals.
First we convert the pressure reading into pascals. We have

$$
\left(35 \frac{\mathrm{lbf}}{\mathrm{in}^{2}}\right)\left(144 \frac{\mathrm{in}^{2}}{\mathrm{ft}^{2}}\right)\left(0.04788 \frac{\mathrm{kPa}}{\mathrm{lbf} / \mathrm{ft}^{2}}\right)=241 \mathrm{kPa} \text { gage }
$$

To find the absolute pressure we simply add the atmospheric pressure to the above value. Using $P_{\mathrm{atm}}=100 \mathrm{kPa}$, we obtain

$$
P=241+100=341 \mathrm{kPa}
$$

EXAMPLE 1.7 The manometer shown in Fig. 1-10 is used to measure the pressure in the water pipc. Determine the water pressure if the manometer reading is 0.6 m . Mercury is 13.6 times heavier than water.

Fig. 1-10
To solve the manometer problem we use the fact that $P_{a}=P_{b}$. The pressure $P_{a}$ is simply the pressure $P$ in the water pipe plus the pressure due to the 0.6 m of water; the pressure $P_{b}$ is the pressure due to 0.6 m of mercury. Thus,

$$
P+(0.6 \mathrm{~m})\left(9810 \mathrm{~N} / \mathrm{m}^{3}\right)=(0.6 \mathrm{~m})(13.6)\left(9810 \mathrm{~N} / \mathrm{m}^{3}\right)
$$

This gives $P=74200 \mathrm{~Pa}$ or 74.2 kPa gage.
EXAMPLE 1.8 Calculate the force due to the pressure acting on the 1 -m-diameter horizontal hatch of a submarine submerged 600 m below the surface.

The pressure acting on the hatch at a depth of 600 m is found from (1.11) as

$$
P=\rho g h=\left(1000 \mathrm{~kg} / \mathrm{m}^{3}\right)\left(9.81 \mathrm{~m} / \mathrm{s}^{2}\right)(600 \mathrm{~m})=5.89 \mathrm{MPa}
$$

The pressure is constant over the area; hence, the force due to the pressure is given by

$$
F=P A=\left(5.89 \times 10^{6} \mathrm{~N} / \mathrm{m}^{2}\right)\left\lceil\frac{\pi(1)^{2}}{4} \mathrm{~m}^{2}\right\rceil=4.62 \times 10^{6} \mathrm{~N}
$$

### 1.9 TEMPERATURE

Temperature is, in reality, a measure of molecular activity. However, in classical thermodynamics the quantities of interest are defined in terms of macroscopic observations only, and a definition of temperature using molecular measurements is not useful. Thus we must proceed without actually defining temperature. What we shall do instead is discuss equality of temperatures.

## Equality of Temperatures

Let two bodies be isolated from the surroundings but placed in contact with each other. If one is hotter than the other, the hotter body will become cooler and the cooler body will become hotter; both bodies will undergo change until all properties (e.g., electrical resistance) of the bodies cease to
change. When this occurs, thermal equilibrium is said to have been established between the two bodies. Hence, we state that two systems have equal temperatures if no change occurs in any of their properties when the systems are brought into contact with each other. In other words, if two systems are in thermal equilibrium their temperatures are postulated to be equal.

A rather obvious observation is referred to as the zeroth law of thermodynamics: if two systems are equal in temperature to a third, they are equal in temperature to each other.

## Relative Temperature Scale

To establish a temperature scale, we choose the number of subdivisions, called degrees, between two fixed, easily duplicated points, the ice point and the steam point. The ice point exists when ice and water are in equilibrium at a pressure of 101 kPa ; the steam point exists when liquid water and its vapor are in a state of equilibrium at a pressure of 101 kPa . On the Fahrenheit scale there are 180 degrees between these two points; on the Celsius (formerly called the Centigrade) scale, 100 degrees. On the Fahrenheit scale the ice point is assigned the value of 32 and on the Celsius scale it is assigned the value 0 . These selections allow us to write

$$
\begin{align*}
t_{\mathrm{F}} & =\frac{9}{5} t_{C}+32  \tag{1.13}\\
t_{C} & =\frac{5}{9}\left(t_{F}-32\right) \tag{1.14}
\end{align*}
$$

## Absolute Temperature Scale

The second law of thermodynamics will allow us to define an absolute temperature scale; however, since we do not have the second law at this point and we have immediate use for absolute temperature, an empirical absolute temperature scale will be presented.

The relations between absolute and relative temperatures are

$$
\begin{align*}
& T_{\mathrm{R}}=t_{\mathrm{F}}+459.67  \tag{1.15}\\
& T_{\mathrm{K}}=t_{\mathrm{C}}+273.15 \tag{1.16}
\end{align*}
$$

(The values 460 and 273 are used where precise accuracy is not required.)
The absolute temperature on the Fahrenheit scale is given in degrees Rankine ( ${ }^{\circ} \mathrm{R}$ ), and on the Celsius scale it is given in kelvins ( K ).

EXAMPLE 1.9 The temperature of a body is $50^{\circ} \mathrm{F}$. Find its temperature in ${ }^{\circ} \mathrm{C}, \mathrm{K}$, and ${ }^{\circ} \mathrm{R}$.
Using the conversion equations,

$$
t_{\mathrm{C}}=\frac{5}{9}(50-32)=10^{\circ} \mathrm{C} \quad T_{\mathrm{K}}=10+273=283 \mathrm{~K} \quad T_{\mathrm{R}}=50+460=510^{\circ} \mathrm{R}
$$

Note that $T$ will refer to absolute temperature and $t$ to relative temperature.

### 1.10 ENERGY

A system may possess several different forms of energy. Assuming uniform properties throughout the system, the kinetic energy is given by

$$
\begin{equation*}
K E=\frac{1}{2} m V^{2} \tag{1.17}
\end{equation*}
$$

where $V$ is the velocity of each lump of substance, assumed constant over the entire system. If the velocity is not constant for each lump, then the kinetic energy is found by integrating over the system. The energy that a system possesses due to its elevation $h$ above some arbitrarily selected datum is its potential energy; it is determined from the equation

$$
\begin{equation*}
P E=m g h \tag{1.18}
\end{equation*}
$$

Other forms of energy include the energy stored in a battery, energy stored in an electrical condenser, electrostatic potential energy, and surface energy. In addition, there is the energy associated with the translation, rotation, and vibration of the molecules, electrons, protons, and neutrons, and the chemical energy due to bonding between atoms and between subatomic particles. These molecular and atomic forms of energy will be referred to as internal energy and designated by the letter $U$. In combustion, energy is released when the chemical bonds between atoms are rearranged; nuclear reactions result when changes occur between the subatomic particles. In thermodynamics our attention will be initially focused on the internal energy associated with the motion of molecules that is influenced by various macroscopic properties such as pressure, temperature, and specific volume. In a later chapter the combustion process is studied in some detail.

Internal energy, like pressure and temperature, is a property of fundamental importance. A substance always has internal energy; if there is molecular activity, there is internal energy. We need not know, however, the absolute value of internal energy, since we will be interested only in its increase or decrease.

We now come to an important law, which is often of use when considering isolated systems. The law of conseriation of energy states that the energy of an isolated system remains constant. Energy cannot be created or destroyed in an isolated system; it can only be transformed from one form to another.

Let us consider the system composed of two automobiles that hit head on and come to rest. Because the energy of the system is the same before and after the collision, the initial KE must simply have been transformed into another kind of energy-in this case, internal energy, primarily stored in the deformed metal.

EXAMPLE 1.10 A $2200-\mathrm{kg}$ automobile traveling at $90 \mathrm{kph}(25 \mathrm{~m} / \mathrm{s})$ hits the rear of a stationary, $1000-\mathrm{kg}$ automobile. After the collision the large automobile slows to $50 \mathrm{kph}(13.89 \mathrm{~m} / \mathrm{s})$, and the smaller vehicle has a speed of $88 \mathrm{kph}(24.44 \mathrm{~m} / \mathrm{s}$ ). What has been the increase in internal energy, taking both vehicles as the system?

The kinetic energy before the collision is ( $V=25 \mathrm{~m} / \mathrm{s}$ )

$$
K E_{1}=\frac{1}{2} m_{a} V_{a 1}^{2}=\left(\frac{1}{2}\right)(2200)\left(25^{2}\right)=687500 \mathrm{~J}
$$

After the collision the kinetic energy is

$$
K E_{2}=\frac{1}{2} m_{a} V_{a 2}^{2}+\frac{1}{2} m_{b} V_{b 2}^{2}=\left(\frac{1}{2}\right)(2200)\left(13.89^{2}\right)+\left(\frac{1}{2}\right)(1000)\left(24.44^{2}\right)=510900 \mathrm{~J}
$$

The conservation of energy requires that

$$
E_{1}=E_{2} \quad K E_{1}+U_{1}=K E_{2}+U_{2}
$$

Thus, $U_{2}-U_{1}=K E_{1}-K E_{2}=687500-510900=176600 \mathrm{~J}$ or 176.6 kJ .

## Solved Problems

1.1 Identify which of the following are extensive properties and which are intensive properties: (a) a $10-\mathrm{m}^{3}$ volume, (b) 30 J of kinetic energy, (c) a pressure of 90 kPa , (d) a stress of 1000 kPa , (e) a mass of 75 kg , and $(f)$ a velocity of $60 \mathrm{~m} / \mathrm{s}$. Convert all extensive properties to intensive properties assuming $m=75 \mathrm{~kg}$.
(a) Extensive. If the mass is doubled, the volume increases.
(b) Extensive. If the mass doubles, the kinetic energy increases.
(c) Intensive. Pressure is independent of mass.
(d) Intensive. Stress is independent of mass.
(e) Extensive. If the mass doubles, the mass doubles.
( $f$ ) Intensive. Velocity is independent of mass.

$$
\frac{V}{m}=\frac{10}{75}=0.1333 \mathrm{~m}^{3} / \mathrm{kg} \quad \frac{E}{m}=\frac{30}{75}=0.40 \mathrm{~J} / \mathrm{kg} \quad \frac{m}{m}=\frac{75}{75}=1.0 \mathrm{~kg} / \mathrm{kg}
$$

1.2 The gas in a cubical volume with sides at different temperatures is suddenly isolated with reference to transfer of mass and energy. Is this system in thermodynamic equilibrium? Why or why not?

It is not in thermodynamic equilibrium. If the sides of the container are at different temperatures, the temperature is not uniform over the entire volume, a requirement of thermodynamic equilibrium. After a period of time elapsed. the sides would all approach the same temperature and equilibrium would eventually be attained.
1.3 Express the following quantities in terms of base SI units ( $\mathrm{kg}, \mathrm{m}$, and s ): (a) power, (b) heat flux. and (c) specific weight.
(a) Power $=($ force $)($ velocity $)=(\mathrm{N})(\mathrm{m} / \mathrm{s})=\left(\mathrm{kg} \cdot \mathrm{m} / \mathrm{s}^{2}\right)(\mathrm{m} / \mathrm{s})=\mathrm{kg} \cdot \mathrm{m}^{2} / \mathrm{s}^{3}$
(b) Heat flux $=$ heat transfer $/$ time $=\mathrm{J} / \mathrm{s}=\mathrm{N} \cdot \mathrm{m} / \mathrm{s}=\mathrm{kg} \cdot \frac{\mathrm{m}}{\mathrm{s}^{2}} \cdot \mathrm{~m} / \mathrm{s}=\mathrm{kg} \cdot \mathrm{m}^{2} / \mathrm{s}^{3}$
(c) Specific weight $=$ weight $/$ volume $=\mathrm{N} / \mathrm{m}^{3}=\mathrm{kg} \cdot \frac{\mathrm{m}}{\mathrm{s}^{2}} / \mathrm{m}^{3}=\mathrm{kg} /\left(\mathrm{s}^{2} \cdot \mathrm{~m}^{2}\right)$
1.4 Determine the force necessary to accelerate a mass of 20 lbm at a rate of $60 \mathrm{ft} / \mathrm{sec}^{2}$ vertically upward.

A free-body diagram of the mass (Fig. 1-11) is helpful. We will assume standard gravity. Newton's second law. $\Sigma F=m a$, then allows us to write

$$
F-20=\left(\frac{20}{32.2}\right)(60) \quad \therefore F=57.3 \mathrm{lbf}
$$

Fig. 1-11
1.5 A cubic meter of water at room temperature has a weight of 9800 N at a location where $g=9.80 \mathrm{~m} / \mathrm{s}^{2}$. What is its specific weight and its density at a location where $g=9.77 \mathrm{~m} / \mathrm{s}^{2}$ ?

The mass of the water is

$$
m=\frac{W}{g}=\frac{9800}{9.8}=1000 \mathrm{~kg}
$$

Its weight where $g=9.77 \mathrm{~m} / \mathrm{s}^{2}$ is $W=m g=(1000)(9.77)=9770 \mathrm{~N}$.
Specific weight:
$\gamma=\frac{W}{V}=\frac{9770}{1}=9770 \mathrm{~N} / \mathrm{m}^{3}$
Density:

$$
\rho=\frac{m}{V}=\frac{1000}{l}=1000 \mathrm{~kg} / \mathrm{m}^{3}
$$

1.6 Assume the acceleration of gravity on a celestial body to be given as a function of altitude by the expression $g=4-1.6 \times 10^{-6} h \mathrm{~m} / \mathrm{s}^{2}$, where $h$ is in meters above the surface of the planet. A space probe weighed 100 kN on earth at sea level. Determine ( $a$ ) the mass of the probe, ( $b$ ) its weight on the surface of the planet, and (c) its weight at an elevation of 200 km above the surface of the planet.
(a) The mass of the space probe is independent of elevation. At the surface of the earth we find its mass to be

$$
m=\frac{W}{g}=\frac{100000}{9.81}=10194 \mathrm{~kg}
$$

(b) The value for gravity on the planet's surface, with $h=0$, is $g=4 \mathrm{~m} / \mathrm{s}^{2}$. The weight is then

$$
W=m g=(10194)(4)=40780 \mathrm{~N}
$$

(c) At $h=200000 \mathrm{~m}$, gravity is $g=4-\left(1.6 \times 10^{6}\right)\left(2 \times 10^{5}\right)=3.68 \mathrm{~m} / \mathrm{s}^{2}$. The probe's weight at 200 km is

$$
W=m g=(10194)(3.68)=37510 \mathrm{~N}
$$

1.7 When a body is accelerated under water, some of the water is also accelerated. This makes the body appear to have a larger mass than it actually has. For a sphere at rest this added mass is equal to the mass of one half of the displaced water. Calculate the force necessary to accelerate a $10-\mathrm{kg}, 300-\mathrm{mm}$-diameter sphere which is at rest under water at the rate of 10 $\mathrm{m} / \mathrm{s}^{2}$ in the horizontal direction. Use $\rho_{\mathrm{Ht}_{2} \mathrm{O}}=1000 \mathrm{~kg} / \mathrm{m}^{3}$.

The added mass is one-half of the mass of the displaced water:

$$
m_{\mathrm{added}}=\frac{1}{2}\left(\frac{4}{3} \pi r^{3} \rho_{\mathrm{H}_{2} \mathrm{O}}\right)=\left(\frac{1}{2}\right)\left(\frac{4}{3}\right)(\pi)\left(\frac{0.3}{2}\right)^{3}(1000)=7.069 \mathrm{~kg}
$$

The apparent mass of the body is then $m_{\text {apparent }}=m+m_{\text {udded }}=10+7.069=17.069 \mathrm{~kg}$. The force needed to accelerate this body is calculated to be

$$
F=m a=(17.069)(10)=170.7 \mathrm{~N}
$$

This is 70 percent greater than the force $(100 \mathrm{~N})$ needed to accelerate the body in air.
1.8 The force of attraction between two masses $m_{1}$ and $m_{2}$ having dimensions that are small compared with their separation distance $R$ is given by Newton's third law, $F=k m_{1} m_{2} / R^{2}$, where $k=6.67 \times 10^{-11} \mathrm{~N} \cdot \mathrm{~m}^{2} / \mathrm{kg}^{2}$. What is the total gravitational force which the sun $\left(1.97 \times 10^{30} \mathrm{~kg}\right)$ and the earth $\left(5.95 \times 10^{24} \mathrm{~kg}\right)$ exert on the moon $\left(7.37 \times 10^{22} \mathrm{~kg}\right)$ at an instant when the earth, moon, and sun form a $90^{\circ}$ angle? The earth-moon and sun-moon distances are $380 \times 10^{3}$ and $150 \times 10^{6} \mathrm{~km}$, respectively.

A free-body diagram (Fig. 1-12) is very helpful. The total force is the vector sum of the two forces. It is

$$
\begin{aligned}
& F=\sqrt{F_{e}^{2}}+F_{s}^{2}=\left\{\left[\frac{\left(6.67 \times 10^{11}\right)\left(7.37 \times 10^{22}\right)\left(5.95 \times 10^{24}\right)}{\left(380 \times 10^{6}\right)^{2}}\right]^{2}\right. \\
&\left.+\left[\frac{\left(6.67 \times 10^{-11}\right)\left(7.37 \times 10^{22}\right)\left(1.97 \times 10^{30}\right)}{\left(150 \times 10^{4}\right)^{2}}\right]^{2}\right\}^{1 / 2} \\
&=\left(4.10 \times 10^{41}+18.5 \times 10^{41}\right)^{1 / 2}=4.75 \times 10^{21} \mathrm{~N}
\end{aligned}
$$

Fig. 1-12
1.9 Calculate the density, specific weight, mass, and weight of a body that occupies $200 \mathrm{ft}^{3}$ if its specific volume is $10 \mathrm{ft}^{3} / \mathrm{lbm}$.

The quantities will not be calculated in the order asked for. The mass is

$$
m=\frac{V}{c}=\frac{200}{10}=20 \mathrm{lbm}
$$

The density is

$$
\rho=\frac{1}{r}=\frac{1}{10}=0.1 \mathrm{lbm} / \mathrm{ft}^{3}
$$

The weight is, assuming $g=32.2 \mathrm{ft} / \mathrm{sec}^{2}, W=m g=(20)(32.2 / 32.2)=20 \mathrm{lbf}$. Finally, the specific weight is calculated to be

$$
\gamma=\frac{W}{V}=\frac{20}{200}=0.1 \mathrm{lbf} / \mathrm{ft}^{3}
$$

Note that using English units, (1.6) would give

$$
\gamma=\rho g=\left(\frac{0.1 \mathrm{lbm} / \mathrm{ft}^{3}}{32.2 \mathrm{lbm}-\mathrm{ft} / \mathrm{sec}^{2}-\mathrm{lbf}}\right)\left(32.2 \mathrm{ft} / \mathrm{sec}^{2}\right)=0.1 \mathrm{lbf} / \mathrm{ft}^{3}
$$

1.10 The pressure at a given point is 50 mmHg absolute. Express this pressure in $\mathrm{kPa}, \mathrm{kPa}$ gage, and m of $\mathrm{H}_{2} \mathrm{O}$ abs if $P_{\mathrm{atm}}=80 \mathrm{kPa}$. Use the fact that mercury is 13.6 times heavier than water.

The pressure in kPa is found, using (1.1I), to be

$$
P=\gamma h=(9810)(13.6)(0.05)=6671 \mathrm{~Pa} \text { or } 6.671 \mathrm{kPa}
$$

The gage pressure is

$$
P_{\text {gage }}=P_{\mathrm{abs}}-P_{\mathrm{atm}}=6.671-80=-73.3 \mathrm{kPa} \text { gage }
$$

The negative gage pressure indicates that this is a vacuum. In meters of water we have

$$
h=\frac{P}{\gamma}=\frac{6671}{9810}=0.68 \mathrm{~m} \text { of } \mathrm{H}_{2} \mathrm{O}
$$

1.11 A manometer tube which contains mercury (Fig. 1-13) is used to measure the pressure $P_{A}$ in the air pipe. Determine the gage pressure $P_{A} \cdot \gamma_{\mathrm{Hg}}=13.6 \gamma_{\mathrm{H}_{2} \mathrm{O}} \mathrm{O}$.

Fig. 1-13

Locate a point $a$ on the left leg on the air-mercury interface and a point $b$ at the same elevation on the right leg. We then have

$$
P_{a}=P_{b} \quad P_{A}=(3)[(9810)(13.6)]=400200 \mathrm{~Pa} \text { or } 400.2 \mathrm{kPa}
$$

This is a gage pressure, since we assumed a pressure of zero at the top of the right leg.
1.12 A large chamber is separated into compartments 1 and 2, as shown in Fig. 1-14, which are kept at different pressures. Pressure gage $A$ reads 300 kPa and pressure gage $B$ reads 120 kPa . If the local barometer reads 720 mmHg , determine the absolute pressures existing in the compartments, and the reading of gage $C$.

Fig. 1-14
The atmospheric pressure is found from the barometer to be

$$
P_{\mathrm{atm}}=(9810)(13.6)(0.720)=96060 \mathrm{~Pa} \text { or } 96.06 \mathrm{kPa}
$$

The absolute pressure in compartment 1 is $P_{1}=P_{A}+P_{\text {atm }}=300+96.06=396.1 \mathrm{kPa}$. If gage $C$ read zero, gage $B$ would read the same as gage $A$. If gage $C$ read the same as gage $A$, gage $B$ would read zero. Hence, our logic suggests that

$$
P_{B}=P_{A}-P_{C} \quad \text { or } \quad P_{C}=P_{A}-P_{B}=300-120=180 \mathrm{kPa}
$$

The absolute pressure in compartment 2 is $P_{2}=P_{C}+P_{\mathrm{atm}}=180+96.06=276.1 \mathrm{kPa}$.
1.13 A tube can be inserted into the top of a pipe transporting liquids, providing the pressure is relatively low, so that the liquid fills the tube a height $h$. Determine the pressure in a water pipe if the water seeks a level at height $h=6 \mathrm{ft}$ above the center of the pipe.

The pressure is found from (1.11) to be

$$
P=\gamma h=(62.4)(6)=374 \mathrm{ibf} / \mathrm{ft}^{2} \text { or } 2.60 \mathrm{psi} \text { gage }
$$

1.14 A $10-\mathrm{kg}$ body falls from rest, with negligible interaction with its surroundings (no friction). Determine its velocity after it falls 5 m .

Conservation of energy demands that the initial energy of the system equal the final energy of the system; that is,

$$
E_{1}=E_{2} \quad \frac{1}{2} m V_{1}^{2}+m g h_{1}=\frac{1}{2} m V_{2}^{2}+m g h_{2}
$$

The initial velocity $V_{1}$ is zero, and the elevation difference $h_{1}-h_{2}=5 \mathrm{~m}$. Thus, we have

$$
m g\left(h_{1}-h_{2}\right)=\frac{1}{2} m V_{2}^{2} \quad \text { or } \quad V_{2}=\sqrt{2 g\left(h_{1}-h_{2}\right)}=\sqrt{(2)(9.81)(5)}=9.90 \mathrm{~m} / \mathrm{s}
$$

1.15 A $0.8-\mathrm{lbm}$ object traveling at $200 \mathrm{ft} / \mathrm{sec}$ enters a viscous liquid and is essentially brought to rest before it strikes the bottom. What is the increase in internal energy, taking the object and the liquid as the system? Neglect the potential energy change.

Conservation of energy requires that the sum of the kinetic energy and internal energy remain constant since we are neglecting the potential energy change. This allows us to write

$$
E_{1}=E_{2} \quad \frac{1}{2} m V_{1}^{2}+U_{1}=\frac{1}{2} m V_{2}^{2}+U_{2}
$$

The final velocity $V_{2}$ is zero, so that the increase in internal energy $\left(U_{2}-U_{1}\right)$ is given by

$$
U_{2}-U_{1}=\frac{1}{2} m V_{1}^{2}=\left(\frac{1}{2}\right)(0.8 \mathrm{lbm})\left(200^{2} \mathrm{ft}^{2} / \mathrm{sec}^{2}\right)=16,000 \mathrm{lbm}-\mathrm{ft}^{2} / \mathrm{sec}^{2}
$$

We can convert the above units to ft-lbf, the usual units on energy:

$$
U_{2}-U_{1}=\frac{16,000 \mathrm{lbm}-\mathrm{ft}^{2} / \mathrm{sec}^{2}}{32.2 \mathrm{lbm}-\mathrm{ft} / \mathrm{sec}^{2}-\mathrm{lbf}}=497 \mathrm{ft}-\mathrm{lbf}
$$

## Supplementary Problems

1.16 Draw a sketch of the following situations identifying the system or control volume, and the boundary of the system or the control surface. (a) The combustion gases in a cylinder during the power stroke, (b) the combustion gases in a cylinder during the exhaust stroke, $(c)$ a balloon exhausting air, ( $d$ ) an automobile tire being heated while driving, and ( $e$ ) a pressure cooker during operation.
Ans. (a) system
(b) control volume
(c) control volume (d) system
(e) control volume
1.17 Which of the following processes can be approximated by a quasiequilibrium process? ( $a$ ) The expansion of combustion gases in the cylinder of an automobile engine, $(b)$ the rupturing of a membrane separating a high and low pressure region in a tube, and (c) the heating of the air in a room with a baseboard heater. Ans. (a) can (b) cannot (c) cannot
1.18 A supercooled liquid is a liquid which is cooled to a temperature below that at which it ordinarily solidifies. Is this system in thermodynamic equilibrium? Why or why not? Ans. no
1.19 Convert the following to SI units: $(a) 6 \mathrm{ft},(b) 4 \mathrm{in}^{3},(c) 2$ slugs, ( $d$ ) $40 \mathrm{ft}-\mathrm{lbf}$, ( $e$ ) $2000 \mathrm{ft}-\mathrm{lbf} / \mathrm{sec}$, ( $f$ ) 150 $\mathrm{hp},(g) 10 \mathrm{ft}^{3} / \mathrm{sec}$.
Ans. (a) 1.829 m
(b) $65.56 \mathrm{~cm}^{3}$
(c) 29.18 kg
(d) $54.24 \mathrm{~N} \cdot \mathrm{~m}$
(e) $2712 \mathrm{~W} \quad(f) 111.9 \mathrm{~kW}$ (g) $0.2832 \mathrm{~m}^{3} / \mathrm{s}$
1.20 Determine the weight of a mass of 10 kg at a location where the acceleration of gravity is $9.77 \mathrm{~m} / \mathrm{s}^{2}$.

Ans. 97.7 N
1.21 The weight of a $10-\mathrm{lb}$ mass is measured at a location where $g=32.1 \mathrm{ft} / \mathrm{sec}^{2}$ on a spring scale originally calibrated in a region where $g=32.3 \mathrm{ft} / \mathrm{sec}^{2}$. What will be the reading? Ans. 9.91 lbf
1.22 The acceleration of gravity is given as a function of elevation above sea level by the relation $g=9.81$ $3.32 \times 10^{-6} \mathrm{~h} \mathrm{~m} / \mathrm{s}^{2}$, with h measured in meters. What is the weight of an airplane at 10 km elevation when its weight at sea level is 40 kN ? Ans. 39.9 kN
1.23 Calculate the force necessary to accelerate a $20,000-\mathrm{lbm}$ rocket vertically upward at the rate of 100 $\mathrm{ft} / \mathrm{sec}^{2}$. Assume $g=32.2 \mathrm{ft} / \mathrm{sec}^{2}$. Ans. $82,100 \mathrm{lbf}$
1.24 Determine the deceleration of ( $a$ ) a $2200-\mathrm{kg}$ car and ( $b$ ) a $1100-\mathrm{kg}$ car, if the brakes are suddenly applied so that all four tires slide. The coefficient of friction $\eta=0.6$ on the dry asphalt. ( $\eta=F / N$ where $N$ is the normal force and $F$ is the frictional force.) Ans. (a) $5.886 \mathrm{~m} / \mathrm{s}^{2} \quad$ (b) $5.886 \mathrm{~m} / \mathrm{s}^{2}$
1.25 The mass which enters into Newton's third law of gravitation (Problem 1.8) is the same as the mass defined by Newton's second law of motion. (a) Show that if $g$ is the gravitational acceleration, then
$g=k m_{e} / R^{2}$, where $m_{e}$ is the mass of the earth and $R$ is the radius of the earth. (b) The radius of the carth is 6370 km . Calculate its mass if the acceleration of gravity is $9.81 \mathrm{~m} / \mathrm{s}^{2}$.
Ans. (b) $5.968 \times 10^{24} \mathrm{~kg}$
1.26 (a) A satellite is orbiting the earth at 500 km above the surface with only the attraction of the earth acting on it. Estimate the speed of the satellite. [Hint: The acceleration in the radial direction of a body moving with velocity $V$ in a circular path of radius $r$ is $V^{2} / r$; this must be equal to the gravitational acceleration (see Prob. 1.22 and 1.25). Ans. $8210 \mathrm{~m} / \mathrm{s}$
(b) The first earth satellite was reported to have circled the earth at $27000 \mathrm{~km} / \mathrm{h}$ and its maximum height above the earth's surface was given as 900 km . Assuming the orbit to be circular and taking the mean diameter of the carth to be 12700 km , determine the gravitational acceleration at this height using ( $a$ ) the force of attraction between two bodies, and ( $b$ ) the radial acceleration of a moving object. Ans. (a) $7.55 \mathrm{~m} / \mathrm{s}^{2} \quad$ (b) $7.76 \mathrm{~m} / \mathrm{s}^{2}$
1.27 Complete the following if $g=9.81 \mathrm{~m} / \mathrm{s}^{2}$ and $V=10 \mathrm{~m}^{3}$.

|  | $\varepsilon\left(\mathrm{m}^{3} / \mathrm{kg}\right)$ | $\rho\left(\mathrm{kg} / \mathrm{m}^{3}\right)$ | $\gamma\left(\mathrm{N} / \mathrm{m}^{3}\right)$ | $m(\mathrm{~kg})$ | $W(\mathrm{~N})$ |
| :--- | :---: | :---: | :---: | :---: | :---: |
| $(a)$ | 20 |  |  |  |  |
| $(b)$ |  | 2 |  |  |  |
| $(c)$ |  |  | 4 |  |  |
| $(d)$ |  |  |  | 100 |  |
| $(e)$ |  |  |  | 100 |  |

Ans. (a) $0.05,0.4905,0.5,4.905 \quad$ (b) $0.5,19.62,20,196.2 \quad$ (c) $2.452,0.4077,4.077,40$ $\begin{array}{ll}\text { (d) } 0.1,10,98.1,981 & \text { (e) } 0.981,1.019,10,10.19\end{array}$
1.28 Complete the following if $P_{\text {attri }}=100 \mathrm{kPa}\left(\gamma_{\mathrm{Hg}}=13.6 \gamma_{\mathrm{H}_{2} \mathrm{O}}\right)$.

|  | kPa <br> gage | kPa <br> absolute | mmHg abs | $\mathrm{mH}_{2} \mathrm{O}$ gage |
| :---: | :---: | :---: | :---: | :---: |
| $\left(\begin{array}{l}\text { a }) \\ (b) \\ (c) \\ (d)\end{array}\right.$ | 5 | 150 |  |  |

Ans. (a) 105, 787, 0.5097 $\begin{array}{llll}\text { (b) } 50,1124,5.097 & \text { (c) }-96,4,-9.786 & \text { (d) } 294.3,394.3,2955\end{array}$
1.29 Determine the pressure difference between the water pipe and the oil pipe (Fig. 1-15).

Ans. 514 kPa

Fig. 1-15
1.30 A bell jar 250 mm in diameter sits on a flat plate and is evacuated until a vacuum of 700 mmHg exists. The local barometer reads 760 mm mercury. Find the absolute pressure inside the jar, and determine the force required to lift the jar off the plate. Neglect the weight of the jar. Ans. $8005 \mathrm{~Pa}, 4584 \mathrm{~N}$
1.31 A horizontal 2-m-diameter gate is located in the bottom of a water tank as shown in Fig. 1-16. Determine the force $F$ required to just open the gate. Ans. 77.0 kN

Fig. 1-16
1.32 A temperature of a body is measured to be $26^{\circ} \mathrm{C}$. Determine the temperature in ${ }^{\circ} \mathrm{R}, \mathrm{K}$, and ${ }^{\circ} \mathrm{F}$. Ans. $538.8^{\circ} \mathrm{R}, 299 \mathrm{~K}, 78.8^{\circ} \mathrm{F}$
1.33 The potential energy stored in a spring is given by $\frac{1}{2} K x^{2}$, where $K$ is the spring constant and $x$ is the distance the spring is compressed. Two springs are designed to absorb the kinetic energy of a $2000-\mathrm{kg}$ vehicle. Determine the spring constant necessary if the maximum compression is to be 100 mm for a vehicle speed of $10 \mathrm{~m} / \mathrm{s}$. Ans. $10 \times 10^{6} \mathrm{~N} / \mathrm{m}$
1.34 A $1500-\mathrm{kg}$ vehicle traveling at $60 \mathrm{~km} / \mathrm{h}$ collides head-on with a 1000 kg vehicle traveling at $90 \mathrm{~km} / \mathrm{h}$. If they come to rest immediately after impact, determine the increase in internal energy, taking both vehicles as the system. Ans. 521 kJ
1.35 Gravity is given by $g=9.81-3.32 \times 10^{-6} \mathrm{~h} \mathrm{~m} / \mathrm{s}^{2}$, where $h$ is the height above sea level. An airplane is traveling at $900 \mathrm{~km} / \mathrm{h}$ at an elevation of 10 km . If its weight at sea level is 40 kN , determine (a) its kinetic energy and ( $b$ ) its potential energy relative to sea level. Ans. (a) $127.4 \mathrm{MJ} \quad(b) 399.3 \mathrm{MJ}$

## Properties of Pure Substances

### 2.1 INTRODUCTION

In this chapter the relationships between pressure, specific volume, and temperature will be presented for a pure substance. A pure substance is homogeneous. It may exist in more than one phase, but each phase must have the same chemical composition. Water is a pure substance. The various combinations of its three phases have the same chemical composition. Air is not a pure substance, and liquid air and air vapor have different chemical compositions. In addition, only a simple compressible substance will be considered, that is, a substance that is essentially free of magnetic, electrical, or surface tension effects. We will find the pure, simple, compressible substance of much use in our study of thermodynamics. In a later chapter we will include some real effects that cause substances to deviate from the ideal state presented in this chapter.

### 2.2 THE $P$-v-T SURFACE

It is well known that a substance can exist in three different phases: solid. liquid, and gas. Consider an experiment in which a solid is contained in a piston-cylinder arrangement such that the pressure is maintained at a constant value; heat is added to the cylinder, causing the substance to pass through all the different phases. Our experiment is shown at various stages in Fig. 2-1. We will record the temperature and specific volume during the experiment. Start with the solid at some low temperature; then add heat until it just begins to melt. Additional heat will completely melt the solid, with the temperature remaining constant. After all the solid is melted, the temperature of the liquid again rises until vapor just begins to form; this state is called the saturated liquid state. Again, during the phase change from liquid to vapor, often called boiling, the temperature remains constant as heat is added. Finally, all the liquid is vaporized and the state of saturated capor exists, after which the temperature again rises with heat addition. This experiment is shown graphically in Fig. 2-2a. Note that the specific volume of the solid and liquid are much less than the specific volume of vapor. The scale is exaggerated in this figure so that the differences are apparent.

If the experiment is repeated a number of times using different pressures, a $T-r$ diagram results. shown in Fig. 2-2b. At pressures that exceed the pressure of the critical point, the liquid simply changes to a vapor without a constant-temperature vaporization process. Property values of the critical point for various substances are included in Table B-3.

The data obtained in an actual experiment could be presented as a three-dimensional surface with $P=P(r, T)$. Figure 2-3 shows a qualitative rendering of a substance that contracts on freezing. For a substance that expands on freezing, the solid-liquid surface would be at a smaller specific volume than for the solid surface. The regions where only one phase exists are labeled solid, liquid, and vapor. Where two phases exist simultaneously the regions are labeled solid-liquid (S-L), solid-vapor (S-V), and liquid-vapor (L-V). Along the triple line, a line of constant temperature and pressure, all three phases coexist.

The $P-\ell^{\prime}-T$ surface may be projected unto the $P-\ell$ plane, the $T-l^{\prime}$ plane, and the $P-T$ plane, thus obtaining the $P-\nu, T-\nu$, and $P-T$ diagrams shown in Fig. 2-4. Again, distortions are made so that the various regions are displayed. Note that when the triple line of Fig. 2-3 is viewed parallel to the $v$ axis it appears to be a point, hence the name triple point. A constant pressure line is shown on the $T-\psi$ diagram and a constant temperature line on the $P-v$ diagram.

Primary practical interest is in situations involving the liquid, liquid-vapor, and vapor regions. A saturated capor lies on the saturated vapor line and a saturated liquid on the saturated liquid line. The region to the right of the saturated vapor line is the superheated capor region; the region to the left of the saturated liquid line is the compressed liquid region (also called the subcooled liquid region). A

Fig. 2-1

Fig. 2-2
supercritical state is encountered when the pressure and temperature are greater than the critical values.

### 2.3 THE LIQUID-VAPOR REGION

At any state $(T, v)$ between saturated points $f$ and $g$, shown in Fig. 2-5, liquid and vapor exist as a mixture in equilibrium. Let $v_{f}$ and $v_{g}$ represent, respectively, the specific volumes of the saturated liquid and the saturated vapor. Let $m$ be the total mass of a system (such as shown in Fig. 2-1), $m_{f}$ the amount of mass in the liquid phase, and $m_{g}$ the amount of mass in the vapor phase. Then for a state of the system represented by ( $T, v$ ) the total volume of the mixture is the sum of the volume occupied by the liquid and that occupied by the vapor, or

$$
\begin{equation*}
m u=m_{f} u_{f}+m_{g} u_{g} \tag{2.1}
\end{equation*}
$$

The ratio of the mass of saturated vapor to the total mass is called the quality of the mixture, designated by the symbol $x$; it is

$$
\begin{equation*}
x=\frac{m_{g}}{m} \tag{2.2}
\end{equation*}
$$

Fig. 2-3

Fig. 2-4

Recognizing that $m=m_{f}+m_{g}$, we may write (2.1), using our definition of quality, as

$$
\begin{equation*}
v=v_{f}+x\left(v_{g}-v_{f}\right) \tag{2.3}
\end{equation*}
$$

Because the difference in saturated vapor and saturated liquid values frequently appears in calculations, we often let the subscript $f g$ denote this difference; that is,

$$
\begin{equation*}
v_{f g}=v_{g}-v_{f} \tag{2.4}
\end{equation*}
$$

Thus, (2.3) is

$$
\begin{equation*}
v=v_{f}+x v_{f g} \tag{2.5}
\end{equation*}
$$

Note that the percentage liquid by mass in a mixture is $100(1-x)$ and the percentage vapor is $100 x$.

Fig. 2-5 A $T-v$ diagram showing the saturated liquid and saturated vapor points.

### 2.4 STEAM TABLES

Tabulations have been made for many substances of the thermodynamic properties $P, i$, and $T$ and additional properties to be identified in subsequent chapters. Values are presented in the appendix in both tabular and graphical form. Table $\mathrm{C}-1$ gives the saturation properties of water as a function of saturation temperature; Table C-2 gives these properties as a function of saturation pressure. The information contained in the two tables is essentially the same, the choice being a matter of convenience. We should note, however, that in the mixture region pressure and temperature are dependent. Thus to establish the state of a mixture, if we specify the pressure, we need to specify a property other than temperature. Conversely, if we specify temperature, we must specify a property other than pressure.

Table C-3 lists the properties of superheated water vapor. To establish the state of a simple substance in the superheated region, it is necessary to specify two properties. While any two may be used, the most common procedure is to use pressure and temperature. Thus, properties such as $r$ are given in terms of the set of independent properties $P$ and $T$.

Table C-4 lists data pertaining to compressed liquid. At a given temperature the specific volume of a liquid is essentially independent of the pressure. For example, for a temperature of $100^{\circ} \mathrm{C}$ in Table C-1, the specific volume $l_{j}$ of liquid is $0.001044 \mathrm{~m}^{3} / \mathrm{kg}$ at a pressure of 100 kPa , whereas at a pressure of 10 MPa the specific volume is $0.001038 \mathrm{~m}^{3} / \mathrm{kg}$, less than a 1 percent decrease in specific volume. Thus it is common in calculations to assume that the specific volume of a compressed liquid is equal to the specific volume of the saturated liquid at the same temperature. Note, however, that the specific volume of saturated liquid increases significantly with temperature, especially at higher temperatures.

Table C-5 gives the properties of a saturated solid and a saturated vapor for an equilibrium condition. Note that the value of the specific volume of ice is relatively insensitive to temperature and pressure for the saturated-solid line. Also, it has a greater value (almost 10 percent greater) than the minimum value on the saturated-liquid line.

EXAMPLE 2.1 Determine the volume change when 1 kg of saturated water is completely vaporized at a pressure of (a) 1 kPa , (b) 100 kPa , and (c) 10000 kPa .

Table C-2 provides the necessary values. The quantity being sought is $r_{f k}=r_{k}-r_{f}$. Note that $P$ is given in MPa .
(a) 1 kPa . Thus, $t_{f g}=129.2-0.001=129.2 \mathrm{~m}^{3} / \mathrm{kg}$.
(b) $100 \mathrm{kPa}=0.1 \mathrm{MPa}$. Again, $v_{f s}=1.694-0.001=1.693 \mathrm{~m}^{3} / \mathrm{kg}$.
(c) $10000 \mathrm{kPa}=10 \mathrm{MPa}$. Finally, $\iota_{f g}=0.01803-0.00145=0.01658 \mathrm{~m}^{3} / \mathrm{kg}$.

Notice the large change in specific volume at low pressures compared with the small change as the critical point is approached. This underscores the distortion of the $P_{-l^{\prime}}$ diagram in Fig. 2-4.

EXAMPLE 2.2 Four kg of water is placed in an enclosed volume of $1 \mathrm{~m}^{3}$. Heat is added until the temperature is $150^{\circ} \mathrm{C}$. Find ( $a$ ) the pressure, ( $b$ ) the mass of vapor, and ( $c$ ) the volume of the vapor.

Table C-1 is used. The volume of 4 kg of saturated vapor at $150^{\circ} \mathrm{C}$ is $(0.3928)(4)=1.5712 \mathrm{~m}^{3}$. Since the given volume is less than this, we assume the state to be in the quality region.
(a) In the quality region the pressure is given as $P=475.8 \mathrm{kPa}$.
(b) To find the mass of the vapor we must determine the quality. It is found from (2.3), using $r=1 / 4 \mathrm{~m}^{3} / \mathrm{kg}$, as

$$
0.25=0.00109+x(0.3928-0.00109)
$$

Thus, $x=0.2489 / 0.3917=0.6354$. Using (2.2), the mass vapor is

$$
m_{g}=m x=(4)(0.6354)=2.542 \mathrm{~kg}
$$

(c) Finally, the volume of the vapor is found from

$$
V_{g}=v_{g} m_{g}=(0.3928)(2.542)=0.9985 \mathrm{~m}^{3}
$$

Note that in mixtures where the quality is not very close to zero the vapor phase occupies most of the volume. In this example, with a quality of 63.54 percent it occupies 99.85 percent of the volume.

EXAMPLE 2.3 Four kg of water is heated at a pressure of 220 kPa to produce a mixture with quality $\boldsymbol{x}=0.8$. Determine the final volume occupied by the mixture.

Use Table C-2. To determine the appropriate numbers at 220 kPa we linearly interpolate between 0.2 and 0.3 MPa . This provides, at 220 kPa ,

$$
v_{g}=\left(\frac{220-200}{300-200}\right)(0.6058-0.8857)+0.8857=0.8297 \mathrm{~m}^{3} / \mathrm{kg} \quad \iota_{f}=0.0011 \mathrm{~m}^{3} / \mathrm{kg}
$$

Note that no interpolation is necessary for $c_{f}$, since for both pressures $v_{f}$ is the same to four decimal places. Using (2.3), we now find

$$
v=v_{f}+x\left(v_{g}-v_{f}\right)=0.0011+(0.8)(0.8297-0.0011)=0.6640 \mathrm{~m}^{3} / \mathrm{kg}
$$

The total volume occupied by 4 kg is $V=m v=(4 \mathrm{~kg})\left(0.6640 \mathrm{~m}^{3} / \mathrm{kg}\right)=2.656 \mathrm{~m}^{3}$.
EXAMPLE 2.4 Two lb of water is contained in a constant-pressure container held at 540 psia. Heat is added until the temperature reaches $700^{\circ} \mathrm{F}$. Determine the final volume of the container.

Use Table C-3E. Since 540 psia lies between the table entry values, the specific volume is simply

$$
v=1.3040+(0.4)(1.0727-1.3040)=1.2115 \mathrm{ft}^{3} / \mathrm{lbm}
$$

The final volume is then $V=m u=(2)(1.2115)=2.423 \mathrm{ft}^{3}$.

### 2.5 THE IDEAL-GAS EQUATION OF STATE

When the vapor of a substance has relatively low density, the pressure, specific volume, and temperature are related by the simple equation

$$
\begin{equation*}
P v=R T \tag{2.6}
\end{equation*}
$$

where $R$ is a constant for a particular gas and is called the gas constant. This equation is an equation of state in that it relates the state properties $P, v$, and $T$; any gas for which this equation is valid is called an ideal gas or a perfect gas. Note that when using the ideal-gas equation the pressure and temperature must be expressed as absolute quantities.

The gas constant $R$ is related to a universal gas constant $\bar{R}$, which has the same value for all gases, by the relationship

$$
\begin{equation*}
R=\frac{\bar{R}}{\bar{M}} \tag{2.7}
\end{equation*}
$$

where $M$ is the molar mass, values of which are tabulated in Tables B-2 and B-3. The mole is that quantity of a substance (i.e., that number of atoms or molecules) having a mass which, measured in
grams, is numerically equal to the atomic or molecular weight of the substance. In the SI system it is convenient to use instead the kilomole ( kmol ), which amounts to $x$ kilograms of a substance of molecular weight $x$. For instance, 1 kmol of carbon is a mass of 12 kg (exactly); 1 kmol of molecular oxygen is 32 kg (very nearly). Stated otherwise, $M=12 \mathrm{~kg} / \mathrm{kmol}$ for C , and $M=32 \mathrm{~kg} / \mathrm{kmol}$ for $\mathrm{O}_{2}$. In the English system one uses the pound-mole (lbmol); for $\mathrm{O}_{2}, \mathrm{M}=32 \mathrm{lbm} / \mathrm{lbmol}$.

The value of $\bar{R}$ is

$$
\begin{equation*}
\bar{R}=8.314 \mathrm{~kJ} /(\mathrm{kmol} \cdot \mathrm{~K})=1545 \mathrm{ft}-\mathrm{lbf} /\left(\mathrm{lbmol}-{ }^{\circ} \mathrm{R}\right) \tag{2.8}
\end{equation*}
$$

For air $M$ is $28.97 \mathrm{~kg} / \mathrm{kmol}(28.97 \mathrm{lbm} / \mathrm{lbmol})$, so that for air $R$ is $0.287 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}\left(53.3 \mathrm{ft}-\mathrm{lbf} / \mathrm{lbm}-{ }^{\circ} \mathrm{R}\right)$, a value used extensively in calculations involving air.

Other forms of the ideal-gas equation are

$$
\begin{equation*}
P V=m R T \quad P=\rho R T \quad P V=n \bar{R} T \tag{2.9}
\end{equation*}
$$

where $n$ is the number of moles.
Care must be taken in using this simple convenient equation of state. A low-density $\rho$ can be experienced by either having a low pressure or a high temperature. For air the ideal-gas equation is surprisingly accurate for a wide range of temperatures and pressures; less than 1 percent error is encountered for pressures as high as 3000 kPa at room temperature, or for temperatures as low as $-130^{\circ} \mathrm{C}$ at atmospheric pressure.

The compressibility factor $Z$ helps us in determining whether or not the ideal-gas equation should be used. It is defined as

$$
\begin{equation*}
Z=\frac{P_{L^{\prime}}}{R T} \tag{2.10}
\end{equation*}
$$

and is displayed in Fig. 2-6 for nitrogen. Since air is composed mainly of nitrogen, this figure is acceptable for air also. If $Z=1$, or very nearly 1 , the ideal-gas equation can be used. If $Z$ is not approximately 1, then (2.10) may be used. Additional real gas effects (deviations from ideal-gas behavior) are considered in a subsequent chapter.

Fig. 2-6

The compressibility factor can be determined for any gas by using a generalized compressibility chart presented in Fig. H-1 in the appendix. In the generalized chart the reduced pressure $P_{R}$ and reduced temperature $T_{R}$ must be used. They are calculated from

$$
\begin{equation*}
P_{R}=\frac{P}{P_{c}} \quad T_{R}=\frac{T}{T_{c}} \tag{2.11}
\end{equation*}
$$

where $P_{c}$ and $T_{c}$ are critical-point pressure and temperature, respectively, of Table B-3.
EXAMPLE 2.5 An automobile tire with a volume of $0.6 \mathrm{~m}^{3}$ is inflated to a gage pressure of 200 kPa . Calculate the mass of air in the tire if the temperature is $20^{\circ} \mathrm{C}$.

Air is assumed to be an ideal gas at the conditions of this example. In the ideal-gas equation, $P V=m R T$, we use absolute pressure and absolute temperature. Thus, using $P_{\mathrm{atm}}=100 \mathrm{kPa}$,

$$
P=200+100=300 \mathrm{kPa} \quad \text { and } \quad T=20+273=293 \mathrm{~K}
$$

The mass is then calculated to be

$$
m=\frac{P V}{R T}=\frac{\left(300000 \mathrm{~N} / \mathrm{m}^{2}\right)\left(0.6 \mathrm{~m}^{3}\right)}{(287 \mathrm{~N} \cdot \mathrm{~m} / \mathrm{kg} \cdot \mathrm{~K})(293 \mathrm{~K})}=2.14 \mathrm{~kg}
$$

The units in the above equation should be checked.

EXAMPLE 2.6 The temperature in the atmosphere near the surface of the earth (up to an elevation of 10000 m ) can be approximated by $T(z)=15-0.00651 z^{\circ} \mathrm{C}$. Determine the pressure at an elevation of 3000 m if at $z=0$, $P=101 \mathrm{kPa}$.

Equation (1.8) relates the pressure change to the elevation change. We can put the ideal-gas cquation for air in the form

$$
P=287 \rho T=\left(\frac{287}{9.81}\right)(y T)=29.3 y T
$$

Hence, (1.8) can be written as

$$
d P=-\frac{P}{29.3 T} d z
$$

Using the given equation for $T(z)$ we have

$$
d P=-\frac{P}{(29.3)(288-0.00651 z)} d z
$$

where we have added 273 to express the temperature in kelvins. To integrate the above equation we must separate variables as

$$
\frac{d P}{P}=-\frac{d z}{(29.3)(288-0.00651 z)}
$$

Now integrate between the appropriate limits:

$$
\begin{aligned}
\int_{101}^{P} \frac{d P}{P} & =-\int_{0}^{3000} \frac{d z}{(29.3)(288-0.00651 z)}=\left(\frac{1}{29.3}\right)\left(\frac{1}{0.00651}\right) \int_{0}^{3000} \frac{-0.00651 d z}{288-0.00651 z} \\
\ln \frac{P}{101} & =[5.24 \ln (288-0.00651 z)]_{0}^{3000}=-0.368
\end{aligned}
$$

There results $P=(101)\left(e^{-0.368}\right)=69.9 \mathrm{kPa}$.

### 2.6 EQUATIONS OF STATE FOR A NONIDEAL GAS

There are many equations of state that have been recommended for use to account for nonideal-gas behavior. Such behavior occurs where the pressure is relatively high ( $>4 \mathrm{MPa}$ for many gases) or when the temperature is near the saturation temperature. There are no acceptable criteria that can be used to determine if the ideal-gas equation can be used or if the nonideal-gas equations of
this section must be used. Usually a problem is stated in such a way that it is obvious that nonideal-gas effects must be included; otherwise a problem is solved assuming an ideal gas.

The van der Waals equation of state is intended to account for the volume occupied by the gas molecules and for the attractive forces between molecules. It is

$$
\begin{equation*}
P=\frac{R T}{v-b}-\frac{a}{v^{2}} \tag{2.12}
\end{equation*}
$$

where the constants $a$ and $b$ are related to the critical-point data of Table B-3 by

$$
\begin{equation*}
a=\frac{27 R^{2} T_{c}^{2}}{64 P_{c}} \quad b=\frac{R T_{c}}{8 P_{c}} \tag{2.13}
\end{equation*}
$$

These constants are also presented in Table B-8 to simplify calculations.
An improved equation is the Redlich-Kwong equation of state:

$$
\begin{equation*}
P=\frac{R T}{v-b}-\frac{a}{v(v+b) \sqrt{T}} \tag{2.14}
\end{equation*}
$$

where the constants are given by

$$
\begin{equation*}
a=0.4275 \frac{R^{2} T_{c}^{2.5}}{P_{c}} \quad b=0.0867 \frac{R T_{c}}{P_{c}} \tag{2.15}
\end{equation*}
$$

and are included in Table B-8.
A virial equation of state presents the product $P v$ as a series expansion. The most common expansion is

$$
\begin{equation*}
P=\frac{R T}{v}+\frac{B(T)}{v^{2}}+\frac{C(T)}{v^{3}}+\cdots \tag{2.16}
\end{equation*}
$$

where interest is focused on $B(T)$ since it represents the first-order correction to the ideal gas law. The functions $B(T), C(T)$, etc., must be specified for the particular gas.

EXAMPLE 2.7 Calculate the pressure of steam at a temperature of $500^{\circ} \mathrm{C}$ and a density of $24 \mathrm{~kg} / \mathrm{m}^{3}$ using (a) the ideal-gas equation, (b) the van der Waals equation, (c) the Redlich-Kwong equation, (d) the compressibility factor, and (e) the steam table.
(a) Using the ideal-gas equation, $P=\rho R T=(24)(0.462)(773)=8570 \mathrm{kPa}$, where the gas constant for steam is found in Table B-2.
(b) Using values for $a$ and $b$ from Table B-8, the van der Waals equation provides

$$
P=\frac{R T}{v-b}-\frac{a}{v^{2}}=\frac{(0.462)(773)}{\frac{1}{24}-0.00169}-\frac{1.703}{\left(\frac{1}{24}\right)^{2}}=7950 \mathrm{kPa}
$$

(c) Using values for $a$ and $b$ from Table B-8, the Redlich-Kwong equation gives

$$
P=\frac{R T}{v-b}-\frac{a}{v(v+b) \sqrt{T}}=\frac{(0.462)(773)}{\frac{1}{24}-0.00117}-\frac{43.9}{\left(\frac{1}{24}\right)\left(\frac{1}{24}+0.00117\right) \sqrt{773}}=7930 \mathrm{kPa}
$$

(d) The compressibility factor is found from the generalized compressibility chart of Fig. H-1 in the appendix. To use the chart we must know the reduced temperature and pressure:

$$
T_{R}=\frac{T}{T_{c}}=\frac{773}{647.4}=1.19 \quad P_{R}=\frac{P}{P_{c}}=\frac{8000}{22100}=0.362
$$

where we have used the anticipated pressure from parts (a), (b), and (c). Using the compressibility chart (it is fairly insensitive to the precise values of $T_{R}$ and $P_{R}$, so estimates of these values are quite acceptable) and (2.10), we find

$$
P=\frac{Z R T}{v^{\prime}}=\frac{(0.93)(0.462)(773)}{1 / 24}=7970 \mathrm{kPa}
$$

(e) The steam table provides the most precise value for the pressure. Using $T=500^{\circ} \mathrm{C}$ and $v=1 / 24=0.0417$ $\mathrm{m}^{3} / \mathrm{kg}$, we find $P=8000 \mathrm{kPa}$. Note that the ideal-gas law has an error of 7.1 percent, and the error of each of the other three equations is less than 1 percent.

## Solved Problems

2.1 For a specific volume of $0.2 \mathrm{~m}^{3} / \mathrm{kg}$, find the quality of steam if the absolute pressure is (a) 40 kPa and (b) 630 kPa . What is the temperature of each case?
(a) Using information from Table C-2 in (2.3), we calculate the quality as follows:

$$
v^{\prime}=v_{f}+x\left(v_{g}-v_{f}\right) \quad 0.2=0.001+x(3.993-0.001) \quad \therefore x=0.04985
$$

The temperature is found in Table C-2 next to the pressure entry: $T=75.9^{\circ} \mathrm{C}$.
(b) We must interpolate to find the correct values in Table $\mathrm{C}-2$. Using the values at 0.6 and 0.8 MPa we have

$$
\tau_{g}=\left(\frac{0.03}{0.2}\right)(0.2404-0.3157)+0.3157=0.3044 \quad \tau_{f}=0.0011
$$

Using (2.3), we have

$$
0.2=0.0011+x(0.3044-0.0011) \quad \therefore x=0.6558
$$

The temperature is interpolated to be

$$
T=\left(\frac{0.03}{0.2}\right)(170.4-158.9)+158.9=160.6^{\circ} \mathrm{C}
$$

2.2 Calculate the specific volume of water at (a) $160^{\circ} \mathrm{C}$ and (b) $221^{\circ} \mathrm{C}$ if the quality is 85 percent.
(a) Using the entries from Table $\mathrm{C}-1$ and (2.3) we find

$$
l_{l}=v_{f}+x\left(v_{g}-v_{f}\right)=0.0011+(0.85)(0.3071-0.0011)=0.2612
$$

(b) We must interpolate to find the values for $v_{g}$ and $\iota_{f}$. Using entries at $220^{\circ} \mathrm{C}$ and $230^{\circ} \mathrm{C}$, we determine

$$
v_{g}=\left(\frac{1}{10}\right)(0.07159-0.08620)+0.08620=0.08474 \quad l_{f}=0.00120
$$

Using (2.3) $t=0.00120+(0.85)(0.08474-0.00120)=0.07221 \mathrm{~m}^{3} / \mathrm{kg}$.
2.3 Ten lb of steam is contained in a volume of $50 \mathrm{ft}^{3}$. Find the quality and the pressure if the temperature is $263^{\circ} \mathrm{F}$.

The temperature is not a direct entry in Table C-1E. We interpolate between temperatures of $260^{\circ} \mathrm{F}$ and $270^{\circ} \mathrm{F}$ to find

$$
t_{g}=\left(\frac{3}{10}\right)(10.066-11.768)+11.768=11.257 \quad v_{f}=0.017
$$

From the given information we calculate

$$
\imath=\frac{V}{m}=\frac{50}{10}=5.0 \mathrm{ft}^{3} / \mathrm{lbm}
$$

The quality is found from (2.3) as follows:

$$
5=0.017+x(11.257-0.017) \quad \therefore x=0.4433
$$

The pressure is interpolated to be

$$
P=\left(\frac{3}{10}\right)(41.85-35.42)+35.42=37.35 \mathrm{psia}
$$

2.4 Saturated water occupies a volume of $1.2 \mathrm{~m}^{3}$. Heat is added until it is completely vaporized. If the pressure is held constant at 600 kPa , calculate the final volume.

The mass is found, using $i_{j}$ from Table C-2, to be

$$
m=\frac{V}{v_{f}}=\frac{1.2}{0.0011}=1091 \mathrm{~kg}
$$

When completely vaporized, the specific volume will be $v_{g}$, so that

$$
V=m c_{k}=(1091)(0.3157)=344.4 \mathrm{~m}^{3}
$$

2.5 Water is contained in a rigid vessel of $5 \mathrm{~m}^{3}$ at a quality of 0.8 and a pressure of 2 MPa . If the pressure is reduced to 400 kPa by cooling the vessel, find the final mass of vapor $m_{k}$ and mass of liquid $m_{f}$.

The initial specific volume is found, using data from Table C-2, to be

$$
v=v_{f}+x\left(v_{\mathrm{g}}-v_{f}\right)=0.00118+(0.8)(0.09963-0.00118)=0.07994 \mathrm{~m}^{3} / \mathrm{kg}
$$

Since the vessel is rigid, the specific volume does not change. Hence the specific volume at a pressure of 400 kPa is also 0.07994 . We can then find the quality as follows:

$$
0.07994=0.0011+x(0.4625-0.0011) \quad \therefore x=0.1709
$$

The total mass of water is

$$
m=\frac{V}{l}=\frac{5}{0.07994}=62.55 \mathrm{~kg}
$$

Now (2.2) gives the mass of vapor: $m_{g}=x m=(0.1709)(62.55)=10.69 \mathrm{~kg}$. The mass of liquid is then

$$
m_{f}=m-m_{g}=62.55-10.69=51.86 \mathrm{~kg}
$$

2.6 Water exists at the critical point in a rigid container. The container and water are cooled until a pressure of 10 psia is reached. Calculate the final quality.

The initial specific volume as found in Table C-2E at a pressure of 3203.6 psia is $r_{1}=0.05053$ $\mathrm{ft}^{3} / \mathrm{lbm}$. Since the container is rigid, the specific volume does not change. Hence, at $P_{2}=10$ psia we have

$$
r_{2}=0.05053=0.01659+x_{2}(38.42-0.01659) \quad \therefore x_{2}=0.000884
$$

This shows that the final state is very close to the saturated liquid line.
2.7 Two kg of Freon 12 is contained in a piston-cylinder arrangement, as sketched in Fig. 2-1. The $20-\mathrm{mm}$-dia, $48-\mathrm{kg}$ piston is allowed to rise freely until the temperature reaches $160^{\circ} \mathrm{C}$. Calculate the final volume.

The absolute pressure inside the cylinder results from the atmospheric pressure and the weight of the piston:

$$
P=P_{\mathrm{atm}}+\frac{W}{A}=100000+\frac{(48)(9.81)}{\pi(0.02)^{2} / 4}=1.60 \times 10^{6} \mathrm{~Pa} \text { or } 1.6 \mathrm{MPa}
$$

At this pressure and a temperature of $160^{\circ} \mathrm{C}$, the Freon 12 is superheated. From Table D-3 the specific volume is $t=0.0169 \mathrm{~m}^{3} / \mathrm{kg}$. The volume is then

$$
V=m u=(2)(0.0169)=0.0338 \mathrm{~m}^{3}
$$

2.8 A mass of 0.01 kg of steam at a quality of 0.9 is contained in the cylinder shown in Fig. 2-7. The spring just touches the top of the piston. Heat is added until the spring is compressed 15.7 cm . Calculate the final temperature.

The initial pressure in the cylinder is due to the atmospheric pressure and the weight of the piston:

$$
P_{1}=P_{\mathrm{atm}}+\frac{W}{A}=100000+\frac{(160)(9.81)}{\pi(0.2)^{2} / 4}=150000 \mathrm{~Pa} \quad \text { or } 0.150 \mathrm{MPa}
$$

The initial specific volume is found by interpolating in Table C-2:

$$
l_{1}=v_{f}+x\left(c_{g_{f}} l_{f}\right)=0.0011+(0.9)(1.164-0.0011)=1.048 \mathrm{~m}^{3} / \mathrm{kg}
$$

Fig. 2-7

The initial volume contained in the cylinder is $V_{1}=v_{1} m=(1.048)(0.01)=0.01048 \mathrm{~m}^{3}$. The height $H$ can now be calculated as follows:

$$
V_{1}=\frac{\pi d^{2}}{4} H \quad 0.01048=\frac{\pi(0.2)^{2}}{4} H \quad \therefore H=0.334 \mathrm{~m}
$$

The final volume is then

$$
V_{2}=\frac{\pi d^{2}}{4}(H+0.157)=\frac{\pi(0.2)^{2}}{4}(0.334+0.157)=0.01543 \mathrm{~m}^{3}
$$

The final specific volume is

$$
r_{2}=\frac{V_{2}}{m}=\frac{0.01543}{0.01}=1.543 \mathrm{~m}^{3} / \mathrm{kg}
$$

The final pressure is

$$
P_{2}=P_{1}+\frac{K x}{\pi d^{2} / 4}=150000+\frac{(50000)(0.157)}{\pi(0.2)^{2} / 4}=400000 \mathrm{~Pa} \quad \text { or } 0.40 \mathrm{MPa}
$$

This pressure and specific volume allow us to determine the temperaturc. It is obviously greater than the last table entry of $800^{\circ} \mathrm{C}$ in the superheat table. We can extrapolate or use the ideal-gas law:

$$
T_{2}=\frac{P_{2} v_{2}}{R}=\frac{(400)(1.543)}{0.4615}=1337 \mathrm{~K} \text { or } 1064^{\circ} \mathrm{C}
$$

2.9 Estimate the difference between the weight of air in a room that measures $20 \times 100 \times 10 \mathrm{ft}$ in the summer when $T=90^{\circ} \mathrm{F}$ and the winter when $T=10^{\circ} \mathrm{F}$. Use $P=14$ psia.

The masses of air in the summer and winter are

$$
\begin{aligned}
& m_{\mathrm{S}}=\frac{P V}{R T}=\frac{(14)(144)[(20)(100)(10)]}{(53.3)(90+460)}=1375.4 \mathrm{lbm} \\
& m_{\mathrm{w}}=\frac{(14)(144)[(20)(100)(10)]}{(53.3)(10+460)}=1609.5 \mathrm{lbm}
\end{aligned}
$$

The difference in the two masses is $\Delta m=1609.5-1375.4=234.1 \mathrm{lbm}$. Assuming a standard gravity the weight and mass are numerically equal, so that $\Delta W=234.1 \mathrm{lbf}$.
2.10 A pressurized can contains air at a gage pressure of 40 psi when the temperature is $70^{\circ} \mathrm{F}$. The can will burst when the gage pressure reaches 200 psi. At what temperature will the can burst?

We will assume the volume to remain constant as the temperature increases. Using (2.9), we can solve for $V$ and write

$$
V=\frac{m R T_{1}}{P_{1}}=\frac{m R T_{2}}{P_{2}}
$$

Since $m$ and $R$ are constant.

$$
\frac{T_{1}}{P_{1}}=\frac{T_{2}}{P_{2}}
$$

Using absolute values for the pressure and temperature, we find that

$$
T_{2}=T_{1} \frac{P_{2}}{P_{1}}=(70+460) \frac{(200+14.7)(144)}{(40+14.7)(144)}=2080^{\circ} \mathrm{R}=1620^{\circ} \mathrm{F}
$$

## Supplementary Problems

2.11 Using the steam tables $C-1$ and $C-2$ in the appendix, plot to scale the (a) $P-t$, ( $b$ ) $P-T$, and (c) $T-t$ diagrams. Choose either a linear-linear plot or a log-log plot. Note the distortions of the various figures in Sections 2.2 and 2.3. Such distortions are necessary if the various regions are to be displayed.
2.12 Calculate the specific volume for the following situations: (a) water at $200^{\circ} \mathrm{C}, 80 \%$ quality; ( $b$ ) Freon 12 at $-60^{\circ} \mathrm{C} .90 \%$ quality: (c) ammonia at $500 \mathrm{kPa}, 85 \%$ quality.
Ans. (a) $0.1022 \mathrm{~m}^{3} / \mathrm{kg} \quad$ (b) $0.5736 \mathrm{~m}^{3} / \mathrm{kg} \quad$ (c) $0.21 .33 \mathrm{~m}^{3} / \mathrm{kg}$
2.13 The quality of each of the following substances is $80 \%$. Calculate the specific volume. (a) Water at 500 psia; ( $b$ ) Froon 12 at 80 psia ; ( $c$ ) ammonia at $20^{\circ} \mathrm{F}$.
Ans. (a) $0.7466 \mathrm{ft}^{3} / \mathrm{lbm} \quad$ (b) $0.4078 \mathrm{ft}^{3} / \mathrm{lbm} \quad$ (c) $4.733 \mathrm{ft}^{3} / \mathrm{lbm}$
2.14 Five $k g$ of steam occupies a volunce of $10 \mathrm{~m}^{3}$. Find the quality and the pressure if the temperature is measured at (a) $40^{\circ} \mathrm{C}$ and (b) $86^{\circ} \mathrm{C}$.
Ans. (a) $0.1024,7.383 \mathrm{kPa} \quad$ (b) $0.7312,60.3 \mathrm{kPa}$
2.15 Determine the final volume of a mixture of water and steam if 3 kg of water is heated at a constant pressure until the quality is 60 percent. The pressure is $(a) 25 \mathrm{kPa}$ and (b) 270 kPa .
Ans. (a) $11.6 \mathrm{~m}^{3} \quad$ (b) $1.24 \mathrm{~m}^{3}$
2.16 Two kg of saturated water at 125 kPa is completely vaporized. Calculate the volume ( $a$ ) before and ( $b$ ) after. Ans. (a) $0.002 \mathrm{~m}^{3} \quad$ (b) $2.76 \mathrm{~m}^{3}$
2.17 The temperature of 10 lb of water is held constant at $205^{\circ} \mathrm{F}$. The pressure is reduced from a very high value until vaporization is complete. Determine the final volume of the steam. Ans. $307.2 \mathrm{ft}^{3}$
2.18 A rigid vessel with a volume of $10 \mathrm{~m}^{3}$ contains a water-vapor mixture at 400 kPa . If the quality is 60 percent, find the mass. The pressure is lowered to 300 kPa by cooling the vessel; find $m_{k}$ and $m_{f}$. Ans. 35.98 kg .16 .47 kg .19 .51 kg
2.19 Steam with a quality of 0.85 is contained in a rigid vessel at a pressure of 200 kPa . Heat is then added until the temperature reaches ( $a$ ) $400^{\circ} \mathrm{C}$ and ( $b$ ) $140^{\circ} \mathrm{C}$. Determine the final pressures.
Ans. (a) $415 \mathrm{kPa} \quad$ (b) 269 kPa
2.20 A rigid vessel contains water at $400^{\circ} \mathrm{F}$. Heat is to be added so that the water passes through the critical point. What should the quality be at the temperature of $400^{\circ} \mathrm{F}$ ? Ans. 0.01728
2.21 Freon 12 is contained in a sealed glass container at $50^{\circ} \mathrm{C}$. As it is cooled, vapor droplets are noted condensing on the sidewalls at $20^{\circ} \mathrm{C}$. Find the original pressure in the container. Ans. 650 kPa
2.22 Two kg of water is contained in a piston-cylinder arrangement by a $16000-\mathrm{kg}, 2-\mathrm{m}$-diameter, frictionless piston. See Fig. 2-1. Heat is added until the temperature reaches (a) $400^{\circ} \mathrm{C}$, (b) $650^{\circ} \mathrm{C}$, and (c) $140^{\circ} \mathrm{C}$. Calculate the final volume. Ans. (a) $4.134 \mathrm{~m}^{3} \quad$ (b) $5.678 \mathrm{~m}^{3} \quad$ (c) $2.506 \mathrm{~m}^{3}$
2.23 Two kg of steam at a quality of 0.80 is contained in the volume shown (Fig. 2-8). A spring is then brought in contact with the top of the piston and heat is added until the temperature reaches $500^{\circ} \mathrm{C}$. Determine the final pressure. (The force in the spring is $K x$, where $x$ is the displacement of the spring. This results in a trial-and-crror solution.) Ans. 220 kPa

Fig. 2-8
2.24 Determine the volume occupied by 10 kg water at a pressure of 10 MPa and a temperature of (a) $5^{\circ} \mathrm{C}$, (b) $200^{\circ} \mathrm{C}$, (c) $400^{\circ} \mathrm{C}$, (d) $800^{\circ} \mathrm{C}$, (e) $1500^{\circ} \mathrm{C}$, and ( $f$ ) $-10^{\circ} \mathrm{C}$.
Ans. (a) $0.00996 \mathrm{~m}^{3}$
(b) $0.0115 \mathrm{~m}^{3}$
(c) $0.2641 \mathrm{~m}^{3}$
(d) $0.4859 \mathrm{~m}^{3}$
(e) $0.8182 \mathrm{~m}^{3}$ (f) $0.01089 \mathrm{~m}^{3}$
2.25 For air at 100 psia and $60^{\circ} \mathrm{F}$ calculate ( $a$ ) the density, $(b)$ the specific volume, ( $c$ ) the specific weight if $g=32.1 \mathrm{ft} / \mathrm{scc}^{2}$, and $(d)$ the mass contained in $200 \mathrm{ft}^{3}$.
Ans. (a) $0.5196 \mathrm{lbm} / \mathrm{ft}^{3}$
(b) $1.925 \mathrm{ft}^{3} / \mathrm{lbm}$
(c) $0.518 \mathrm{lbf} / \mathrm{ft}^{3}$
(d) 103.9 lbm
2.26 Provide the missing information for air at an elevation where $g=9.82 \mathrm{~m} / \mathrm{s}^{2}$.

|  | $P(\mathrm{kPa})$ | $T\left({ }^{\circ} \mathrm{C}\right)$ | $v\left(\mathrm{~m}^{3} / \mathrm{kg}\right)$ | $\rho\left(\mathrm{kg} / \mathrm{m}^{3}\right)$ | $\gamma\left(\mathrm{N} / \mathrm{m}^{3}\right)$ |
| :--- | :---: | :---: | :---: | :---: | :---: |
| $(a)$ | 100 | 20 |  |  |  |
| $(b)$ |  | 100 | 2 |  |  |
| $(c)$ | 500 |  | 0.1 |  | 20 |
| $(d)$ |  | 400 |  | 2 |  |
| $(e)$ | 200 |  |  |  |  |

Ans.
(a) $0.8409,1.189,11.68$
(b) $53.53,0.5,4.91$
(c) $-98.8,10,98.2$,
(d) $393.4,0.491,2.037$ (e) $75.4,0.5,19.64$
2.27 Assuming the atmosphere to be isothermal at an average temperature of $-20^{\circ} \mathrm{C}$, determine the pressure at elevations of (a) 3000 m and (b) 10000 m . Let $P=101 \mathrm{kPa}$ at the earth's surface. Compare with measured values of 70.1 kPa and 26.5 kPa , respectively, by calculating the percent error.
Ans. (a) $67.3 \mathrm{kPa},-3.99 \%$
(b) $26.2 \mathrm{kPa},-1.13 \%$
2.28 (a) Assuming the temperature in the atmosphere to be given by $T=15-0.00651 z{ }^{\circ} \mathrm{C}$, determine the pressure at an elevation of 10 km . Let $P=101 \mathrm{kPa}$ at sea level. ( $b$ ) Compare the result of ( $a$ ) with a measured value of 26.5 kPa by calculating the percent error. Ans. (a) 26.3 kPa , (b) $-0.74 \%$
2.29 The gage pressure reading on an automobile tire is 35 psi when the temperature is $0^{\circ} \mathrm{F}$. The automobile is driven to a warmer climate and the temperature increases to $120^{\circ} \mathrm{F}$. Estimate the increased pressure in the tire.
Ans. 47.97 psig
2.30 Nitrogen is contained in a $4-\mathrm{m}^{3}$ rigid vessel at a pressure of 4200 kPa . Determine the mass if the temperature is (a) $30^{\circ} \mathrm{C}$ and $(b)-120^{\circ} \mathrm{C}$.
Ans. (a) $0.1867 \mathrm{~kg} \quad$ (b) 0.3697 kg
2.31 Estimate the pressure of nitrogen at a temperature of 220 K and a specific volume of $0.04 \mathrm{~m}^{3} / \mathrm{kg}$ using ( $a$ ) the ideal-gas equation, ( $b$ ) the van der Waals equation, ( $c$ ) the Redlich-Kwong equation, and ( $d$ ) the compressibility factor.
Ans. (a) 1630 kPa
(b) 1580 kPa
(c) 1590 kPa
(d) 1600 kPa
2.32 Ten kg of $600^{\circ} \mathrm{C}$ steam is contained in a 182 -liter tank. Find the pressure using ( $a$ ) the ideal-gas equation, ( $b$ ) the van der Waals equation, ( $c$ ) the Redlich-Kwong equation, ( $d$ ) the compressibility factor. and ( $e$ ) the steam tables.
Ans. (a) 22.2 MPa
(b) 19.3 MPa
(c) 19.5 MPa
(d) 19.5 MPa
(e) 20 MPa
2.33 Freon 12 at $200^{\circ} \mathrm{F}$ has a density of $1.84 \mathrm{lbm} / \mathrm{ft}^{3}$. Find the pressure using (a) the ideal-gas equation, (b) the van der Waals equation, (c) the Redlich-Kwong equation, (d) the compressibility factor, and (e) the Freon 12 tables.
Ans. (a) 108 psia
(b) 101 psia
(c) 100 psia
(d) 100 psia
(e) 100 psia

## Work and Heat

### 3.1 INTRODUCTION

In this chapter we will discuss the two quantities that result from energy transfer across the boundary of a system: work and heat. This will lead into a presentation of the first law of thermodynamics. Work will be discussed in detail and will be calculated for several common situations. Heat, however, is a quantity that requires substantial analysis for its calculation. In most engineering programs the subject of heat transfer is covered in a separate course. In thermodynamics, heat is either a given quantity or it is calculated as an unknown in an algebraic equation.

### 3.2 DEFINITION OF WORK

The term work is so broad that we must be very particular in a technical definition. It must comprehend, for example, the work done by expanding exhaust gases after combustion occurs in the cylinder of an automobile engine, as shown in Fig. 3-1. The energy released during the combustion process is transferred to the crankshaft by means of the connecting rod, in the form of work. Thus, in this example, work can be thought of as energy being transferred across the boundary of a system, the system being the gases in the cylinder.

Work, designated $W$, is often defined as the product of a force and the distance moved in the direction of the force. This is a mechanical definition of work. A more general definition of work is the thermodynamic definition: Work, an interaction between a system and its surroundings, is done by a system if the sole external effect on the surroundings could be the raising of a weight. The magnitude of the work is the product of the weight and the distance it could be lifted. Figure $3-2 b$ shows that the interaction of Fig. 3-2a qualifies as work in the thermodynamic sense.

The convention chosen for positive work is that if the system performs work on the surroundings it is positive. A piston compressing a fluid is doing negative work, whereas a fluid expanding against a piston is doing positive work. The units of work are quickly observed from the units of a force multiplied by a distance: in the SI system, newton-meters ( $\mathrm{N} \cdot \mathrm{m}$ ) or joules ( J ); in the English system, ft -lbf.

The rate of doing work, designated $\dot{W}$, is called power. In the SI system, power has units joules per second ( $\mathrm{J} / \mathrm{s}$ ), or watts ( W ); in the English system, $\mathrm{ft}-\mathrm{lbf} / \mathrm{sec}$. We will find occasion to use the unit of horsepower because of its widespread use in rating engines. To convert we simply use $1 \mathrm{hp}=0.746$ $\mathrm{kW}=550 \mathrm{ft}-\mathrm{lbf} / \mathrm{sec}$.

The work associated with a unit mass will be designated $w$ :

$$
\begin{equation*}
w=\frac{W}{m} \tag{3.1}
\end{equation*}
$$

A final general comment concerning work relates to the choice of the system. Note that if the system in Fig. 3-2 included the entire battery-resistor setup in part ( $a$ ), or the entire battery-motor-pulley-weight setup in part ( $b$ ), no energy would cross the system boundary, with the result that no work would be done. The identification of the system is very important in determining work.

### 3.3 QUASIEQUILIBRIUM WORK DUE TO A MOVING BOUNDARY

There are a number of work modes that occur in various engineering situations. These include the work needed to stretch a wire, to rotate a shaft, to move against friction, to cause a current to flow through a resistor, and to charge a capacitor. Many of these work modes are covered in other courses.

Fig. 3-1

(a)

(b)

Fig. 3-2

In this book we are primarily concerned with the work required to move a boundary against a pressure force.

Consider the piston-cylinder arrangement shown in Fig. 3-3. There is a seal to contain the gas in the cylinder, the pressure is uniform throughout the cylinder, and there are no gravity, magnetic, or electric effects. This assures us of a quasiequilibrium process, one in which the gas is assumed to pass through a series of equilibrium states. Now, allow an expansion of the gas to occur by moving the piston upward a small distance $d l$. The total force acting on the piston is the pressure times the area of the piston. This pressure is expressed as absolute pressure since pressure is a result of molecular activity; any molecular activity will yield a pressure which will result in work being done when the boundary moves. The infinitesimal work which the system (the gas) does on the surroundings (the piston) is then the force multiplied by the distance:

$$
\begin{equation*}
\delta W=P A d l \tag{3.2}
\end{equation*}
$$

Fig. 3-3

The symbol $\delta W$ will be discussed shortly. The quantity $A d l$ is simply $d V$, the differential volume, allowing (3.2) to be written in the form

$$
\begin{equation*}
\delta W=P d V \tag{3.3}
\end{equation*}
$$

As the piston moves from some position $l_{1}$ to another position $l_{2}$, the above expression can be integrated to give

$$
\begin{equation*}
W_{1-2}=\int_{V_{1}}^{V_{2}} P d V \tag{3.4}
\end{equation*}
$$

where we assume the pressure is known for each position as the piston moves from volume $V_{1}$ to volume $V_{2}$. Typical pressure-volume diagrams are shown in Fig. 3-4. The work $W_{1-2}$ is the area under the $P-V$ curve.

Fig. 3-4

Consideration of the integration process highlights two very important features in (3.4). First, as we proceed from state 1 to state 2 , the area representing the work is very dependent on the path that we follow. That is, states 1 and 2 in Fig. $3-4(a)$ and $(b)$ are identical, yet the areas under the $P-V$ curves are very different; in addition to being dependent on the end points, work depends on the actual path that connects the two end points. Thus, work is a path function, as contrasted to a point function, which is dependent only on the end points. The differential of a path function is called an inexact differential, whereas the differential of a point function is an exact differential. An inexact differential will be denoted with the symbol $\delta$. The integral of $\delta W$ is $W_{1-2}$, where the subscript emphasizes that the work is associated with the path as the process passes from state 1 to state 2 ; the subscript may be omitted, however, and work done written simply as $W$. We would never write $W_{i}$ or $W_{2}$, since work is not associated with a state but with a process. Work is not a property. The integral of an exact differential, for example $d T$, would be

$$
\begin{equation*}
\int_{T_{1}}^{T_{2}} d T=T_{2}-T_{1} \tag{3.5}
\end{equation*}
$$

where $T_{1}$ is the temperature at state 1 and $T_{2}$ is the temperature at state 2 .
The second observation to be made from (3.4) is that the pressure is assumed to be constant throughout the volume at each intermediate position. The system passes through each equilibrium state shown in the $P-V$ diagrams of Fig. 3-4. An equilibrium state can usually be assumed even though the variables may appear to be changing quite rapidly. Combustion is a very rapid process that cannot be modeled as a quasiequilibrium process. The other processes in the internal combustion engine (expansion, exhaust, intake, and compression) can be assumed to be quasiequilibrium processes; they occur at a slow rate, thermodynamically.

As a final comment regarding work we may now discuss what is meant by a simple system, as defined in Chapter 1. For a system free of surface, magnetic, and electrical effects the only work mode is that due to pressure acting on a moving boundary. For such simple systems only two independent
variables are necessary to establish an equilibrium state of the system composed of a homogeneous substance. If other work modes are present, such as a work mode due to an electric field, then additional independent variables would be necessary, such as the electric field intensity.

EXAMPLE 3.1 One kg of steam with a quality of 20 percent is heated at a constant pressure of 200 kPa until the temperature reaches $400^{\circ} \mathrm{C}$. Calculate the work done by the steam.

The work is given by

$$
W=\int P d V=P\left(V_{2}-V_{1}\right)=m P\left(v_{2}-v_{1}\right)
$$

To evaluate the work we must determine $v_{1}$ and $v_{2}$. Using Table C-2 we find

$$
v_{1}=v_{f}+x\left(v_{g}-v_{f}\right)=0.001061+(0.2)(0.8857-0.001061)=0.1780 \mathrm{~m}^{3} / \mathrm{kg}
$$

From the superheat table we locate state 2 at $T_{2}=400^{\circ} \mathrm{C}$ and $P_{2}=0.2 \mathrm{MPa}$ :

$$
v_{2}=1.549 \mathrm{~m}^{3} / \mathrm{kg}
$$

The work is then

$$
W=(1)(200)(1.549-0.1780)=274.2 \mathrm{~kJ}
$$

Note: With the pressure having units of $\mathbf{k P a}$, the result is in kJ .

EXAMPLE 3.2 A $110-\mathrm{mm}$-diameter cylinder contains $100 \mathrm{~cm}^{3}$ of water at $60^{\circ} \mathrm{C}$. A $50-\mathrm{kg}$ piston sits on top of the water. If heat is added until the temperature is $200^{\circ} \mathrm{C}$, find the work done.

The pressure in the cylinder is due to the weight of the piston and remains constant. Assuming a frictionless seal (this is always done unless information is given to the contrary), a force balance provides

$$
m g=P A-P_{\mathrm{atm}} A \quad(50)(9.81)=(P-100000) \frac{\pi(0.110)^{2}}{4} \quad \therefore P=151600 \mathrm{~Pa}
$$

The atmospheric pressure is included so that absolute pressure results. The volume at the initial state 1 is given as

$$
V_{1}=100 \times 10^{-6}=10^{-4} \mathrm{~m}^{3}
$$

Using $v_{1}$ at $60^{\circ} \mathrm{C}$, the mass is calculated to be

$$
m=\frac{V_{1}}{v_{1}}=\frac{10^{-4}}{0.001017}=0.09833 \mathrm{~kg}
$$

At state 2 the temperature is $200^{\circ} \mathrm{C}$ and the pressure is 0.15 MPa (this pressure is within 1 percent of the pressure of 0.1516 MPa , so it is acceptable). The volume is then

$$
V_{2}=m v_{2}=(0.09833)(1.444)=0.1420 \mathrm{~m}^{3}
$$

Finally, the work is calculated to be

$$
W=P\left(V_{2}-V_{1}\right)=151(600)(0.1420-0.0001)=21500 \mathrm{~J} \quad \text { or } 21.5 \mathrm{~kJ}
$$

EXAMPLE 3.3 Energy is added to a piston-cylinder arrangement, and the piston is withdrawn in such a way that the quantity $P V$ remains constant. The initial pressure and volume are 200 kPa and $2 \mathrm{~m}^{3}$, respectively. If the final pressure is 100 kPa , calculate the work done by the gas on the piston.

The work is found from (3.4) to be

$$
W_{1-2}=\int_{2}^{V_{2}} P d V=\int_{2}^{V_{2} C} \frac{C}{V} d V
$$

where we have used $P V=C$. To calculate the work we must find $C$ and $V_{2}$. The constant $C$ is found from

$$
C=P_{1} V_{1}=(200)(2)=400 \mathrm{~kJ}
$$

To find $V_{2}$ we use $P_{2} V_{2}=P_{1} V_{1}$, which is, of course, the equation that would result from an isothermal process (constant temperature) involving an ideal gas. This can be written as

$$
V_{2}=\frac{P_{1} V_{1}}{P_{2}}=\frac{(200)(2)}{100}=4 \mathrm{~m}^{3}
$$

Finally,

$$
W_{1-2}=\int_{2}^{4} \frac{400}{V} d V=400 \ln \frac{4}{2}=277 \mathrm{~kJ}
$$

This is positive, since work is done during the expansion process by the system (the gas contained in the cylinder).
EXAMPLE 3.4 Determine the horsepower required to overcome the wind drag on a streamlined car traveling $90 \mathrm{~km} / \mathrm{h}$ if the drag coefficient $C_{D}$ is 0.2 . The drag force is given by $F_{D}=\frac{1}{2} \rho V^{2} A C_{D}$, where $A$ is the projected area of the car and $V$ is the velocity. The density $\rho$ of air is $1.23 \mathrm{~kg} / \mathrm{m}^{3}$. Use $A=2.3 \mathrm{~m}^{2}$.

To find the drag force on a car we must express the velocity in $\mathrm{m} / \mathrm{s}$ : $V=(90)(1000 / 3600)=25 \mathrm{~m} / \mathrm{s}$. The drag force is then

$$
\begin{aligned}
F_{D} & =\frac{1}{2} p V^{2} A C_{D} \\
& =\left(\frac{1}{2}\right)(1.23)\left(25^{2}\right)(2.3)(0.2)=177 \mathrm{~N}
\end{aligned}
$$

To move this drag force at $25 \mathrm{~m} / \mathrm{s}$ the engine must do work at the rate

$$
\dot{W}=F_{D} V=(177)(25)=4425 W
$$

The horsepower is then

$$
\mathrm{Hp}=\frac{4425 \mathrm{~W}}{746 \mathrm{~W} / \mathrm{hp}}=5.93 \mathrm{hp}
$$

### 3.4 NONEQUILIBRIUM WORK

It must be emphasized that the area on a $P-V$ diagram represents the work for a quasiequilibrium process only. For nonequilibrium processes the work cannot be calculated using $\int P d V$; either it must be given for the particular process or it must be determined by some other means. Two examples will be given. Consider a system to be formed by the gas in Fig. 3-5. In part ( $a$ ) work is obviously crossing the boundary of the system by means of the rotating shaft; yet the volume does not change. We could calculate the work input by multiplying the weight by the distance it dropped, neglecting friction in the pulley system. This would not, however, be equal to $\int P d V$, which is zero. The paddle wheel provides us with a nonequilibrium work mode.

Fig. 3-5
Suppose the membrane in Fig. 3-5b ruptures, allowing the gas to expand and fill the evacuated volume. There is no resistance to the expansion of the gas at the moving boundary as the gas fills the volume; hence, there is no work done. Yet there is a change in volume. The sudden expansion is a nonequilibrium process, and again we cannot use fPdV to calculate the work.

EXAMPLE 3.5 A 100 - kg mass drops 3 m , resulting in an increased volume in the cylinder of $0.002 \mathrm{~m}^{3}$ (Fig. 3-6). The weight and the piston maintain a constant gage pressure of 100 kPa . Determine the net work done by the gas on the surroundings. Neglect all friction.

Fig. 3-6

The paddle wheel does work on the system, the gas, due to the $100-\mathrm{kg}$ mass dropping 3 m . That work is negative and is

$$
W=-(F)(d)=-(100)(9.81)(3)=-2940 \mathrm{~J}
$$

The work done by the system on this frictionless piston is positive since the system is doing the work. It is

$$
\mathrm{W}=(P A)(h)=P V=(200000)(0.002)=400 \mathrm{~J}
$$

where absolute pressure has been used. The net work done is thus

$$
W_{\mathrm{vet}}=-2940+400=-2540 \mathrm{~J}
$$

### 3.5 OTHER WORK MODES

Work transferred by a rotating shaft (Fig. 3-7) is a common occurrence in mechanical systems. The work results from the shearing forces due to the shearing stress $\tau$, which varies linearly with the radius over the cross-sectional area, moving with angular velocity $\omega$ as the shaft rotates. The shearing force is

$$
\begin{equation*}
d F=\tau d A=\tau(2 \pi r d r) \tag{3.6}
\end{equation*}
$$

Fig. 3-7

The linear velocity with which this force moves is $r \omega$. Hence, the rate of doing work. which is force times velocity, is

$$
\begin{equation*}
\dot{W}=\int_{A} r \omega d F=\int_{0}^{R}(r \omega) \tau(2 \pi r) d r=2 \pi \omega \int_{0}^{R} \tau r^{2} d r \tag{3.7}
\end{equation*}
$$

where $R$ is the radius of the shaft. The torque $T$ is found from the shearing stresses by integrating over the area:

$$
\begin{equation*}
T=\int_{A} r d F=2 \pi \int_{0}^{R} r r^{2} d r \tag{3.8}
\end{equation*}
$$

Combining this with (3.7) above, we have

$$
\begin{equation*}
\dot{W}=T \omega \tag{3.9}
\end{equation*}
$$

To find the work transferred in a given time, we simply multiply (3.9) by the number of seconds:

$$
\begin{equation*}
W=T \omega \Delta t \tag{3.10}
\end{equation*}
$$

Of course, the angular velocity must be expressed in rad $/ \mathrm{s}$.
The work necessary to stretch a linear spring (Fig. 3-8) with spring constant $K$ from a length $x_{1}$ to $x_{2}$ can be found by using the relation

$$
\begin{equation*}
F=K x \tag{3.11}
\end{equation*}
$$

where $x$ is the distance the spring is stretched from the unstretched position. Note that the force is dependent on the variable $x$. Hence, we must integrate the force over the distance the spring is stretched; this results in

$$
\begin{equation*}
W=\int_{x_{1}}^{x_{2}} F d x=\int_{x_{1}}^{x_{2}} K x d x=\frac{1}{2} K\left(x_{2}^{2}-x_{1}^{2}\right) \tag{3.12}
\end{equation*}
$$

Fig. 3-8

Fig. 3-9

As a final type let us discuss an electrical work mode, illustrated in Fig. 3-9. The potential difference $V$ across the battery terminals is the "force" that drives the charge $q$ through the resistor during the time increment $\Delta t$. The current $i$ is related to the charge by

$$
\begin{equation*}
i=\frac{d q}{d t} \tag{3.13}
\end{equation*}
$$

For a constant current the charge is

$$
\begin{equation*}
q=i \Delta t \tag{3.14}
\end{equation*}
$$

The work from this nonequilibrium work mode, is then

$$
\begin{equation*}
W=V i \Delta t \tag{3.15}
\end{equation*}
$$

The power would be the rate of doing work, or

$$
\begin{equation*}
\dot{W}=V i \tag{3.16}
\end{equation*}
$$

This relationship is actually used to define the electric potential, the voltage $V$, since the ampere is a base unit and the watt has already been defined. One volt is one watt divided by one ampere.

EXAMPLE 3.6 The drive shaft in an automobile delivers $100 \mathrm{~N} \cdot \mathrm{~m}$ of torque as it rotates at 3000 rpm . Calculate the horsepower delivered.

The power is found by using $\dot{W}=T \omega$. This requires $\omega$ to be expressed in rad/s:

$$
\omega=(3000)(2 \pi)\left(\frac{1}{60}\right)=314.2 \mathrm{rad} / \mathrm{s}
$$

Hence $\dot{W}=(100)(314.2)=31420 \mathrm{~W} \quad$ or $\quad \mathrm{Hp}=\frac{31420}{746}=42.1 \mathrm{hp}$

EXAMPLE 3.7 The air in a circular cylinder (Fig. 3-10) is beated until the spring is compressed 50 mm . Find the work done by the air on the frictionless piston. The spring is initially unstretched, as shown.

Fig. 3-10

The pressure in the cylinder is initially found from a force balance:

$$
\begin{aligned}
& P_{1} A_{1}=P_{\mathrm{atm}} A+W \quad P_{1} \frac{\pi(0.1)^{2}}{4}=(100000) \frac{\pi(0.1)^{2}}{4}+(50)(9.81) \\
& \therefore P_{1}=162500 \mathrm{~Pa}
\end{aligned}
$$

To raise the piston a distance of 50 mm , without the spring, the pressure would be constant and the work required would be force times distance:

$$
W=P A \times d=(162500) \frac{\pi(0.1)^{2}}{4}(0.05)=63.81 \mathrm{~J}
$$

Using (3.12), the work required to compress the spring is calculated to be

$$
W=\frac{1}{2} K\left(x_{2}^{2}-x_{1}^{2}\right)=\left(\frac{1}{2}\right)(2500)\left(0.05^{2}\right)=3.125 \mathrm{~J}
$$

The total work is then found by summing the above two values: $\boldsymbol{W}_{\text {total }}=63.81+3.125=66.94 \mathrm{~J}$.

### 3.6 HEAT

In the preceding section we considered several work modes by which energy is transferred macroscopically to or from a system. Energy can also be transferred microscopically to or from a system by means of interactions between the molecules that form the surface of the system and those that form the surface of the surroundings. If the molecules of the system boundary are more active than those of the boundary of the surroundings, they will transfer energy from the system to the surroundings, with the faster molecules transferring energy to the slower molecules. On this microscopic scale the energy is transferred by a work mode: collisions between particles. A force occurs over an extremely short time span, with work transferring energy from the faster molecules to the slower ones. Our problem is that this microscopic transfer of energy is not observable macroscopically as any of the work modes; we must devise a macroscopic quantity to account for this microscopic transfer of energy.

We have noted that temperature is a property which increases with increased molecular activity. Thus it is not surprising that we can relate microscopic energy transfer to the macroscopic property temperature. This macroscopic transfer of energy that we cannot account for by any of the macroscopic work modes will be called heat. Heat is energy transferred across the boundary of a system due to a difference in temperature between the system and the surroundings of the system. A system does not contain heat, it contains energy, and heat is energy in transit.

To illustrate, consider a hot block and a cold block of equal mass. The hot block contains more energy than the cold block due to its greater molecular activity, that is, its higher temperature. When
the blocks are brought into contact with each other, energy flows from the hot block to the cold one by means of heat transfer. Eventually, the blocks will attain thermal equilibrium, with both blocks arriving at the same temperature. The heat transfer has ceased, the hot block has lost energy, and the cold block has gained energy.

Heat, like work, is something that crosses a boundary. Because a system does not contain heat, heat is not a property. Thus, its differential is inexact and is written as $\delta Q$, where $Q$ is the heat transfer. For a particular process between state 1 and state 2 the heat transfer could be written as $Q_{1-2}$, but it will generally be denoted by $Q$. The rate of heat transfer will be denoted by $\dot{Q}$.

By convention, if heat is transferred to a system it is considered positive. If it is transferred from a system it is negative. This is opposite from the convention chosen for work; if a system performs work on the surroundings it is positive. Positive heat transfer adds energy to a system, whereas positive work subtracts energy from a system. A process in which there is zero heat transfer is called an adiabatic process. Such a process is approximated experimentally by insulating the system so that negligible heat is transferred.

It should be noted that the energy contained in a system may be transferred to the surroundings either by work done by the system or by heat transferred from the system. Thus, heat and work are quantitatively equivalent and are expressed in the same units. An equivalent reduction in energy is accomplished if 100 J of heat is transferred from a system or if 100 J of work is performed by a system. In Fig. 3-11 the burner illustrates heat being added to the system and the rotating shaft illustrates work being done on the system.

Fig. 3-11
It is sometimes convenient to refer to heat transfer per unit mass. Heat transfer per unit mass will be designated $q$ and defined by

$$
\begin{equation*}
q=\frac{Q}{m} \tag{3.17}
\end{equation*}
$$

EXAMPLE 3.8 A paddle wheel adds work to a rigid container by rotations caused by dropping a $50-\mathrm{kg}$ weight a distance of 2 m from a pulley. How much heat must be transferred to result in an equivalent effect?

For this non-quasiequilibrium process the work is given by $W=(m g)(d)=(50)(9.8)(2)=980 \mathrm{~J}$. The heat $Q$ that must be transferred equals the work, 980 J .

## Solved Problems

3.1 Four kg of saturated liquid water is maintained at a constant pressure of 600 kPa while heat is added until the temperature reaches $600^{\circ} \mathrm{C}$. Determine the work done by the water.

The work for a constant-pressure process is $W=\int P d V=P\left(V_{2}-V_{1}\right)=\boldsymbol{m P}\left(v_{2}-v_{1}\right)$. Using entries from Table C-2 and Table C-3, we find

$$
W=(4)(600)(0.6697-0.0011)=1605 \mathrm{~kJ}
$$

Fig. 3-12
3.2 The frictionless piston shown in Fig. 3-12 has a mass of 16 kg . Heat is added until the temperature reaches $400^{\circ} \mathrm{C}$. If the initial quality is 20 percent, find ( $a$ ) the initial pressure, (b) the mass of water, $(c)$ the quality when the piston hits the stops, $(d)$ the final pressure, and (e) the work done on the piston.
(a) A force balance on the piston allows us to calculate the initial pressure. Including the atmospheric pressure, which is assumed to be 100 kPa , we have

$$
\begin{aligned}
& P_{1} A=W+P_{\mathrm{atm}} A \quad P_{1} \frac{\pi(0.1)^{2}}{4}=(16)(9.81)+(100000) \frac{\pi(0.1)^{2}}{4} \\
& \therefore P_{1}=120000 \mathrm{~Pa} \quad \text { or } 120 \mathrm{kPa}
\end{aligned}
$$

(b) To find the mass, we need the specific volume. Using entries from Table C-2, we find

$$
v_{1}=v_{f}+x\left(v_{g}-v_{f}\right)=0.001+(0.2)(1.428-0.001)=0.286 \mathrm{~m}^{3} / \mathrm{kg}
$$

The mass is then

$$
m=V_{1} / v_{1}=\frac{\pi(0.1)^{2}}{4}\left(\frac{0.05}{0.286}\right)=0.001373 \mathrm{~kg}
$$

(c) When the piston just hits the stops, the pressure is still 120 kPa . The specific volume increases to

$$
l_{2}=V_{2} / m=\frac{\pi(0.1)^{2}}{4}\left(\frac{0.08}{0.001373}\right)=0.458 \mathrm{~m}^{3} / \mathrm{kg}
$$

The quality is then found as follows, using the entries at $120^{\circ} \mathrm{C}$ :

$$
0.458=0.001+x_{2}(1.428-.001) \quad \therefore x_{2}=0.320 \text { or } 32.0 \%
$$

(d) After the piston hits the stops, the specific volume ceases to change since the volume remains constant. Using $T_{3}=400^{\circ} \mathrm{C}$ and $v_{3}=0.458$, we can interpolate in Table C-3, between pressure 0.6 MPa and 0.8 MPa at $400^{\circ} \mathrm{C}$, to find

$$
P_{3}=\left(\frac{0.5137-0.458}{0.5137-0.3843}\right)(0.8-0.6)+0.6=0.686 \mathrm{MPa}
$$

(e) There is zero work done on the piston after it hits the stops. From the initial state until the piston hits the stops, the pressure is constant at 120 kPa ; the work is then

$$
W=P\left(v_{2}-v_{1}\right) m=(120)(0.458-0.286)(0.001373)=0.0283 \mathrm{~kJ} \quad \text { or } 28.3 \mathrm{~J}
$$

3.3 Air is compressed in a cylinder such that the volume changes from 100 to $10 \mathrm{in}^{3}$. The initial pressure is 50 psia and the temperature is held constant at $100^{\circ} \mathrm{F}$. Calculate the work.

The work is given by $W=\int P d V$. For the isothermal process the equation of state allows us to write

$$
P V=m R T=\text { const. }
$$

since the mass $m$, the gas constant $R$, and the temperature $T$ are all constant. Letting the constant be $P_{1} V_{1}$, the above becomes $P=P_{1} V_{1} / V$, so that

$$
W=P_{1} V_{1} \int_{V_{1}}^{V_{2}} \frac{d V}{V}=P_{1} V_{1} \ln \frac{V_{2}}{V_{1}}=(50)(144)\left(\frac{100}{1728}\right) \ln \frac{10}{100}=-959 \mathrm{ft}-\mathrm{lbf}
$$

3.4 Six $g$ of air is contained in the cylinder shown in Fig. 3-13. The air is heated until the piston raises 50 mm . The spring just touches the piston initially. Calculate ( $a$ ) the temperature when the piston leaves the stops and $(b)$ the work done by the air on the piston.
(a) The pressure in the air when the piston just raises from the stops is found by balancing the forces on the piston:

$$
\begin{aligned}
& P A=P_{\mathrm{atm}} A+W \quad \frac{P \pi(0.2)^{2}}{4}=(100000) \frac{\pi(0.2)^{2}}{4}+(300)(9.81) \\
& \therefore P=193700 \mathrm{~Pa} \text { or } 193.7 \mathrm{kPa}
\end{aligned}
$$

The temperature is found from the ideal-gas law:

$$
T=\frac{P V}{m R}=\frac{(193.7)(0.15)(\pi)(0.2)^{2} / 4}{(0.006)(0.287)}=530 \mathrm{~K}
$$

(b) The work done by the air is considered to be composed of two parts: the work to raise the piston and the work to compress the spring. The work required to raise the piston a distance of 0.05 m is

$$
W=(F)(d)=(P)(A)(d)=(193.7) \frac{\pi(0.2)^{2}}{4}(0.05)=0.304 \mathrm{~kJ}
$$

The work required to compress the spring is $W=\frac{1}{2} K x^{2}=\frac{1}{2}(400)\left(0.05^{2}\right)=0.5 \mathrm{~kJ}$. The total work required by the air to raise the piston is

$$
W=0.304+0.5=0.804 \mathrm{~kJ}
$$

Fig. 3-13

Fig. 3-14
3.5 Two kg of air experiences the three-process cycle shown in Fig. 3-14. Calculate the net work.

The work for the constant-volume process from state 1 to state 2 is zero since $d V=0$. For the constant-pressure process the work is

$$
W_{2-3}=\int P d V=P\left(V_{3}-V_{2}\right)=(100)(10-2)=800 \mathrm{~kJ}
$$

The work needed for the isothermal process is

$$
W_{3-1}=\int P d V=\int \frac{m R T}{V} d V=m R T \int_{V_{3}}^{V_{1}} \frac{d V}{V}=m R T \ln \frac{V_{1}}{V_{3}}
$$

To find $W_{3-1}$ we need the temperature. It is found from state 3 to be

$$
T_{3}=\frac{P_{3} V_{3}}{m R}=\frac{(100)(10)}{(2)(0.287)}=1742^{\circ} \mathrm{R}
$$

Thus, the work for the constant-temperature process is

$$
W_{3-1}=(2)(0.287)(1742) \ln \frac{2}{10}=-1609 \mathrm{~kJ}
$$

Finally, the net work is

$$
W_{\mathrm{nct}}=W_{1-2}{ }^{10}+W_{2-3}+W_{3-1}=800-1609=-809 \mathrm{~kJ}
$$

The negative sign means that there must be a net input of work to complete the cycle in the order shown above.
3.6 A paddle wheel (Fig. 3-15) requires a torque of 20 ft -lbf to rotate it at 100 rpm . If it rotates for 20 s , calculate the net work done by the air if the frictionless piston raises 2 ft during this time.

Fig. 3-15

The work input by the paddle wheel is

$$
W=-T \omega \Delta t=(-20 \mathrm{ft}-\mathrm{lbf})\left[\frac{(100)(2 \pi)}{60} \mathrm{rad} / \mathrm{sec}\right](20 \mathrm{~s})=-4190 \mathrm{ft}-\mathrm{lbf}
$$

The negative sign accounts for work being done on the system, the air. The work needed to raise the piston requires that the pressure be known. It is found as follows:

$$
P A=P_{\mathrm{atm}} A+W \quad P \frac{\pi(6)^{2}}{4}=(14.7) \frac{\pi(6)^{2}}{4}+500 \quad \therefore P=32.4 \mathrm{psia}
$$

The work done by the air to raise the piston is then

$$
W=(F)(d)=(P)(A)(d)=(32.4) \frac{\pi(6)^{2}}{4}(2)=1830 \mathrm{ft}-\mathrm{lbf}
$$

and the net work is $W_{\text {net }}=1830-4190=-2360 \mathrm{ft}$-lbf.
3.7 The force needed to compress a nonlinear spring is given by the expression $F=200 x+$ $30 x^{2} \mathrm{~N}$, where $x$ is the displacement of the spring from its unstretched length measured in meters. Determine the work needed to compress the spring a distance of 60 cm .

The work is given by

$$
W=\int F d x=\int_{0}^{0.6}\left(200 x+30 x^{2}\right) d x=\left(100 \times 0.6^{2}\right)+\left(10 \times 0.6^{3}\right)=38.16 \mathrm{~J}
$$

## Supplementary Problems

3.8 Two kg of saturated steam at 400 kPa is contained in a piston-cylinder arrangement. The steam is heated at constant pressure to $300^{\circ} \mathrm{C}$. Calculate the work done by the steam. Ans. 153.8 kJ
3.90 .025 kg of steam at a quality of 10 percent and a pressure of 200 kPa is heated in a rigid container until the temperature reaches $200^{\circ} \mathrm{C}$. Find ( $a$ ) the final quality and ( $b$ ) the work done by the steam.
Ans. (a) 0.7002 (b) 0.0
3.10 The frictionless piston shown in equilibrium has a mass of 64 kg (Fig. 3-16). Energy is added until the temperature reaches $220^{\circ} \mathrm{C}$. The atmospheric pressure is 100 kPa . Determinc ( $a$ ) the initial pressure, ( $b$ ) the initial quality, $(c)$ the quality when the piston just hits the stops, $(d)$ the final quality (or pressure if superheat), (e) the work done on the piston.
Ans. (a) 120 kPa
(b) (0.0620
(c) 0.0963
(d) 1.52 MPa
(e) 0.0754 kJ

Fig. 3-16
3.11 Saturated water vapor at $180^{\circ} \mathrm{C}$ is contained in a piston-cylinder arrangement at an initial volume of $0.1 \mathrm{~m}^{3}$. Energy is added and the piston withdrawn so that the temperature remains constant until the pressure is 100 kPa .
(a) Find the work done. (Since there is no equation that relates $p$ and $V$, this must be done graphically.)
(b) Use the ideal-gas law and calculate the work.
(c) What is the percent error in using the ideal-gas law?

Ans. (a) $252 \mathrm{~kJ} \quad$ (b) $248 \mathrm{~kJ} \quad$ (c) $-1.6 \%$
3.12 A $75-\mathrm{lb}$ piston and weights resting on a stop (Fig. 3-17). The volume of the cylinder at this point is $40 \mathrm{in}^{3}$. Energy is added to the 0.4 fbm of water mixture until the temperature reaches $300^{\circ} \mathrm{F}$. Atmospheric pressure is 14 psia.

Fig. 3-17
(a) What is the initial specific volume of the mixture of vapor and liquid?
(b) What is the temperature in the cylinder when the piston just lifts off the stop?
(c) Determine the work done during the entire process.

Ans. (a) $0.05787 \mathrm{ft}^{3} / \mathrm{lbm} \quad$ (b) $228^{\circ} \mathrm{F} \quad$ (c) $25,700 \mathrm{ft}-\mathrm{lbf}$
3.13 Air is compressed in a cylinder such that the volume changes from 0.2 to $0.02 \mathrm{~m}^{3}$. The pressure at the beginning of the process is 200 kPa . Calculate the work if $(a)$ the pressure is constant, and ( $b$ ) the temperature is constant at $50^{\circ} \mathrm{C}$. Sketch each process on a $P-V$ diagram.
Ans. (a) $-36 \mathrm{~kJ} \quad$ (b) -92.1 kJ
3.14 Air contained in a circular cylinder (Fig. 3-18) is heated until a $100-\mathrm{kg}$ weight is raised 0.4 m . Calculate the work done by the expanding air on the weight. Atmospheric pressure is 80 kPa . Ans. 2.654 kJ

Fig. 3-18
3.15 A process for an ideal gas is represented by $P V^{n}=$ const., where $n$ takes on a particular value for a given process. Show that the expression for the work done for a process between states 1 and 2 is given by

$$
W=\frac{P_{2} V_{2}-P_{1} V_{1}}{1-n}
$$

Is this valid for an isothermal process? If not, determine the correct expression.
Ans. No. $P_{1} V_{1} \ln \left(V_{2} / V_{1}\right)$
3.16 The pressure in the gas contained in a piston-cylinder arrangement changes according to $P=a+30 / V$ where $P$ is in psi and $V$ is in $\mathrm{ft}^{3}$. Initially the pressure is 7 psia and the volume is $3 \mathrm{ft}^{3}$. Determine the work done if the final pressure is 50 psia. Show the area that represents the work on a $P-V$ diagram. Ans. $-6153 \mathrm{ft}-\mathrm{lbf}$
3.17 Air undergoes a three-process cycle. Find the net work done for 2 kg of air if the processes are
$1 \rightarrow 2$ : constant-pressure expansion
$2 \rightarrow 3$ : constant volume
$3 \rightarrow 1$ : constant-temperature compression
The necessary information is $T_{1}=100^{\circ} \mathrm{C}, T_{2}=600^{\circ} \mathrm{C}$, and $P_{1}=200 \mathrm{kPa}$. Sketch the cycle on a $P-V$ diagram. Ans. 105 kJ
3.18 An unstretched spring is attached to a horizontal piston (Fig. 3-19). Energy is added to the gas until the pressure in the cylinder is 400 kPa . Find the work done by the gas on the piston. Use $P_{\mathrm{atm}}=75 \mathrm{kPa}$. Ans. 0.2976 kJ

Fig. 3-19
3.19 Air is expanded in a piston-cylinder arrangement at a constant pressure of 200 kPa from a volume of $0.1 \mathrm{~m}^{3}$ to a volume of $0.3 \mathrm{~m}^{3}$. Then the temperature is held constant during an expansion of $0.5 \mathrm{~m}^{3}$. Determine the total work done by the air. Ans. 70.65 kJ
3.20 A 60 -ft-diameter balloon is to be filled with helium from a pressurized tank. The balloon is initially empty $(r=0)$ at an elevation where the atmospheric pressure is 12 psia . Determine the work done by the helium while the balloon is being filled. The pressure varies with radius according to $P=0.04(r-30)^{2}+12$ where $P$ is in psi. Ans. $2.54 \times 10^{\times} \mathrm{ft}-\mathrm{lbf}$
3.21 Estimate the work necessary to compress the air in an air-compressor cylinder from a pressure of 100 kPa to 2000 kPa . The initial volume is $1000 \mathrm{~cm}^{3}$. An isothermal process is to be assumed.
Ans. $\quad-0.300 \mathrm{~kJ}$
3.22 An electric motor draws 3 A from the 12-V battery (Fig. 3-20). Ninety percent of the energy is used to spin the paddle wheel shown. After 50 s of operation the $30-\mathrm{kg}$ piston is raised a distance of 100 mm . Determine the net work done by the gas on the surroundings. Use $P_{\mathrm{atm}}=95 \mathrm{kPa}$. Ans. -919 J

Fig. 3-20
3.23 A torque of 2 ft -lbf is necessary to rotate a paddle wheel at a rate of $20 \mathrm{rad} / \mathrm{s}$. The paddle wheel is located in a rigid vessel containing gas. What is the net work done on the gas during 10 min of operation?
Ans. $24,000 \mathrm{ft}-\mathrm{lbf}$
3.24 Estimate the work done by a gas during an unknown process. Data obtained that relates pressure and volume are:

| $P$ | 200 | 250 | 300 | 350 | 400 | 450 | 500 | kPa |
| :---: | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $V$ | 800 | 650 | 550 | 475 | 415 | 365 | 360 | $\mathrm{~cm}^{3}$ |

Ans. 132 J
3.25 Wind is blowing at 80 kph around a $250-\mathrm{mm}$-diameter tower that is 100 m high. The drag coefficient is 0.4 (see Example 3.4). Calculate the total force acting on the tower and the rate at which the wind does work on the tower. Ans. 3040 N, 0.0
3.26 Derive an expression for the work required to stretch an unstretched length of wire a relatively small distance $l$. The force is related to the amount of stretch $x$ by $F=E A x / L$, where $L$ is the original length of the wire, $A$ is the cross-sectional area, and $E$ is a material constant, and modulus of elasticity.
Ans. $E A l^{2} / 2 L$
3.27 A linear spring with a free length of 0.8 ft requires a work input of $4 \mathrm{ft}-\mathrm{lbf}$ to extend it to its maximum usable length. If the spring constant is $100 \mathrm{lbf} / \mathrm{ft}$, determine the maximum length of the spring.
Ans. 1.0828 ft
3.28 A linear spring requires 20 J of work to compress it from an unstretched length of 100 mm to a length of 20 mm . Find the spring constant. Ans. $6250 \mathrm{~N} / \mathrm{m}$
3.29 The force necessary to compress a nonlinear spring is given by $F=10 x^{2} \mathrm{~N}$, where $x$ is the distance the spring is compressed, measured in meters. Calculate the work needed to compress the spring from 0.2 t 0 0.8 m . Ans. 1.68 J
3.30 An automobile engine develops $100 \mathrm{hp}, 96$ percent of which is transferred to the drive shaft. Calculate the torque transferred by the driveshaft if it is rotating at 300 rpm . Ans. $2280 \mathrm{~N} \cdot \mathrm{~m}$
3.31 A paddle wheel is placed in a small creek in an attempt to generate electricity. The water causes the tip of the 2-ft-radius paddles to travel at $4 \mathrm{ft} / \mathrm{sec}$ while a force of 100 lbf acts at an average distance of 1.2 ft from the hub. Determine the maximum continuous amperage output which could be used to charge a bank of $12-\mathrm{V}$ batteries. Ans. 27.1 A
3.32 An electrical voltage of 110 V is applied across a resistor with the result that a current of 12 A fows through the resistor. Determine ( $a$ ) the power necessary to accomplish this and ( $b$ ) the work done during a period of 10 min . Ans. (a) 1320 W , (b) 792 kJ
3.33 A gasoline engine drives a small generator that is to supply sufficient electrical energy for a motor home. What is the minimum horsepower engine that would be necessary if a maximum of 200 A is anticipated from the $12-\mathrm{V}$ system? Ans. 3.22 hp

## Chapter 4

## The First Law of Thermodynamics

### 4.1 INTRODUCTION

The first law of thermodynamics is commonly called the law of conservation of energy. In elementary physics courses, the study of conservation of energy emphasizes changes in kinetic and potential energy and their relationship to work. A more general form of conservation of energy includes the effects of heat transfer and internal energy changes. This more general form is usually called the first law of thermodynamics. Other forms of energy may also be included, such as electrostatic, magnetic, strain, and surface energy. We will present the first law for a system and then for a control volume.

### 4.2 THE FIRST LAW OF THERMODYNAMICS APPLIED TO A CYCLE

Having discussed the concepts of work and heat, we are now ready to present the first law of thermodynamics. Recall that a law is not derived or proved from basic principles but is simply a statement that we write based on our observations of many experiments. If an experiment shows a law to be violated, either the law must be revised or additional conditions must be placed on the applicability of the law. Historically, the first law of thermodynamics was stated for a cycle: the net heat transfer is equal to the net work done for a system undergoing a cycle. This is expressed in equation form by

$$
\begin{equation*}
\Sigma W=\Sigma Q \tag{4.1}
\end{equation*}
$$

or

$$
\begin{equation*}
\oint \delta W=\oint \delta Q \tag{4.2}
\end{equation*}
$$

where the symbol $\phi$ implies an integration around a complete cycle.
The first law can be illustrated by considering the following experiment. Let a weight be attached to a pulley-paddle-wheel setup, such as that shown in Fig.4-1a. Let the weight fall a certain distance thereby doing work on the system, contained in the tank shown, equal to the weight multiplied by the distance dropped. The temperature of the system (the fluid in the tank) will immediately rise an amount $\Delta T$. Now, the system is returned to its initial state (the completion of the cycle) by transferring heat to the surroundings, as implied by the $Q$ in Fig. 4-1b. This reduces the temperature of the system to its initial temperature. The first law states that this heat transfer will be exactly equal to the work which was done by the falling weight.

EXAMPLE 4.1 A spring is stretched a distance of 0.8 m and attached to a paddle wheel (Fig. 4-2). The paddle wheel then rotates until the spring is unstretched. Calculate the heat transfer necessary to return the system to its initial state.

The work donc by the spring on the system is given by

$$
W_{1-2}=\int_{0}^{10.8} F d x=\int_{0}^{10.8} 100 x d x=(100)\left[\frac{(0.8)^{2}}{2}\right]=32 \mathrm{~N} \cdot \mathrm{~m}
$$

Since the heat transfer returns the system to its initial state, a cycle results. The first law then states that $Q_{2-1}=W_{1-2}=32 \mathrm{~J}$.

### 4.3 THE FIRST LAW APPLIED TO A PROCESS

The first law of thermodynamics is often applied to a process as the system changes from one state to another. Realizing that a cycle results when a system undergoes several processes and returns to

Fig. 4-1

Fig. 4-2
the initial state, we could consider a cycle composed of the two processes represented by $A$ and $B$ in Fig. 4-3. Using the first law of (4.2), we can show that the difference of the two inexact differentials $(\delta Q-\delta W)$ is an exact differential, designated $d E$ :

$$
\begin{equation*}
\delta Q-\delta W=d E \tag{4.3}
\end{equation*}
$$

Fig. 4-3
The quantity $E$ is an extensive property of the system and can be shown experimentally to represent the energy of the system at a particular state. Equation (4.3) can be integrated to yield

$$
\begin{equation*}
Q_{1-2}-W_{1-2}=E_{2}-E_{1} \tag{4.4}
\end{equation*}
$$

where $Q_{1-2}$ is the heat transferred to the system during the process from state 1 to state $2, W_{1-2}$ is the work done by the system on the surroundings during the process, and $E_{2}$ and $E_{1}$ are the values of the property $E$. More often than not the subscripts will be dropped on $Q$ and $W$ when working problems.

The property $E$ represents all of the energy: kinetic energy $K E$, potential energy $P E$, and internal energy $U$ which includes chemical energy and the energy associated with the atom. Any other form of energy is also included in the total energy $E$. Its associated intensive property is designated $e$.

The first law of thermodynamics then takes the form

$$
\begin{align*}
Q_{1-2}-W_{1-2} & =K E_{2}-K E_{1}+P E_{2}-P E_{1}+U_{2}-U_{1} \\
& =\frac{m}{2}\left(V_{2}^{2}-V_{1}^{2}\right)+m g\left(z_{2}-z_{1}\right)+U_{2}-U_{1} \tag{4.5}
\end{align*}
$$

If we apply the first law to an isolated system, one for which $Q_{1-2}=W_{1-2}=0$, the first law becomes the conservation of energy; that is,

$$
\begin{equation*}
E_{2}=E_{1} \tag{4.6}
\end{equation*}
$$

The internal energy $U$ is an extensive property. Its associated intensive property is the specific internal energy $u$; that is, $u=U / m$. For simple systems in equilibrium, only two properties are necessary to establish the state of a pure substance, such as air or steam. Since internal energy is a property, it depends only on, say, pressure and temperature; or, for saturated steam, it depends on quality and temperature (or pressure). Its value for a particular quality would be

$$
\begin{equation*}
u=u_{f}+x\left(u_{k}-u_{i}\right) \tag{4.7}
\end{equation*}
$$

We can now apply the first law to systems involving working fluids with tabulated property values. Before we apply the first law to systems involving substances such as ideal gases or solids, it is convenient to introduce several additional properties that will simplify that task.

EXAMPLE 4.2 A 5 -hp fan is used in a large room to provide for air circulation. Assuming a well-insulated, sealed room determine the internal energy increase after 1 h of operation.

By assumption, $Q=0$. With $\triangle P E=\Delta K E=0$ the first law becomes $-W=\Delta U$. The work input is

$$
W=(-5 \mathrm{hp})(1 \mathrm{~h})(746 \mathrm{~W} / \mathrm{hp})(3600 \mathrm{~s} / \mathrm{h})=-1.343 \times 10^{7} \mathrm{~J}
$$

The negative sign results because the work is input to the system. Finally, the internal energy increase is

$$
\Delta U=-\left(-1.343 \times 10^{7}\right)=1.343 \times 10^{7} \mathrm{~J}
$$

EXAMPLE 4.3 A rigid volume contains $6 \mathrm{ft}^{3}$ of steam originally at a pressure of 400 psia and a temperature of $900^{\circ} \mathrm{F}$. Estimate the final temperature if 800 Btu of heat is added.

The first law of thermodynamics, with $\Delta K E=\Delta P E=0$, is $Q-W=\Delta U$. For a rigid container the work is zero. Thus,

$$
Q=\Delta U=m\left(u_{2}-u_{1}\right)
$$

From the steam tables we find $u_{1}=1324 \mathrm{Btu} / \mathrm{lbm}$ and $c_{1}=1.978 \mathrm{ft}^{3} / \mathrm{lbm}$. The mass is then

$$
m=\frac{V}{L}=\frac{6}{1.978}=3.033 \mathrm{lbm}
$$

The energy transferred to the volume by heat is given. Thus,

$$
800=3.033\left(u_{2}-1324\right) \quad \therefore u_{2}=1588 \mathrm{Btu} / \mathrm{lbm}
$$

From Table C-3E we must find the temperature for which $c^{\prime}{ }_{2}=1.978 \mathrm{ft}^{3} / \mathrm{lbm}$ and $u_{2}=1588 \mathrm{Btu} / \mathrm{lbm}$. This is not a simple task since we do not know the pressure. At 500 psia if $v^{\prime}=1.978 \mathrm{ft}^{3} / \mathrm{lbm}$, then $u=1459 \mathrm{Btu} / \mathrm{lbm}$ and $T=1221^{\circ} \mathrm{F}$. At 600 psia if $r=1.978 \mathrm{ft}^{3} / \mathrm{lbm}$, then $u=1603 \mathrm{Btu} / \mathrm{lbm}$ and $T=1546^{\circ} \mathrm{F}$. Now we linearly interpolate to find the temperature at $u_{2}=1588 \mathrm{Btu} / \mathrm{lbm}$ :

$$
T_{2}=1546-\left(\frac{1603-1588}{1603-1459}\right)(1546-1221)=1512^{\circ} \mathrm{F}
$$

EXAMPLE 4.4 A frictionless piston is used to provide a constant pressure of 400 kPa in a cylinder containing steam originally at $200^{\circ} \mathrm{C}$ with a volume of $2 \mathrm{~m}^{3}$. Calculate the final temperature if 3500 kJ of heat is added.

The first law of thermodynamics, using $\Delta P E=\Delta K E=0$, is $Q-W=\Delta U$. The work done during the motion of the piston is

$$
W=\int P d V=P\left(V_{2}-V_{1}\right)=400\left(V_{2}-V_{1}\right)
$$

The mass beiore and after remains unchanged. Using the steam tables, this is expressed as

$$
m=\frac{V_{1}}{l_{1}}=\frac{2}{0.5342}=3.744 \mathrm{~kg}
$$

The volume $V_{2}$ is written as $V_{2}=m v_{2}=3.744 v_{2}$. The first law is then, finding $u_{1}$ from the steam tables,

$$
3500-(400)\left(3.744 l_{2}-2\right)=\left(u_{2}-2647\right) \times(3.744)
$$

This requires a trial-and-crror process. One plan for obtaining a solution is to guess a value for $v_{2}$ and calculate $u_{2}$ from the equation above. If this value checks with the $u_{2}$ from the steam tables at the same temperature, then the guess is the correct one. For example, guess $t_{2}=1.0 \mathrm{~m}^{3} / \mathrm{kg}$. Then the equation gives $u_{2}=3395 \mathrm{~kJ} / \mathrm{kg}$. From the steam tables, with $P=0.4 \mathrm{MPa}$, the $u_{2}$ value allows us to interpolate $T_{2}=654^{\circ} \mathrm{C}$ and the $v_{2}$ gives $T_{2}=600^{\circ} \mathrm{C}$. Therefore, the guess must be revised. Try $v_{2}=1.06 \mathrm{~m}^{3} / \mathrm{kg}$. The equation gives $u_{2}=3372 \mathrm{~kJ} / \mathrm{kg}$. The tables are interpolated to give $T_{2}=640^{\circ} \mathrm{C}$; for $v_{2}, T_{2}=647^{\circ} \mathrm{C}$. The actual $v_{2}$ is a little less than 1.06 $\mathrm{m}^{3} / \mathrm{kg}$, with the final temperature being approximately

$$
T_{2}=644^{\circ} \mathrm{C}
$$

### 4.4 ENTHALPY

In the solution of problems involving systems, certain products or sums of properties occur with regularity. One such combination of properties can be demonstrated by considering the addition of heat to the constant-pressure situation shown in Fig. 4-4. Heat is added slowly to the system (the gas in the cylinder), which is maintained at constant pressure by assuming a frictionless seal between the piston and the cylinder. If the kinetic energy changes and potential energy changes of the system are neglected and all other work modes are absent, the first law of thermodynamics requires that

$$
\begin{equation*}
Q-W=U_{2}-U_{1} \tag{4.8}
\end{equation*}
$$

Fig. 4-4 Constant-Pressure Heat Addition

The work done raising the weight for the constant-pressure process is given by

$$
\begin{equation*}
W=P\left(V_{2}-V_{1}\right) \tag{4.9}
\end{equation*}
$$

The first law can then be written as

$$
\begin{equation*}
Q=(U+P V)_{2}-(U+P V)_{1} \tag{4.10}
\end{equation*}
$$

The quantity in parentheses is a combination of properties and is thus a property itself. It is called the enthalpy $H$ of the system; that is,

$$
\begin{equation*}
H=U+P V \tag{4.11}
\end{equation*}
$$

The specific enthalpy $h$ is found by dividing by the mass. It is

$$
\begin{equation*}
h=u+P v \tag{4.12}
\end{equation*}
$$

Enthalpy is a property of a system and is also found in the steam tables. The energy equation can now
be written for a constant-pressure equilibrium process as

$$
\begin{equation*}
Q_{1-2}=H_{2}-H_{1} \tag{4.13}
\end{equation*}
$$

The enthalpy was defined using a constant-pressure system with the difference in enthalpies between two states being the heat transfer. For a variable-pressure process, the difference in enthalpy loses its physical significance. But enthalpy is still of use in engineering problems; it remains a property as defined by (4.11). In a nonequilibrium constant-pressure process $\Delta H$ would not equal the heat transfer.

Because only changes in enthalpy or internal energy are important, we can arbitrarily choose the datum from which to measure $h$ and $u$. We choose saturated liquid at $0^{\circ} \mathrm{C}$ to be the datum point for water substance.

EXAMPLE 4.5 Using the concept of enthalpy solve the problem presented in Example 4.4.
The energy equation for a constant-pressure process is (with the subscript on the heat transfer omitted)

$$
Q=H_{2}-H_{1} \quad \text { or } \quad 3500=\left(h_{2}-2860\right) m
$$

Using the steam tables as in Example 4.4, the mass is

$$
m=\frac{V}{L^{\prime}}=\frac{2}{0.5342}=3.744 \mathrm{~kg}
$$

Thus,

$$
h_{2}=\frac{3500}{3.744}+2860=3795 \mathrm{~kJ} / \mathrm{kg}
$$

From the steam tables this interpolates to

$$
T_{2}=600+\left(\frac{92.6}{224}\right)(100)=641^{\circ} \mathrm{C}
$$

Obviously, enthalpy was very useful in solving this constant-pressure problem. Trial and error was unnecessary, and the solution was rather straightforward. We illustrated that the quantity we made up. enthalpy, is not necessary, but it is quite handy. We will use it often in our calculations.

### 4.5 LATENT HEAT

The amount of energy that must be transferred in the form of heat to a substance held at constant pressure in order that a phase change occur is called the latent heat. It is the change in enthalpy of the substance at the saturated conditions of the two phases. The heat that is necessary to melt a unit mass of a substance at constant pressure is the heat of fusion and is equal to $h_{i f}=h_{f}-h_{i}$, where $h_{\text {, }}$ is the enthalpy of saturated solid and $h_{f}$ is the enthalpy of saturated liquid. The heat of raporization is the heat required to completely vaporize a unit mass of saturated liquid; it is equal to $h_{f g}=h_{g}-h_{f}$. When a solid changes phase directly to a gas, sublimation occurs; the heat of sublimation is equal to $h_{i g}=h_{g}-h_{i}$.

The heat of fusion and the heat of sublimation are relatively insensitive to pressure or temperature changes. For ice the heat of fusion is approximately $320 \mathrm{~kJ} / \mathrm{kg}(140 \mathrm{Btu} / \mathrm{lbm})$ and the heat of sublimation is about $2040 \mathrm{~kJ} / \mathrm{kg}(880 \mathrm{Btu} / \mathrm{lbm})$. The heat of vaporization of water is included as $h_{f k}$ in Tables C-1 and C-2.

### 4.6 SPECIFIC HEATS

For a simple system only two independent variables are necessary to establish the state of the system. Consequently, we can consider the specific internal energy to be a function of temperature and specific volume; that is,

$$
\begin{equation*}
u=u(T, v) \tag{4.14}
\end{equation*}
$$

Using the chain rule from calculus we express the differential in terms of the partial derivatives as

$$
\begin{equation*}
d u=\left.\frac{\partial u}{\partial T}\right|_{c} d T+\left.\frac{\partial u}{\partial r^{C}}\right|_{T} d v \tag{4.15}
\end{equation*}
$$

Since $u, u$, and $T$ are all properties, the partial derivative is also a property and is called the constant-tolume specific heat $c_{r}$; that is,

$$
\begin{equation*}
c_{r}=\left.\frac{\partial u}{\partial T}\right|_{r} \tag{4.16}
\end{equation*}
$$

One of the classical experiments of thermodynamics, first performed by Joule in 1843, is illustrated in Fig. 4-5. Pressurize volume $A$ with an ideal gas and evacuate volume $B$. After equilibrium is attained, open the valve. Even though the pressure and volume of the ideal gas have changed markedly, the temperature does not change. Because there is no change in temperature, there is no net heat transfer to the water. Observing that no work is done we conclude, from the first law, that the internal energy of an ideal gas does not depend on pressure or volume.

Fig. 4-5

For such a gas, which behaves as an ideal gas, we have

$$
\begin{equation*}
\left.\frac{\partial u}{\partial L}\right|_{T}=0 \tag{4.17}
\end{equation*}
$$

Combining (4.15), (4.16), and (4.17),

$$
\begin{equation*}
d u=c, d T \tag{4.18}
\end{equation*}
$$

This can be integrated to give

$$
\begin{equation*}
u_{2}-u_{1}=\int_{T_{1}}^{T_{2}} c_{r} d T \tag{4.19}
\end{equation*}
$$

For a known $c_{l}(T)$ this can be integrated to find the change in internal energy over any temperature interval for an ideal gas.

Likewise, considering specific enthalpy to be dependent on the two variables $T$ and $P$, we have

$$
\begin{equation*}
d h=\left.\frac{\partial h}{\partial T}\right|_{P} d T+\left.\frac{\partial h}{\partial \mathscr{P}}\right|_{T} d P \tag{4.20}
\end{equation*}
$$

The constant-pressure specific heat $c_{p}$ is defined as

$$
\begin{equation*}
c_{p}=\left.\frac{\partial h}{\partial T}\right|_{p} \tag{4.2I}
\end{equation*}
$$

For an ideal gas we have, returning to the definition of enthalpy, (4.12),

$$
\begin{equation*}
h=u+P v=u+R T \tag{4.22}
\end{equation*}
$$

where we have used the ideal-gas equation of state. Since $u$ is only a function of $T$, we see that $h$ is also only a function of $T$ for an ideal gas. Hence, for an ideal gas

$$
\begin{equation*}
\left.\frac{\partial h}{\partial P}\right|_{T}=0 \tag{4.23}
\end{equation*}
$$

and we have, from (4.20),

$$
\begin{equation*}
d h=c_{p} d T \tag{4.24}
\end{equation*}
$$

Over the temperature range $T_{1}$ to $T_{2}$ this is integrated to give

$$
\begin{equation*}
h_{2}-h_{1}=\int_{T_{1}}^{T_{2}} c_{p} d T \tag{4.25}
\end{equation*}
$$

for an ideal gas.
It is often convenient to specify specific heats on a per-mole, rather than a per-unit-mass, basis; these molar specific heats are notated $\bar{c}_{t}$ and $\bar{c}_{p}$. Clearly, we have the relations

$$
\bar{c}_{v}=M c_{i} \quad \text { and } \quad \bar{c}_{p}=M c_{p}
$$

where $M$ is the molar mass. Thus values of $\bar{c}_{t}$ and $\bar{c}_{p}$ may be simply derived from the values of $c_{t}$ and $c_{p}$ listed in Table B-2. (The "overbar notation" for a molar quantity is used throughout this book.)

The equation for enthalpy can be used to relate, for an ideal gas, the specific heats and the gas constant. In differential form (4.12) takes the form

$$
\begin{equation*}
d h=d u+\bar{d}(P v) \tag{4.26}
\end{equation*}
$$

Introducing the specific heat relations and the ideal-gas equation, we have

$$
\begin{equation*}
c_{p} d T=c_{c} d T+R d T \tag{4.27}
\end{equation*}
$$

which, after dividing by $d T$, gives

$$
\begin{equation*}
c_{p}=c_{v}+R \tag{4.28}
\end{equation*}
$$

This relationship-or its molar equivalent $\bar{c}_{p}=\bar{c}_{v}+\bar{R}$-allows $c_{r}$ to be determined from tabulated values or expressions for $c_{p}$. Note that the difference between $c_{p}$ and $c_{t}$ for an ideal gas is always a constant, even though both are functions of temperature.

The specific heat ratio $k$ is also a property of particular interest; it is defined as

$$
\begin{equation*}
k=\frac{c_{p}}{c_{i}} \tag{4.29}
\end{equation*}
$$

This can be substituted into (4.28) to give

$$
\begin{equation*}
c_{p}=R \frac{k}{k-1} \tag{4.30}
\end{equation*}
$$

or

$$
\begin{equation*}
c_{t}=\frac{R}{k-1} \tag{4.31}
\end{equation*}
$$

Obviously, since $R$ is a constant for an ideal gas, the specific heat ratio will depend only on temperature.

For gases, the specific heats slowly increase with increasing temperature. Since they do not vary significantly over fairly large temperature differences, it is often acceptable to treat $c_{r}$ and $c_{p}$ as constants. For such situations there results

$$
\begin{align*}
& u_{2}-u_{1}=c_{c}\left(T_{2}-T_{1}\right)  \tag{4.32}\\
& h_{2}-h_{1}=c_{p}\left(T_{2}-T_{1}\right) \tag{4.33}
\end{align*}
$$

For air we will use $c_{r}=0.717 \mathrm{~kJ} / \mathrm{kg} \cdot{ }^{\circ} \mathrm{C}\left(0.171 \mathrm{Btu} / \mathrm{lbm}-{ }^{\circ} \mathrm{R}\right)$ and $c_{p}=1.00 \mathrm{~kJ} / \mathrm{kg} \cdot{ }^{\circ} \mathrm{C}(0.24$ $\mathrm{Btu} / \mathrm{lbm}-{ }^{\circ} \mathrm{R}$ ), unless otherwise stated. For more accurate calculations with air, or other gases, one
should consult ideal-gas tables, such as those in Appendix F , which tabulate $h(T)$ and $u(T)$, or integrate using expressions for $c_{p}(T)$ found in Table B-5.

For liquids and solids the specific heat $c_{p}$ is tabulated in Table B-4. Since it is quite difficult to maintain constant volume while the temperature is changing, $c_{v}$ values are usually not tabulated for liquids and solids; the difference $c_{p}-c_{t}$ is usually quite small. For most liquids the specific heat is relatively insensitive to temperature change. For water we will use the nominal value of 4.18 $\mathrm{kJ} / \mathrm{kg} \cdot{ }^{\circ} \mathrm{C}\left(1.00 \mathrm{Btu} / \mathrm{lbm}-{ }^{\circ} \mathrm{R}\right)$. For ice the specific heat in $\mathrm{kJ} / \mathrm{kg} \cdot{ }^{\circ} \mathrm{C}$ is approximately $c_{p}=2.1+$ $0.0069 T$, where $T$ is measured in ${ }^{\circ} \mathrm{C}$; and in English units of $\mathrm{Btu} / \mathrm{lbm}-{ }^{\circ} \mathrm{F}$ it is $c_{p}=0.47+0.001 \mathrm{~T}$, where $T$ is measured in ${ }^{\circ} \mathrm{F}$. The variation of specific heat with pressure is usually quite slight except for special situations.

EXAMPLE 4.6 The specific heat of superheated steam at approximately 150 kPa can be determined by the equation

$$
c_{p}=2.07+\frac{T-400}{1480} \quad \mathrm{~kJ} / \mathrm{kg} \cdot{ }^{\circ} \mathrm{C}
$$

(a) What is the enthalpy change between $300^{\circ} \mathrm{C}$ and $700^{\circ} \mathrm{C}$ for 3 kg of steam? Compare with the steam tables. (b) What is the average value of $c_{p}$, between $3000^{\circ} \mathrm{C}$ and $700^{\circ} \mathrm{C}$ based on the equation and based on the tabulated data?
(a) The enthalpy change is found to be

$$
\Delta H=m \int_{T_{1}}^{T_{2}} c_{p} d T=3 \int_{3(0)}^{7(61)}\left(2.07+\frac{T-400}{1480}\right) d T=2565 \mathrm{~kJ}
$$

From the tables we find, using $P=150 \mathrm{kPa}$,

$$
\Delta H=(3)(3928-3073)=2565 \mathrm{~kJ}
$$

(b) The average value $c_{p, a v}$ is found by using the relation

$$
m c_{p, \mathrm{av}} \Delta T=m \int_{T_{1}}^{T_{3}} c_{p} d T \quad \text { or } \quad(3)\left(400 c_{p, \mathrm{av}}\right)=3 \int_{3(\mathrm{xo})}^{7(\mathrm{kN})}\left(2.07+\frac{T-400}{1480}\right) d T
$$

The integral was evaluated in part ( $a$ ); hence, we have

$$
c_{p, \mathrm{av}}=\frac{2565}{(3)(400)}=2.14 \mathrm{~kJ} / \mathrm{kg} \cdot{ }^{\circ} \mathrm{C}
$$

Using the values from the steam table, we have

$$
c_{p . \mathrm{av}}=\frac{\Delta h}{\Delta T}=(3928-3073) / 400=2.14 \mathrm{~kJ} / \mathrm{kg} \cdot{ }^{\circ} \mathrm{C}
$$

Because the steam tables give the same values as the linear equation of this example, we can safely assume that the $c_{p}(T)$ relationship for steam over this temperature range is closely approximated by a linear relation. This linear relation would change, however, for each pressure chosen; hence. the steam tables are essential.

EXAMPLE 4.7 Determine the value of $c_{p}$ for steam at $T=800^{\circ} \mathrm{F}$ and $P=800$ psia.
To determine $c_{p}$, we use a finite-difference approximation to (4.21). We use the entrics at $T=900^{\circ} \mathrm{F}$ and $T=700^{\circ} \mathrm{F}$, which gives a better approximation to the slope compared to using the values at $800^{\circ} \mathrm{F}$ and $750^{\circ} \mathrm{F}$ or at $9000^{\circ} \mathrm{F}$ and $8000^{\circ} \mathrm{F}$. Table C-3E provides us with

$$
c_{p} \cong \frac{\Delta h}{\Delta T}=\frac{1455.6-1338.0}{200}=0.588 \mathrm{Btu} / \mathrm{lbm}-{ }^{\circ} \mathrm{F}
$$

Figure 4-6 shows why it is better to use values on either side of the position of interest. If values at $900^{\circ} \mathrm{F}$ and $800^{\circ} \mathrm{F}$ are used (a forward difference), $c_{p}$ is too low. If values at $800^{\circ} \mathrm{F}$ and $750^{\circ} \mathrm{C}$ are used, (a backward difference), $c_{p}$ is too high. Thus, both a forward and a backward value (a central difference) should be used, resulting in a more accurate estimate of the slope.

Fig. 4-6
EXAMPLE 4.8 Determine the enthalpy change for 1 kg of nitrogen which is heated from 300 to 1200 K by ( $a$ ) using the gas tables, ( $b$ ) integrating $c_{p}(T)$, and ( $c$ ) assuming constant specific heat. Use $M=28 \mathrm{~kg} / \mathrm{kmol}$.
(a) Using the gas table in Appendix F , find the enthalpy change to be

$$
\Delta h=36777-8723=28054 \mathrm{~kJ} / \mathrm{kmol} \quad \text { or } \quad 28054 / 28=1002 \mathrm{~kJ} / \mathrm{kg}
$$

(b) The expression for $c_{p}(T)$ is found in Table B-5. The enthalpy change is

$$
\begin{aligned}
\Delta h= & \int_{300}^{1200}\left[39.06-512.79\left(\frac{T}{100}\right)^{-1.5}+1072.7\left(\frac{T}{100}\right)^{-2}-820.4\left(\frac{T}{100}\right)^{-3}\right] d t \\
= & (39.06)(1200-300)-(512.79)\left(\frac{100}{-0.5}\right)\left(12^{-0.5}-3^{-0.5}\right) \\
& +(1072.7)\left(\frac{100}{-1}\right)\left(12^{-1}-3^{-1}\right)-(820.4)\left(\frac{100}{-2}\right)\left(12^{-2}-3^{-2}\right) \\
= & 28093 \mathrm{~kJ} / \mathrm{kmol} \text { or } 1003 \mathrm{~kJ} / \mathrm{kg}
\end{aligned}
$$

(c) Assuming constant specific heat (found in Table B-2) the enthalpy change is found to be

$$
\Delta h=c_{p} \Delta T=(1.042)(1200-300)=938 \mathrm{~kJ} / \mathrm{kg}
$$

Note the value found by integrating is essentially the same as that found from the gas tables. However, the enthalpy change found by assuming constant specific heat is in error by over 6 percent.

### 4.7 THE FIRST LAW APPLIED TO VARIOUS PROCESSES

## The Constant-Temperature Process

For the isothermal process, tables may be consulted for substances for which tabulated values are available. Internal energy and enthalpy vary slightly with pressure for the isothermal process, and this variation must be accounted for in processes involving many substances. The energy equation is

$$
\begin{equation*}
Q-W=\Delta U \tag{4.34}
\end{equation*}
$$

For a gas that approximates an ideal gas, the internal energy depends only on the temperature and thus $\Delta U=0$ for an isothermal process; for such a process

$$
\begin{equation*}
Q=W \tag{4.35}
\end{equation*}
$$

Using the ideal-gas equation $P V=m R T$, the work for a quasiequilibrium process can be found to be

$$
\begin{equation*}
W=\int_{V_{1}}^{V_{2}} P d V=m R T \int_{V_{1}}^{V_{2}} \frac{d V}{V}=m R T \ln \frac{V_{2}}{V_{1}}=m R T \ln \frac{P_{1}}{P_{2}} \tag{4.36}
\end{equation*}
$$

## The Constant-Volume Process

The work for a constant-volume quasiequilibrium process is zero, since $d V$ is zero. For such a process the first law becomes

$$
\begin{equation*}
Q=\Delta U \tag{4.37}
\end{equation*}
$$

If tabulated values are available for a substance, we may directly determine $\Delta U$. For a gas, approximated by an ideal gas, we would have

$$
\begin{equation*}
Q=m \int_{T_{1}}^{T_{2}} c_{v} d T \tag{4.38}
\end{equation*}
$$

or, for a process for which $c_{l}$ is essentially constant,

$$
\begin{equation*}
Q=m c_{c} \Delta T \tag{4.39}
\end{equation*}
$$

If nonequilibrium work, such as paddle-wheel work, is present, that work must be accounted for in the first law.

Equation (4.39) provides the motivation for the name "specific heat" for $c_{v}$. Historically, this equation was used to define $c_{c}$; thus, it was defined as the heat necessary to raise the temperature of one unit of substance one degree in a constant-volume process. Today scientists prefer the definition of $c_{r}$ to be in terms of properties only, without reference to heat transfer, as in (4.16).

## The Constant-Pressure Process

The first law, for a constant-pressure quasiequilibrium process, was shown in Sec. 4.4 to be

$$
\begin{equation*}
Q=\Delta H \tag{4.40}
\end{equation*}
$$

Hence, the heat transfer for such a process can easily be found using tabulated values, if available.
For a gas that behaves as an ideal gas, we have

$$
\begin{equation*}
Q=m \int_{T_{1}}^{T_{2}} c_{p} d T \tag{4.41}
\end{equation*}
$$

For a process involving an ideal gas for which $c_{p}$ is constant there results

$$
\begin{equation*}
Q=m c_{p} \Delta T \tag{4.42}
\end{equation*}
$$

For a nonequilibrium process the work must be accounted for directly in the first law and cannot be expressed as $P\left(V_{2}-V_{1}\right)$. For such a process ( 4.40 ) would not be valid.

## The Adiabatic Process

There are numerous examples of processes for which there is no, or negligibly small, heat transfer, e.g., the compression of air in an automobile engine or the exhaust of nitrogen from a nitrogen tank. The study of such processes is, however, often postponed until after the second law of thermodynamics is presented. This postponement is not necessary, and because of the importance of the adiabatic quasiequilibrium process, it is presented here.

The differential form of the first law for the adiabatic process is

$$
\begin{equation*}
-\delta w=d u \tag{4.43}
\end{equation*}
$$

or, for a quasiequilibrium process, using $\delta w=P d v$ (there are no nonequilibrium work modes),

$$
\begin{equation*}
d u+P d v=0 \tag{4.44}
\end{equation*}
$$

The sum of the differential quantities on the left represents a perfect differential which we shall
designate as $d \psi, \psi$ being a property of the system. This is similar to the motivation for defining the enthalpy $h$ as a property. Since

$$
\begin{equation*}
d \psi=d u+P d v \tag{4.45}
\end{equation*}
$$

is a property of the system, it is defined for processes other than the adiabatic quasiequilibrium process.

Let us investigate the adiabatic quasiequilibrium process for an ideal gas with constant specific heats. For such a process, (4.44) takes the form

$$
\begin{equation*}
c_{\mathrm{r}} d T+\frac{R T}{v} d v=0 \tag{4.46}
\end{equation*}
$$

Rearranging, we have

$$
\begin{equation*}
\frac{c_{1}}{R} \frac{d T}{T}=-\frac{d v}{v} \tag{4.47}
\end{equation*}
$$

This is integrated, assuming constant $c_{i}$, between states 1 and 2 to give

$$
\begin{equation*}
\frac{c_{v}}{R} \ln \frac{T_{2}}{T_{1}}=-\ln \frac{c_{2}}{c_{1}} \tag{4.48}
\end{equation*}
$$

which can be put in the form

$$
\begin{equation*}
\frac{T_{2}}{T_{1}}=\left(\frac{v_{1}}{v_{2}}\right)^{R / c_{i}}=\left(\frac{v_{1}}{v_{2}}\right)^{k-1} \tag{4.49}
\end{equation*}
$$

referring to (4.31). Using the ideal-gas law, this can be written as

$$
\begin{equation*}
\frac{T_{2}}{T_{1}}=\left(\frac{P_{2}}{P_{1}}\right)^{(k-1) / k} \quad \frac{P_{2}}{P_{1}}=\left(\frac{v_{1}}{v_{2}}\right)^{k} \tag{4.50}
\end{equation*}
$$

Finally, the above three relations can be put in general forms, without reference to particular points. For the adiabatic quasiequilibrium process involving an ideal gas with constant $c_{p}$ and $c_{r}$, we have

$$
\begin{equation*}
T v^{k-1}=\text { const } . \quad T P^{(1-k) / k}=\text { const } . \quad P_{l^{k}}=\text { const } . \tag{4.51}
\end{equation*}
$$

For a substance that does not behave as an ideal gas, we must utilize tables. For such a process we return to (4.45) and recognize that $d \psi=0$, or $\psi=$ const. We do not assign the property $\psi$ a formal name, but, as we shall show in Chap. 7 , the $\psi$ function is constant whenever the quantity denoted by $s$, the entropy, is constant. Hence, when using the tables, an adiabatic quasiequilibrium process between states 1 and 2 requires $s_{1}=s_{2}$.

## The Polytropic Process

A careful inspection of the special quasiequilibrium processes presented in this chapter suggests that each process can be expressed as

$$
\begin{equation*}
P V^{n}=\text { const } . \tag{4.52}
\end{equation*}
$$

The work is calculated

$$
\begin{equation*}
W=\int_{V_{1}}^{V_{2}} P d V=P_{1} V_{1}^{n} \int_{V_{1}}^{V_{2}} V^{-n} d V=\frac{P_{1} V_{1}^{n}}{1-n}\left(V_{2}^{1-n}-V_{1}^{1-n}\right)=\frac{P_{2} V_{2}-P_{1} V_{1}}{1-n} \tag{4.53}
\end{equation*}
$$

except (4.36) is used if $n=1$. The heat transfer follows from the first law.
Each quasiequilibrium process is associated with a particular value for $n$ as follows:

| Isothermal: | $n=1$ |
| :--- | :--- |
| Constant-volume: | $n=\infty$ |
| Constant-pressure: | $n=0$ |
| Adiabatic: | $n=k$ |

The processes are displayed on a $(\ln P)$ vs. ( $\ln V$ ) plot in Fig. 4-7. The slope of each straight line is the exponent on $V$ in (4.52). If the slope is none of the values $\infty, k, 1$, or zero, then the process can be

Fig. 4-7 Polytropic exponents for various processes.
referred to as a polytropic process. For such a process any of the equations (4.49), (4.50), or (4.51) can be used with $k$ simply replaced by $n$; this is convenient in processes in which there is some heat transfer but which do not maintain temperature, pressure, or volume constant.

EXAMPLE 4.9 Determine the heat transfer necessary to increase the pressure of 70 percent quality steam from 200 to 800 kPa , maintaining the volume constant at $2 \mathrm{~m}^{3}$. Assume a quasiequilibrium process.

For the constant-volume quasiequilibrium process the work is zero. The first law reduces to $Q=m\left(u_{2}-u_{1}\right)$. The mass is found to be

$$
m=\frac{V}{v}=\frac{2}{0.0011+(0.7)(0.8857-0.0011)}=\frac{2}{0.6203}=3.224 \mathrm{~kg}
$$

The internal energy at state 1 is

$$
u_{1}=504.5+(0.7)(2529.5-504.5)=1922 \mathrm{~kJ} / \mathrm{kg}
$$

The constant-volume process demands that $c_{2}=c_{1}=0.6203 \mathrm{~m}^{3} / \mathrm{kg}$. From the steam tables at 800 kPa we find, by extrapolation, that

$$
u_{2}=\left(\frac{0.6203-0.6181}{0.6181-0.5601}\right)(3661-3476)=3668 \mathrm{~kJ} / \mathrm{kg}
$$

Note that extrapolation was necessary since the temperature at state 2 exceeds the highest tabulated temperature of $800^{\circ} \mathrm{C}$. The heat transfer is then

$$
Q=(3.224)(3668-1922)=5629 \mathrm{~kJ}
$$

EXAMPLE 4.10 A piston-cylinder arrangement contains $0.02 \mathrm{~m}^{3}$ of air at $50^{\circ} \mathrm{C}$ and 400 kPa . Heat is added in the amount of 50 kJ and work is done by a paddle wheel until the temperature reaches $700^{\circ} \mathrm{C}$. If the pressure is held constant how much paddle-wheel work must be added to the air? Assume constant specific heats.

The process cannot be approximated by a quasiequilibrium process because of the paddle-wheel work. Thus, the heat transfer is not equal to the enthalpy change. The first law may be written as

$$
Q-W_{\text {paddle }}=m\left(h_{2}-h_{1}\right)=m c_{p}\left(T_{2}-T_{1}\right)
$$

To find $m$ we use the ideal-gas equation. It gives us

$$
m=\frac{P V}{R T}=\frac{(400000)(0.02)}{(287)(273+50)}=0.0863 \mathrm{~kg}
$$

From the first law the paddle-wheel work is found to be

$$
W_{\text {paddle }}=Q-m c_{p}\left(T_{2}-T_{1}\right)=50-(0.0863)(1.00)(700-50)=-6.095 \mathrm{~kJ}
$$

Note: We could have used the first law as $Q-W_{\text {net }}=m\left(u_{2}-u_{1}\right)$ and then let $W_{\text {padde }}=W_{\text {net }}-P\left(V_{2}-V_{1}\right)$. We would then need to calculate $V_{2}$.

EXAMPLE 4.11 Calculate the work necessary to compress air in an insulated cylinder from a volume of $6 \mathrm{ft}^{3}$ to a volume of $1.2 \mathrm{ft}^{3}$. The initial temperature and pressure are $50^{\circ} \mathrm{F}$ and 30 psia , respectively.

We will assume that the compression process is approximated by a quasiequilibrium process, which is acceptable for most compression processes, and that the process is adiabatic due to the presence of the insulation. The first law is then written as

$$
-W=m\left(u_{2}-u_{1}\right)=m c_{i}\left(T_{2}-T_{1}\right)
$$

The mass is found from the ideal-gas equation to be

$$
m=\frac{P V}{R T}=\frac{[(30)(144)](6)}{(53.3)(460+50)}=0.9535 \mathrm{lbm}
$$

The final temperature $T_{2}$ is found for the adiabatic quasiequilibrium process from (4.49); it is

$$
T_{2}=T_{1}\left(\frac{V_{1}}{V_{2}}\right)^{k-1}=(510)\left(\frac{6.0}{1.2}\right)^{1.4-1}=970.9^{\circ} \mathrm{R}
$$

Finally, $W=(-0.9535 \mathrm{lbm})\left(0.171 \mathrm{Btu} / \mathrm{lbm}-{ }^{\circ} \mathrm{R}\right)(970.9-510)^{\circ} \mathrm{R}=-75.1 \mathrm{Btu}$.

### 4.8 GENERAL FORMULATION FOR CONTROL VOLUMES

In the application of the various laws we have thus far restricted ourselves to systems, with the result that no mass has crossed the system boundaries. This restriction is acceptable for many problems of interest and may, in fact, be imposed on the power plant schematic shown in Fig. 4-8. However, if the first law is applied to this system, only an incomplete analysis can be accomplished. For a more complete analysis we must relate $W_{i n}, Q_{i n}, W_{\text {out }}$, and $Q_{\text {out }}$ to the pressure and temperature changes for the pump, boiler, turbine, and condenser, respectively. To do this we must consider each device of the power plant as a control volume into which and from which a fluid flows. For example, water flows into the pump at a low pressure and leaves the pump at a high pressure; the work input into the pump is obviously related to this pressure rise. We must formulate equations that allow us to make this necessary calculation. For most applications that we will consider it will be acceptable to assume both a steady flow (the flow variables do not change with time) and a uniform flow (the velocity, pressure, and density are constant over the cross-sectional area). We will, however, develop the unsteady, nonuniform flow case which will find some application in our study of thermodynamics. Fluid mechanics treats the more general unsteady, nonuniform situations in much greater depth.

Fig. 4-8

Fig. 4-9

## The Continuity Equation

Consider a general control volume with an area $A_{1}$ where fluid enters and an area $A_{2}$ where fluid leaves, as shown in Fig. 4-9. It could have any shape and any number of entering and exiting areas, but we will derive the continuity equation using the geometry shown. Conservation of mass requires that

$$
\left.\left.\binom{\text { Mass entering }}{\text { control volume }} \quad-\quad\binom{\text { Mass leaving }}{\text { control volume }}=\begin{array}{c}
\text { Change in mass }  \tag{4.54}\\
m_{1}
\end{array}\right)=\begin{array}{cc}
\text { within control volume }
\end{array}\right)
$$

The mass that crosses an area $A$ over a time increment $\Delta t$ can be expressed as $\rho A V \Delta t$, where $V \Delta t$ is the distance the mass particles travel and $A V \Delta t$ is the volume swept out by the mass particles. Equation (4.54) can thus be put in the form

$$
\begin{equation*}
\rho_{1} A_{1} V_{1} \Delta t-\rho_{2} A_{2} V_{2} \Delta t=\Delta m_{\mathrm{c} . \mathrm{v}} \tag{4.55}
\end{equation*}
$$

where the velocities $V_{1}$ and $V_{2}$ are perpendicular to the areas $A_{1}$ and $A_{2}$, respectively. We have assumed the velocity and density to be uniform over the two areas, a good assumption for the turbulent flows most often encountered entering and leaving the devices of interest.

If we divide by $\Delta t$ and let $\Delta t \rightarrow 0$, the derivative results and we have the continuity equation,

$$
\begin{equation*}
\rho_{1} A_{1} V_{1}-\rho_{2} A_{2} V_{2}=\frac{d m_{\mathrm{c} . V_{.}}}{d t} \tag{4.56}
\end{equation*}
$$

For the steady-flow situation, in which the mass in the control volume remains constant, the continuity equation reduces to

$$
\begin{equation*}
\rho_{1} A_{1} V_{1}=\rho_{2} A_{2} V_{2} \tag{4.57}
\end{equation*}
$$

which will find much use in problems involving flow into and from various devices.
The quantity of mass crossing an area each second is termed the mass flux $\dot{m}$ and has units $\mathrm{kg} / \mathrm{s}$ ( $\mathrm{lbm} / \mathrm{sec}$ ). It is given by the expression

$$
\begin{equation*}
\dot{m}=\rho A V \tag{4.58}
\end{equation*}
$$

The quantity $A V$ is the flow-rate with units of $\mathrm{m}^{3} / \mathrm{s}\left(\mathrm{ft}^{3} / \mathrm{sec}\right)$.
If the velocity and density are not uniform over the entering and exiting areas, the variation across the areas must be accounted for. This is done by recognizing that the mass flowing through a differential area element $d A$ each second is given by $\rho V d A$, providing $V$ is normal to $d A$. In this case (4.58) is replaced by $\dot{m}=j_{A} \rho V d A$. Observe that for incompressible flow ( $\rho=$ constant), (4.58) holds whatever the velocity distribution, provided only that $V$ be interpreted as the average normal celocity over the area $A$.

EXAMPLE 4.12 Water is flowing in a pipe that changes diameter from 20 to 40 mm . If the water in the $20-\mathrm{mm}$ section has a velocity of $40 \mathrm{~m} / \mathrm{s}$, determine the velocity in the $40-\mathrm{mm}$ section. Also calculate the mass flux.

The continuity equation (4.57) is used. There results, using $\rho_{1}=\rho_{2}$,

$$
A_{1} V_{1}=A_{2} V_{2} \quad\left[\frac{\pi(0.02)^{2}}{4}\right](40)=\frac{\pi(0.04)^{2}}{4} V_{2} \quad \therefore V_{2}=10 \mathrm{~m} / \mathrm{s}
$$

The mass flux is found to be

$$
\dot{m}=\rho A_{1} V_{1}=(1000)\left(\frac{\pi(0.02)^{2}}{4}\right)(40)=12.57 \mathrm{~kg} / \mathrm{s}
$$

where $\rho=1000 \mathrm{~kg} / \mathrm{m}^{3}$ is the standard value for water.

## The Energy Equation

Consider again a general control volume as sketched in Fig. 4-10. The first law of thermodynamics for this control volume can be stated as

$$
\left.\begin{array}{cccc}
\left(\begin{array}{c}
\text { Net energy } \\
\text { transferred to } \\
\text { the c.v. }
\end{array}\right) & + & -\left(\begin{array}{c}
\text { Energy } \\
\text { entering } \\
\text { the c.v. }
\end{array}\right) & -\left(\begin{array}{c}
\text { Energy } \\
\text { leaving } \\
\text { the c.v. }
\end{array}\right)
\end{array}=\left(\begin{array}{c}
E_{1}-W-
\end{array}\right)=\begin{array}{l}
\begin{array}{l}
\text { Change of } \\
\text { energy in } \\
\text { the c.v. }
\end{array}
\end{array}\right)
$$

Fig. 4-10

The work $W$ is composed of two parts: the work due to the pressure needed to move the fluid, sometimes called flow work, and the work that results from a rotating shaft, called shaft work $W_{s}$. This is expressed as

$$
\begin{equation*}
W=P_{2} A_{2} V_{2} \Delta t-P_{1} A_{1} V_{1} \Delta t+W_{S} \tag{4.60}
\end{equation*}
$$

where $P A$ is the pressure force and $V \Delta t$ is the distance it moves during the time increment $\Delta t$. The negative sign results because the work done on the system is negative when moving the fluid into the control volume.

The energy $E$ is composed of kinetic energy, potential energy, and internal energy. Thus,

$$
\begin{equation*}
E=\frac{1}{2} m V^{2}+m g z+m u \tag{4.61}
\end{equation*}
$$

The first law can now be written as

$$
\begin{align*}
Q- & W_{S}-P_{2} A_{2} V_{2} \Delta t+P_{1} A_{1} V_{1} \Delta t+\rho_{1} A_{1} V_{1}\left(\frac{V_{1}^{2}}{2}+g z_{1}+u_{1}\right) \Delta t \\
& -\rho_{2} A_{2} V_{2}\left(\frac{V_{2}^{2}}{2}+g z_{2}+u_{2}\right) \Delta t=\Delta E_{\mathrm{c} . \mathrm{v} .} \tag{4.62}
\end{align*}
$$

Divide through by $\Delta t$ to obtain the energy equation

$$
\begin{equation*}
\dot{Q}-\dot{W}_{s}=\dot{m}_{2}\left(\frac{V_{2}^{2}}{2}+g z_{2}+u_{2}+\frac{P_{2}}{\rho_{2}}\right)-\dot{m}_{1}\left(\frac{V_{1}^{2}}{2}+g z_{1}+u_{1}+\frac{P_{1}}{\rho_{1}}\right)+\frac{d E_{c . v .}}{d t} \tag{4.63}
\end{equation*}
$$

where we have used

$$
\begin{equation*}
\dot{Q}=\frac{Q}{\Delta t} \quad \dot{W}_{s}=\frac{W}{\Delta t} \quad \dot{m}=\rho A V \tag{4.64}
\end{equation*}
$$

For steady flow, a very common situation, the energy equation becomes

$$
\begin{equation*}
\dot{Q}-\dot{W}_{s}=\dot{m}\left[h_{2}-h_{1}+g\left(z_{2}-z_{1}\right)+\left(V_{2}^{2}-V_{1}^{2}\right) / 2\right] \tag{4.65}
\end{equation*}
$$

where the enthalpy of (4.12) has been introduced. This is the form most often used when a gas or a vapor is flowing.

Quite often the kinetic energy and potential energy changes are negligible. The first law then takes the simplified form

$$
\begin{equation*}
\dot{Q}-\dot{W}_{s}=\dot{m}\left(h_{2}-h_{1}\right) \tag{4.66}
\end{equation*}
$$

or

$$
\begin{equation*}
q-w_{s}=h_{2}-h_{1} \tag{4.67}
\end{equation*}
$$

where $q=\dot{Q} / \dot{m}$ and $w_{s}=\dot{W}_{s} / \dot{m}$. This simplified form of the energy equation has a surprisingly large number of applications.

For a control volume through which a liquid flows, it is most convenient to return to (4.63). For a steady flow with $\rho_{2}=\rho_{1}=\rho$, neglecting the heat transfer and changes in internal energy, the energy equation takes the form

$$
\begin{equation*}
-\dot{W}_{s}=\dot{m}\left[\frac{P_{2}-P_{1}}{\rho}+\frac{V_{2}^{2}-V_{1}^{2}}{2}+g\left(z_{2}-z_{1}\right)\right] \tag{4.68}
\end{equation*}
$$

This is the form to use for a pump or a hydroturbine. If $\dot{Q}$ and $\Delta u$ are not zero, simply include them.

### 4.9 APPLICATIONS OF THE ENERGY EQUATION

There are several points that must be considered in the analysis of most problems in which the energy equation is used. As a first step, it is very important to identify the control volume selected in the solution of the problems; dotted lines are used to outline the control surface. If at all possible, the control surface should be chosen so that the flow variables are uniform or known functions over the areas where the fluid enters or exits the control volume. For example, in Fig. 4-11 the area could be chosen as in part ( $a$ ), but the velocity and the pressure are certainly not uniform over the area. In part (b), however, the control surface is chosen sufficiently far downstream from the abrupt area change that the exiting velocity and pressure can be approximated by uniform distributions.

It is also necessary to specify the process by which the flow variables change. Is it incompressible? isothermal? constant-pressure? adiabatic? A sketch of the process on a suitable diagram is often of use in the calculations. If the working substance behaves as an ideal gas, then the appropriate equations may be used; if not, tabulated values must be used, such as those provided for steam. For real gases that do not behave as ideal gases, specialized equations may be available for calculations; some of these equations will be presented in a later chapter.

Often heat transfer from a device or an internal energy change across a device, such as flow through a pump, is not desired. For such situations, the heat transfer and internal energy change may

Fig. 4-11
be lumped together as losses. In a pipeline losses occur because of friction; in a pump, losses occur because of poor fluid motion around the rotating blades. For many devices the losses are included as an efficiency of the device. Examples will illustrate.

Kinetic energy or potential energy changes can often be neglected in comparison with other terms in the energy equation. Potential energy changes are usually included only in situations where liquid is involved and where the inlet and exit areas are separated by a large vertical distance. The following applications will illustrate many of the above points.

## Throttling Devices

A throttling device involves a steady-flow adiabatic process that provides a pressure drop with no significant potential energy or kinetic energy changes. The process occurs relatively rapidly, with the result that negligible heat transfer occurs. Two such devices are sketched in Fig. 4-12. If the energy equation is applied to such a device, obviously there is no work done; neglecting kinetic and potential energy changes, we have, for the adiabatic process [see (4.67)],

$$
\begin{equation*}
h_{1}=h_{2} \tag{4.69}
\end{equation*}
$$

where section 1 is upstream and section 2 is downstream. Most valves are throttling devices, for which the energy equation takes the form of (4.69). They are also used in many refrigeration units in which the sudden drop in pressure causes a change in phase of the working substance. The throttling process is analogous to the sudden expansion of Fig. 3-5b.

Fig. 4-12

EXAMPLE 4.13 Steam enters a throttling valve at 8000 kPa and $300^{\circ} \mathrm{C}$ and leaves at a pressure of 1600 kPa . Determine the final temperature and specific volume of the steam.

The enthalpy of the steam as it enters is found from the superheat steam table to be $h_{1}=2785 \mathrm{~kJ} / \mathrm{kg}$. This must equal the exiting enthalpy as demanded by (4.69). The exiting steam is in the quality region, since at 1600 $\mathrm{kPa} h_{8}=2794 \mathrm{~kJ} / \mathrm{kg}$. Thus the final temperature is $T_{2}=201.4^{\circ} \mathrm{C}$.

To find the specific volume we must know the quality. It is found from

$$
h_{2}=h_{f}+x_{2} h_{f g} \quad 2785=859+1935 x_{2} \quad x_{2}=0.995
$$

The specific volume is then $v_{2}=0.0012+(0.995)(0.1238-0.0012)=0.1232 \mathrm{~m}^{3} / \mathrm{kg}$.

## Compressors, Pumps, and Turbines

A pump is a device which transfers energy to a liquid flowing through the pump with the result that the pressure is increased. Compressors and blowers also fall into this category but have the primary purpose of increasing the pressure in a gas. A turbine, on the other hand, is a device in which work is done by the fluid on a set of rotating blades. As a result there is a pressure drop from the inlet to the outlet of the turbine. In some situations there may be heat transferred from the device to the surroundings, but often the heat transfer can be assumed negligible. In addition the kinetic and potential energy changes are usually neglected. For such devices operating in a steady-state mode the
energy equation takes the form [see (4.66)]

$$
\begin{equation*}
-\dot{W}_{S}=\dot{m}\left(h_{2}-h_{1}\right) \quad \text { or } \quad-w_{S}=h_{2}-h_{1} \tag{4.70}
\end{equation*}
$$

where $\dot{W}_{S}$ is negative for a compressor and positive for a gas or steam turbine. In the event that heat transfer does occur, from perhaps a high-temperature working fluid, it must, of course be included in the above equation.

For liquids, such as water, the energy equation (4.68), neglecting kinetic and potential energy changes, becomes

$$
\begin{equation*}
-w_{S}=\frac{P_{2}-P_{1}}{\rho} \tag{4.71}
\end{equation*}
$$

EXAMPLE 4.14 Steam enters a turbine at 4000 kPa and $500^{\circ} \mathrm{C}$ and leaves as shown in Fig. 4-13. For an inlet velocity of $200 \mathrm{~m} / \mathrm{s}$ calculate the turbine power output. (a) Neglect any heat transfer and kinetic energy change. (b) Show that the kinetic energy change is negligible.

Fig. 4-13
(a) The energy equation in the form of (4.70) is $-\dot{W}_{T}=\left(h_{2}-h_{1}\right) \dot{m}$. We find $\dot{m}$ as follows:

$$
\dot{m}=\rho_{1} A_{1} V_{1}=\frac{1}{v_{1}} A_{1} V_{1}=\frac{\pi(0.025)^{2}(200)}{0.08643}=4.544 \mathrm{~kg} / \mathrm{s}
$$

The enthalpies are found from Tables C-3 and C-2 to be

$$
h_{1}=3445.2 \mathrm{~kJ} / \mathrm{kg} \quad h_{2}=2665.7 \mathrm{~kJ} / \mathrm{kg}
$$

The maximum power output is then $\dot{W}_{T}=-(2665.7-3445.2)(4.544)=3542 \mathrm{~kJ} / \mathrm{s}$ or 3.542 MW .
(b) The exiting velocity is found to be

$$
V_{2}=\frac{A_{1} V_{1} \rho_{1}}{A_{2} \rho_{2}}=\frac{\pi(0.025)^{2}(200 / 0.08643)}{\pi(0.125)^{2} / 2.087}=193 \mathrm{~m} / \mathrm{s}
$$

The kinetic energy change is then

$$
\Delta K E=\dot{m}\left(\frac{V_{2}^{2}-V_{1}^{2}}{2}\right)=(4.544)\left(\frac{193^{2}-200^{2}}{2}\right)=-6250 \mathrm{~J} / \mathrm{s} \quad \text { or }-6.25 \mathrm{~kJ} / \mathrm{s}
$$

This is less than 0.1 percent of the enthalpy change and is indeed negligible. Kinetic energy changes are usually omitted in the analysis of a turbine.

Fig. 4-14

EXAMPLE 4.15 Determine the maximum pressure increase across the 10 -hp pump shown in Fig. 4-14. The inlet velocity of the water is $30 \mathrm{ft} / \mathrm{sec}$.

The energy equation (4.68) is used. By neglecting the heat transfer and assuming no increase in internal energy, we establish the maximum pressure rise. Neglecting the potential energy change, the energy equation takes the form

$$
-\dot{W}_{s}=\dot{m}\left(\frac{P_{2}-P_{1}}{\rho}+\frac{V_{2}^{2}-V_{1}^{2}}{2}\right)
$$

The velocity $V_{1}$ is given, and $V_{2}$ is found from the continuity equation as follows:

$$
\rho A_{1} V_{1}=\rho A_{2} V_{2} \quad\left[\frac{\pi(1)^{2}}{4}\right](30)=\frac{\pi(1.5)^{2}}{4} V_{2} \quad \therefore V_{2}=13.33 \mathrm{ft} / \mathrm{sec}
$$

The mass flux, needed in the energy equation, is then, using $\rho=62.4 \mathrm{lbm} / \mathrm{ft}^{3}$,

$$
\dot{m}=\rho A V=(62.4)\left[\frac{\pi(1)^{2}}{(4 \times 144)}\right](30)=10.21 \mathrm{lbm} / \mathrm{sec}
$$

Recognizing that the pump work is negative, the energy equation is

$$
-(-10)(550) \mathrm{ft}-\mathrm{lbf} / \mathrm{sec}=(10.21 \mathrm{lbm} / \mathrm{sec})\left[\frac{\left(P_{2}-P_{1}\right) \mathrm{lbf} / \mathrm{ft}^{2}}{62.4 \mathrm{lbm} / \mathrm{ft}^{3}}+\frac{\left(13.33^{2}-30^{2}\right) \mathrm{ft}^{2} / \mathrm{sec}^{2}}{(2)\left(32.2 \mathrm{lbm}-\mathrm{ft} / \mathrm{sec}^{2}-\mathrm{lbf}\right)}\right]
$$

where the factor $32.2 \mathrm{lbm}-\mathrm{ft} / \mathrm{sec}^{2}-\mathrm{lbf}$ is needed to obtain the correct units on the kinetic energy term. This predicts a pressure rise of

$$
P_{2}-P_{1}=(62.4)\left[\frac{5500}{10.21}-\frac{13.33^{2}-30^{2}}{(2)(32.2)}\right]=34,310 \mathrm{lbf} / \mathrm{ft}^{2} \quad \text { or } 238.3 \mathrm{psi}
$$

Note that in this example the kinetic energy terms are retained because of the difference in inlet and exit areas; if they were omitted, only a 2 percent error would result. In most applications the inlet and exit areas will be equal so that $V_{2}=V_{1}$; but even with different areas, as in this example, kinetic energy changes are usually ignored in a pump or turbine and (4.71) is used.

## Nozzles and Diffusers

A nozzle is a device that is used to increase the velocity of a flowing fluid. It does this by reducing the pressure. A diffuser is a device that increases the pressure in a flowing fluid by reducing the velocity. There is no work input into the devices and usually negligible heat transfer. With the additional assumptions of negligible internal energy and potential energy changes, the energy equation takes the form

$$
\begin{equation*}
0=\frac{V_{2}^{2}}{2}-\frac{V_{1}^{2}}{2}+h_{2}-h_{1} \tag{4.72}
\end{equation*}
$$

Based on our intuition we expect a nozzle to have a decreasing area in the direction of flow and a diffuser to have an increasing area in the direction of flow. This is indeed the case for a subsonic flow in which $V<\sqrt{k R T}$. For a supersonic flow in which $V>\sqrt{k R T}$ the opposite is true: a nozzle has an increasing area and a diffuser has a decreasing area. This is shown in Fig. 4-15.

Fig. 4-15
Three equations may be used for nozzle and diffuser flow; energy, continuity, and a process equation, such as for an adiabatic quasiequilibrium flow. Thus, we may have three unknowns at the exit, given the entering conditions. There may also be shock waves in supersonic flows or "choked" subsonic flows. These more complicated flows are included in a compressible flow course. Only the more simple situations will be included here.

EXAMPLE 4.16 Air flows through the supersonic nozzle shown in Fig. 4-16. The inlet conditions are 7 kPa and $420^{\circ} \mathrm{C}$. The nozzle exit diameter is adjusted such that the exiting velocity is $700 \mathrm{~m} / \mathrm{s}$. Calculate ( $a$ ) the exit temperature, ( $b$ ) the mass flux, and (c) the exit diameter. Assume an adiabatic quasiequilibrium flow.

Fig. 4-16
(a) To find the exit temperature the energy equation (4.72) is used. It is, using $\Delta h=c_{p} \Delta T$,

$$
\frac{V_{1}^{2}}{2}+c_{p} T_{1}=\frac{V_{2}^{2}}{2}+c_{p} T_{2}
$$

We then have, using $c_{p}=1000 \mathrm{~J} / \mathrm{kg} \cdot \mathrm{K}$,

$$
T_{2}=\frac{V_{1}^{2}-V_{2}^{2}}{2 c_{p}}+T_{1}=\frac{400^{2}-700^{2}}{(2)(1000)}+420=255^{\circ} \mathrm{C}
$$

(b) To find the mass flux we must find the density at the entrance. From the inlet conditions we have

$$
\rho_{1}=\frac{P_{1}}{R T_{1}}=\frac{7000}{(287)(693)}=0.03520 \mathrm{~kg} / \mathrm{m}^{3}
$$

The mass flux is then $\dot{m}=\rho_{1} A_{1} V_{1}=(0.0352)(\pi)(0.1)^{2}(400)=0.4423 \mathrm{~kg} / \mathrm{s}$.
(c) To find the exit diameter we would use the continuity equation $\rho_{1} A_{1} V_{1}=\rho_{2} A_{2} V_{2}$. This requires the density at the exit. It is found by assuming adiabatic quasiequilibrium flow. Referring to (4.49), we have

$$
\rho_{2}=\rho_{1}\left(\frac{T_{2}}{T_{1}}\right)^{1 /(k-1)}=(0.0352)\left(\frac{528}{693}\right)^{1 /(1.4-1)}=0.01784 \mathrm{~kg} / \mathrm{m}^{3}
$$

Hence,

$$
d_{2}^{2}=\frac{\rho_{1} d_{1}^{2} V_{1}}{\rho_{2} V_{2}}=\frac{(0.0352)\left(0.2^{2}\right)(400)}{(0.01784)(700)}=0.0451 \quad \therefore d_{2}=0.212 \mathrm{~m} \quad \text { or } 212 \mathrm{~mm}
$$

## Heat Exchangers

An important device that has many applications in engineering is the heat exchanger. Heat exchangers are used to transfer energy from a hot body to a colder body or to the surroundings by means of heat transfer. Energy is transferred from the hot gases after combustion in a power plant to the water in the pipes of the boiler and from the hot water that leaves an automobile engine to the atmosphere, and electrical generators are cooled by water flowing through internal flow passages.

Many heat exchangers utilize a flow passage into which a fluid enters and from which the fluid exits at a different temperature. The velocity does not normally change, the pressure drop through the passage is usually neglected, and the potential energy change is assumed zero. The energy equation then results in

$$
\begin{equation*}
\dot{Q}=\left(h_{2}-h_{1}\right) \dot{m} \tag{4.73}
\end{equation*}
$$

since no work occurs in the heat exchanger.
Energy may be exchanged between two moving fluids, as shown schematically in Fig. 4-17. For a control volume including the combined unit, which is assumed to be insulated, the energy equation, as applied to the control volume of Fig. 4-17a, would be

$$
\begin{equation*}
0=\dot{m}_{A}\left(h_{A 2}-h_{A 1}\right)+\dot{m}_{B}\left(h_{B 2}-h_{B 1}\right) \tag{4.74}
\end{equation*}
$$

The energy that leaves fluid $A$ is transferred to fluid $B$ by means of the heat transfer $\dot{Q}$. For the control volumes shown in Fig. 4-17b we have

$$
\begin{equation*}
\dot{Q}=\dot{m}_{B}\left(h_{B 2}-h_{B 1}\right) \quad-\dot{Q}=\dot{m}_{A}\left(h_{A 2}-h_{A 1}\right) \tag{4.75}
\end{equation*}
$$

(a) Combined unit

(b) Separated control volumes

Fig. 4-17

EXAMPLE 4.17 Liquid sodium, flowing at $100 \mathrm{~kg} / \mathrm{s}$, enters a heat exchanger at $450^{\circ} \mathrm{C}$ and exits at $350^{\circ} \mathrm{C}$. The specific heat of sodium is $1.25 \mathrm{~kJ} / \mathrm{kg} \cdot{ }^{\circ} \mathrm{C}$. Water enters at 5000 kPa and $20^{\circ} \mathrm{C}$. Determine the minimum mass flux of the water so that the water does not completely vaporize. Neglect the pressure drop through the exchanger. Also, calculate the rate of heat transfer.

The energy equation (4.75) is used as $\dot{m}_{s}\left(h_{s 1}-h_{s 2}\right)=\dot{m}_{w}\left(h_{w \cdot 2}-h_{w 11}\right)$, or

$$
\dot{m}_{s} c_{p}\left(T_{s 1}-T_{s 2}\right)=\dot{m}_{w}\left(h_{w 2}-h_{w 1}\right)
$$

Using the given values, we have (use Table C-4 to find $h_{w 1}$ )

$$
(100)(1.25) \times(450-350)=\dot{m}_{w}(2792.8-88.7) \quad \therefore \dot{m}_{w}=4.623 \mathrm{~kg} / \mathrm{s}
$$

where we have assumed a saturated vapor state for the exiting steam to obtain the maximum allowable exiting enthalpy. The heat transfer is found using the energy equation (4.75) applied to one of the separate control volumes.

$$
\dot{Q}=\dot{m}_{w}\left(h_{w 2}-h_{w 1}\right)=(4.623)(2792.8-88.7)=12,500 \mathrm{~kW} \quad \text { or } 12.5 \mathrm{MW}
$$

## Power and Refrigeration Cycles

When energy in the form of heat is transferred to a working fluid, energy in the form of work may be extracted from the working fluid. The work may be converted to an electrical form of energy, such as is done in a power plant, or to a mechanical form, such as is done in an automobile. In general, such conversions of energy are accomplished by a power cycle. One such cycle is shown in Fig. 4-18. In the boiler (a heat exchanger) the energy contained in a fuel is transferred by heat to the water which enters, causing a high-pressure steam to exit and enter the turbine. A condenser (another heat exchanger) discharges heat, and a pump increases the pressure lost through the turbine.

Fig. 4-18

The energy transferred to the working fluid in the boiler in the simple power cycle of Fig. 4-18 is the energy that is available for conversion to useful work; it is the energy that must be purchased. The thermal efficiency $\eta$ is defined to be the ratio of the net work produced to the energy input. In the simple power cycle being discussed it is

$$
\begin{equation*}
\eta=\frac{\dot{W}_{T}-\dot{W}_{P}}{\dot{Q}_{B}} \tag{4.76}
\end{equation*}
$$

When we consider the second law of thermodynamics, we will show that there is an upper limit to the thermal efficiency of a particular power cycle. Thermal efficiency is, however, a quantity that is determined solely by first-law energy considerations.

Other components can be combined in an arrangement like that shown in Fig. 4-19, resulting in a refrigeration cycle. Heat is transferred to the working fluid (the refrigerant) in the evaporator (a heat exchanger). The working fluid is then compressed by the compressor. Heat is transferred from the working fluid in the condenser, and then its pressure is suddenly reduced in the expansion valve. A refrigeration cycle may be used to add energy to a body (heat transfer $\dot{Q}_{C}$ ) or it may be used to extract energy from a body (heat transfer $\dot{Q}_{E}$ ).

Fig. 4-19 A Simple Refrigeration Cycle

It is not useful to calculate the thermal efficiency of a refrigeration cycle since the objective is not to do work but to accomplish heat transfer. If we are extracting energy from a body, our purpose is to cause maximum heat transfer with minimum work input. To measure this, we define a coefficient of performance (abbreviated COP) as

$$
\begin{equation*}
\mathrm{COP}=\frac{\dot{Q}_{E}}{\dot{W}_{\mathrm{comp}}}=\frac{\dot{Q}_{E}}{\dot{Q}_{C}-\dot{Q}_{E}} \tag{4.77}
\end{equation*}
$$

If we are adding energy to a body, our purpose is, again, to do so with a minimum work input. In this case the coefficient of performance is defined as

$$
\begin{equation*}
\mathrm{COP}=\frac{\dot{Q}_{C}}{\dot{W}_{\mathrm{comp}}}=\frac{\dot{Q}_{C}}{\dot{Q}_{C}-\dot{Q}_{E}} \tag{4.78}
\end{equation*}
$$

A device which can operate with this latter objective is called a heat pump; if it operates with the former objective only it is a refrigerator.

It should be apparent from the definitions that thermal efficiency can never be greater than unity but that the coefficient of performance can be greater than unity. Obviously, the objective of the engineer is to maximize either one in a particular design. The thermal efficiency of a power plant is around 35 percent; the thermal efficiency of an automobile engine is around 20 percent. The coefficient of performance for a refrigerator or a heat pump ranges from 2 to 6 , with a heat pump having the greater values.

Fig. 4-20

EXAMPLE 4.18 Steam leaves the boiler of a simple steam power cycle at 4000 kPa and $600^{\circ} \mathrm{C}$. It exits the turbine at 20 kPa as saturated steam. It then exits the condenser as saturated water. (See Fig. 4-20.) Determine the thermal efficiency if there is no loss in pressure through the condenser and the boiler.

To determine the thermal efficiency we must calculate the heat transferred to the water in the boiler, the work done by the turbine, and the work required by the pump. We will make the calculations for 1 kg of steam since the mass is unknown. The boiler heat transfer is, neglecting kinetic and potential energy changes, $a_{B}=h_{3}-h_{2}$. To find $h_{2}$ we assume that the pump simply increases the pressure [see (4.71)]:

$$
w_{P}=\left(P_{2}-P_{1}\right) v=(4000-20)(0.001)=3.98 \mathrm{~kJ} / \mathrm{kg}
$$

The enthalpy $h_{2}$ is thus found to be, using (4.70),

$$
h_{2}=w_{P}+h_{1}=3.98+251.4=255.4 \mathrm{~kJ} / \mathrm{kg}
$$

where $h_{1}$ is assumed to be that of saturated water at 20 kPa . From the steam tables we find $h_{3}=3674 \mathrm{~kJ} / \mathrm{kg}$. There results

$$
q_{B}=3674-255.4=3420 \mathrm{~kJ} / \mathrm{kg}
$$

The work output from the turbine is $w_{T}=h_{3}-h_{4}=3674-2610=1064 \mathrm{~kJ} / \mathrm{kg}$. Finally, the thermal efficiency is

$$
\eta=\frac{w_{T}-w_{P}}{q_{B}}=\frac{1064-4}{3420}=0.310 \text { or } 31.0 \%
$$

Note that the pump work could have been neglected with no significant change in the results.

## Transient Flow

If the steady-flow assumption of the preceding sections is not valid, then the time dependence of the various properties must be included. The filling of a rigid tank with a gas and the release of gas from a pressurized tank are examples that we will consider.

The energy equation is written as

$$
\begin{equation*}
\dot{Q}-\dot{W}_{S}=\frac{d E_{\mathrm{c} . \mathrm{v}}}{d t}+\dot{m}_{2}\left(\frac{V_{2}^{2}}{2}+g z_{2}+h_{2}\right)-\dot{m}_{1}\left(\frac{V_{1}^{2}}{2}+g z_{1}+h_{1}\right) \tag{4.79}
\end{equation*}
$$

We will consider the kinetic energy and potential energy terms to be negligible so that $E_{\text {c.v. }}$ will consist of internal energy only. The first problem we wish to study is the filling of a rigid tank, as sketched in Fig. 4-21. In the tank, there is only an entrance. With no shaft work present the energy

Fig. 4-21
equation reduces to

$$
\begin{equation*}
\dot{Q}=\frac{d}{d t}(u m)-\dot{m}_{1} h_{1} \tag{4.80}
\end{equation*}
$$

where $m$ is the mass in the control volume. If we multiply this equation by $d t$ and integrate from an initial time $t_{i}$ to some final time $t_{f}$, we have

$$
\begin{equation*}
Q=u_{f} m_{f}-u_{i} m_{i}-m_{1} h_{1} \tag{4.81}
\end{equation*}
$$

where $m_{1}=$ mass that enters
$m_{f}=$ final mass in control volume
$m_{i}=$ initial mass in control volume
In addition, for the filling process the enthalpy $h_{1}$ is assumed constant over the time interval.
The continuity equation for the unsteady-flow situation may be necessary in the solution process. Since the final mass is equal to the initial mass plus the mass that entered, this is expressed as

$$
\begin{equation*}
m_{f}=m_{i}+m_{1} \tag{4.82}
\end{equation*}
$$

Now consider the discharge of a pressurized tank. This problem is more complicated than the filling of a tank in that the properties at the exiting area are not constant over the time interval of interest; we must include the variation of the variables with time. We will assume an insulated tank, so that no heat transfer occurs, and again neglect kinetic energy and potential energy. The energy equation becomes, assuming no shaft work,

$$
\begin{equation*}
0=\frac{d}{d t}(u m)+\dot{m}_{2}\left(P_{2} v_{2}+u_{2}\right) \tag{4.83}
\end{equation*}
$$

where $m$ is the mass in the control volume. From the continuity equation,

$$
\begin{equation*}
\frac{d m}{d t}=-\dot{m}_{2} \tag{4.84}
\end{equation*}
$$

If this is substituted into (4.83), we have

$$
\begin{equation*}
d(u m)=\left(P_{2} v_{2}+u_{2}\right) d m \tag{4.85}
\end{equation*}
$$

We will assume that the gas escapes through a small valve opening, as shown in Fig. 4-22. Just

Fig. 4-22
upstream of the valve is area $A_{2}$ with properties $P_{2}, v_{2}$, and $u_{2}$. The velocity at this exiting area is assumed to be quite small so that $P_{2}, v_{2}$, and $u_{2}$ are approximately the same as the respective quantities in the control volume. With this assumption (4.85) becomes

$$
\begin{equation*}
d(u m)=(P v+u) d m \tag{4.86}
\end{equation*}
$$

Letting $d(u m)=u d m+m d u$, there results

$$
\begin{equation*}
m d u=P v d m \tag{4.87}
\end{equation*}
$$

Now we will restrict ourselves to a gas that behaves as an ideal gas. For such a gas $d u=c_{\imath} d T$ and $P_{v}=R T$, and we obtain

$$
\begin{equation*}
m c_{\imath} d T=R T d m \tag{4.88}
\end{equation*}
$$

This is put in the form

$$
\begin{equation*}
\frac{c_{1}}{R} \frac{d T}{T}=\frac{d m}{m} \tag{4.89}
\end{equation*}
$$

which can be integrated from the initial state, signified by the subscript $i$, to the final state, signified by the subscript $f$. There results

$$
\begin{equation*}
\frac{c_{c}}{R} \ln \frac{T_{f}}{T_{i}}=\ln \frac{m_{f}}{m_{i}} \quad \text { or } \quad \frac{m_{f}}{m_{i}}=\left(\frac{T_{f}}{T_{i}}\right)^{1 /(k-1)} \tag{4.90}
\end{equation*}
$$

where we have used $c_{r} / R=1 /(k-1)$; see (4.31). In terms of the pressure ratio, (4.50) allows us to write

$$
\begin{equation*}
\frac{m_{f}}{m_{i}}=\left(\frac{P_{f}}{P_{i}}\right)^{1 / k} \tag{4.91}
\end{equation*}
$$

Remember that these equations are applicable if there is no heat transfer from the volume; the process is quasistatic in that the properties are assumed uniformly distributed throughout the control volume (this requires a relatively slow discharge velocity, say, $100 \mathrm{~m} / \mathrm{s}$ or less); and the gas behaves as an ideal gas.

EXAMPLE 4.19 A completely evacuated, insulated, rigid tank with a volume of $300 \mathrm{ft}^{3}$ is filled from a steam line transporting steam at $800^{\circ} \mathrm{F}$ and 500 psia. Determine (a) the temperature of steam in the tank when its pressure is 500 psia and ( $b$ ) the mass of steam that flows into the tank.
(a) The energy equation used is (4.81). With $Q=0$ and $m_{i}=0$, we have $u_{f} m_{f}=m_{1} h_{1}$. The continuity equation (4.82) allows us to write $m_{f}=m_{1}$, which states that the final mass $m_{f}$ in the tank is equal to the mass $m_{1}$ that entered the tank. Thus, there results $u_{f}=h_{1}$. From Table-C3E, $h_{1}$ is found, at $800^{\circ} \mathrm{F}$ and 500 psia, to be $1412.1 \mathrm{Btu} / \mathrm{lbm}$. Using $P_{4}=500 \mathrm{psia}$ as the final tank pressure, we can interpolate for the temperature, using $u_{f}=1412.1 \mathrm{Btu} / \mathrm{lbm}$, and find

$$
T_{f}=\left(\frac{1412.1-1406.0}{1449.2-1406.0}\right)(100)+1100=1114.1^{\circ} \mathrm{F}
$$

(b) We recognize that $m_{1}=m_{f}=V_{\text {tank }} / c_{f}$. The specific volume of the steam in the tank at 500 psia and $1114.1^{\circ} \mathrm{F}$ is

$$
v_{f}=\left(\frac{1114.1-1100}{100}\right)(1.9518-1.8271)+1.8271=1.845 \mathrm{ft}^{3} / \mathrm{lbm}
$$

This gives $m_{f}=300 / 1.845=162.6 \mathrm{lbm}$.
EXAMPLE 4.20 An air tank with a volume of $20 \mathrm{~m}^{3}$ is pressurized to 10 MPa . The tank eventually reaches room temperature of $25^{\circ} \mathrm{C}$. If the air is allowed to escape with no heat transfer until $P_{f}=200 \mathrm{kPa}$, determine the mass of air remaining in the tank and the final temperature of air in the tank.

The initial mass of air in the tank is found to be

$$
m_{i}=\frac{P_{i} V}{R T_{i}}=\frac{10 \times 10^{6}(20)}{(287)(298)}=2338 \mathrm{~kg}
$$

Equation (4.91) gives, using $k=1.4$,

$$
m_{f}=m_{i}\left(\frac{P_{f}}{P_{i}}\right)^{1 / k}=(2338)\left(\frac{2 \times 10^{5}}{10 \times 10^{6}}\right)^{1 / 1.4}=143.0 \mathrm{~kg}
$$

To find the final temperature (4.90) is used:

$$
T_{f}=T_{i}\left(\frac{m_{f}}{m_{i}}\right)^{k-1}=(298)(143 / 2338)^{0.4}=97.46 \mathrm{~K} \quad \text { or }-175.5^{\circ} \mathrm{C}
$$

A person who accidently comes in contact with a flow of gas from a pressurized tank faces immediate freezing.

## Solved Problems

4.1 A $1500-\mathrm{kg}$ automobile traveling at $30 \mathrm{~m} / \mathrm{s}$ is brought to rest by impacting a shock absorber $\sim f_{+}$composed of a piston with small holes that moves in a cylinder containing water. How much heat must be removed from the water to return it to its original temperature?

As the piston moves through the water, work is done due to the force of impact moving with the piston. The work that is done is equal to the kinetic energy change; that is,

$$
W=\frac{1}{2} m V^{2}=\left(\frac{1}{2}\right)(1500)(30)^{2}=675000 \mathrm{~J}
$$

The first law for a cycle requires that this amount of heat must be transferred from the water to return it to its original temperature; hence, $Q=675 \mathrm{~kJ}$.
4.2 A piston moves upward a distance of 5 cm while 200 J of heat is added (Fig. 4-23). Calculate the change in internal energy of the vapor if the spring is originally unstretched.

Fig. 4-23

The work needed to raise the weight and compress the spring is

$$
\begin{aligned}
W & =(m g)(h)+\frac{1}{2} K x^{2}+\left(P_{\mathrm{atm}}\right)(A)(h) \\
& =(60)(9.81)(0.05)+\left(\frac{1}{2}\right)(50000)(0.05)^{2}+(100000)\left[\frac{\pi(0.2)^{2}}{4}\right](0.05)=250 \mathrm{~J}
\end{aligned}
$$

The first law for a process without kinetic or potential energy changes is

$$
Q-W=\Delta U
$$

Thus, we have $\Delta U=200-250=-50 \mathrm{~J}$.
4.3 A system undergoes a cycle consisting of the three processes listed in the table. Compute the missing values. All quantities are in kJ .

| Process | $Q$ | $W$ | $\Delta E$ |
| :--- | :---: | :---: | :---: |
| $1 \rightarrow 2$ | $a$ | 100 | 100 |
| $2 \rightarrow 3$ | $b$ | -50 | $c$ |
| $3 \rightarrow 1$ | 100 | $d$ | -200 |

Use the first law in the form $Q-W=\Delta E$. Applied to process $1 \rightarrow 2$, we have

$$
a-100=100 \quad \therefore a=200 \mathrm{~kJ}
$$

Applied to process $3 \rightarrow 1$, there results

$$
100-d=-200 \quad \therefore d=300 \mathrm{~kJ}
$$

The net work is then $\Sigma W=W_{1-2}+W_{2-3}+W_{3-1}=100-50+300=350 \mathrm{~kJ}$. The first law for a cycle demands that

$$
\Sigma Q=\Sigma W \quad 200+b+100=350 \quad \therefore b=50 \mathrm{~kJ}
$$

Finally, applying the first law to process $2 \rightarrow 3$ provides

$$
50-(-50)=c \quad \therefore c=100 \mathrm{~kJ}
$$

Note that, for a cycle, $\Sigma \Delta E=0$; this, in fact, could have been used to determine the value of $c$ :

$$
\Sigma \Delta E=100+c-200=0 \quad \therefore c=100 \mathrm{~kJ}
$$

4.4 A $6-\mathrm{V}$ insulated battery delivers a $5-\mathrm{A}$ current over a period of 20 min . Calculate the heat transfer that must occur to return the battery to its initial temperature.

The work done by the battery is $\left.W_{1-2}=V I \Delta t=(6)(5)(20)(60)\right]=36 \mathrm{~kJ}$. According to the first law, this must equal $-\left(U_{2}-U_{1}\right)$ since $Q_{1-2}=0$ (the battery is insulated). To return the battery to its initial state, the first law, for this second process in which no work is done, gives

$$
Q_{2-1}-W_{2-1}^{0}=\Delta U=U_{1}-U_{2}
$$

Consequently, $Q_{2-1}=+36 \mathrm{~kJ}$, where the positive sign indicates that heat must be transferred to the battery.
4.5 A refrigerator is situated in an insulated room; it has a 2 -hp motor that drives a compressor. Over a 30 -minute period of time it provides 5300 kJ of cooling to the refrigerated space and 8000 kJ of heating from the coils on the back of the refrigerator. Calculate the increase in internal energy in the room.

In this problem we consider the insulated room as the system. The refrigerator is nothing more than a component in the system. The only transfer of energy across the boundary of the system is via the
electrical wires of the refrigerator. For an insulated room ( $Q=0$ ) the first law provides

$$
Q^{+0}-W=\Delta U
$$

Hence, $\Delta U=-(-2 \mathrm{hp})(0.746 \mathrm{~kW} / \mathrm{hp})(1800 \mathrm{~s})=2686 \mathrm{~kJ}$.
4.6 A $2-\mathrm{ft}^{3}$ rigid volume contains water at $120^{\circ} \mathrm{F}$ with a quality of 0.5 . Calculate the final temperature if 8 Btu of heat is added.

The first law for a process demands that $Q-W=m \Delta u$. To find the mass, we must use the specific volume as follows:

$$
\begin{aligned}
v_{1} & =v_{f}+x\left(v_{g}-v_{f}\right)=0.016+(0.5)(203.0-0.016)=101.5 \mathrm{ft}^{3} / \mathrm{lbm} \\
\therefore m & =\frac{V}{v}=\frac{2}{101.5}=0.0197 \mathrm{lbm}
\end{aligned}
$$

For a rigid volume the work is zero since the volume does not change. Hence, $Q=m \Delta u$. The value of the initial internal energy is

$$
u_{1}=u_{f}+x u_{f g}=87.99+(0.5)(961.9)=568.9 \mathrm{Btu} / \mathrm{lbm}
$$

The final internal energy is then calculated from the first law:

$$
8=0.0197\left(u_{2}-568.9\right) \quad \therefore u_{2}=975 \mathrm{Btu} / \mathrm{lbm}
$$

This is less than $u_{g}$; consequently, state 2 is in the wet region with $v_{2}=101.5 \mathrm{ft}^{3} / \mathrm{lbm}$. This requires a trial-and-error procedure to find state 2 :
At $T=140^{\circ} \mathrm{F}$ :

$$
\begin{aligned}
101.5 & =0.016+x_{2}(122.9-0.016) \quad \therefore x_{2}=0.826 \\
975 & =108+948.2 x_{2} \quad \therefore x_{2}=0.914
\end{aligned}
$$

At $T=150^{\circ} \mathrm{F}$ :

$$
\begin{aligned}
v_{g} & =96.99 \quad \therefore \text { slightly superheat } \\
975 & =118+941.3 x_{2} \quad \therefore x_{2}=0.912
\end{aligned}
$$

Obviously, state 2 lies between $140^{\circ} \mathrm{F}$ and $150^{\circ} \mathrm{F}$. Since the quality is insensitive to the internal energy, we find $T_{2}$ such that $v_{g}=101.5 \mathrm{ft}^{3} / \mathrm{lbm}$ :

$$
T_{2}=150-\left(\frac{101.5-96.99}{122.88-96.99}\right)(10)=148^{\circ} \mathrm{F}
$$

A temperature slightly less than this provides us with $T_{2}=147^{\circ} \mathrm{F}$.
4.7 A frictionless piston provides a constant pressure of 400 kPa in a cylinder containing Freon 12 with an initial quality of 80 percent. Calculate the final temperature if $80 \mathrm{~kJ} / \mathrm{kg}$ of heat is transferred to the cylinder.

The original enthalpy is found, using values from Table $\mathrm{D}-2$, to be

$$
h_{1}=h_{f}+x_{1} h_{f g}=43.64+(0.8)(147.33)=161.5 \mathrm{~kJ} / \mathrm{kg}
$$

For this constant-pressure process, the first law demands that

$$
q=h_{2}-h_{1} \quad 80=h_{2}-161.5 \quad \therefore h_{2}=241.5 \mathrm{~kJ} / \mathrm{kg}
$$

Using $P_{2}=400 \mathrm{kPa}$ and $h_{2}=241.5 \mathrm{~kJ} / \mathrm{kg}$, we interpolate in Table D-3 to find

$$
T_{2}=\left(\frac{241.5-239.0}{245.8-239.0}\right)(10)+80=83.7^{\circ} \mathrm{C}
$$

4.8 A piston-cylinder arrangement contains 2 kg of steam originally at $200^{\circ} \mathrm{C}$ and 90 percent quality. The volume triples while the temperature is held constant. Calculate the heat that must be transferred and the final pressure.

The first law for this constant-temperature process is $Q-W=m\left(u_{2}-u_{1}\right)$. The initial specific volume and specific internal energy are, respectively,

$$
\begin{aligned}
& v_{1}=0.0012+(0.9)(0.1274-0.0012)=0.1148 \mathrm{~m}^{3} / \mathrm{kg} \\
& u_{1}=850.6+(0.9)(2595.3-850.6)=2421 \mathrm{~kJ} / \mathrm{kg}
\end{aligned}
$$

Using $T_{2}=200^{\circ} \mathrm{C}$ and $v_{2}=(3)(0.1148)=0.3444 \mathrm{~m}^{3} / \mathrm{kg}$, we interpolate in Table C-3 and find the final pressure $P_{2}$ to be

$$
P_{2}=0.8-\left(\frac{0.3444-0.2608}{0.3520-0.2608}\right)(0.2)=0.617 \mathrm{MPa}
$$

We can also interpolate to find that the specific internal energy is

$$
u_{2}=2638.9-(2638.9-2630.6)\left(\frac{0.617-0.6}{0.8-0.6}\right)=2638.2 \mathrm{~kJ} / \mathrm{kg}
$$

To find the heat transfer we must know the work $W$. It is estimated using graph paper by plotting $P$ vs. $v$ and graphically integrating (counting squares). The work is twice this area since $m=2 \mathrm{~kg}$. Doing this, we find

$$
W=(2)(227.8)=455.6 \mathrm{~kJ}
$$

Thus $Q=W+m\left(u_{2}-u_{1}\right)=455.6+(2)(2638.2-2421)=890 \mathrm{~kJ}$.
4.9 Estimate the constant-pressure specific heat and the constant-volume specific heat for Freon 12 at 30 psia and $100^{\circ} \mathrm{F}$.

We write the derivatives in finite-difference form and, using values on either side of $100^{\circ} \mathrm{F}$ for greatest accuracy, we find

$$
\begin{aligned}
c_{p} & \cong \frac{\Delta h}{\Delta T}=\frac{94.843-88.729}{120-80}=0.153 \mathrm{Btu} / \mathrm{lbm}-{ }^{\circ} \mathrm{F} \\
c_{v} & \cong \frac{\Delta u}{\Delta T}=\frac{\Delta h-P_{2} v_{2}+P_{1} v_{1}}{\Delta T}=\frac{6.114-[(30)(1.66)-(30)(1.5306)](144 / 778)}{120-80} \\
& =0.135 \mathrm{Btu} / \mathrm{lbm}-{ }^{\circ} \mathrm{F}
\end{aligned}
$$

4.10 Calculate the change in enthalpy of air which is heated from 300 K to 700 K if
(a) $c_{p}=1.006 \mathrm{~kJ} / \mathrm{kg} \cdot{ }^{\circ} \mathrm{C}$.
(b) $c_{p}=0.946+0.213 \times 10^{-3} T-0.031 \times 10^{-6} T^{2} \mathrm{~kJ} / \mathrm{kg} \cdot{ }^{\circ} \mathrm{C}$.
(c) The gas tables are used.
(d) Compare the calculations of (a) and (b) with (c).
(a) Assuming the constant specific heat, we find that

$$
\Delta h=c_{p}\left(T_{2}-T_{1}\right)=(1.006)(700-300)=402.4 \mathrm{~kJ} / \mathrm{kg}
$$

(b) If $c_{p}$ depends on temperature, we must integrate as follows:

$$
\Delta h=\int_{T_{1}}^{T_{2}} c_{p} d T=\int_{300}^{700}\left(0.946+0.213 \times 10^{-3} T-0.031 \times 10^{-6} T^{2}\right) d T=417.7 \mathrm{~kJ} / \mathrm{kg}
$$

(c) Using Table F-1, we find $\Delta h=h_{2}-h_{1}=713.27-300.19=413.1 \mathrm{~kJ} / \mathrm{kg}$.
(d) The assumption of constant specific heat results in an error of -2.59 percent; the expression for $c_{p}$ produces an error of +1.11 percent. All three methods are acceptable for the present problem.
4.11 Sixteen ice cubes, each with a temperature of $-10^{\circ} \mathrm{C}$ and a volume of 8 milliliters, are added to 1 liter of water at $20^{\circ} \mathrm{C}$ in an insulated container. What is the equilibrium temperature? Use $\left(c_{p}\right)_{\text {ice }}=2.1 \mathrm{~kJ} / \mathrm{kg} \cdot{ }^{\circ} \mathrm{C}$.

Assume that all of the ice melts. The ice warms up to $0^{\circ} \mathrm{C}$, melts at $0^{\circ} \mathrm{C}$, and then warms up to the final temperature $T_{2}$. The water cools from $20^{\circ} \mathrm{C}$ to the final temperature $T_{2}$. The mass of ice is calculated to be

$$
m_{i}=\frac{V}{v_{i}}=\frac{(16)\left(8 \times 10^{-6}\right)}{0.00109}=0.1174 \mathrm{~kg}
$$

where $v_{i}$ is found in Table C-5. If energy is conserved, we must have
Energy gained by ice $=$ energy lost by water

$$
\begin{aligned}
m_{i}\left[\left(c_{p}\right)_{i} \Delta T+h_{i f}+\left(c_{p}\right)_{w} \Delta T\right] & =m_{w}\left(c_{p}\right)_{w} \Delta T \\
0.1174\left[(2.1)(10)+320+(4.18)\left(T_{2}-0\right)\right] & =\left(1000 \times 10^{-3}\right)(4.18)\left(20-T_{2}\right) \\
T_{2} & =9.33^{\circ} \mathrm{C}
\end{aligned}
$$

4.12 A 5 - kg block of copper at $300^{\circ} \mathrm{C}$ is submerged in 20 liters of water at $0^{\circ} \mathrm{C}$ contained in an insulated tank. Estimate the final equilibrium temperature.

Conservation of energy requires that the energy lost by the copper block is gained by the water. This is expressed as

$$
m_{c}\left(c_{p}\right)_{c}(\Delta T)_{c}=m_{w}\left(c_{p}\right)_{w}(\Delta T)_{w}
$$

Using average values of $c_{p}$ from Table B-4, this becomes

$$
(5)(0.39)\left(300-T_{2}\right)=(0.02)(1000)(4.18)\left(T_{2}-0\right) \quad \therefore T_{2}=6.84^{\circ} \mathrm{C}
$$

4.13 Two lb of air is compressed from 20 psia to 200 psia while maintaining the temperature constant at $100^{\circ} \mathrm{F}$. Calculate the heat transfer needed to accomplish this process.

The first law, assuming air to be an ideal gas, requires that

$$
Q=W+\Delta U^{0}=m R T \ln \frac{P_{1}}{P_{2}}=(2 \mathrm{lbm})\left(53.3 \frac{\mathrm{ft}-\mathrm{lbf}}{\mathrm{lbm}{ }^{\circ} \mathrm{R}}\right)\left(560^{\circ} \mathrm{R}\right)\left(\frac{1}{778} \frac{\mathrm{Btu}}{\mathrm{ft}-\mathrm{lbf}}\right) \ln \frac{20}{200}=-176.7 \mathrm{Btu}
$$

4.14 Helium is contained in a $2-\mathrm{m}^{3}$ rigid volume at $50^{\circ} \mathrm{C}$ and 200 kPa . Calculate the heat transfer needed to increase the pressure to 800 kPa .

The work is zero for this constant-volume process. Consequently, the first law gives

$$
Q=m \Delta u=m c_{\iota} \Delta T=\frac{P V}{R T} c_{\iota}\left(T_{2}-T_{1}\right)
$$

The ideal-gas law, $P V=m R T$, allows us to write

$$
\frac{P_{1}}{T_{1}}=\frac{P_{2}}{T_{2}} \quad \frac{200}{323}=\frac{800}{T_{2}} \quad \therefore T_{2}=1292 \mathrm{~K}
$$

The heat transfer is then

$$
Q=\frac{(200)(2)}{(2.077)(323)}(3.116)(1292-323)=1800 \mathrm{~kJ}
$$

4.15 The air in the cylinder of an air compressor is compressed from 100 kPa to 10 MPa . Estimate the final temperature and the work required if the air is initially at $100^{\circ} \mathrm{C}$.

Since the process occurs quite fast, we assume an adiabatic quasiequilibrium process. Then

$$
T_{2}=T_{1}\left(\frac{P_{2}}{P_{1}}\right)^{(k-1) / k}=(373)\left(\frac{10000}{100}\right)^{(1.4-1) / 1.4}=1390 \mathrm{~K}
$$

The work is found by using the first law with $Q=0$ :

$$
w=-\Delta u=-c_{v}\left(T_{2}-T_{1}\right)=-(0.717)(1390-373)=-729 \mathrm{~kJ} / \mathrm{kg}
$$

The work per unit mass is calculated since the mass (or volume) was not specified.
4.16 Nitrogen at $100^{\circ} \mathrm{C}$ and 600 kPa expands in such a way that it can be approximated by a polytropic process with $n=1.2$ [see (4.52)]. Calculate the work and the heat transfer if the final pressure is 100 kPa .

The final temperature is found to be

$$
T_{2}=T_{1}\left(\frac{P_{2}}{P_{1}}\right)^{(n-1) / n}=(373)\left(\frac{100}{600}\right)^{(1.2-1) / 1.2}=276.7 \mathrm{~K}
$$

The specific volumes are

$$
v_{1}=\frac{R T_{1}}{P_{1}}=\frac{(0.297)(373)}{600}=0.1846 \mathrm{~m}^{3} / \mathrm{kg} \quad v_{2}=\frac{R T_{2}}{P_{2}}=\frac{(0.297)(276.7)}{100}=0.822 \mathrm{~m}^{3} / \mathrm{kg}
$$

The work is then [or use (4.53)]

$$
w=\int P d v=P_{1} v_{1}^{n} \int v^{-n} d v=(600)(0.1846)^{1.2}\left(\frac{1}{-0.2}\right)\left(0.822^{-0.2}-0.1846^{-0.2}\right)=143 \mathrm{~kJ} / \mathrm{kg}
$$

The first law provides us with the heat transfer:

$$
q-w=\Delta u=c_{\nu}\left(T_{2}-T_{1}\right) \quad q-143=(0.745)(276.7-373) \quad \therefore q=71.3 \mathrm{~kJ} / \mathrm{kg}
$$

4.17 How much work must be input by the paddle wheel in Fig. 4-24 to raise the piston 5 in? The initial temperature is $100^{\circ} \mathrm{F}$.

Fig. 4-24

The first law, with $Q=0$, is

$$
W=\Delta U \quad \text { or } \quad-P A \Delta h-W_{\text {paddle }}=m c_{v}\left(T_{2}-T_{1}\right)
$$

The pressure is found from a force balance on the piston:

$$
P=14.7+\frac{175}{\pi(4)^{2}}=18.18 \mathrm{psia}
$$

The mass of the air is found from the ideal-gas law:

$$
m=\frac{P V}{R T}=\frac{(18.18)(144)(\pi)(4)^{2}(10) / 1728}{(53.3)(560)}=0.0255 \mathrm{lbm}
$$

The temperature $T_{2}$ is

$$
T_{2}=\frac{P V_{2}}{m \bar{R}}=\frac{(18.18)(144)(\pi)(4)^{2}(15) / 1728}{(0.0255)(53.3)}=840^{\circ} \mathrm{R}
$$

Finally, the paddle-wheel work is found to be

$$
\begin{aligned}
W_{\text {paddle }} & =-P A \Delta h-m c_{v}\left(T_{2}-T_{1}\right)=-(18.18)(\pi)(4)^{2}(5 / 12)-(0.0255)(0.171)(778)(840-560) \\
& =-1331 \mathrm{ft}-\mathrm{lbf}
\end{aligned}
$$

4.18 For the cycle in Fig. 4-25 find the work output and the net heat transfer if the 0.1 kg of air is contained in a piston-cylinder arrangement.

Fig. 4-25

The temperatures and $V_{3}$ are

$$
\begin{gathered}
T_{1}=\frac{P_{1} V_{1}}{m R}=\frac{(100)(0.08)}{(0.1)(0.287)}=278.7 \mathrm{~K} \quad T_{2}=T_{3}=\frac{(800)(0.08)}{(0.1)(0.287)}=2230 \mathrm{~K} \\
V_{3}=\frac{P_{2} V_{2}}{P_{3}}=\frac{(800)(0.08)}{100}=0.64 \mathrm{~m}^{3}
\end{gathered}
$$

Using the definition of work for each process, we find

$$
\begin{aligned}
& W_{1-2}=0 \quad W_{2-3}=m R T \ln \frac{p_{2}}{p_{3}}=(0.1)(0.287)(2230) \ln \frac{800}{100}=133.1 \mathrm{~kJ} \\
& W_{3-1}=P\left(V_{1}-V_{3}\right)=(100)(0.08-0.64)=-56 \mathrm{~kJ}
\end{aligned}
$$

The work output is then' $W_{\text {net }}=0+133.1-56.0=77.1 \mathrm{~kJ}$. Since this is a complete cycle, the first law for a cycle provides us with

$$
Q_{\text {net }}=W_{\text {net }}=77.1 \mathrm{~kJ}
$$

4.19 Water enters a radiator through a 4 - $\mathbf{c m}$-diameter hose at $0.02 \mathrm{~kg} / \mathrm{s}$. It travels down through all the rectangular passageways on its way to the water pump. The passageways are each $10 \times 1 \mathrm{~mm}$ and there are 800 of them in a cross section. How long does it take water to traverse from the top to the bottom of the $60-\mathrm{cm}$-high radiator?

The average velocity through the passageways is found from the continuity equation, using $\rho_{\text {water }}=1000 \mathrm{~kg} / \mathrm{m}^{3}$ :

$$
\dot{m}=\rho_{1} V_{1} A_{1}=\rho_{2} V_{2} A_{2} \quad \therefore V_{2}=\frac{\dot{m}}{\rho_{2} A_{2}}=\frac{0.02}{(1000)[(800)(0.01)(0.001)]}=0.0025 \mathrm{~m} / \mathrm{s}
$$

The time to travel 60 cm at this constant velocity is

$$
t=\frac{L}{V}=\frac{0.60}{0.0025}=240 \mathrm{~s} \mathrm{or} 4 \mathrm{~min}
$$

4.20 A $10-\mathrm{m}^{3}$ tank is being filled with steam at 800 kPa and $400^{\circ} \mathrm{C}$. It enters the tank through a 10 -cm-diameter pipe. Determine the rate at which the density in the tank is varying when the velocity of the steam in the pipe is $20 \mathrm{~m} / \mathrm{s}$.

The continuity equation with one inlet and no outlets is [see (4.56)]:

$$
\rho_{1} A_{1} V_{1}=\frac{d m_{c, v}}{d t}
$$

Since $m_{c . v .}=\rho V$, where $V$ is the volume of the tank, this becomes

$$
V \frac{d \rho}{d t}=\frac{1}{v_{1}} A_{1} V_{1} \quad 10 \frac{d \rho}{d t}=\left(\frac{1}{0.3843}\right)(\pi)(0.05)^{2}(20) \quad \frac{d \rho}{d t}=0.04087 \mathrm{~kg} / \mathrm{m}^{3} \cdot \mathrm{~s}
$$

4.21 Water enters a 4-ft-wide, $1 / 2$-in-high channel with a mass flux of $15 \mathrm{lbm} / \mathrm{sec}$. It leaves with a parabolic distribution $V(y)=V_{\max }\left(1-y^{2} / h^{2}\right)$, where $h$ is half the channel height. Calculate $V_{\max }$ and $V_{\text {avg }}$, the average velocity over any cross section of the channel. Assume that the water completely fills the channel.

The mass flux is given by $\dot{m}=\rho A V_{\text {avg }}$; hence,

$$
V_{\mathrm{avg}}=\frac{\dot{m}}{\rho A}=\frac{15}{(62.4)[(4)(1 / 24)]}=1.442 \mathrm{ft} / \mathrm{sec}
$$

At the exit the velocity profile is parabolic. The mass flux, a constant, then provides us with

$$
\begin{aligned}
\dot{m} & =\int_{A} \rho V d A \\
15 & =\rho \int_{-h}^{h} V_{\max }\left(1-\frac{y^{2}}{h^{2}}\right) 4 d y=(62.4)\left(4 V_{\max }\right)\left[y-\frac{y^{3}}{3 h^{2}}\right]_{-h}^{h}=(62.4)\left(4 V_{\max }\right)\left[\frac{(4)(1 / 48)}{3}\right] \\
\therefore V_{\max } & =2.163 \mathrm{ft} / \mathrm{sec}
\end{aligned}
$$

4.22 Freon 12 enters a valve at 800 kPa and $30^{\circ} \mathrm{C}$. The pressure downstream of the valve is measured to be 60 kPa . Calculate the internal energy downstream.

The energy equation across the valve, recognizing that heat transfer and work are zero, is $h_{1}=h_{2}$. The enthalpy before the valve is that of compressed liquid. The enthalpy of a compressed liquid is essentially equal to that of a saturated liquid at the same temperature. Hence, at $30^{\circ} \mathrm{C}$ in Table D-1, $h_{1}=64.54 \mathrm{~kJ} / \mathrm{kg}$. Using Table D-2 at 60 kPa we find

$$
h_{2}=64.54=h_{f}+x_{2} h_{f g}=-1.25+170.19 x_{2} \quad \therefore x_{2}=0.387
$$

The internal energy is then

$$
u_{2}=u_{f}+x_{2}\left(u_{g}-u_{f}\right)-1.29+(0.387)[153.49-(-1.29)]=58.6 \mathrm{~kJ} / \mathrm{kg}
$$

4.23 The pressure of $200 \mathrm{~kg} / \mathrm{s}$ of water is to be increased by 4 MPa . The water enters through a $20-\mathrm{cm}$-diameter pipe and exits through a $12-\mathrm{cm}$-diameter pipe. Calculate the minimum horsepower required to operate the pump.

The energy equation (4.68) provides us with

$$
-\dot{W}_{P}=\dot{m}\left(\frac{\Delta P}{\rho}+\frac{V_{2}^{2}-V_{1}^{2}}{2}\right)
$$

The inlet and exit velocities are calculated as follows:

$$
V_{1}=\frac{\dot{m}}{\rho A_{1}}=\frac{200}{(1000)(\pi)(0.1)^{2}}=6.366 \mathrm{~m} / \mathrm{s} \quad V_{2}=\frac{\dot{m}}{\rho A_{2}}=\frac{200}{(1000)(\pi)(0.06)^{2}}=17.68 \mathrm{~m} / \mathrm{s}
$$

The energy equation then gives

$$
\dot{W}_{P}=-200\left[\frac{4000000}{1000}+\frac{(17.68)^{2}-(6.366)^{2}}{2}\right]=-827200 \mathrm{~W} \quad \text { or } 1109 \mathrm{hp}
$$

Note: The above power calculation provides a minimum since we have neglected any internal energy increase. Also, the kinetic energy change represents only a 3 percent effect on $\dot{W}_{\rho}$ and could be neglected.
4.24 A hydroturbine operates on a stream in which $100 \mathrm{~kg} / \mathrm{s}$ of water flows. Estimate the maximum power output if the turbine is in a dam with a distance of 40 m from the surface of the reservoir to the surface of the backwater.

The energy equation (4.68), neglecting kinetic energy changes, takes the form $-\dot{W}_{T}=\dot{m} g\left(z_{2}-z_{1}\right)$, where we have assumed the pressure to be atmospheric on the water's surface above and below the dam. The maximum power output is then

$$
\dot{W}_{T}=-(100)(9.81)(-40)=39240 \mathrm{~W} \text { or } 39.24 \mathrm{~kW}
$$

4.25 A turbine accepts superheated steam at 800 psia and $1200^{\circ} \mathrm{F}$ and rejects it as saturated vapor at 2 psia (Fig. 4-26). Predict the horsepower output if the mass flux is $1000 \mathrm{lbm} / \mathrm{min}$. Also, calculate the velocity at the exit.

Fig. 4-26

Assuming zero heat transfer, the energy equation (4.66) provides us with

$$
-\dot{W}_{T}=\dot{m}\left(h_{2}-h_{1}\right)=\left(\frac{1000}{60}\right)(1116.1-1623.8)=-8462 \mathrm{Btu} / \mathrm{sec} \text { or } 11970 \mathrm{hp}
$$

where Tables $\mathrm{C}-3 \mathrm{E}$ and $\mathrm{C}-2 \mathrm{E}$ have provided the enthalpies. By (4.58),

$$
V=\frac{i \dot{m}}{A}=\frac{(173.75)(1000 / 60)}{\pi(2)^{2}}=230 \mathrm{ft} / \mathrm{sec}
$$

4.26 Air enters a compressor at atmospheric conditions of $20^{\circ} \mathrm{C}$ and 80 kPa and exits at 800 kPa and $200^{\circ} \mathrm{C}$. Calculate the rate of heat transfer if the power input is 400 kW . The air exits at 20 $\mathrm{m} / \mathrm{s}$ through an exit diameter of 10 cm .

The energy equation, neglecting kinetic and potential energy changes, is $\dot{Q}-\dot{W}_{s}=\dot{m} c_{p}\left(T_{2}-T_{1}\right)$; the mass flux is calculated to be

$$
\dot{m}=\rho A V=\frac{P}{R T} A V=\frac{800}{(0.287)(473)}(\pi)(0.05)^{2}(20)=0.9257 \mathrm{~kg} / \mathrm{s}
$$

Hence $\dot{Q}=(0.9257)(1.00)(200-20)+(-400)=-233.4 \mathrm{~kW}$. Note that the power input is negative, and a negative heat transfer implies that the compressor is losing heat.
4.27 Air travels through the $4 \times 2 \mathrm{~m}$ test section of a wind tunnel at $20 \mathrm{~m} / \mathrm{s}$. The gage pressure in the test section is measured to be -20 kPa and the temperature $20^{\circ} \mathrm{C}$. After the test section, a diffuser leads to a 6 -m-diameter exit pipe. Estimate the velocity and temperature in the exit pipe.

The energy equation (4.72) for air takes the form

$$
V_{2}^{2}=V_{1}^{2}+2 c_{p}\left(T_{1}-T_{2}\right)=20^{2}+(2)(1.00)\left(293-T_{2}\right)
$$

The continuity equation, $\rho_{1} A_{1} V_{1}=\rho_{2} A_{2} V_{2}$, yields

$$
\frac{P_{1}}{R T_{1}} A_{1} V_{1}=\rho_{2} A_{2} V_{2} \quad \therefore \rho_{2} V_{2}=\left[\frac{80}{(0.287)(293)}\right]\left[\frac{8}{\pi(3)^{2}}\right](20)=5.384 \mathrm{~kg} / \mathrm{m}^{2} \cdot \mathrm{~s}
$$

The best approximation to the actual process is the adiabatic quasiequilibrium process. Using (4.49). letting $\rho=1 / l$, we have

$$
\frac{T_{2}}{T_{1}}=\left(\frac{\rho_{2}}{\rho_{1}}\right)^{k-1} \quad \text { or } \quad \frac{T_{2}}{\rho_{2}^{1.4}}=\frac{293}{[80 /(0.287)(293)]^{0.4}}=298.9
$$

The above three equations include the three unknowns $T_{2}, V_{2}$, and $\rho_{2}$. Substitute for $T_{2}$ and $V_{2}$ back into the energy equation and find

$$
\frac{5.384^{2}}{\rho_{2}^{2}}=20^{2}+(2)(1.00)\left[293-(298.9)\left(\rho_{2}^{0.4}\right)\right]
$$

This can be solved by trial and error to yield $\rho_{2}=3.475 \mathrm{~kg} / \mathrm{m}^{3}$. The velocity and temperature are then

$$
V_{2}=\frac{5.384}{\rho_{2}}=\frac{5.384}{3.475}=1.55 \mathrm{~m} / \mathrm{s} \quad T_{2}=(298.9)\left(\rho_{2}^{(1.4}\right)=(298.9)(3.475)^{0.4}=492 \quad \text { or } 219^{\circ} \mathrm{C}
$$

4.28 Steam with a mass flux of $600 \mathrm{lbm} / \mathrm{min}$ exits a turbine as saturated steam at 2 psia and passes through a condenser (a heat exchanger). What mass flux of cooling water is needed if the steam is to exit the condenser as saturated liquid and the cooling water is allowed a $15^{\circ} \mathrm{F}$ temperature rise?

The energy equations (4.75) are applicable to this situation. The heat transfer rate for the steam is, assuming no pressure drop through the condenser,

$$
\dot{Q}_{s}=\dot{m}_{s}\left(h_{s 2}-h_{s 1}\right)=(600)(94.02-1116.1)=-613,200 \mathrm{Btu} / \mathrm{min}
$$

This energy is gained by the water. Hence,

$$
\dot{Q}_{w}=\dot{m}_{w}\left(h_{w 2}-h_{w 1}\right)=\dot{m}_{w} c_{p}\left(T_{w 2}-T_{w 1}\right) \quad 613,200=\dot{m}_{w}(1.00)(15) \quad \dot{m}_{w}=40,880 \mathrm{lbm} / \mathrm{min}
$$

4.29 A simple steam power plant operates on $20 \mathrm{~kg} / \mathrm{s}$ of steam, as shown in Fig. 4-27. Neglecting losses in the various components, calculate $(a)$ the boiler heat transfer rate, ( $b$ ) the turbine power output, $(c)$ the condenser heat transfer rate, $(d)$ the pump power requirement, ( $e$ ) the velocity in the boiler exit pipe, and $(f)$ the thermal efficiency of the cycle.

Fig. 4-27
(a) $\dot{Q}_{B}=\dot{m}\left(h_{3}-h_{2}\right)=(20)(3625.3-167.5)=69.15 \mathrm{MW}$, where we have taken the enthalpy $h_{2}$ to be $h_{f}$ at $40^{\circ} \mathrm{C}$.
(b) $\dot{W}_{T}=\dot{m}\left(h_{4}-h_{3}\right)=-(20)(2584.6-3625.3)=20.81 \mathrm{MW}$.
(c) $\dot{Q}_{c}=\dot{m}\left(h_{1}-h_{4}\right)=(20)(167.57-2584.7)=-48.34 \mathrm{MW}$.
(d) $\dot{W}_{P}=\dot{m}\left(P_{2}-P_{1}\right) / \rho=(20)(10000-10 / 1000)=0.2 \mathrm{MW}$.
(e) $V=\dot{m} v / A=(20)(0.03837) / \pi(0.15)^{2}=10.9 \mathrm{~m} / \mathrm{s}$.
(f) $\eta=\left(\dot{W}_{T}-\dot{W}_{P}\right) / \dot{Q}_{B}=(20.81-0.2) / 69.15=0.298$ or $29.8 \%$.
4.30 An insulated $4-\mathrm{m}^{3}$ evacuated tank is connected to a $4-\mathrm{MPa} 600^{\circ} \mathrm{C}$ steam line. A valve is opened and the steam fills the tank. Estimate the final temperature of the steam in the tank and the final mass of the steam in the tank.

From (4.81), with $Q=0$ and $m_{i}=0$, there results $u_{f}=h_{1}$, since the final mass $m_{f}$ is equal to the mass $m_{1}$ that enters. We know that across a valve the enthalpy is constant; hence,

$$
h_{1}=h_{\text {line }}=3674.4 \mathrm{~kJ} / \mathrm{kg}
$$

The final pressure in the tank is 4 MPa , achieved when the steam ceases to flow into the tank. Using $P_{f}=4 \mathrm{MPa}$ and $u_{f}=3674.4 \mathrm{~kJ} / \mathrm{kg}$, we find the temperature in Table C-3 to be

$$
T_{f}=\left(\frac{3674.4-3650.1}{3650.1-3555.5}\right)(500)+800=812.8^{\circ} \mathrm{C}
$$

The specific volume at 4 MPa and $812.8^{\circ} \mathrm{C}$ is

$$
v_{f}=\left(\frac{812.8-800}{50}\right)(0.1229-0.1169)+0.1229=0.1244 \mathrm{ft}^{3} / \mathrm{lbm}
$$

The mass of steam in the tank is then

$$
m_{f}=\frac{V_{f}}{v_{f}}=\frac{4}{0.1244}=32.15 \mathrm{~kg}
$$

## Supplementary Problems

4.31 An unknown mass is attached by a pulley to a paddle wheel which is inserted in a volume of water. The mass is then dropped a distance of 3 m . If 100 J of heat must be transferred from the water in order to return the water to its initial state, determine the mass in kilograms. Ans. 3.398 kg
4.32 While 300 J of heat is added to the air in the cylinder of Fig. 4-28, the piston raises a distance of 0.2 m . Determine the change in internal energy. Ans. 123.3 J

Fig. 4-28

Fig. 4-29
4.33 A constant force of 600 lbf is required to move the piston shown in Fig. 4-29. If 2 Btu of heat is transferred from the cylinder when the piston moves the entire length, what is the change in internal energy? Ans. 0.49 Btu
4.34 Each of the letters ( $a$ ) through (e) in the accompanying table represents a process. Supply the missing values, in kJ .

|  | $Q$ | $W$ | $\Delta E$ | $E_{2}$ | $E_{1}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $(a)$ | 20 | 5 |  |  | 7 |
| $(b)$ |  | -3 | 6 |  | 8 |
| $(c)$ | 40 |  |  | 30 | 15 |
| $(d)$ | -10 |  | 20 | 10 |  |
| $(e)$ |  | 10 |  | -8 | 6 |

Ans.
(a) 15,22
(b) 3, 14
(c) 25,15
(d) $-30,-10$
(e) $-4,-14$
4.35 A system undergoes a cycle consisting of four processes. Some of the values of the energy transfers and energy changes are given in the table. Fill in all the missing values. All units are kJ .

| Process | $Q$ | $W$ | $\Delta U$ |
| :---: | :---: | :---: | :---: |
| $1 \rightarrow 2$ | -200 | $(a)$ | 0 |
| $2 \rightarrow 3$ | 800 | $(b)$ | $(c)$ |
| $3 \rightarrow 4$ | $(d)$ | 600 | 400 |
| $4 \rightarrow 1$ | 0 | $(e)$ | -1200 |

Ans. (a) -200
(b) 0
(c) 800
(d) 1000
(e) 1200
4.36 A 12-V battery is charged by supplying 3 A over a period of 6 h . If a heat loss of 400 kJ occurs from the battery during the charging period, what is the change in energy stored within the battery?
Ans. 378 kJ
4.37 A $12-\mathrm{V}$ battery delivers a current of 10 A over a $30-\mathrm{min}$ time period. The stored energy decreases by 300 kJ . Determine the heat lost during the time period for the battery. Ans. 84 kJ
4.38 A 110-V heater draws 15 A while heating a particular air space. During a 2-h period the internal energy in the space increases by 8000 Btu . Calculate the amount of heat lost in Btu. Ans. 3260 Btu
4.39 How much heat must be added to a $0.3-\mathrm{m}^{3}$ rigid volume containing water at $200^{\circ} \mathrm{C}$ in order that the final temperature be raised to $800^{\circ} \mathrm{C}$ ? The initial pressure is 1 MPa . Ans. 1505 kJ
4.40 A $0.2-\mathrm{m}^{3}$ rigid volume contains steam at 600 kPa and a quality of 0.8 . If 1000 kJ of heat is added, determine the final temperature. Ans. $787^{\circ} \mathrm{C}$
4.41 A piston-cylinder arrangement provides a constant pressure of 120 psia on steam which has an initial quality of 0.95 and an initial volume of $100 \mathrm{in}^{3}$. Determine the heat transfer necessary to raise the temperature to $1000^{\circ} \mathrm{F}$. Work this problem without using enthalpy. Ans. 6.277 Btu
4.42 Steam is contained in a 4-liter volume at a pressure of 1.5 MPa and a temperature of $200^{\circ} \mathrm{C}$. If the pressure is held constant by expanding the volume while 40 kJ of heat is added, find the final temperature. Work this problem without using enthalpy. Ans. $785^{\circ} \mathrm{C}$
4.43 Work Prob. 4.41 using enthalpy. Ans. 6.274 Btu
4.44 Work Prob. 4.42 using enthalpy. Ans. $787^{\circ} \mathrm{C}$
4.45 Calculate the heat transfer necessary to raise the temperature of 2 kg of steam, at a constant pressure of $100 \mathrm{kPa}(a)$ from $50^{\circ} \mathrm{C}$ to $400^{\circ} \mathrm{C}$ and (b) from $400^{\circ} \mathrm{C}$ to $750^{\circ} \mathrm{C}$.
Ans. (a) $6140 \mathrm{~kJ} \quad$ (b) 1531 kJ
4.46 Steam is contained in a $1.2-\mathrm{m}^{3}$ volume at a pressure of 3 MPa and a quality of 0.8 . The pressure is held constant. What is the final temperature if $(a) 3 \mathrm{MJ}$ and $(b) 30 \mathrm{MJ}$ of heat is added? Sketch the process on a $T$ - $u$ diagram. Ans. (a) $233.9^{\circ} \mathrm{C} \quad$ (b) $645^{\circ} \mathrm{C}$
4.47 Estimate the constant-pressure specific heat for steam at $400^{\circ} \mathrm{C}$ if the pressure is (a) $10 \mathrm{kPa},(b) 100$ kPa , and (c) 30000 kPa .
Ans. (a) $2.06 \mathrm{~kJ} / \mathrm{kg} \cdot{ }^{\circ} \mathrm{C}$
(b) $2.07 \mathrm{~kJ} / \mathrm{kg} \cdot{ }^{\circ} \mathrm{C}$
(c) $13.4 \mathrm{~kJ} / \mathrm{kg} \cdot{ }^{\circ} \mathrm{C}$
4.48 Determine approximate values for the constant-volume specific heat for steam at $800^{\circ} \mathrm{F}$ if the pressure is (a) $1 \mathrm{psia},(b) 14.7 \mathrm{psia}$, and (c) 3000 psia .
Ans. (a) 0.386 Btu/ $/ \mathrm{lbm}{ }^{\circ} \mathrm{F}$
(b) $0.388 \mathrm{Btu} / \mathrm{lbm}-{ }^{\circ} \mathrm{F}$
(c) $0.93 \mathrm{Btu} / \mathrm{lbm}-{ }^{\circ} \mathrm{F}$
4.49 Calculate the change in enthalpy of 2 kg of air which is heated from 400 K to 600 K if ( $a$ ) $c_{p}=1.006$ $\mathrm{kJ} / \mathrm{kg} \cdot \mathrm{K}$, (b) $c_{p}=0.946+0.213 \times 10^{-3} T-0.031 \times 10^{-6} T^{2} \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}$, and (c) the gas tables are used. Ans. (a) $402 \mathrm{~kJ} \quad$ (b) $418 \mathrm{~kJ} \quad$ (c) 412 kJ
4.50 Compare the enthalpy change of 2 kg of water for a temperature change from $10^{\circ} \mathrm{C}$ to $60^{\circ} \mathrm{C}$ with that of 2 kg of ice for a temperature change from $-60^{\circ} \mathrm{C}$ to $-10^{\circ} \mathrm{C}$. Ans. 418 kJ vs. 186 kJ
4.51 Two MJ of heat is added to 2.3 kg of ice held at a constant pressure of 200 kPa , at ( $a$ ) $-60^{\circ} \mathrm{C}$ and (b) $0^{\circ} \mathrm{C}$. What is the final temperature? Sketch the process on a $T-v$ diagram.
$\begin{array}{ll}\text { Ans. (a) } 104^{\circ} \mathrm{C} & \text { (b) } 120.2^{\circ} \mathrm{C}\end{array}$
4.52 What is the heat transfer required to raise the temperature of 10 lbm of water from $0^{\circ} \mathrm{F}$ (ice) to $600^{\circ} \mathrm{F}$ (vapor) at a constant pressure of 30 psia? Sketch the process on a $T$ - $v$ diagram. Ans. 14,900 Btu
4.53 Five ice cubes ( $4 \times 2 \times 2 \mathrm{~cm}$ ) at $-20^{\circ} \mathrm{C}$ are added to an insulated glass of cola at $20^{\circ} \mathrm{C}$. Estimate the final temperature (if above $0^{\circ} \mathrm{C}$ ) or the percentage of ice melted (if at $0^{\circ} \mathrm{C}$ ) if the cola volume is (a) 2 liters and (b) 0.25 liters. Use $\rho_{\text {ise }}=917 \mathrm{~kg} / \mathrm{m}^{3}$. Ans. (a) $16.2^{\circ} \mathrm{C} \quad$ (b) $76.3 \%$
4.54 A 40-lbm block of copper at $200^{\circ} \mathrm{F}$ is dropped in an insulated tank containing $3 \mathrm{ft}^{3}$ of water at $60^{\circ} \mathrm{F}$. Calculate the final equilibrium temperature. Ans. $62.7^{\circ} \mathrm{F}$
4.55 A $50-\mathrm{kg}$ block of copper at $0^{\circ} \mathrm{C}$ and a $100-\mathrm{kg}$ block of iron at $200^{\circ} \mathrm{C}$ are brought into contact in an insulated space. Predict the final equilibrium temperature. Ans. $139.5^{\circ} \mathrm{C}$
4.56 Determine the enthalpy change and the internal energy change for 4 kg of air if the temperature changes from $100^{\circ} \mathrm{C}$ to $400^{\circ} \mathrm{C}$. Assume constant specific heats. Ans. $1200 \mathrm{~kJ}, 860 \mathrm{~kJ}$
4.57 For each of the following quasiequilibrium processes supply the missing information. The working fluid is 0.4 kg of air in a cylinder.

|  | Process | $Q(\mathrm{~kJ})$ | $W(\mathrm{~kJ})$ | $\Delta U(\mathrm{~kJ})$ | $\Delta H(\mathrm{~kJ})$ | $T_{2}\left({ }^{\circ} \mathrm{C}\right)$ | $T_{1}\left({ }^{\circ} \mathrm{C}\right)$ | $P_{2}(\mathrm{kPa})$ | $P_{1}(\mathrm{kPa})$ | $V_{2}\left(\mathrm{~m}^{3}\right)$ | $V_{1}\left(\mathrm{~m}^{3}\right)$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $(a)$ | $T=C$ | 60 |  |  |  | 100 |  | 50 |  |  |  |
| $(b)$ | $V=C$ |  |  |  | 80 | 300 |  | 200 |  |  |  |
| $(c)$ | $P=C$ | 100 |  |  |  |  | 200 |  | 500 |  |  |
| $(d)$ | $Q=0$ |  |  |  |  |  | 250 |  |  | 0.1 | 0.48 |

Ans. (a) 60, 0, 0, 100, 203, 0.856, 0.211;
(b) $57.4,0,57.4,100,130,0.329,0.329$;
(c) $28.3,71.7,100,450,500,0.166,0.109$;
(d) $0,-131,131,182,706,1124,125$
4.58 For each of the quasiequilibrium processes presented in the table in Prob. 4.57, supply the missing information if the working fluid is 0.4 kg of steam. [Note: for process (a) it is necessary to integrate graphically.]
Ans. (a) 49.4, 10.2, 11.8, 100, 101, 1.37, 0.671 ;
(b) $62,0,62,200,167,1.316,1.316$;
(c) $23.5,76.5,100,320,500,0.226,0.177$;
(d) $0,-190,190,245,550,1500,200$
4.59 One thousand Btu of heat is added to 2 lbm of steam maintained at 60 psia. Calculate the final temperature if the initial temperature of the steam is (a) $600^{\circ} \mathrm{F}$ and (b) $815^{\circ} \mathrm{F}$.
Ans. (a) $1551^{\circ} \mathrm{F} \quad$ (b) $1741^{\circ} \mathrm{F}$
4.60 Fifty kJ of heat is transferred to air maintained at 400 kPa with an initial volume of $0.2 \mathrm{~m}^{3}$. Determine the final temperature if the initial temperature is $(a) 0^{\circ} \mathrm{C}$ and $(b) 200^{\circ} \mathrm{C}$.
Ans. (a) $49.0^{\circ} \mathrm{C}$ (b) $249.0^{\circ} \mathrm{C}$
4.61 The initial temperature and pressure of $8000 \mathrm{~cm}^{3}$ of air are $100^{\circ} \mathrm{C}$ and 800 kPa , respectively. Determine the necessary heat transfer if the volume does not change and the final pressure is (a) 200 kPa and (b) 3000 kPa . Ans. (a) $-12.0 \mathrm{~kJ} \quad$ (b) 44.0 kJ
4.62 Calculate the heat transfer necessary to raise the temperature of air, initially at $10^{\circ} \mathrm{C}$ and 100 kPa , to a temperature of $27^{\circ} \mathrm{C}$ if the air is contained in an initial volume with dimensions $3 \times 5 \times 2.4 \mathrm{~m}$. The pressure is held constant. Ans. 753 kJ
4.63 Heat is added to a fixed $0.15-\mathrm{m}^{3}$ volume of steam initially at a pressure of 400 kPa and a quality of 0.5 . Determine the final pressure and temperature if ( $a$ ) 800 kJ and ( $b$ ) 200 kJ of heat is added. Sketch the process on a $P-i$ diagram. Ans. (a) $1137 \mathrm{kPa}, 314^{\circ} \mathrm{C} \quad$ (b) $533 \mathrm{kPa}, 154^{\circ} \mathrm{C}$
4.64 Two hundred Btu of heat is added to a rigid air tank which has a volume of $3 \mathrm{ft}^{3}$. Find the final temperature if initially ( $a$ ) $P=60 \mathrm{psia}$ and $T=30^{\circ} \mathrm{F}$ and $(b) P=600 \mathrm{psia}$ and $T=820^{\circ} \mathrm{F}$. Use the air tables. Ans. (a) $1135^{\circ} \mathrm{F} \quad$ (b) $1195^{\circ} \mathrm{F}$
4.65 A system consisting of 5 kg of air is initially at 300 kPa and $20^{\circ} \mathrm{C}$. Determine the heat transfer necessary to ( $a$ ) increase the volume by a factor of two at constant pressure, ( $b$ ) increase the pressure by a factor of two at constant volume, (c) increase the pressure by a factor of two at constant temperature, and (d) increase the absolute temperature by a factor of 2 at constant pressure.
Ans. (a) 1465 kJ
(b) 1050 kJ
(c) -291 kJ
(d) 1465 kJ
4.66 Heat is added to a container holding $0.5 \mathrm{~m}^{3}$ of steam initially at a pressure of 400 kPa and a quality of 80 percent (Fig. 4-30). If the pressure is held constant, find the heat transfer necessary if the final temperature is ( $a$ ) $500^{\circ} \mathrm{C}$ and (b) $675^{\circ} \mathrm{C}$. Also determine the work done. Sketch the process on a $T-v$ diagram. Ans. (a) $1584 \mathrm{~kJ} \quad$ (b) 2104 kJ

Fig. 4-30
4.67 A rigid $1.5-\mathrm{m}^{3}$ tank at a pressure of 200 kPa contains 5 liters of liquid and the remainder steam. Calculate the heat transfer necessary to ( $a$ ) completely vaporize the water, (b) raise the temperature to $400^{\circ} \mathrm{C}$, and (c) raise the pressure to 800 kPa . Ans. (a) $9.85 \mathrm{MJ} \quad$ (b) $12.26 \mathrm{MJ} \quad$ (c) 9.55 MJ
4.68 Ten Btu of heat is added to a rigid container holding 4 lbm of air in a volume of $100 \mathrm{ft}^{3}$. Determine $\Delta H$. Ans. 14.04 Btu
4.69 Eight thousand $\mathrm{cm}^{3}$ of air in a piston-cylinder arrangement is compressed isothermally at $30^{\circ} \mathrm{C}$ from a pressure of 200 kPa to a pressure of 800 kPa . Find the heat transfer. Ans. -2.22 kJ
4.70 Two kg of air is compressed in an insulated cylinder from 400 kPa to 15000 kPa . Determine the final temperature and the work necessary if the initial temperature is (a) $200^{\circ} \mathrm{C}$ and (b) $350^{\circ} \mathrm{C}$.
Ans. (a) $-1230 \mathrm{~kJ} \quad$ (b) -1620 kJ
4.71 Air is compressed in an insulated cylinder from the position shown in Fig. $4-31$ so that the pressure increases to 5000 kPa from atmospheric pressure of 100 kPa . What is the required work if the mass of the air is 0.2 kg ? Ans. -116 kJ

Fig. 4-31
4.72 The average person emits approximately 400 Btu of heat per hour. There are 1000 people in an unventilated room $10 \times 75 \times 150 \mathrm{ft}$. Approximate the increase in temperature after 15 min , assuming ( $a$ ) constant pressure and ( $b$ ) constant volume. ( $c$ ) Which assumption is the more realistic?
Ans. (a) $49.4^{\circ} \mathrm{F}$
(b) $69.4^{\circ} \mathrm{F}$
(c) constant pressure
4.73 Two hundred kJ of work is transferred to the air by means of a paddle wheel inserted into an insulated volume (Fig. 4-32). If the initial pressure and temperature are 200 kPa and $100^{\circ} \mathrm{C}$, respectively, determine the final temperature and pressure. Ans. $174.7^{\circ} \mathrm{C}, 240.1 \mathrm{kPa}$

Fig. 4-32
4.74 A $2-\mathrm{kg}$ rock falls from 10 m and lands in a $10-\mathrm{liter}$ container of water. Neglecting friction during the fall, calculate the maximum temperature increase in the water. Ans. $4.69^{\circ} \mathrm{C}$
4.75 A torque of $10 \mathrm{~N} \cdot \mathrm{~m}$ is required to turn a paddle wheel at the rate of $100 \mathrm{rad} / \mathrm{s}$. During a 45-s time period a volume of air, in which the paddle wheel rotates, is increased from 0.1 to $0.4 \mathrm{~m}^{3}$. The pressure is maintained constant at 400 kPa . Determine the heat transfer necessary if the initial temperature is (a) $0^{\circ} \mathrm{C}$ and (b) $300^{\circ} \mathrm{C}$. Ans. (a) $373 \mathrm{~kJ} \quad$ (b) 373 kJ
4.76 For the cycle shown in Fig. 4-33 find the work output and the net heat transfer, if 0.8 lbm of air is contained in a cylinder with $T_{1}=800^{\circ} \mathrm{F}$, assuming the process from 3 to 1 is ( $a$ ) an isothermal process and ( $b$ ) an adiabatic process. Ans. (a) 7150 ft -lbf, $9.19 \mathrm{Btu} \quad$ (b) 9480 ft -lbf, 12.2 Btu

Fig. 4-33

Fig. 4-34
4.77 For the cycle shown in Fig. 4-34 find the net heat transfer and work output if steam is contained in a cylinder. Ans. $1926 \mathrm{~kJ}, 1926 \mathrm{~kJ}$
4.78 If 0.03 kg of air undergoes the cycle shown in Fig. 4-35, a piston-cylinder arrangement, calculate the work output. Ans. 4.01 kJ
4.79 Air is flowing at an average speed of $100 \mathrm{~m} / \mathrm{s}$ through a $10-\mathrm{cm}$-diameter pipe. If the pipe undergoes an enlargement to 20 cm in diameter, determine the average specd in the enlarged pipe.
Ans. $\quad 25 \mathrm{~m} / \mathrm{s}$

Fig. 4-35

Fig. 4-36
4.80 Air enters a vacuum cleaner through a 2 -in-diameter pipe at a speed of $150 \mathrm{ft} / \mathrm{sec}$. It passes through a rotating impeller (Fig. 4-36), of thickness of 0.5 in., through which the air exits. Determine the average velocity exiting normal to the impeller. Ans. $37.5 \mathrm{ft} / \mathrm{sec}$
4.81 Air enters a device at 4 MPa and $300^{\circ} \mathrm{C}$ with a velocity of $150 \mathrm{~m} / \mathrm{s}$. The inlet area is $10 \mathrm{~cm}^{2}$ and the outlet area is $50 \mathrm{~cm}^{2}$. Determine the mass flux and the outlet velocity if the air exits at 0.4 MPa and $100^{\circ} \mathrm{C}$. Ans. $3.65 \mathrm{~kg} / \mathrm{s}, 195.3 \mathrm{~m} / \mathrm{s}$
4.82 Air enters the device shown in Fig. 4-37 at 2 MPa and $350^{\circ} \mathrm{C}$ with a velocity of $125 \mathrm{~m} / \mathrm{s}$. At one outlet area the conditions are 150 kPa and $150^{\circ} \mathrm{C}$ with a velocity of $40 \mathrm{~m} / \mathrm{s}$. Determine the mass flux and the velocity at the second outlet for conditions of 0.45 MPa and $200^{\circ} \mathrm{C}$. Ans. $6.64 \mathrm{~kg} / \mathrm{s}, 255 \mathrm{~m} / \mathrm{s}$

Fig. 4-37
4.83 Steam at 400 kPa and $250^{\circ} \mathrm{C}$ is being transferred through a $50-\mathrm{cm}$-diameter pipe at a speed of $30 \mathrm{~m} / \mathrm{s}$. It splits into two pipes with equal diameters of 25 cm . Calculate the mass flux and the velocity in each of the smaller pipes if the pressure and temperature are 200 kPa and $200^{\circ} \mathrm{C}$, respectively.
Ans. $4.95 \mathrm{~kg} / \mathrm{s}, 109 \mathrm{~m} / \mathrm{s}$
4.84 Steam enters a device through a $2-i n^{2}$ area at 500 psia and $600^{\circ} \mathrm{F}$. It exits through a $10-\mathrm{in}^{2}$ area at 20 psia and $400^{\circ} \mathrm{F}$ with a velocity of $800 \mathrm{ft} / \mathrm{sec}$. What are the mass flux and the entering velocity?
Ans. $2.18 \mathrm{lbm} / \mathrm{sec}, 182.2 \mathrm{ft} / \mathrm{sec}$
4.85 Steam enters a $10-\mathrm{m}^{3}$ tank at 2 MPa and $600^{\circ} \mathrm{C}$ through an 8 -cm-diameter pipe with a velocity of 20 $\mathrm{m} / \mathrm{s}$. It leaves at 1 MPa and $400^{\circ} \mathrm{C}$ through a $12-\mathrm{cm}$-diameter pipe with a velocity of $10 \mathrm{~m} / \mathrm{s}$. Calculate the rate at which the density in the tank is changing. Ans. $0.01348 \mathrm{~kg} / \mathrm{m}^{3} \cdot \mathrm{~s}$
4.86 Water flows into a $1.2-\mathrm{cm}$-diameter pipe with a uniform velocity of $0.8 \mathrm{~m} / \mathrm{s}$. At some distance down the pipe a parabolic velocity profile is established. Determine the maximum velocity in the pipe and the mass flux. The parabolic profile can be expressed as $V(r)=V_{\text {max }}\left(1-r^{2} / R^{2}\right)$, where $R$ is the radius of the pipe. Ans. $1.6 \mathrm{~m} / \mathrm{s}, 0.0905 \mathrm{~kg} / \mathrm{s}$
4.87 Water enters the contraction shown in Fig. 4-38with a parabolic profile $V(r)=2\left(1-r^{2}\right) \mathrm{m} / \mathrm{s}$, where $r$ is measured in centimeters. The exiting profile after the contraction is essentially uniform. Determine the mass flux and the exit velocity. Ans. $0.314 \mathrm{~kg} / \mathrm{s}, 16 \mathrm{~m} / \mathrm{s}$

Fig. 4-38
4.88 Air enters a $4-\mathrm{in}$. constant-diameter pipe at $100 \mathrm{ft} / \mathrm{sec}$ with a pressure of 60 psia and a temperature of $100^{\circ} \mathrm{F}$. Heat is added to the air, causing it to pass a downstream area at $70 \mathrm{psia}, 300^{\circ} \mathrm{F}$. Calculate the downstream velocity and the heat transfer rate. Ans. $116.3 \mathrm{ft} / \mathrm{sec}, 121.2 \mathrm{Btu} / \mathrm{sec}$
4.89 Water at 9000 kPa and $300^{\circ} \mathrm{C}$ flows through a partially open valve. The pressure immediately after the valve is measured to be 600 kPa . Calculate the specific internal energy of the water leaving the valve. Neglect kinetic energy changes. (Note: the enthalpy of slightly compressed liquid is essentially equal to the enthalpy of saturated liquid at the same temperature.) Ans. $1282 \mathrm{~kJ} / \mathrm{kg}$
4.90 Steam at 9000 kPa and $600^{\circ} \mathrm{C}$ passes through a throttling process so that the pressure is suddenly reduced to 400 kPa . ( $a$ ) What is the expected temperature after the throttle? (b) What area ratio is necessary for the kinetic energy change to be zero? Ans. (a) $569^{\circ} \mathrm{C}$ (b) 22.3
4.91 Water at $70^{\circ} \mathrm{F}$ flows through the partially open valve shown in Fig. 4-39. The area before and after the valve is the same. Determine the specific internal energy downstream of the valve.
Ans. $39.34 \mathrm{Btu} / \mathrm{lbm}$

Fig. 4-39
4.92 The inlet conditions on an air compressor are 50 kPa and $20^{\circ} \mathrm{C}$. To compress the air to $400 \mathrm{kPa}, 5 \mathrm{~kW}$ of energy is needed. Neglecting heat transfer and kinetic and potential energy changes, estimate the mass flux. Assume an adiabatic, quasiequilibrium process. Ans. $0.021 \mathrm{~kg} / \mathrm{s}$
4.93 The air compressor shown in Fig. 4-40 draws air from the atmosphere and discharges it at 500 kPa . Determine the minimum power required to drive the insulated compressor. Assume atmospheric conditions of $25^{\circ} \mathrm{C}$ and 80 kPa and an adiabatic quasiequilibrium process. Ans. 571 kW

Fig. 4-40
4.94 The power required to compress $0.01 \mathrm{~kg} / \mathrm{s}$ of steam from a saturated vapor state at $50^{\circ} \mathrm{C}$ to a pressure of 800 kPa at $200^{\circ} \mathrm{C}$ is 6 kW . Find the rate of heat transfer from the compressor. Ans. 3.53 kW
4.95 Two thousand $\mathrm{lb} / \mathrm{h}$ of saturated water at 2 psia is compressed by a pump to a pressure of 2000 psia . Neglecting heat transfer and kinetic energy change, estimate the power required by the pump.
Ans. 4.72 hp

The pump in Fig. $4-41$ increases the pressure in the water from 200 to 4000 kPa . What is the minimum horsepower motor required to drive the pump for a flow rate of $0.1 \mathrm{~m}^{3} / \mathrm{s}$ ? Ans. 346 hp

Fig. 4-41
4.97 A turbine at a hydroclectric plant accepts $20 \mathrm{~m}^{3} / \mathrm{s}$ of water at a gage pressure of 300 kPa and discharges it to the atmosphere. Determine the maximum power output. Ans. 6 MW
4.98 Water flows in a creek at $1.5 \mathrm{~m} / \mathrm{s}$. It has cross-sectional dimensions of $0.6 \times 1.2 \mathrm{~m}$ upstream of a proposed dam which would be capable of developing a head of 2 m above the outlet of a turbine. Determine the maximum power output of the turbine. Ans. 21.19 kW
4.99 Superheated steam at 800 psia and $1000^{\circ} \mathrm{F}$ enters a turbine at a power plant at the rate of $30 \mathrm{lb} / \mathrm{sec}$. Saturated steam exits at 5 psia. If the power output is 10 MW , determine the heat transfer rate.
Ans. - 1954 Bu/sec
4.100 Superheated steam enters an insulated turbine (Fig. 4-42) at 4000 kPa and $500^{\circ} \mathrm{C}$ and leaves at 20 kPa . If the mass flux is $6 \mathrm{~kg} / \mathrm{s}$, determine the maximum power output and the exiting velocity. Assume an adiabatic quasiequilibrium process so that $s_{2}=s_{1}$. Ans. $6.65 \mathrm{MW}, 80.8 \mathrm{~m} / \mathrm{s}$

Fig. 4-42
4.101 Air enters a turbine at 600 kPa and $100^{\circ} \mathrm{C}$ through a $100-\mathrm{mm}$-diameter pipe at a speed of $100 \mathrm{~m} / \mathrm{s}$. The air exits at 140 kPa and $20^{\circ} \mathrm{C}$ through a $400-\mathrm{mm}$-diameter pipe. Calculate the power output, neglecting heat transfer. Ans. 373 kW
4.102 A turbine delivers 500 kW of power by extracting energy from air at 450 kPa and $100^{\circ} \mathrm{C}$ flowing in a $120-\mathrm{mm}$-diameter pipe at $150 \mathrm{~m} / \mathrm{s}$. For an exit pressure of 120 kPa and a temperature of $20^{\circ} \mathrm{C}$ determine the heat transfer rate. Ans. -70.5 kW
4.103 Water flows through a nozzle that converges from 4 in . to 0.8 in . in diameter. For a mass flux of 30 $1 \mathrm{bm} / \mathrm{sec}$ calculate the upstream pressure if the downstream pressure is 14.7 psia. Ans. 142.1 psia

Air enters a nozzle like that shown in Fig. 4-43 at a temperature of $195^{\circ} \mathrm{C}$ and a velocity of $100 \mathrm{~m} / \mathrm{s}$. If the air exits to the atmosphere where the pressure is 85 kPa , find ( $a$ ) the exit temperature, ( $b$ ) the exit velocity, and (c) the exit diameter. Assume an adiabatic quasiequilibrium process.
Ans. (a) $-3.3^{\circ} \mathrm{C}$
(b) $637 \mathrm{~m} / \mathrm{s}$
(c) 158 mm

Fig. 4-43
4.105 Nitrogen enters a diffuser at $200 \mathrm{~m} / \mathrm{s}$ with a pressure of 80 kPa and a temperature of $-20^{\circ} \mathrm{C}$. It leaves with a velocity of $15 \mathrm{~m} / \mathrm{s}$ at an atmospheric pressure of 95 kPa . If the inlet diameter is 100 mm , calculate (a) the mass flux and (b) the exit temperature. Ans. (a) $1.672 \mathrm{~kg} / \mathrm{s}$ (b) $-0.91{ }^{\circ} \mathrm{C}$
4.106 Steam enters a diffuser as a saturated vapor at $220^{\circ} \mathrm{F}$ with a velocity of $600 \mathrm{ft} / \mathrm{sec}$. It leaves with a velocity of $50 \mathrm{ft} / \mathrm{sec}$ at 20 psia . What is the exit temperature? Ans. $237^{\circ} \mathrm{F}$
4.107 Water is used in a heat exchanger (Fig. 4-44) to cool $5 \mathrm{~kg} / \mathrm{s}$ of air from $400^{\circ} \mathrm{C}$ to $200^{\circ} \mathrm{C}$. Calculate ( $a$ ) the minimum mass flux of the water and ( $b$ ) the quantity of heat transferred to the water each second. Ans. $23.9 \mathrm{~kg} / \mathrm{s}, 1 \mathrm{MJ}$

Fig. 4-44
4.108 A simple steam power plant, shown schematically in Fig. 4-45, operates on $8 \mathrm{~kg} / \mathrm{s}$ of steam. Losses in the connecting pipes and through the various components are to be neglected. Calculate ( $a$ ) the power

Fig. 4-45
output of the turbine, (b) the power needed to operate the pump, (c) the velocity in the pump exit pipe, $(d)$ the heat transfer rate necessary in the boiler, ( $e$ ) the heat transfer rate realized in the condenser, ( $f$ ) the mass flux of cooling water required, and ( $g$ ) the thermal efficiency of the cycle.
Ans. (a) 9.78 MW
(b) 63.8 kW
(c) $4.07 \mathrm{~m} / \mathrm{s}$
(d) 27.4 MW
(e) 17.69 MW (f) $141 \mathrm{~kg} / \mathrm{s}$ (g) $35.5 \%$

A feed water heater is used to preheat water before it enters a boiler, as shown schematically in Fig. $4-46$. A mass flux of $30 \mathrm{~kg} / \mathrm{s}$ flows through the system and, $7 \mathrm{~kg} / \mathrm{s}$ is withdrawn from the turbine for the feed water heater. Neglecting losses through the various pipes and components determine ( $a$ ) the feed water heater outlet temperature, $(b)$ the boiler heat transfer rate, $(c)$ the turbine power output, $(d)$ the total pump power required, ( $e$ ) the energy rejected by the condenser, ( $f$ ) the cooling water mass flux, and ( $g$ ) the thermal efficiency of the cycle.
Ans. (a) $197^{\circ} \mathrm{C}$
(b) 83.4 MW
(c) 30.2 MW
(d) 289 kW
(e) 53.5 MW
(f) $512 \mathrm{~kg} / \mathrm{s}$ (g) $35.9 \%$

Fig. 4-46
4.110 A turbine is required to provide a total output of 100 hp . The mass flux of fuel is negligible compared with the mass flux of air. The exhaust gases can be assumed to behave as air. If the compressor and turbine (Fig. 4-47) are assumed adiabatic, calculate the following, neglecting all losses: (a) the mass flux of the air, $(b)$ the horsepower required by the compressor, and ( $c$ ) the power supplied by the fuel.
Ans. (a) $0.1590 \mathrm{~kg} / \mathrm{s} \quad$ (b) $37.7 \mathrm{hp} \quad$ (c) 126.1 kW

Fig. 4-47
4.111 A steam line containing superheated steam at 1000 psia and $1200^{\circ} \mathrm{F}$ is connected to a $50-\mathrm{ft}^{3}$ evacuated insulated tank by a small line with a valve. The valve is closed when the pressure in the tank just reaches 800 psia. Calculate ( $a$ ) the final temperature in the tank and ( $b$ ) the mass of steam that entered the tank. Ans. (a) $1587^{\circ} \mathrm{F} \quad$ (b) 33.1 lbm
4.112 Air is contained in a $3-\mathrm{m}^{3}$ tank at 250 kPa and $25^{\circ} \mathrm{C}$. Heat is added to the tank as the air escapes, thereby maintaining the temperature constant at $25^{\circ} \mathrm{C}$. How much heat is required if the air escapes until the final pressure is atmospheric. Assume $P_{\mathrm{atm}}=80 \mathrm{kPa}$. Ans. 503 kJ
4.113 An air line carries air at 800 kPa (Fig. 4-48). An insulated tank initially contains $20^{\circ} \mathrm{C}$ air at atmospheric pressure of 90 kPa . The valve is opened and air flows into the tank. Determine the final temperature of the air in the tank and the mass of air that enters the tank if the valve is left open. Ans. $184^{\circ} \mathrm{C}, 25.1 \mathrm{~kg}$

Fig. 4-48
4.114 An insulated tank is evacuated. Air from the atmosphere at 12 psia and $70^{\circ} \mathrm{F}$ is allowed to flow into the $100-\mathrm{ft}^{3}$ tank. Calculate ( $a$ ) the final temperature and ( $b$ ) the final mass of air in the tank just after the flow ceases. Ans. (a) $284^{\circ} \mathrm{F} \quad$ (b) 4.36 lbm
4.115 (a) An insulated tank contains pressurized air at 2000 kPa and $30^{\circ} \mathrm{C}$. The air is allowed to escape to the atmosphere ( $P_{\mathrm{atm}}=95 \mathrm{kPa}, T_{\mathrm{atm}}=30^{\circ} \mathrm{C}$ ) until the flow ceases. Determine the final temperature in the tank. ( $b$ ) Eventually, the air in the tank will reach atmospheric temperature. If a valve was closed after the initial flow ceased, calculate the pressure that is eventually reached in the tank.
Ans. (a) $-146^{\circ} \mathrm{C}$,
(b) 227 kPa
4.116 An insulated tank with a volume of $4 \mathrm{~m}^{3}$ is pressurized to 800 kPa at a temperature of $30^{\circ} \mathrm{C}$. An automatic valve allows the air to leave at a constant rate of $0.02 \mathrm{~kg} / \mathrm{s}$. (a) What is the temperature after 5 min ? (b) What is the pressure after 5 min ? (c) How long will it take for the temperature to drop to $-20^{\circ} \mathrm{C}$ ? Ans. (a) $9.2^{\circ} \mathrm{C} \quad$ (b) $624 \mathrm{kPa} \quad$ (c) 11.13 min
4.117 A tank with a volume of $2 \mathrm{~m}^{3}$ contains 90 percent liquid water and 10 percent water vapor by volume at 100 kPa . Heat is transferred to the tank at $10 \mathrm{~kJ} / \mathrm{min}$. A relief valve attached to the top of the tank allows vapor to discharge when the gage pressure reaches 600 kPa . The pressure is maintained at that value as more heat is transferred. ( $a$ ) What is the temperature in the tank at the instant the relief valve opens? ( $b$ ) How much mass is discharged when the tank contains 50 percent vapor by volume? ( $c$ ) How long does it take for the tank to contain 75 percent vapor by volume?
Ans. (a) $158.9^{\circ} \mathrm{C}$
(b) 815 kg
(c) 11.25 h

## Chapter 5

## The Second Law of Thermodynamics

### 5.1 INTRODUCTION

Water flows down a hill, heat flows from a hot body to a cold one, rubber bands unwind, fluid flows from a high-pressure region to a low-pressure region, and we all get old! Our experiences in life suggest that processes have a definite direction. The first law of thermodynamics relates the several variables involved in a physical process but does not give any information as to the direction of the process. It is the second law of thermodynamics which helps us establish the direction of a particular process.

Consider, for example, the situation illustrated in Fig. 5-1. Here, the first law states that the work done by the falling weight is converted to internal energy of the air contained in the fixed volume, provided the volume is insulated so that $Q=0$. It would not be a violation of the first law if we postulated that an internal energy decrease of the air is used to turn the paddle and raise the weight. This, however, would be a violation of the second law of thermodynamics and would thus be an impossibility.

### 5.2 HEAT ENGINES, HEAT PUMPS, AND REFRIGERATORS

We refer to a device operating on a cycle as a heat engine, a heat pump, or a refrigerator, depending on the objective of the particular device. If the objective of the device is to perform work it is a heat engine; if its objective is to supply energy to a body it is a heat pump; if its objective is to extract energy from a body it is a refrigerator. A schematic diagram of a simple heat engine is shown in Fig. 5-2.

The net work produced by the engine in one cycle would be equal to the net heat transfer, a consequence of the first law:

$$
\begin{equation*}
W=Q_{H}-Q_{L} \tag{5.1}
\end{equation*}
$$

If the cycle of Fig. 5-2 were reversed, a net work input would be required, as shown in Fig. 5-3. A heat pump would provide energy as heat $Q_{H}$ to the warmer body (e.g., a house), and a refrigerator would extract energy as heat $Q_{L}$ from the cooler body (e.g., a freezer). The work would also be given by (5.1). Here we use magnitudes only.

The thermal efficiency of the heat engine and the coefficients of performance of the refrigerator and the heat pump are as defined in Sec. 4.9:

$$
\begin{equation*}
\eta=\frac{W}{Q_{H}} \quad \operatorname{CoP}_{\text {refrig }}=\frac{Q_{L}}{W} \quad \operatorname{CoP}_{\text {h.p. }}=\frac{Q_{H}}{W} \tag{5.2}
\end{equation*}
$$

The second law of thermodynamics will place limits on the above measures of performance. The first law would allow a maximum of unity for the thermal efficiency and an infinite coefficient of performance. The second law, however, establishes limits that are surprisingly low, limits that cannot be exceeded regardless of the cleverness of proposed designs.

One additional note concerning heat engines is appropriate. There are devices that we will refer to as heat engines which do not strictly meet our definition; they do not operate on a thermodynamic cycle but instead exhaust the working fluid and then intake new fluid. The internal combustion engine is an example. Thermal efficiency, as defined above, remains a quantity of interest for such devices.

Fig. 5-1

Fig. 5-2

Fig. 5-3

### 5.3 STATEMENTS OF THE SECOND LAW OF THERMODYNAMICS

As with the other basic laws presented, we do not derive a basic law but merely observe that such a law is never violated. The second law of thermodynamics can be stated in a variety of ways. Here we present two: the Clausius statement and the Kelvin-Planck statement. Neither is presented in mathematical terms. We will, however, provide a property of the system, entropy, which can be used to determine whether the second law is being violated for any particular situation. The first statement of the second law is:

Clausius Statement It is impossible to construct a device which operates in a cycle and whose sole effect is the transfer of heat from a cooler body to a hotter body.

This statement relates to a refrigerator (or a heat pump). It states that it is impossible to construct a refrigerator that transfers energy from a cooler body to a hotter body without the input of work; this violation is shown in Fig. 5-4a.

The second statement of the second law takes the following form:
Kelvin-Planck Statement It is impossible to construct a device which operates in a cycle and produces no other effect than the production of work and the transfer of heat from a single body.

In other words, it is impossible to construct a heat engine that extracts energy from a reservoir, does work, and does not transfer heat to a low-temperature reservoir. This rules out any heat engine that is 100 percent efficient, like the one shown in Fig. 5-4(b).

(a)

(b)

Fig. 5-4

Note that the two statements of the second law are negative statements. Neither has ever been proved; they are expressions of experimental observations. No experimental evidence has ever been obtained that violates either statement of the second law. It should also be noted that the two statements are equivalent. This will be demonstrated with an example.

EXAMPLE 5.1 Show that the Clausius and Kelvin-Planck statements of the second law are equivalent.
We will show that a violation of the Clausius statement implies a violation of the Kelvin-Planck statement, and vice versa, demonstrating that the two statements are equivalent. Consider the system shown in Fig. 5-5(a). The device on the left transfers heat and violates the Clausius statement, since it has no work input. Let the heat engine transfer the same amount of heat $Q_{L}$. Then $Q_{H}^{\prime}$ is greater than $Q_{L}$ by the amount $W$. If we simply transfer the heat $Q_{L}$ directly from the engine to the device, as shown in Fig. 5-5(b), there is no need for the low-temperature reservoir and the net result is a conversion of energy ( $Q_{H}^{\prime}-Q_{H}$ ) from the high-temperature reservoir into an equivalent amount of work, a violation of the Kelvin-Planck statement of the second law.

Conversely (Problem 5.13), a violation of the Kelvin-Planck is equivalent to a violation of the Clausius statement.

Fig. 5-5

### 5.4 REVERSIBILITY

In our study of the first law we made use of the concept of equilibrium and we defined equilibrium, or quasiequilibrium, with reference to the system only. We must now introduce the concept of reversibility so that we can discuss the most efficient engine that can possibly be constructed, an engine that operates with reversible processes only. Such an engine is called a reversible engine.

A reversible process is defined as a process which, having taken place, can be reversed and in so doing leave no change in either the system or the surroundings. Observe that our definition of a reversible process refers to both the system and the surroundings. The process obviously has to be a quasiequilibrium process; additional requirements are:

1. No friction is involved in the process.
2. Heat transfer occurs due to an infinitesimal temperature difference only.
3. Unrestrained expansion does not occur.

The mixing of different substances and combustion also lead to irreversibilities.
To illustrate that friction makes a process irreversible consider the system of block plus inclined plane shown in Fig. 5-6. Weights are added until the block is raised to the position shown in part (b). Now, to return the system to its original state some weight must be removed so that the block will slide back down the plane, as shown in part (c). Note that the surroundings have experienced a

Fig. 5-6
significant change; the weights must be raised, which requires a work input. Also, the block and plane are at a higher temperature due to the friction, and heat must be transferred to the surroundings to return the system to its original state. This will also change the surroundings. Because there has been a change in the surroundings as a result of the process and the reversed process, we conclude that the process was irreversible.

To demonstrate the fact that heat transfer across a finite temperature difference makes a process irreversible, consider a system composed of two blocks, one at a higher temperature than the other. Bringing the blocks together results in a heat transfer process; the surroundings are not involved in this process. To return the system to its original state, we must refrigerate the block that had its temperature raised. This will require a work input, demanded by the second law, resulting in a change in the surroundings. Hence, the heat transfer across a finite temperature difference is an irreversible process.

For an example of unrestrained expansion, consider the high-pressure gas contained in the cylinder of Fig. 5-7a. Pull the pin and let the piston suddenly move to the stops shown. Note that the only work done by the gas on the surroundings is to move the piston against atmospheric pressure. Now, to reverse this process it is necessary to exert a force on the piston. If the force is sufficiently large, we can move the piston to its original position, shown in part ( $d$ ). This will demand a considerable amount of work, to be supplied by the surroundings. In addition, the temperature will increase substantially, and this heat must be transferred to the surroundings to return the temperature to its original value. The net result is a significant change in the surroundings, a consequence of irreversibility.

Fig. 5-7

### 5.5 THE CARNOT ENGINE

The heat engine that operates the most efficiently between a high-temperature reservoir and a low-temperature reservoir is the Carnot engine. It is an ideal engine that uses reversible processes to form its cycle of operation; thus it is also called a reversible engine. We will determine the efficiency of
the Carnot engine and also evaluate its reverse operation. The Carnot engine is very useful, since its efficiency establishes the maximum possible efficiency of any real engine. If the efficiency of a real engine is significantly lower than the efficiency of a Carnot engine operating between the same limits, then additional improvements may be possible.

The cycle associated with the Carnot engine is shown in Fig. 5-8, using an ideal gas as the working substance. It is composed of the following four reversible processes:
$\mathbf{1 \rightarrow 2 :}$ An isothermal expansion. Heat is transferred reversibly from the high-temperature reservoir at the constant temperature $T_{H}$. The piston in the cylinder is withdrawn and the volume increases.
$\mathbf{2 \rightarrow 3 :}$ An adiabatic reversible expansion. The cylinder is completely insulated so that no heat transfer occurs during this reversible process. The piston continues to be withdrawn, with the volume increasing.
$3 \rightarrow 4:$ An isothermal compression. Heat is transferred reversibly to the low-temperature reservoir at the constant temperature $T_{L}$. The piston compresses the working substance, with the volume decreasing.
$4 \rightarrow$ 1: An adiabatic reversible compression. The completely insulated cylinder allows no heat transfer during this reversible process. The piston continues to compress the working substance until the original volume, temperature, and pressure are reached, thereby completing the cycle.

Fig. 5-8
Applying the first law to the cycle, we note that

$$
\begin{equation*}
Q_{H}-Q_{L}=W_{\text {net }} \tag{5.3}
\end{equation*}
$$

where $Q_{L}$ is assumed to be a positive value for the heat transfer to the low-temperature reservoir. This allows us to write the thermal efficiency [see (4.76)] for the Carnot cycle as

$$
\begin{equation*}
\eta=\frac{Q_{H}-Q_{L}}{Q_{H}}=1-\frac{Q_{L}}{Q_{H}} \tag{5.4}
\end{equation*}
$$

The following examples will be used to prove the following three postulates:
Postulate 1 It is impossible to construct an engine, operating between two given temperature reservoirs, that is more efficient than the Carnot engine.

Postulate 2 The efficiency of a Carnot engine is not dependent on the working substance used or any particular design feature of the engine.
Postulate 3 All reversible engines, operating between two given temperature reservoirs, have the same efficiency as a Carnot engine operating between the same two temperature reservoirs.

EXAMPLE 5.2 Show that the efficiency of a Carnot engine is the maximum possible efficiency.
Assume that an engine exists; operating between two reservoirs, that has an efficiency greater than that of a Carnot engine, also, assume that a Carnot engine operates as a refrigerator between the same two reservoirs, as sketched in Fig. 5-9a. Let the heat transferred from the high-temperature reservoir to the engine be equal to the heat rejected by the refrigerator; then the work produced by the engine will be greater than the work required by the refrigerator (that is, $Q_{L}^{\prime}<Q_{L}$ ) since the efficiency of the engine is greater than that of a Carnot engine. Now, our system can be organized as shown in Fig. 5-9b. The engine drives the refrigerator using the rejected heat from the refrigerator. But, there is some net work ( $W^{\prime}-W$ ) that leaves the system. The net result is the conversion of energy from a single reservoir into work, a violation of the second law. Thus, the Carnot engine is the most efficient engine operating between two particular reservoirs.

Fig. 5-9

EXAMPLE 5.3 Show that the efficiency of a Carnot engine operating between two reservoirs is independent of the working substance used by the engine.

Suppose that a Carnot engine drives a Carnot refrigerator as shown in Fig. 5-10a. Let the heat rejected by the engine be equal to the heat required by the refrigerator. Suppose the working fluid in the engine results in
$T_{H}$

$$
Q_{H}-Q_{L}=W \quad Q_{H}^{\prime}-Q_{L}=W^{\prime} \quad \therefore W>W^{\prime}
$$

(a)

(b)

Fig. 5-10
$Q_{H}$ being greater than $Q_{H}^{\prime}$; then $W$ would be greater than $W^{\prime}$ (a consequence of the first law) and we would have the equivalent system shown in Fig. 5-10b. The net result is a transfer of heat ( $Q_{H}-Q_{H}^{\prime}$ ) from a single reservoir and the production of work, a clear violation of the second law. Thus, the efficiency of a Carnot engine is not dependent on the working substance.

### 5.6 CARNOT EFFICIENCY

Since the efficiency of a Carnot engine is dependent only on the two reservoir temperatures, the objective of this article will be to determine that relationship. We will assume the working substance to be an ideal gas and simply perform the required calculations for the four processes of Fig. 5-8.

The heat transfer for each of the four processes is as follows:

$$
\begin{array}{ll}
\mathbf{1} \rightarrow \mathbf{2}: & Q_{H}=W_{1-2}=\int_{V_{1}}^{V_{2}} P d V=m R T_{H} \ln \frac{V_{2}}{V_{1}} \\
\mathbf{2} \rightarrow \mathbf{3 :} & Q_{2-3}=0 \\
\mathbf{3} \rightarrow \mathbf{4 :} & Q_{L}=-W_{3-4}=-\int_{V_{3}}^{V_{4}} P d V=-m R T_{L} \ln \frac{V_{4}}{V_{3}}  \tag{5.5}\\
\mathbf{4} \rightarrow \mathbf{1}: & Q_{4-1}=0
\end{array}
$$

Note that we want $Q_{L}$ to be a positive quantity, as in the thermal efficiency relationship; hence, the negative sign. The thermal efficiency is then [see (5.4)]

$$
\begin{equation*}
\eta=1-\frac{Q_{L}}{Q_{H}}=1+\frac{T_{L}}{T_{H}} \frac{\ln V_{4} / V_{3}}{\ln V_{2} / V_{1}} \tag{5.6}
\end{equation*}
$$

During the reversible adiabatic processes $2 \rightarrow 3$ and $4 \rightarrow 1$, we know that [see (4.49)]

$$
\begin{equation*}
\frac{T_{L}}{T_{H}}=\left(\frac{V_{2}}{V_{3}}\right)^{k-1} \quad \frac{T_{L}}{T_{H}}=\left(\frac{V_{1}}{V_{4}}\right)^{k-1} \tag{5.7}
\end{equation*}
$$

Thus, we see that

$$
\begin{equation*}
\frac{V_{2}}{V_{3}}=\frac{V_{1}}{V_{4}} \quad \text { or } \quad \frac{V_{4}}{V_{3}}=\frac{V_{1}}{V_{2}} \tag{5.8}
\end{equation*}
$$

Substituting into (5.5), we obtain the result (recognizing that $\ln V_{2} / V_{1}=-\ln V_{1} / V_{2}$ )

$$
\begin{equation*}
\eta=1-\frac{T_{L}}{T_{H}} \tag{5.9}
\end{equation*}
$$

We have simply replaced $Q_{L} / Q_{H}$ with $T_{L} / T_{H}$. We can do this for all reversible engines or refrigerators. We see that the thermal efficiency of a Carnot engine is dependent only on the high and low absolute temperature of the reservoirs. The fact that we used an ideal gas to perform the calculations is not important since we have shown that Carnot efficiency is independent of the working substance. Consequently, the relationship (5.9) is applicable for all working substances, or for all reversible engines, regardless of the particular design characteristics.

The Carnot engine, when operated in reverse, becomes a heat pump or a refrigerator, depending on the desired heat transfer. The coefficient of performance for a heat pump becomes

$$
\begin{equation*}
\mathrm{COP}=\frac{Q_{H}}{W_{\text {net }}}=\frac{Q_{H}}{Q_{H}-Q_{L}}=\frac{1}{1-T_{L} / T_{H}} \tag{5.10}
\end{equation*}
$$

The coefficient of performance for a refrigerator takes the form

$$
\begin{equation*}
\mathrm{COP}=\frac{Q_{L}}{W_{\text {net }}}=\frac{Q_{L}}{Q_{H}-Q_{L}}=\frac{1}{T_{H} / T_{L}-1} \tag{5.11}
\end{equation*}
$$

The above measures of performance set limits that real devices can only approach. The reversible cycles assumed are obviously unrealistic, but the fact that we have limits which we know we cannot
exceed is often very helpful in evaluating proposed designs and determining the direction for further effort.

EXAMPLE 5.4 A Carnot engine operates between two temperature reservoirs maintained at $200^{\circ} \mathrm{C}$ and $20^{\circ} \mathrm{C}$, respectively. If the desired output of the engine is 15 kW , as shown in Fig. 5-11, determine the heat transfer from the high-temperature reservoir and the heat transfer to the low-temperature reservoir.

Fig. 5-11

The efficiency of a Carnot engine is given by

$$
\eta=\frac{\dot{W}}{\dot{Q}_{H}}=1-\frac{T_{L}}{T_{H}}
$$

This gives, converting the temperatures to absolute temperatures,

$$
\dot{Q}_{H}=\frac{\dot{W}}{1-T_{L} / T_{H}}=\frac{15}{1-293 / 473}=39.42 \mathrm{~kW}
$$

Using the first law, we have $\dot{Q}_{L}=\dot{Q}_{H}-\dot{W}=39.42-15=24.42 \mathrm{~kW}$.
EXAMPLE 5.5 A refrigeration unit is cooling a space to $-5^{\circ} \mathrm{C}$ by rejecting energy to the atmosphere at $20^{\circ} \mathrm{C}$. It is desired to reduce the temperature in the refrigerated space to $-25^{\circ} \mathrm{C}$. Calculate the minimum percentage increase in work required, by assuming a Carnot refrigerator, for the same amount of energy removed.

For a Carnot refrigerator we know that

$$
\mathrm{COP}=\frac{Q_{L}}{W}=\frac{1}{T_{H} / T_{L}-1}
$$

For the first situation we have $W_{1}=Q_{L}\left(T_{H} / T_{L}-1\right)=Q_{L}(293 / 268-1)=0.0933 Q_{L}$. For the second situation there results $W_{2}=Q_{L}(293 / 248-1)=0.181 Q_{L}$. The percentage increase in work is then

$$
\frac{W_{2}-W_{1}}{W_{1}}=\left(\frac{0.181 Q_{L}-0.0933 Q_{L}}{0.0933 Q_{L}}\right)(100)=94.0 \%
$$

Note the large increase in energy required to reduce the temperature in a refrigerated spacc. And this is a minimum percentage increase, since we have assumed an ideal refrigerator.

EXAMPLE 5.6 A Carnot engine operates with air, using the cycle shown in Fig. 5-12. Determine the thermal efficiency and the work output for each cycle of operation. The thermal efficiency is found to be

$$
\eta=1-\frac{T_{L}}{T_{H}}=1-\frac{300}{500}=0.4 \quad \text { or } 40 \%
$$

Fig. 5 -12

To find the work output we can determine the heat added during the constant temperature expansion and determine $w$ from $\eta=W / Q_{H}=w / q_{H}$. We find $q_{H}$ from the first law using $\Delta u=0$ :

$$
q_{H}=w_{2-3}=\int P d v=R T_{H} \int_{v_{2}}^{v_{3}} \frac{d v}{v}=R T_{H} \ln \frac{v_{3}}{v_{2}}
$$

To find $v_{2}$ first we must find $v_{1}$ :

$$
v_{1}=\frac{R T_{1}}{P_{1}}=\frac{(287)(300)}{80000}=1.076 \mathrm{~m}^{3} / \mathrm{kg}
$$

Using (4.49), we have

$$
v_{2}=v_{1}\left(\frac{T_{1}}{T_{2}}\right)^{1 /(k-1)}=(1.076)(300 / 500)^{1 /(1.4-1)}=0.300 \mathrm{~m}^{3} / \mathrm{kg}
$$

Likewise, $v_{3}=v_{4}\left(T_{4} / T_{3}\right)^{1 /(k-1)}=(10)(300 / 500)^{2.5}=2.789 \mathrm{~m}^{3} / \mathrm{kg}$. Hence,

$$
q_{H}=(287)(500) \ln \frac{2.789}{0.300}=320.0 \mathrm{~kJ} / \mathrm{kg}
$$

Finaliy, the work for each cycle is $w=\eta q_{H}=(0.4)(320.0)=128 \mathrm{~kJ} / \mathrm{kg}$.

## Solved Problems

5.1 A refrigerator is rated at a COP of 4. The refrigerated space that it cools requires a peak
 cooling rate of $30000 \mathrm{~kJ} / \mathrm{h}$. What size electrical motor (rated in horsepower) is required for the refrigerator?

The definition of the COP for a refrigerator is $\operatorname{COP}=\dot{Q}_{L} / \dot{W}_{\text {net }}$. The net power required is then

$$
\dot{W}_{\text {net }}=\frac{\dot{Q}_{L}}{\mathrm{COP}}=\frac{30000 / 3600}{4}=2.083 \mathrm{~kW} \text { or } 2.793 \mathrm{hp}
$$

5.2 A Carnot heat engine produces 10 hp by transferring energy between two reservoirs at $40^{\circ} \mathrm{F}$ and $212^{\circ} \mathrm{F}$. Calculate the rate of heat transfer from the high-temperature reservoir.

The engine efficiency is

$$
\eta=1-\frac{T_{L}}{T_{H}}=1-\frac{500}{672}=0.2560
$$

The efficiency is also given by $\eta=\dot{W} / \dot{Q}_{H}$. Thus,

$$
\dot{Q}_{H}=\frac{\dot{W}}{\eta}=\frac{(10 \mathrm{hp})(2545 \mathrm{Btu} / \mathrm{hr} / \mathrm{hp})}{0.2560}=99,410 \mathrm{Btu} / \mathrm{hr}
$$

5.3 An inventor proposes an engine that operates between the $27^{\circ} \mathrm{C}$ warm surface layer of the ocean and a $10^{\circ} \mathrm{C}$ layer a few meters down. The inventor claims that the engine produces 100 kW by pumping $20 \mathrm{~kg} / \mathrm{s}$ of seawater. Is this possible?

The maximum temperature drop for the seawater is $17^{\circ} \mathrm{C}$. The maximum rate of heat transfer from the high-temperature water is then

$$
\dot{Q}_{H}=\dot{m} c_{p} \Delta T=(20)(4.18)(17)=1421 \mathrm{~kW}
$$

The efficiency of the proposed engine is then $\eta=\dot{W} / \dot{Q}_{H}=100 / 1421=0.0704$ or $7.04 \%$. The efficiency of a Carnot engine operating between the same two temperatures is

$$
\eta=1-\frac{T_{L}}{T_{H}}=1-\frac{283}{300}=0.0567 \text { or } 5.67 \%
$$

The proposed engine's efficiency exceeds that of a Carnot engine; hence, the inventor's claim is impossible.
5.4 A power utility company desires to use the hot groundwater from a hot spring to power a heat engine. If the groundwater is at $95^{\circ} \mathrm{C}$, estimate the maximum power output if a mass flux of $0.2 \mathrm{~kg} / \mathrm{s}$ is possible. The atmosphere is at $20^{\circ} \mathrm{C}$.

The maximum possible efficiency is

$$
\eta=1-\frac{T_{L}}{T_{H}}=1-\frac{293}{368}=0.2038
$$

assuming the water is rejected at atmospheric temperature. The rate of heat transfer from the energy source is

$$
\dot{Q}_{H}=\dot{m} c_{p} \Delta T=(0.2)(4.18)(95-20)=62.7 \mathrm{~kW}
$$

The maximum power output is then

$$
\dot{W}=\eta \dot{Q}_{H}=(0.2038)(62.7)=12.8 \mathrm{~kW}
$$

5.5 Two Carnot engines operate in series between two reservoirs maintained at $600^{\circ} \mathrm{F}$ and $100^{\circ} \mathrm{F}$, respectively. The energy rejected by the first engine is input into the second engine. If the first engine's efficiency is 20 percent greater than the second engine's efficiency, calculate the intermediate temperature.

The efficiencies of the two engines are

$$
\eta_{1}=1-\frac{T}{1060} \quad \eta_{2}=1-\frac{560}{T}
$$

where $T$ is the unknown intermediate temperature in ${ }^{\circ} \mathrm{R}$. It is given that $\eta_{1}=\eta_{2}+0.2 \eta_{2}$. Substituting for $\eta_{1}$ and $\eta_{2}$ results in

$$
1-\frac{T}{1060}=1.2\left(1-\frac{560}{T}\right)
$$

or

$$
T^{2}+212 T-712,320=0 \quad \therefore T=744.6^{\circ} \mathrm{R} \quad \text { or } 284.6^{\circ} \mathrm{F}
$$

5.6 A Carnot engine operating on air accepts $50 \mathrm{~kJ} / \mathrm{kg}$ of heat and rejects $20 \mathrm{~kJ} / \mathrm{kg}$. Calculate the high and low reservoir temperatures if the maximum specific volume is $10 \mathrm{~m}^{3} / \mathrm{kg}$ and the pressure after the isothermal expansion is 200 kPa .

The thermal efficiency is

$$
\eta=1-\frac{q_{L}}{q_{H}}=1-\frac{20}{50}=0.6
$$

Hence, $T_{L} / T_{H}=0.4$. For the adiabatic processes we know that (see Fig. 5-8)

$$
\frac{T_{L}}{T_{H}}=\left(\frac{v_{2}}{v_{3}}\right)^{k-1} \quad \therefore \frac{v_{2}}{v_{3}}=0.4^{2.5}=0.1012
$$

The maximum specific volume is $v_{3}$; thus, $v_{2}=0.1012 v_{3}=(0.1012)(10)=1.012 \mathrm{~m}^{3} / \mathrm{kg}$. Now, the high temperature is

$$
T_{H}=\frac{P_{2} C_{2}}{R}=\frac{(200)(1.012)}{0.287}=705.2 \mathrm{~K} \quad \text { or } 432.2^{\circ} \mathrm{C} .
$$

The low temperature is then $T_{L}=0.4 T_{H}=(0.4)(705.2)=282.1 \mathrm{~K}$ or $9.1^{\circ} \mathrm{C}$.
5.7 A heat engine operates on a Carnot cycle with an efficiency of 75 percent. What COP would a refrigerator operating on the same cycle have? The low temperature is $0^{\circ} \mathrm{C}$.

The efficiency of the heat engine is given by $\eta=1-T_{L} / T_{H}$. Hence,

$$
T_{H}=\frac{T_{L}}{1-\eta}=\frac{273}{1-0.75}=1092 \mathrm{~K}
$$

The COP for the refrigerator is then

$$
\mathrm{COP}=\frac{T_{L}}{T_{H}-T_{L .}}=\frac{273}{1092-273}=0.3333
$$

5.8 Two Carnot refrigerators operate in series between two reservoirs maintained at $20^{\circ} \mathrm{C}$ and $200^{\circ} \mathrm{C}$, respectively. The energy output by the first refrigerator is used as the heat energy input to the second refrigerator. If the COPs of the two refrigerators are the same, what should the intermediate temperature be?

The COP for a refrigerator is given by $\operatorname{COP}=T_{L} /\left(T_{H}-T_{L}\right)$. Requiring that the two COPs be equal gives

$$
\frac{293}{T-293}=\frac{T}{473-T} \quad \text { or } \quad T^{2}=138589 \quad \text { or } \quad T=372.3 \mathrm{~K}=99.3^{\circ} \mathrm{C}
$$

5.9 A heat pump is proposed in which $50^{\circ} \mathrm{F}$ groundwater is used to heat a house to $70^{\circ} \mathrm{F}$. The groundwater is to experience a temperature drop of $12^{\circ} \mathrm{F}$, and the house requires 75,000 $\mathrm{Btu} / \mathrm{hr}$. Calculate the minimum mass flux of the groundwater and the minimum horsepower required.

The COP for the heat pump is

$$
\mathrm{COP}=\frac{T_{H}}{T_{H}-T_{L}}=\frac{530}{530-510}=26.5
$$

This is also given by

$$
\mathrm{COP}=\frac{\dot{Q}_{H}}{\dot{Q}_{H}-\dot{Q}_{L}} \quad 26.5=\frac{75,000}{75,000-\dot{Q}_{L}} \quad \dot{Q}_{L}=72,170 \mathrm{Btu} / \mathrm{hr}
$$

The groundwater mass flux is then

$$
\dot{Q}_{L}=\dot{m} c_{p} \Delta T \quad 72,170=(\dot{m})(1.00)(12) \quad \dot{m}=6014 \mathrm{lbm} / \mathrm{hr}
$$

The minimum horsepower required is found as follows:

$$
\mathrm{COP}=\frac{\dot{Q}_{H}}{\dot{W}} \quad 26.5=\frac{75,000}{\dot{W}} \quad \dot{W}=2830 \mathrm{Btu} / \mathrm{hr} \quad \text { or } 1.11 \mathrm{hp}
$$

## Supplementary Problems

5.10 A heat pump provides $75 \mathrm{MJ} / \mathrm{h}$ to a house. If the compressors require an electrical energy input of 4 kW, calculate the COP. Ans. 5.21
5.11 A power plant burns 1000 kg of coal each hour and produces 500 kW of power. Calculate the overall thermal efficiency if each kg of coal produces 6 MJ of energy. Ans. $30 \%$
5.12 An automobile that has a gas mileage of $13 \mathrm{~km} / \mathrm{L}$ is traveling at $100 \mathrm{~km} / \mathrm{h}$. At this speed essentially all the power produced by the engine is used to overcome air drag. If the air drag force is given by $\frac{1}{2} \rho V^{2} A C_{D}$ determine the thermal efficiency of the engine at this speed using projected area $A=2 \mathrm{~m}^{2}$, drag coefficient $C_{D}=0.28$, and heating value of gasoline $9000 \mathrm{~kJ} / \mathrm{kg}$. Gasoline has a density of 740 $\mathrm{kg} / \mathrm{m}^{2}$. Ans. $51.9 \%$
5.13 Show that a violation of the Kelvin-Planck statement of the second law implies a violation of the Clausius statement.
5.14 A battery does work by producing an electric current while transferring heat with a constant-temperature atmosphere. Is this a violation of the sccond law? Explain. Ans. No. This is not a cycle.
5.15 Show that all reversible engines, operating between two given temperature reservoirs, have the same efficiency as a Carnot engine operating between the same two temperature reservoirs.
5.16 A Carnot cycle operates between $200^{\circ} \mathrm{C}$ and $1200^{\circ} \mathrm{C}$. Calculate ( $a$ ) its thermal efficiency if it operates as a power cycle, $(b)$ its COP if it operates as a refrigerator, and ( $c$ ) its COP if it operates as a heat pump. $\begin{array}{llll}\text { Ans. (a) } 67.7 \% & \text { (b) } 0.473 & \text { (c) } 1.473\end{array}$
5.17 A Carnot engine rejects 80 MJ of energy every hour by transferring heat to a reservoir at $10^{\circ} \mathrm{C}$. Determine the temperature of the high-temperature reservoir and the power produced if the rate of energy addition is 40 kW . Ans. $236.4^{\circ} \mathrm{C}, 17.78 \mathrm{~kW}$
5.18 A proposed power cycle is designed to operate between temperature reservoirs, as shown in Fig. 5-13. It is supposed to produce 43 hp from the 2500 kJ of energy extracted each minute. Is the proposal feasible? Ans. No

Fig. 5-13
5.19 (a) What is the maximum efficiency that can result from an engine that operates on the thermal gradients in the ocean? The surface waters at the proposed location are at $85^{\circ} \mathrm{F}$ and those at a reasonable depth are at $50^{\circ} \mathrm{F}$. (b) What would be the maximum COP of a heat pump, operating between the two layers, used to heat an off-shore oil rig? Ans. (a) $6.42 \% \quad$ (b) 15.57
5.20 A Carnot engine operates between reservoirs at temperatures $T_{1}$ and $T_{2}$, and a second Carnot engine operates between reservoirs maintained at $T_{2}$ and $T_{3}$. Express the efficiency $\eta_{3}$ of the third engine operating between $T_{1}$ and $T_{3}$ in terms of the efficiencies $\eta_{1}$ and $\eta_{2}$ of the other two engines.
Ans. $\quad \eta_{1}+\boldsymbol{\eta}_{2}-\eta_{1} \eta_{2}$
5.21 Two Carnot engines operate in series between two reservoirs maintained at $500^{\circ} \mathrm{C}$ and $40^{\circ} \mathrm{C}$, respectively. The energy rejected by the first engine is utilized as energy input to the second engine. Determine the temperature of this intermediate reservoir between the two engines if the efficiencies of both engines are the same. Ans. $218.9^{\circ} \mathrm{C}$
5.22 A Carnot engine operates on air with the cycle shown in Fig. 5-14. If there are $30 \mathrm{~kJ} / \mathrm{kg}$ of heat added from the high-temperature reservoir maintained at $200^{\circ} \mathrm{C}$ determine the work produced.
Ans. $16.74 \mathrm{~kJ} / \mathrm{kg}$

Fig. 5-14
5.23 A Carnot engine operates between a low pressure of 15 psia and a high pressure of 400 psia. The corresponding volumes are 250 and $25 \mathrm{in}^{3}$. If there is 0.01 lbm of air, calculate the work output. Ans. $\quad 178 \mathrm{ft} \cdot \mathrm{lbf}$
5.24 A Carnot engine using hydrogen gas operates with the high-temperature reservoir maintained at 600 K . The pressure ratio for the adiabatic compression is 15 to 1 and the volume during the beat-addition process is tripled. If the minimum pressure is 100 kPa . determine the thermal efficiency and work produced. Ans. $54.4 \%, 1480 \mathrm{~kJ}$
5.25 A heat pump is to maintain a house at $20^{\circ} \mathrm{C}$ when the outside air is at $-25^{\circ} \mathrm{C}$. It is determined that 1800 kJ is required each minute to accomplish this. Calculate the minimum horsepower required.
Ans. 6.18 hp
5.26 If the heat pump of Prob. 5.25 is to be used as an air conditioner, calculate the maximum outside temperature for which the inside temperature can be maintained at $23^{\circ} \mathrm{C}$. Assume a linear relationship between temperature difference and heat flux, using the information from Prob. 5.25.
Ans. $71.7^{\circ} \mathrm{C}$
5.27 A heat pump uses a 5 -hp compressor while extracting 500 Btu of energy from groundwater each minute. What is the COP ( $a$ ) if the purpose is to cool the groundwater and ( $b$ ) if the purpose is to heat a building?
Ans. (a) 2.36
(b) 3.36
5.28 A Carnot refrigeration cycle is used to estimate the energy requirement in an attempt to reduce the temperature of a specimen to absolute zero. Suppose that we wish to remove 0.01 J of energy from the specimen when it is at $2 \times 10^{-6} \mathrm{~K}$. How much work is necessary if the high-temperature reservoir is at $20^{\circ} \mathrm{C}$ ? Ans. 1465 kJ
5.29 A refrigerator is proposed that will require 10 hp to extract 3 MJ of energy each minute from a space which is maintained at $-18^{\circ} \mathrm{C}$. The outside air is at $20^{\circ} \mathrm{C}$. Is this possible? Ans. Yes
5.30 A reversible refrigeration unit is used to cool a space to $5^{\circ} \mathrm{C}$ by transferring heat to the surroundings which are at $25^{\circ} \mathrm{C}$. The same unit is then used to cool the space to $-20^{\circ} \mathrm{C}$. Estimate the cooling rate for the second condition if the cooling rate for the first is 5 tons. Ans. 7.12 kW

## Chapter 6

## Entropy

### 6.1 INTRODUCTION

To allow us to apply the second law of thermodynamics to a process we will identify a property called entropy. This will parallel our discussion of the first law; first we stated the first law for a cycle and then derived a relationship for a process.

### 6.2 DEFINITION

Consider the reversible Carnot engine operating on a cycle consisting of the processes described in Sec. 5.5. The quantity $\phi \delta Q / T$ is the cyclic integral of the heat transfer divided by the absolute temperature at which the heat transfer occurs. Since the temperature $T_{H}$ is constant during the heat transfer $Q_{H}$, and $T_{L}$ is constant during heat transfer $Q_{L}$, the integral is given by

$$
\begin{equation*}
\oint \frac{\delta Q}{T}=\frac{Q_{H}}{T_{H}}-\frac{Q_{L}}{T_{L}} \tag{6.1}
\end{equation*}
$$

where the heat $Q_{L}$ leaving the Carnot engine is considered to be positive. Using (5.4) and (5.9) we see that, for the Carnot cycle,

$$
\begin{equation*}
\frac{Q_{L}}{Q_{H}}=\frac{T_{L}}{T_{H}} \quad \text { or } \quad \frac{Q_{H}}{T_{H}}=\frac{Q_{L}}{T_{L}} \tag{6.2}
\end{equation*}
$$

Substituting this into (6.1), we find the interesting result

$$
\begin{equation*}
\oint \frac{\delta Q}{T}=0 \tag{6.3}
\end{equation*}
$$

Thus, the quantity $\delta Q / T$ is a perfect differential, since its cyclic integral is zero. We let this perfect differential be denoted by $d S$, where $S$ represents a scalar function that depends only on the state of the system. This, in fact, was our definition of a property of a system. We shall call this extensive property entropy; its differential is given by

$$
\begin{equation*}
d S=\left.\frac{\delta Q}{T}\right|_{\mathrm{rev}} \tag{6.4}
\end{equation*}
$$

where the subscript "rev" emphasizes the reversibility of the process. This can be integrated for a process to give

$$
\begin{equation*}
\Delta S=\left.\int_{1}^{2} \frac{\delta Q}{T}\right|_{\mathrm{rev}} \tag{6.5}
\end{equation*}
$$

From the above equation we see that the entropy change for a reversible process can be either positive or negative depending on whether energy is added to or extracted from the system during the heat transfer process. For a reversible adiabatic process the entropy change is zero.

We often sketch a temperature-entropy diagram for cycles or processes of interest. The Carnot cycle provides a simple display when plotting temperature vs. entropy. It is shown in Fig. 6-1. The change in entropy for the first process from state 1 to state 2 is

$$
\begin{equation*}
S_{2}-S_{1}=\int_{1}^{2} \frac{\delta Q}{T}=\frac{Q_{H}}{T_{H}} \tag{6.6}
\end{equation*}
$$

The entropy change for the reversible adiabatic process from state 2 to state 3 is zero. For the process from state 3 to state 4 the entropy change is numerically equal to that of the first process; the process

Fig. 6-1
from state 4 to state 1 is also a reversible adiabatic process and is accompanied with a zero entropy change.

The heat transfer during a reversible process can be expressed in differential form [see (6.4)] as

$$
\begin{equation*}
\delta Q=T d S \tag{6.7}
\end{equation*}
$$

Hence, the area under the curve in the $T-S$ diagram represents the heat transfer during any reversible process. The rectangular area in Fig. 6-1 thus represents the net heat transfer during the Carnot cycle. Since the heat transfer is equal to the work done for a cycle, the area also represents the net work accomplished by the system during the cycle. Here, $Q_{\text {net }}=W_{\text {net }}=\Delta T \Delta S$.

The first law of thermodynamics, for a reversible infinitesimal change, becomes, using (6.7),

$$
\begin{equation*}
T d S-P d V=d U \tag{6.8}
\end{equation*}
$$

This is an important relationship in our study of simple systems. We arrived at it assuming a reversible process. However, since it involves only properties of the system, it holds for an irreversible process also. If we have an irreversible process, in general, $\delta W \neq P d V$ and $\delta Q \neq T d S$ but (6.8) still holds as a relationship between the properties. Dividing by the mass, we have

$$
\begin{equation*}
T d s-P d v=d u \tag{6.9}
\end{equation*}
$$

where the specific entropy is defined to be

$$
\begin{equation*}
s=\frac{S}{m} \tag{6.10}
\end{equation*}
$$

To relate the entropy change to the enthalpy change we differentiate (4.12) and obtain

$$
\begin{equation*}
d h=d u+P d v+v d P \tag{6.11}
\end{equation*}
$$

Substituting into (6.9) for $d u$, we have

$$
\begin{equation*}
T d s=d h-\imath d P \tag{6.12}
\end{equation*}
$$

Equations ( 6.9 ) and ( 6.12 ) will be used in subsequent sections of our study of thermodynamics for various reversible and irreversible processes.

### 6.3 ENTROPY FOR AN IDEAL GAS WITH CONSTANT SPECIFIC HEATS

Assuming an ideal gas, ( 6.9 ) becomes

$$
\begin{equation*}
d s=\frac{d u}{T}+\frac{P d v}{T}=c_{v} \frac{d T}{T}+R \frac{d v}{v} \tag{6.13}
\end{equation*}
$$

where we have used

$$
\begin{equation*}
d u=c_{v} d T \quad P v=R T \tag{6.14}
\end{equation*}
$$

(6.13) is integrated, assuming constant specific heat, to yield

$$
\begin{equation*}
s_{2}-s_{1}=c_{v} \ln \frac{T_{2}}{T_{1}}+R \ln \frac{v_{2}}{v_{1}} \tag{6.15}
\end{equation*}
$$

Similarly, (6.12) is rearranged and integrated to give

$$
\begin{equation*}
s_{2}-s_{1}=c_{p} \ln \frac{T_{2}}{T_{1}}-R \ln \frac{P_{2}}{P_{1}} \tag{6.16}
\end{equation*}
$$

Note again that the above equations were developed assuming a reversible process; however, they relate the change in entropy to other thermodynamic properties at the two end states. Since the change of a property is independent of the process used in going from one state to another, the above relationships hold for any process, reversible or irreversible, providing the working substance can be approximated by an ideal gas with constant specific heats.

If the entropy change is zero, as in a reversible adiabatic process (6.15) and (6.16) can be used to obtain

$$
\begin{equation*}
\frac{T_{2}}{T_{1}}=\left(\frac{v_{1}}{v_{2}}\right)^{k-1} \quad \frac{T_{2}}{T_{1}}=\left(\frac{P_{2}}{P_{1}}\right)^{(k-1) / k} \tag{6.17}
\end{equation*}
$$

These two equations are combined to give

$$
\begin{equation*}
\frac{P_{2}}{P_{1}}=\left(\frac{v_{1}}{v_{2}}\right)^{k} \tag{6.18}
\end{equation*}
$$

These are, of course, identical to the equations obtained in Chap. 4 when an ideal gas undergoes a quasiequilibrium adiabatic process. We now refer to such a process as an isentropic process.

EXAMPLE 6.1 Air is contained in an insulated, rigid volume at $20^{\circ} \mathrm{C}$ and 200 kPa . A paddle wheel, inserted in the volume, does 720 kJ of work on the air. If the volume is $2 \mathrm{~m}^{3}$, calculate the entropy increase assuming constant specific heats.

To determine the final state of the process we use the energy equation, assuming zero heat transfer. We have $-W=\Delta U=m c_{c} \Delta T$. The mass $m$ is found from the ideal-gas equation to be

$$
m=\frac{P V}{R T}=\frac{(200)(2)}{(0.287)(293)}=4.76 \mathrm{~kg}
$$

The first law, taking the paddle-wheel work as negative, is then

$$
720=(4.76)(0.717)\left(T_{2}-293\right) \quad \therefore T_{2}=504.0 \mathrm{~K}
$$

Using (6.15) for this constant-volume process there results

$$
\Delta S=m c_{i} \ln \frac{T_{2}}{T_{1}}=(4.76)(0.717) \ln \frac{504}{293}=1.851 \mathrm{~kJ} / \mathrm{K}
$$

EXAMPLE 6.2 After a combustion process in a cylinder the pressure is 1200 kPa and the temperature is $350{ }^{\circ} \mathrm{C}$. The gases are expanded to 140 kPa with a reversible adiabatic process. Calculate the work done by the gases, assuming they can be approximated by air with constant specific heats.

The first law can be used, with zero heat transfer, to give $-w=\Delta u=c_{t}\left(T_{2}-T_{1}\right)$. The temperature $T_{2}$ is found from (6.17) to be

$$
T_{2}=T_{1}\left(\frac{P_{2}}{P_{1}}\right)^{(k-1) / k}=(623)\left(\frac{140}{1200}\right)^{(1.4-1) / 1.4}=337 \mathrm{~K}
$$

This allows the specific work to be calculated: $w=c_{t}\left(T_{1}-T_{2}\right)=(0.717(623-337)=205 \mathrm{~kJ} / \mathrm{kg}$.

### 6.4 ENTROPY FOR AN IDEAL GAS WITH VARIABLE SPECIFIC HEATS

If the specific heats for an ideal gas cannot be assumed constant over a particular temperature range we return to (6.12) and write

$$
\begin{equation*}
d s=\frac{d h}{T}-\frac{v d P}{T}=\frac{c_{p}}{T} d T-\frac{R}{P} d P \tag{6.19}
\end{equation*}
$$

The gas constant $R$ can be removed from the integral, but $c_{p}=c_{p}(T)$ cannot. Hence, we integrate (6.19) and obtain

$$
\begin{equation*}
s_{2}-s_{1}=\int_{T_{1}}^{T_{2}} \frac{c_{p}}{T} d T-R \ln \frac{P_{2}}{P_{1}} \tag{6.20}
\end{equation*}
$$

The integral in the above equation depends only on temperature, and we can evaluate its magnitude from the gas tables. It is found, using the tabulated function $\phi$, to be

$$
\begin{equation*}
\phi_{2}-\phi_{1}=\int_{T_{1}}^{T_{2} c_{p}} \frac{T}{T} d T \tag{6.21}
\end{equation*}
$$

Thus, the entropy change is (in some textbooks $s^{\circ}$ is used rather than $\phi$ )

$$
\begin{equation*}
s_{2}-s_{1}=\phi_{2}-\phi_{1}-R \ln \frac{P_{2}}{P_{1}} \tag{6.22}
\end{equation*}
$$

This more exact expression for the entropy change is used only when improved accuracy is desired.
For an isentropic process we cannot use (6.17) and (6.18) if the specific heats are not constant. However, we can use (6.22) and obtain, for an isentropic process,

$$
\begin{equation*}
\frac{P_{2}}{P_{1}}=\exp \left(\frac{\phi_{2}-\phi_{1}}{R}\right)=\frac{\exp \left(\phi_{2} / R\right)}{\exp \left(\phi_{1} / R\right)}=\frac{f\left(T_{2}\right)}{f\left(T_{1}\right)} \tag{6.23}
\end{equation*}
$$

Thus, we define a relatice pressure $P_{r}$, which depends only on the temperature, as

$$
\begin{equation*}
P_{r}=e^{\phi / R} \tag{6.24}
\end{equation*}
$$

It is included as an entry in the gas tables. The pressure ratio for an isentropic process is then

$$
\begin{equation*}
\frac{P_{2}}{P_{1}}=\frac{P_{r 2}}{P_{r 1}} \tag{6.25}
\end{equation*}
$$

The volume ratio can be found using the ideal-gas equation of state. It is

$$
\begin{equation*}
\frac{v_{2}}{v_{1}}=\frac{P_{1}}{P_{2}} \frac{T_{2}}{T_{1}} \tag{6.26}
\end{equation*}
$$

where we would assume an isentropic process when using the relative pressure ratio. Consequently, we define a relatice specific colume $c_{r}$, dependent solely on the temperature, as

$$
\begin{equation*}
\iota_{r}=\frac{T}{P_{r}} \tag{6.27}
\end{equation*}
$$

Using its value from the gas tables we find the specific volume ratio for an isentropic process; it is

$$
\begin{equation*}
\frac{v_{2}}{v_{1}}=\frac{v_{r 2}}{v_{r 1}} \tag{6.28}
\end{equation*}
$$

With the entries from the gas tables we can perform the calculations required in working problems involving an ideal gas with variable specific heats.

EXAMPLE 6.3 Repeat Example 6.1 assuming variable specific heats.
Using the gas tables, we write the first law as $-W=\Delta U=m\left(u_{2}-u_{1}\right)$. The mass is found from the ideal-gas equation to be

$$
m=\frac{P V}{R T}=\frac{(200)(2)}{(0.287)(293)}=4.76 \mathrm{~kg}
$$

The first law is then written as

$$
u_{2}=-\frac{W}{m}+u_{1}=-\frac{-720}{4.76}+209.1=360.4 \mathrm{~kJ} / \mathrm{kg}
$$

where $u_{1}$ is found at 293 K in the gas tables by interpolation. Now, using this value for $u_{2}$, we can interpolate to find

$$
T_{2}=501.2 \mathrm{~K} \quad \phi_{2}=2.222
$$

The value for $\phi_{1}$ is interpolated to be $\phi_{1}=1.678$. The pressure at state 2 is found using the ideal-gas equation for our constant-volume process:

$$
\frac{P_{2}}{T_{2}}=\frac{P_{1}}{T_{1}} \quad P_{2}=P_{1} \frac{T_{2}}{T_{1}}=(200)\left(\frac{501.2}{293}\right)=342.1 \mathrm{kPa}
$$

Finally, the entropy change is

$$
\Delta S=m\left(\phi_{2}-\phi_{1}-R \ln \frac{P_{2}}{P_{1}}\right)=4.76\left(2.222-1.678-0.287 \ln \frac{342.1}{200}\right)=1.856 \mathrm{~kJ} / \mathrm{K}
$$

The approximate result of Example 6.1 is seen to be less than $0.3 \%$ in error.

EXAMPLE 6.4 After a combustion process in a cylinder the pressure is 1200 kPa and the temperature is $350^{\circ} \mathrm{C}$. The gases are expanded to 140 kPa in a reversible, adiabatic process. Calculate the work done by the gases, assuming they can be approximated by air with variable specific heats.

First, at 623 K the relative pressure $P_{r 1}$ is interpolated to be $P_{r 1}\left(\frac{3}{20}\right)(20.64-18.36)+18.36=18.70$. For an isentropic process.

$$
P_{r 2}=P_{r 1} \frac{P_{2}}{P_{1}}=(18.70)\left(\frac{140}{1200}\right)=2.182
$$

With this value for the relative pressure at state 2 .

$$
T_{2}=\left(\frac{2.182-2.149}{2.626-\overline{2} .149}\right)(20)+340=341 \mathrm{~K}
$$

The work is found from the first law to be

$$
\begin{aligned}
w & =u_{1}-u_{2} \\
& =\left[\frac{3}{20}(465.5-450.1)+450.1\right]-\left[\left(\frac{2.182-2.149}{2.626-2.149}\right)(257.2-242.8)+242.8\right]=208.6 \mathrm{~kJ} / \mathrm{kg}
\end{aligned}
$$

### 6.5 ENTROPY FOR SUBSTANCES SUCH AS STEAM, SOLIDS, AND LIQUIDS

The entropy change has been found for an ideal gas with constant specific heats and for an ideal gas with variable specific heats. For pure substances, such as steam, entropy is included as an entry in the tables. In the quality region, it is found using the relation

$$
\begin{equation*}
s=s_{f}+x s_{f k} \tag{6.29}
\end{equation*}
$$

Note that the entropy of saturated liquid water at $0^{\circ} \mathrm{C}$ is arbitrarily set equal to zero. It is only the change in entropy that is of interest; hence, this arbitrary datum for entropy is of no consequence. In the superheated region it is tabulated as a function of temperature and pressure along with the other properties.

For a compressed liquid it is included as an entry in Table C-4, the compressed liquid table, or it can be approximated by the saturated liquid values $s_{f}$ at the given temperature. From the compressed liquid table at 10 MPa and $100^{\circ} \mathrm{C}, s=1.30 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}$, and from the saturated steam table at $100^{\circ} \mathrm{C}$, $s=1.31 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}$; this is an insignificant difference.

The temperature-entropy diagram is of particular interest and is often sketched during the problem solution. A $T$-s diagram is sketched in Fig. 6-2a; it is essentially symmetric about the critical point. Note that the high-pressure lines in the compressed liquid region are indistinguishable from the

Fig. 6-2
saturated liquid line. It is often helpful to visualize a process on a $T$-s diagram, since such a diagram illustrates assumptions regarding irreversibilities.

In addition to a $T$-s diagram, an $h$-s diagram, which is also called a Mollier diagram, is often useful in solving particular types of problems. The general shape of an $h$-s diagram is sketched in Fig. 6-2b.

For a solid or a liquid, the entropy change can be found quite easily if we can assume the specific heat to be constant. Returning to (6.9), we can write, assuming the solid or liquid to be incompressible so that $d v=0$,

$$
\begin{equation*}
T d s=d u=c d T \tag{6.30}
\end{equation*}
$$

where we have dropped the subscript on the specific heat since for solids and liquids $c_{p} \equiv c_{r}$. Tables usually list values for $c_{p}$; these are assumed to be equal to $c$. Assuming a constant specific heat, we find that

$$
\begin{equation*}
\Delta s=\int c \frac{d T}{T}=c \ln \frac{T_{2}}{T_{1}} \tag{6.3l}
\end{equation*}
$$

If the specific heat is a known function of temperature, the integration can be performed. Specific heats for solids and liquids are listed in Table B-4.

EXAMPLE 6.5 Steam is contained in a rigid container at an initial pressure of 100 psia and $600^{\circ} \mathbf{F}$. The pressure is reduced to 10 psia by removing energy via heat transfer. Calculate the entropy change and the heat transfer and sketch a $T$-s diagram.

From the steam tables, $l_{1}=c_{2}=6.216 \mathrm{ft}^{3} / \mathrm{lbm}$. State 2 is in the quality region. Using the above value for $c_{2}$, the quality is found as follows:

$$
6.216=0.0166+x(38.42-0.0166) \quad x=0.1614
$$

The entropy at state 2 is $s_{2}=0.2836+(0.1614)(1.5041)=0.5264 \mathrm{Btu} / \mathrm{lbm}-{ }^{\circ} \mathrm{R}$; the entropy change is then

$$
\Delta s=s_{2}-s_{1}=0.5264-1.7582=-1.232 \mathrm{Btu} / \mathrm{lbm} \cdot{ }^{\circ} \mathrm{R}
$$

The heat transfer is found from the first law using $w=0$ :

$$
q=u_{2}-u_{1}=[161.2+(0.1614)(911.01)]-1214.2=-906 \mathrm{Btu} / \mathrm{lbm}
$$

The process is displayed in the $T$-s diagram shown in Fig. 6-3.

Fig. 6-3

### 6.6 THE INEQUALITY OF CLAUSIUS

The Carnot cycle is a reversible cycle and produces work which we will refer to as $W_{\text {rev }}$. Consider an irreversible cycle operating between the same two reservoirs, shown in Fig. 6-4. Obviously, since the Carnot cycle possesses the maximum possible efficiency, the efficiency of the irreversible cycle must be less than that of the Carnot cycle. In other words, for the same amount of heat addition $Q_{t i}$, we must have

$$
\begin{equation*}
W_{\mathrm{irr}}<W_{\mathrm{rev}} \tag{6.32}
\end{equation*}
$$

From the first law applied to a cycle ( $W=Q_{H}-Q_{L}$ ) we see that, assuming that $\left(Q_{H}\right)_{\mathrm{irr}}$ and $\left(Q_{H}\right)_{\mathrm{rev}}$ are the same,

$$
\begin{equation*}
\left(Q_{L}\right)_{\mathrm{rev}}<\left(Q_{L}\right)_{\mathrm{irr}} \tag{6.33}
\end{equation*}
$$

This requires, referring to (6.1) and (6.3),

$$
\begin{equation*}
\oint\left(\frac{\delta Q}{T}\right)_{\mathrm{irr}}<0 \tag{6.34}
\end{equation*}
$$

since the above integral for a reversible cycle is zero.

Fig. 6-4

If we were considering an irreversible refrigerator rather than an engine, we would require more work for the same amount of refrigeration $Q_{L}$. By applying the first law to refrigerators, we would arrive at the same inequality as in (6.34). Hence, for all cycles, reversible or irreversible, we can write

$$
\begin{equation*}
\oint \frac{\delta Q}{T} \leqslant 0 \tag{6.35}
\end{equation*}
$$

This is known as the inequality of Clausius. It is a consequence of the second law of thermodynamics.
EXAMPLE 6.6 It is proposed to operate a simple steam power plant as shown in Fig. 6-5. The water is completely vaporized in the boiler so that the heat transfer $Q_{B}$ takes place at constant temperature. Does this proposal comply with the inequality of Clausius? Assume no heat transfer occurs from the pump or the turbine.

Fig. 6-5

The quantity that we seek is $\phi \delta Q / T$. Since the proposed heat transfer occurs at constant temperature, this takes the form

$$
\oint \frac{\delta Q}{T}=\frac{Q_{B}}{T_{B}}-\frac{Q_{C}}{T_{C}}
$$

From the steam tables we can find the following for each kilogram of water ( $m=1 \mathrm{~kg}$ ):

$$
\begin{aligned}
& T_{B}=179.9^{\circ} \mathrm{C} \quad T_{C}=60.1^{\circ} \mathrm{C} \quad Q_{B}=m\left(h_{3}-h_{2}\right)=2778-763=2015 \mathrm{~kJ} \\
& Q_{C}=m\left(h_{4}-h_{1}\right)=[251+(0.88)(2358)]-[251+(0.18)(2358)]=1651 \mathrm{~kJ}
\end{aligned}
$$

Thus, we have

$$
\oint \frac{\delta Q}{T}=\frac{2015}{452.9}-\frac{1651}{333.1}=-0.507 \mathrm{~kJ} / \mathrm{K}
$$

This is negative, as it must be if the proposed power plant is to satisfy the inequality of Clausius.

### 6.7 ENTROPY CHANGE FOR AN IRREVERSIBLE PROCESS

Consider a cycle to be composed of two reversible processes, shown in Fig. 6-6. Suppose that we can also return from state 2 to state 1 along the irreversible process marked by path $C$. For the reversible cycle we have

$$
\begin{equation*}
\int_{1}^{2} \frac{\delta Q}{T}+\int_{2}^{1} \frac{\delta Q}{T}=0 \tag{6.36}
\end{equation*}
$$

For the cycle involving the irreversible process, the Clausius inequality demands that

$$
\begin{equation*}
\int_{1}^{2} \frac{\delta Q}{T}+\int_{\substack{ \\\text { along } A}}^{1} \frac{\delta Q}{T}<0 \tag{6.37}
\end{equation*}
$$

Fig. 6-6

Subtracting (6.36) from (6.37),

$$
\begin{equation*}
\underset{\substack{\text { along } B}}{\int_{\substack{1}} \frac{\delta Q}{T}>\int_{2}^{1} \frac{\delta Q}{T}} \tag{6.38}
\end{equation*}
$$

But, along the reversible path $B, \delta Q / T=d S$. Thus, for any path representing any process,

$$
\begin{equation*}
\Delta S \geqslant \int \frac{\delta Q}{T} \quad \text { or } \quad d S \geqslant \frac{\delta Q}{T} \tag{6.39}
\end{equation*}
$$

The equality holds for a reversible process and the inequality for an irreversible process.
Relationship (6.39) leads to an important conclusion in thermodynamics. Consider an infinitesimal heat transfer $\delta Q$ to a system at absolute temperature $T$. If the process is reversible, the differential change in entropy is $\delta Q / T$; if the process is irreversible, the change in entropy is greater than $\delta Q / T$. We thus conclude that the effect of irreversibility (e.g., friction) is to increase the entropy of a system.

Finally, in our application of the second law to a process, (6.39) can summarize our results. If we wish to investigate whether a proposed process satisfies the second law, we simply check using (6.39). We see that entropy and the second law are synonymous in the same way that energy and the first law are synonymous.

Finally, consider an isolated system, a system which exchanges no work or heat with its surroundings. For such a system the first law demands that $U_{2}=U_{1}$ for any process. Equation (6.39) takes the form

$$
\begin{equation*}
\Delta S \geqslant 0 \tag{6.40}
\end{equation*}
$$

demanding that the entropy of an isolated system either remain constant or increase, depending on whether the process is reversible or irreversible. Hence, for any real process the entropy of an isolated system increases.

We can generalize the above by considering a larger system to include both the system under consideration and its surroundings, often referred to as the universe. For the universe we can write

$$
\begin{equation*}
\Delta S_{\text {univ }}=\Delta S_{\text {sys }}+\Delta S_{\text {surr }} \geqslant 0 \tag{6.41}
\end{equation*}
$$

where the equality applies to a (ideal) reversible process and the inequality to a (real) irreversible process. Relation (6.41), the principle of entropy increase, is often used as the mathematical statement of the second law. Often $\Delta S_{\text {umv }}$ is called $\Delta S_{\text {zenerued }}$ or $\Delta S_{\text {met }}$.

EXAMPLE 6.7 Air is contained in one half of the insulated tank shown in Fig. 6-7. The other side is completely evacuated. The membrane is punctured and the air quickly fills the entire volume. Calculate the specific entropy change of this isolated system.

Fig. 6-7
The entire tank is chosen as the system boundary. No heat transfer occurs across the boundary and no work is done by the air. The first law then takes the form $\Delta U=m c_{v}\left(T_{2}-T_{1}\right)=0$. Hence, the final temperature is equal to the initial temperature. Using (6.15) for the entropy change, we have, with $T_{1}=T_{2}$,

$$
\Delta s=R \ln \frac{v_{2}}{v_{1}}=\frac{53.3}{778} \ln 2=0.04749 \mathrm{Btu} / \mathrm{lbm}-{ }^{\circ} \mathrm{R}
$$

Note that this satisfies (6.39) since for this example $Q=0$, so that $\int \delta Q / T=0<m \Delta s$.
EXAMPLE 6.8 Two kg of superheated steam at $400^{\circ} \mathrm{C}$ and 600 kPa is cooled at constant pressure by transferring heat from a cylinder until the steam is completely condensed. The surroundings are at $25^{\circ} \mathrm{C}$. Determine the net entropy change of the universe due to this process.

The entropy of the steam which defines our system decreases since heat is transferred from the system to the surroundings. From the steam tables this change is found to be

$$
\Delta S_{\mathrm{sys}}=m\left(s_{2}-s_{1}\right)=(2)(1.9316-7.7086)=-11.55 \mathrm{~kJ} / \mathrm{K}
$$

The heat transfer to the surroundings occurs at constant temperature. Hence, the entropy change of the surroundings is

$$
\Delta S_{\mathrm{surr}}=\int \frac{\delta Q}{T}=\frac{Q}{T}
$$

The heat transfer for the constant-pressure process is

$$
Q=m \Delta h=2(3270.2-670.6)=5199 \mathrm{~kJ}
$$

giving $\Delta S_{\text {surr }}=5199 / 298=17.45 \mathrm{~kJ} / \mathrm{K}$ and

$$
\Delta S_{\text {univ }}=\Delta S_{\text {surr }}+\Delta S_{\text {sys }}=17.45-11.55=5.90 \mathrm{~kJ} / \mathrm{K}
$$

### 6.8 THE SECOND LAW APPLIED TO A CONTROL VOLUME

The second law has been applied thus far in this chapter to a system, a particular collection of mass particles. We now wish to apply the second law to a control volume, following the same strategy used in our study of the first law. In Fig. 6-8 a control volume is enclosed by the control surface shown

Fig. 6-8
with the dashed lines surrounding some device or volume of interest. The second law can then be expressed over a time increment $\Delta t$ as

$$
\begin{equation*}
\binom{\text { Entropy change }}{\text { of control volume }}+\binom{\text { Entropy }}{\text { exiting }}-\binom{\text { Entropy }}{\text { entering }}+\binom{\text { Entropy change }}{\text { of surroundings }} \geqslant 0 \tag{6.42}
\end{equation*}
$$

This is expressed as

$$
\begin{equation*}
\Delta S_{\mathrm{c} . \mathrm{v} \cdot}+m_{2} s_{2}-m_{1} s_{1}+\frac{Q_{\text {surr }}}{T_{\text {surr }}} \geqslant 0 \tag{6.43}
\end{equation*}
$$

If we divide the above equation by $\Delta t$ and use dots to denote rates, we arrive at the rate equation

$$
\begin{equation*}
\dot{S}_{c . \mathrm{v} .}+\dot{m}_{2} s_{2}-\dot{m}_{1} s_{1}+\frac{\dot{Q}_{\text {surr }}}{T_{\text {surr }}} \geqslant 0 \tag{6.44}
\end{equation*}
$$

The equality is associated with a reversible process. The inequality is associated with irreversibilities such as viscous effects, which are always present in a material flow; separations of the flow from boundaries where abrupt changes in geometry occur; and shock waves in high-speed compressible flow.

For a steady-flow process the entropy of the control volume remains constant with time. We can then write, recognizing that $\dot{m}_{2}=\dot{m}_{1}=\dot{m}$,

$$
\begin{equation*}
\dot{m}\left(s_{2}-s_{1}\right)+\frac{\dot{Q}_{\text {surr }}}{T_{\text {surr }}} \geqslant 0 \tag{6.45}
\end{equation*}
$$

By transferring energy to the body via heat transfer, we can obviously increase the entropy of the fluid flowing from the control volume. However, we also note that for an adiabatic steady-flow process the entropy also increases from inlet to exit due to irreversibilities since, for that case, (6.45) reduces to

$$
\begin{equation*}
s_{2} \geqslant s_{1} \tag{6.46}
\end{equation*}
$$

For the reversible adiabatic process the inlet entropy and exit entropy are equal, an isentropic process. We use this fact when solving reversible adiabatic processes involving steam, such as flow through an ideal turbine.

We may be particularly interested in the entropy production; we define the rate of entropy production to be the left side of (6.44):

$$
\begin{equation*}
\dot{S}_{\mathrm{prod}} \equiv \dot{S}_{\mathrm{c}, \mathrm{v} .}+\dot{m}_{2} s_{2}-\dot{m}_{1} s_{1}+\frac{\dot{Q}_{\mathrm{surr}}}{T_{\mathrm{surr}}} \tag{6.47}
\end{equation*}
$$

This production rate is zero for reversible processes and positive for irreversible processes.
One last comment is in order regarding irreversible steady-flow processes, such as that in an actual turbine. We desire a quantity that can easily be used as a measure of the irreversibilities that exist in a particular device. The efficiency sometimes called the adiabatic efficiency, of a device is one such measure; it is defined as the ratio of the actual performance of a device to the ideal performance. The ideal performance is often that associated with an isentropic process. For example, the efficiency of a turbine would be

$$
\begin{equation*}
\eta_{T}=\frac{w_{a}}{w_{s}} \tag{6.48}
\end{equation*}
$$

where $w_{u}$ is the actual (specific) work output and $w_{s}$ is the (specific) work output associated with an isentropic process. In general, the efficiency is defined using the desired output as the measure; for a diffuser we would use the pressure increase and for a nozzle the kinetic energy increase. For a compressor the actual work required is greater than the ideal work requirement of an isentropic process. For a compressor or pump the efficiency is defined to be

$$
\begin{equation*}
\eta_{C}=\frac{w_{s}}{w_{a}} \tag{6.49}
\end{equation*}
$$

The efficiencies above are also called the adiabatic efficiencies since each efficiency is based on an adiabatic process.

Fig. 6-9
EXAMPLE 6.9 A preheater is used to preheat water in a power plant cycle, as shown in Fig. 6-9. The superheated steam is at a temperature of $250^{\circ} \mathrm{C}$ and the entering water is subcooled at $45^{\circ} \mathrm{C}$. All pressures are 600 kPa . Calculate the rate of entropy production.

From conservation of mass, $\dot{m}_{3}=\dot{m}_{2}+\dot{m}_{1}=0.5+4=4.5 \mathrm{~kg} / \mathrm{s}$. The first law allows us to calculate the temperature of the exiting water. Neglecting kinetic-energy and potential-energy changes and assuming zero heat transfer, the first law takes the form $\dot{m}_{3} h_{3}=\dot{m}_{2} h_{2}+\dot{m}_{1} h_{1}$. Using the steam tables ( $h_{1}$ is the enthalpy of saturated water at $45^{\circ} \mathrm{C}$ ),

$$
4.5 h_{3}=(0.5)(2957.2)+(4)(188.4) \quad \therefore h_{3}=496 \mathrm{~kJ} / \mathrm{kg}
$$

This enthalpy is less than that of saturated liquid at 600 kPa . Thus, the exiting water is also subcooled. Its temperature is interpolated from the saturated steam tables (find $T$ that gives $h_{f}=496 \mathrm{~kJ} / \mathrm{kg}$ ) to be

$$
T_{3}=\left(\frac{496-461.3}{503.7-461.3}\right)(10)+110=118^{\circ} \mathrm{C}
$$

The entropy at this temperature is then interpolated (using $s_{f}$ ) to be $s_{3}=1.508 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}$. The entropy of the entering superheated steam is found to be $s_{2}=7.182 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}$. The entering entropy of the subcooled water is $s_{f}$ at $T_{1}=45^{\circ} \mathrm{C}$, or $s_{1}=0.639 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}$. Finally, modifying ( 6.47 ), to account for two inlets, we have

$$
\dot{S}_{\text {prod }}=\dot{m}_{3} s_{3}-\dot{m}_{2} s_{2}-\dot{m}_{1} s_{1}=(4.5)(1.508)-(0.5)(7.182)-(4)(0.639)=0.639 \mathrm{~kW} / \mathrm{K}
$$

This is positive, indicating that entropy is produced, a consequence of the second law. The mixing process between the superheated steam and the subcooled water is indeed an irreversible process.

EXAMPLE 6.10 Superheated steam enters a turbine, as shown in Fig. 6-10a, and exits at 2 psia. If the mass flux is $4 \mathrm{lbm} / \mathrm{sec}$, determine the power output if the process is assumed to be reversible and adiabatic. Sketch the process on a $T$-s diagram.

(a)

(b)

Fig. 6-10

If we neglect kinetic-energy and potential-energy changes, the first law, for an adiabatic process, is $-\dot{W}_{T}=\dot{m}\left(h_{2}-h_{1}\right)$. Since the process is also assumed to be reversible, the entropy exiting is the same as the entropy entering, as shown in Fig. 6-10b (such a sketch is quite useful in visualizing the process). From the steam tables,

$$
h_{1}=1531 \mathrm{Btu} / \mathrm{lbm} \quad s_{1}=s_{2}=1.8827 \mathrm{Btu} / \mathrm{lbm}-{ }^{\circ} \mathbf{R}
$$

With the above value for $s_{2}$, we see that state 2 is in the quality region. The quality is determined as follows:

$$
s_{2}=s_{f}+x_{2} s_{f g} \quad 1.8827=0.1750+1.7448 x_{2} \quad x_{2}=0.9787
$$

Then $h_{2}=h_{f}+x_{2} h_{f g}=94.02+(0.9787)(1022.1)=1094 \mathrm{Btu} / \mathrm{lbm}$ and

$$
\dot{W}_{T}=(4)(1531-1094)=1748 \mathrm{Btu} / \mathrm{sec} \quad \text { or } 2473 \mathrm{hp}
$$

EXAMPLE 6.11 The turbine of Example 6.10 is assumed to be 80 percent efficient. Determine the entropy and temperature of the final state. Sketch the real process on a $T$-s diagram.

Using the definition of efficiency, the actual power output is found to be

$$
\dot{W}_{a}=(0.8) \dot{W}_{s}=(0.8)(1748)=1398 \mathrm{Btu} / \mathrm{sec}
$$

From the first law, $-\dot{W}_{a}=\dot{m}\left(h_{2^{\prime}}-h_{1}\right)$, we have $h_{2^{\prime}}=h_{1}-\dot{W}_{a} / \dot{m}=1521-1398 / 4=1182 \mathrm{Btu} / \mathrm{lbm}$. Using this value and $P_{2^{\prime}}=2$ psia, we see that state $2^{\prime}$ lies in the superheated region, since $h_{2^{\prime}}>h_{g}$. This is shown in Fig. 6-11. At $P_{2}=2$ and $h_{2^{\prime}}=1182$ we interpolate to find the value of $T_{2^{\prime}}$ :

$$
T_{2^{\prime}}=-\left(\frac{1186-1182}{1186-1168}\right)(280-240)+280=271^{\circ} \mathrm{F}
$$

The entropy is $s_{2^{\prime}}=2.0526 \mathrm{Btu} / \mathrm{lbm} \cdot{ }^{\circ} \mathrm{R}$.

Fig. 6-11

Note that the irreversibility has the desired effect of moving state 2 into the superheated region, thereby eliminating the formation of droplets due to the condensation of moisture. In an actual turbine, moisture formation cannot be tolerated because of damage to the turbine blades.

## Solved Problems

6.1 A Carnot engine delivers 100 kW of power by operating between temperature reservoirs at $100^{\circ} \mathrm{C}$ and $1000^{\circ} \mathrm{C}$. Calculate the entropy change of each reservoir and the net entropy change of the two reservoirs after 20 min of operation.

The efficiency of the engine is

$$
\eta=1-\frac{T_{L}}{T_{H}}=1-\frac{373}{1273}=0.7070
$$

The high-temperature heat transfer is then $\dot{Q}_{H}=\dot{W} / \eta=100 / 0.7070=141.4 \mathrm{~kW}$. The low-
temperature heat transfer is

$$
\dot{Q}_{L}=\dot{Q}_{H}-\dot{W}=141.4-100=41.4 \mathrm{~kW}
$$

The entropy changes of the reservoirs are then

$$
\begin{aligned}
& \Delta S_{H}=-\frac{Q_{H}}{T_{H}}=-\frac{\dot{Q}_{H} \Delta t}{T_{H}}=-\frac{(141.4)[(20)(60)]}{1273}=-133.3 \mathrm{~kJ} / \mathrm{K} \\
& \Delta S_{L}=\frac{Q_{L}}{T_{L}}=\frac{\dot{Q}_{L} \Delta t}{T_{L}}=\frac{(41.4)[(20)(60)]}{373}=133.2 \mathrm{~kJ} / \mathrm{K}
\end{aligned}
$$

The net entropy change of the two reservoirs is $\Delta S_{\text {net }}=\Delta S_{H}+\Delta S_{L}=133.3+133.2=-0.1 \mathrm{~kJ} / \mathrm{K}$. This is zero, except for round-off error, in compliance with (6.2).
6.2 Two kg of air is heated at constant pressure of 200 kPa to $500^{\circ} \mathrm{C}$. Calculate the entropy change if the initial volume is $0.8 \mathrm{~m}^{3}$.

The initial temperature is found to be

$$
T_{1}=\frac{P_{1} V_{1}}{m R}=\frac{(200)(0.8)}{(2)(0.287)}=278.7 \mathrm{~K}
$$

The entropy change is then found, using (6.16) to be

$$
\Delta S=m\left[c_{p} \ln \frac{T_{2}}{T_{1}}-R \ln 1\right]=(2)(1.00) \ln \frac{773}{278.7}=2.040 \mathrm{~kJ} / \mathrm{K}
$$

6.3 Air is compressed in an automobile cylinder from 14.7 to 2000 psia . If the initial temperature is $60^{\circ} \mathrm{F}$, estimate the final temperature.

Compression occurs very rapidly in an automobile cylinder; hence, we approximate the process with an adiabatic reversible process. Using (6.17), we find the final temperature to be

$$
T_{2}=T_{1}\left(\frac{P_{2}}{P_{1}}\right)^{(k-1) / k}=(520)\left(\frac{2000}{14.7}\right)^{0.4 / 1.4}=2117^{\circ} \mathrm{R} \quad \text { or } 1657^{\circ} \mathrm{F}
$$

6.4 A piston allows air to expand from 6 MPa to 200 kPa . The initial volume and temperature are $500 \mathrm{~cm}^{3}$ and $800^{\circ} \mathrm{C}$. If the temperature is held constant, calculate the heat transfer and the entropy change.

The first law, using the work for an isothermal process, provides us with

$$
Q=W=m R T \ln \frac{P_{1}}{P_{2}}=\left(\frac{P_{1} V_{1}}{R T_{1}}\right) R T_{1} \ln \frac{P_{1}}{P_{2}}=(6000)\left(500 \times 10^{-6}\right) \ln \frac{6000}{200}=10.20 \mathrm{~kJ}
$$

The entropy change is then

$$
\Delta S=m c_{p} \ln 1-m R \ln \frac{P_{2}}{P_{1}}=-\frac{P_{1} V_{1}}{T_{1}} \ln \frac{P_{2}}{P_{1}}=-\frac{(6000)\left(500 \times 10^{-6}\right)}{1073} \ln \frac{200}{6000}=9.51 \mathrm{~J} / \mathrm{K}
$$

6.5 A paddle wheel provides 200 kJ of work to the air contained in a $0.2-\mathrm{m}^{3}$ rigid volume, initially at 400 kPa and $40^{\circ} \mathrm{C}$. Determine the entropy change if the volume is insulated.

The first law, with zero heat transfer because of the insulation, provides

$$
-W=m \Delta u=m c \Delta T \quad-(-200)=\frac{(400)(0.2)}{(0.287)(313)}(0.717)\left(T_{2}-313\right) \quad T_{2}=626.2 \mathrm{~K}
$$

The entropy change is then found to be

$$
\Delta S=m c_{r} \ln \frac{T_{2}}{T_{1}}+m R \ln 1=\frac{(400)(0.2)}{(0.287)(313)}(0.717) \ln \frac{626.2}{313}=0.4428 \mathrm{~kJ} / \mathrm{K}
$$

6.6 Air is compressed in an automobile cylinder from 14.7 to 2000 psia. Predict the final temperature if the initial temperature is $60^{\circ} \mathrm{F}$. Do not assume constant specific heat.

Since the process is quite rapid, with little chance for heat transfer, we will assume an adiabatic reversible process. For such a process we may use (6.25) and find

$$
P_{r 2}=P_{r 1} \frac{P_{2}}{P_{1}}=(1.2147)\left(\frac{2000}{14.7}\right)=165.3
$$

where $P_{r 1}$ is found in Table F-1E. The temperature is now interpolated, using $P_{r 2}$ to be

$$
T_{2}=\left(\frac{165.3-141.5}{174.0-141.5}\right)(2000-1900)+1900=1973^{\circ} \mathrm{R}
$$

This compares with $2117^{\circ} \mathrm{R}$ of Prob. 6.3, in which the specific heat was assumed constant. Note the significant error (over 7 percent) in $T_{2}$ of Prob. 6.3. This occurs for large $\Delta T$.
6.7 Air expands from 200 to $1000 \mathrm{~cm}^{3}$ in a cylinder while the pressure is held constant at 600 kPa . If the initial temperature is $20^{\circ} \mathrm{C}$, calculate the heat transfer assuming (a) constant specific heat and ( $b$ ) variable specific heat.
(a) The air mass is

$$
m=\frac{P V}{R T}=\frac{(600)\left(200 \times 10^{-6}\right)}{(0.287)(293)}=0.001427 \mathrm{~kg}
$$

The final temperature is found using the ideal-gas law:

$$
T_{2}=T_{1} \frac{V_{2}}{V_{1}}:=(293)\left(\frac{1000}{200}\right)=1465 \mathrm{~K}
$$

The heat transfer is then (constant-pressure process)

$$
Q=m c_{p}\left(T_{2}-T_{1}\right)=(0.001427)(1.00)(1465-293)=1.672 \mathrm{~kJ}
$$

(b) The mass and $T_{2}$ are as computed in part (a). The first law again provides, using $h_{2}$ and $h_{1}$ from Table F-1,

$$
Q=m\left(h_{2}-h_{1}\right)=(0.001427)(1593.7-293.2)=1.856 \mathrm{~kJ}
$$

This shows that a 9.9 percent error results from assuming constant specific heat. This is due to the large temperature difference between the end states of the process.
6.8 Water is maintained at a constant pressure of 400 kPa while the temperature changes from $20^{\circ} \mathrm{C}$ to $400^{\circ} \mathrm{C}$. Calculate the heat transfer and the entropy change.

Using $c_{1}=i_{f}$ at $20^{\circ} \mathrm{C}$ [state 1 is compressed liquid],

$$
w=P\left(c_{2}-c_{1}\right)=(400)(0.7726-0.001002)=308.6 \mathrm{~kJ} / \mathrm{kg}
$$

The first law gives $q=u_{2}-u_{1}+w=2964.4-83.9+308.6=3189 \mathrm{~kJ} / \mathrm{kg}$ and the entropy change is

$$
\Delta s=s_{2}-s_{1}=7.8992-0.2965=7.603 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K}
$$

6.9 Two kg of steam is contained in a 6 -liter tank at $60^{\circ} \mathrm{C}$. If 1 MJ of heat is added, calculate the final entropy.

The initial quality is found as follows:

$$
v_{1}=\frac{V_{1}}{m}=\frac{6 \times 10^{-3}}{2}=0.001017+x_{1}(7.671-0.001) \quad \therefore x_{1}=0.0002585
$$

The initial specific internal energy is then

$$
u_{1}=u_{f}+x_{1}\left(u_{g}-u_{f}\right)=251.1+(0.0002585)(2456.6-251.1)=251.7 \mathrm{~kJ} / \mathrm{kg}
$$

The first law, with $W=0$, gives

$$
Q=m\left(u_{2}-u_{1}\right) \text { or } u_{2}=u_{1}+\frac{Q}{m}=251.7+\frac{1000}{2}=751.7 \mathrm{~kJ} / \mathrm{kg}
$$

Using $v_{2}=v_{1}=0.003 \mathrm{~m}^{3} / \mathrm{kg}$ and $u_{2}=751.7 \mathrm{~kJ} / \mathrm{kg}$, we locate state 2 by trial and error. The quality must be the same for the temperature selected.

$$
\begin{array}{lll}
\mathrm{T}_{2}=170^{\circ} \mathrm{C}: & 0.003=0.0011+\mathrm{x}_{2}(0.2428-0.0011) & \therefore \mathrm{x}_{2}=0.00786 \\
& 751.7=718.3+\mathrm{x}_{2}(2576.5-718.3) & \therefore \mathrm{x}_{2}=0.01797 \\
\mathrm{~T}_{2}=177^{\circ} \mathrm{C}: & 0.003=0.0011+\mathrm{x}_{2}(0.2087-0.0011) & \therefore \mathrm{x}_{2}=0.00915 \\
& 751.7=750.0+\mathrm{x}_{2}(2581.5-750.0) & \therefore \mathrm{x}_{2}=0.00093
\end{array}
$$

A temperature of $176^{\circ} \mathrm{C}$ is chosen. The quality from $\nu_{2}$ is used since it is less sensitive to temperature change. At $176^{\circ} \mathrm{C}$, we interpolate to find

$$
0.003=0.0011+x_{2}(0.2136-0.0011) \quad \therefore x_{2}=0.00894
$$

whence $S_{2}=m\left(s_{f}+x_{2} s_{f g}\right)=(2)[2.101+(0.00894)(4.518)]=4.28 \mathrm{~kJ} / \mathrm{K}$
6.10 Five ice cubes (each 1.2 in $^{3}$ ) at $0^{\circ} \mathrm{F}$ are placed in a $16-\mathrm{oz}$ glass of water at $60^{\circ} \mathrm{F}$. Calculate the final equilibrium temperature and the net entropy change, assuming an insulated glass.

The first law allows us to determine the final temperature. We will assume that not all of the ice melts so that $T_{2}=32^{\circ} \mathrm{F}$. The ice warms up and some of it then melts. The original water cools. First, we calculate the mass of the ice (see Table C-5E) and the water:

$$
\left.m_{i}=\frac{(5)(1.2 / 1728)}{0.01745}=0.199 \mathrm{lbm}, \quad m_{w}=1 \mathrm{lbm} \quad \text { (a pint's a pound }\right)
$$

The first law is expressed as $m_{i}\left(c_{p}\right)_{i} \Delta T+m_{l} \Delta h_{I}=m_{w}\left(c_{p}\right)_{w} \Delta T$, where $m_{l}$ is the amount of ice that melts. This becomes

$$
(0.199)(0.49)(32-0)+\left(m_{l}\right)(140)=(1)(1.0)(60-32) \quad \therefore m_{I}=0.1777 \mathrm{lbm}
$$

The net entropy change of the ice and water is then

$$
\begin{aligned}
\Delta S_{\text {net }} & =m_{i} c_{p} \ln \frac{T_{2}}{T_{1 i}}+m_{I}\left(s_{w}-s_{i}\right)+m_{w} c_{p} \ln \frac{T_{2}}{T_{1 w}} \\
& =(0.199)(0.49) \ln \frac{492}{460}+(0.1777)[0.0-(-0.292)]+(1)(1.0) \ln \frac{492}{520}=0.00311 \mathrm{Btu} /{ }^{\circ} \mathbf{R}
\end{aligned}
$$

6.11 The steam in a Carnot engine is compressed adiabatically from 10 kPa to 6 MPa with saturated liquid occurring at the end of the process. If the work output is $500 \mathrm{~kJ} / \mathrm{kg}$, calculate the quality at the end of the isothermal expansion.

For a cycle, the work output equals the net heat input, so that

$$
W=\Delta T \Delta s \quad 500=(275.6-45.8)\left(s_{2}-3.0273\right) \quad s_{2}=5.203 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K}
$$

This $s_{2}$ is the entropy at the end of the isothermal expansion. Using the values of $s_{f}$ and $s_{f g}$ at 6 MPa , we have

$$
5.203=3.0273+2.8627 x_{2} \quad \therefore x_{2}=0.760
$$

6.12 The Freon 12 in a Carnot refrigerator operates between saturated liquid and vapor during the heat rejection process. If the cycle has a high temperature of $50^{\circ} \mathrm{C}$ and a low temperature of $-20^{\circ} \mathrm{C}$, calculate the heat transfer from the refrigerated space and the quality at the beginning of the heat addition process.

The cycle COP is given as

$$
\mathrm{COP}=\frac{T_{L}}{T_{H}-T_{L}}=\frac{253}{323-253}=3.614
$$

The COP is also given by COP $=q_{\mathrm{L}} / w$, where

$$
w=\Delta T \Delta s=[50-(-20)](0.6792-0.3034)=26.31 \mathrm{~kJ} / \mathrm{kg}
$$

Hence, the heat transfer that cools is $q_{L}=(\operatorname{COP})(w)=(3.614)(26.31)=95.08 \mathrm{~kJ} / \mathrm{kg}$.
The quality at the beginning of the heat addition process is found by equating the entropy at the end of the heat rejection process to the entropy at the beginning of the heat addition process:

$$
0.3034=0.0730+0.6352 x \quad \therefore x=0.3627
$$

6.13 Show that the inequality of Clausius is satisfied by a Carnot engine operating with steam between pressures of 40 kPa and 4 MPa . The work output is $350 \mathrm{~kJ} / \mathrm{kg}$, and saturated vapor enters the adiabatic expansion process.

Referring to Table C-2, the high and low temperatures are $250.4^{\circ} \mathrm{C}$ and $75.9^{\circ} \mathrm{C}$. The work output allows us to calculate the entropy at the beginning of the heat-addition process as follows:

$$
w=\Delta T \Delta s \quad 350=(250.4-75.9) \Delta s \quad \therefore \Delta s=2.006 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K}
$$

The heat addition is then $q_{H}=T_{H} \Delta s=(250.4+273)(2.006)=1049.9 \mathrm{~kJ} / \mathrm{kg}$, and the heat extraction is

$$
q_{L}=T_{L} \Delta s=(75.9+273)(2.006)=699.9 \mathrm{~kJ} / \mathrm{kg}
$$

For the (reversible) Carnot cycle the inequality of Clausius should become an equality:

$$
\oint \frac{\delta Q}{T}=\frac{Q_{H}}{T_{H}}-\frac{Q_{L}}{T_{L}}=\frac{1049.9}{523.4}-\frac{699.9}{348.9}=2.006-2.006=0 \quad(\mathrm{O} . \mathrm{K} .)
$$

6.14 A 5-lb block of copper at $200^{\circ} \mathrm{F}$ is submerged in 10 lbm of water at $50^{\circ} \mathrm{F}$, and after a period of time, equilibrium is established. If the container is insulated, calculate the entropy change of the universe.

First, we find the final equilibrium temperature. Since no energy leaves the container, we have, using specific heat values from Table B-4E,
$m_{c}\left(c_{p}\right)_{c}(\Delta T)_{c}=m_{w}\left(c_{P}\right)_{w}(\Delta T)_{w} \quad 5 \times 0.093\left(200-T_{2}\right)=(10)(1.00)\left(T_{2}-50\right) \quad T_{2}=56.66{ }^{\circ} \mathrm{F}$
The entropy changes are found to be

$$
\begin{aligned}
& (\Delta S)_{c}=m_{c}\left(c_{p}\right)_{c} \ln \frac{T_{2}}{\left(T_{1}\right)_{c}}=(5)(0.093) \ln \frac{516.7}{660}=-0.1138 \mathrm{Btu} /{ }^{\circ} \mathrm{R} \\
& (\Delta S)_{w}=m_{w}\left(c_{p}\right)_{w} \ln \frac{T_{2}}{\left(T_{1}\right)_{w}}=(10)(1.00) \ln \frac{516.7}{510}=0.1305 \mathrm{Btu} /{ }^{\circ} \mathrm{R}
\end{aligned}
$$

Since no heat leaves the container, there is no entropy change of the surroundings. Hence

$$
\Delta S_{\text {universe }}=(\Delta S)_{c}+(\Delta S)_{w}=-0.1138+0.1305=0.0167 \mathrm{Btu} /{ }^{\circ} \mathrm{R}
$$

6.15 Two kg of saturated steam is contained in $0.2-\mathrm{m}^{3}$ rigid volume. Heat is transferred to the surroundings at $30^{\circ} \mathrm{C}$ until the quality reaches 20 percent. Calculate the entropy change of the universe.

The initial specific volume is $u_{1}=0.2 / 2=0.1 \mathrm{~m}^{3} / \mathrm{kg}$. By studying Tables C-1 and C-2 for the nearest $v_{g}$ we see that this occurs at $P_{1}=2 \mathrm{MPa}$. We also observe that $T_{1}=212.4^{\circ} \mathrm{C}, s_{1}=6.3417$ $\mathrm{kJ} / \mathrm{kg} \cdot \mathrm{K}$, and $u_{1}=2600.3 \mathrm{~kJ} / \mathrm{kg}$. Since the volume is rigid, we can locate state 2 by trial and error as follows.

$$
\begin{aligned}
& \text { Try } P_{2}=0.4 \mathrm{MPa}: v_{2}=0.0011+0.2(0.4625-0.0011)=0.0934 \\
& \text { Try } P_{2}=0.3 \mathrm{MPa}: v_{2}=0.0011+0.2(0.6058-0.0011)=0.122
\end{aligned}
$$

Obviously, $v_{2}=0.1$, so that state 2 is between 0.4 and 0.3 MPa . We interpolate to find

$$
P_{2}=\left(\frac{0.122-0.1}{0.122-0.0934}\right)(0.1)+0.3=0.377 \mathrm{MPa}
$$

The entropy and internal energy are also interpolated as follows:

$$
s_{2}=1.753+(0.2)(5.166)=2.786 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K} \quad u_{2}=594.3+(0.2)(2551.3-594.3)=986 \mathrm{~kJ} / \mathrm{kg}
$$

The heat transfer is then, with $W=0$ for the rigid volume,

$$
Q=m\left(u_{2}-u_{1}\right)=(2)(986-2600)=-3230 \mathrm{~kJ} \quad \text { [heat to surroundings] }
$$

The entropy change for the universe is calculated as

$$
\Delta S_{\text {universe }}=m \Delta S_{\text {sys }}+\Delta S_{\text {surr }}=(2)(2.786-6.3417)+\frac{3230}{273+30}=3.55 \mathrm{~kJ} / \mathrm{K}
$$

6.16 A steam turbine accepts $2 \mathrm{~kg} / \mathrm{s}$ of steam at 6 MPa and $600^{\circ} \mathrm{C}$ and exhausts saturated steam at 20 kPa while producing 2000 kW of work. If the surroundings are at $30^{\circ} \mathrm{C}$ and the flow is steady, calculate the rate of entropy production.

The first law for a control volume allows us to calculate the heat transfer from the turbine to the surroundings:

$$
\dot{Q}_{T}=\dot{m}\left(h_{2}-h_{1}\right)+\dot{W}_{T}=(2)(2609.7-3658.4)+2000=-97.4 \mathrm{~kW}
$$

Hence, $\dot{Q}_{\text {surr }}=-\dot{Q}_{T}=+97.4 \mathrm{~kW}$. The rate of entropy production is then found from (6.47) to be

$$
\dot{S}_{\text {prod }}=\dot{S}_{\mathrm{c} . \mathrm{v} .}+\dot{m}\left(s_{2}-s_{1}\right)+\frac{\dot{Q}_{\text {surr }}}{T_{\text {surr }}}=0+(2)(7.9093-7.1685)+\frac{97.4}{303}=1.80 \mathrm{~kW} / \mathrm{K}
$$

6.17 A rigid tank is sealed when the temperature is $0^{\circ} \mathrm{C}$. On a hot day the temperature in the tank reaches $50^{\circ} \mathrm{C}$. If a small hole is drilled in the tank, estimate the velocity of the escaping air.

As the tank heats up, the volume remains constant. Assuming atmospheric pressure at the initial state, the ideal-gas law yields

$$
P_{2}=P_{1} \frac{T_{2}}{T_{1}}=(100)\left(\frac{323}{273}\right)=118.3 \mathrm{kPa}
$$

The temperature at the exit, as the air expands from $P_{2}$ to $P_{3}$ as it escapes out of the hole, is found by assuming an isentropic process:

$$
T_{3}=T_{2}\left(\frac{P_{3}}{P_{2}}\right)^{(k-1) / k}=(323)\left(\frac{100}{118.3}\right)^{(1.4-1) / 1.4}=307.9 \mathrm{~K}
$$

where we have assumed pressure $P_{3}$ outside the tank to be atmospheric. The control-volume energy equation is now used to find the exit velocity $V_{3}$ :

$$
0=\frac{V_{3}^{2}-V_{2}^{2 \pi^{0}}}{2}+c_{p}\left(T_{3}-T_{2}\right) \quad V_{3}=\sqrt{2 c_{p}\left(T_{2}-T_{3}\right)}=\sqrt{(2)(1000)(323-307.9)}=173.8 \mathrm{~m} / \mathrm{s}
$$

Note that we have used $c_{p}=1000 \mathrm{~J} / \mathrm{kg} \cdot \mathrm{K}$, not $c_{p}=1.00 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}$. This provides the correct units; that is, $\mathrm{J} / \mathrm{kg} \cdot \mathrm{K}=\mathrm{N} \cdot \mathrm{m} / \mathrm{kg} \cdot \mathrm{K}=\mathrm{m}^{2} / \mathrm{s}^{2} \cdot \mathrm{~K}$.
6.18 Steam expands isentropically through a turbine from 6 MPa and $600^{\circ} \mathrm{C}$ to 10 kPa . Calculate the power output if the mass flux is $2 \mathrm{~kg} / \mathrm{s}$.

The exit state is at the same entropy as the inlet. This allows us to determine the exit quality as follows (use entries at 10 kPa ):

$$
s_{2}=s_{1}=7.1685=0.6491+7.5019 x_{2} \quad \therefore x_{2}=0.8690
$$

The exit enthalpy is $h_{2}=h_{f}+x_{2} h_{f g}=191.8+(0.8690)(2392.8)=2271 \mathrm{~kJ} / \mathrm{kg}$. The control-volume energy equation then allows us to calculate

$$
\dot{W}_{T}=-\dot{m}\left(h_{2}-h_{1}\right)=-(2)(2271-3658.4)=2774 \mathrm{~kW}
$$

This is the maximum possible power output for this turbine operating between the temperature and pressure limits imposed.
6.19 A steam turbine produces 3000 hp from a mass flux of $20,000 \mathrm{lbm} / \mathrm{hr}$. The steam enters at $1000^{\circ} \mathrm{F}$ and 800 psia and exits at 2 psia. Calculate the efficiency of the turbine.

The maximum possible work output is calculated first. For an isentropic process, state 2 is located as follows:

$$
s_{2}=s_{1}=1.6807=0.1750+1.7448 x_{2} \quad \therefore x_{2}=0.8630
$$

The exit enthalpy is then $h_{2}=h_{f}+x_{2} h_{f g}=94.02+(0.8630)(1022.1)=976.1 \mathrm{Btu} / \mathrm{lbm}$. The work output $w_{s}$ associated with the isentropic process is

$$
w_{s}=-\left(h_{2}-h_{1}\right)=-(976.1-1511.9)=535.8 \mathrm{Btu} / \mathrm{lbm}
$$

The actual work output $w_{a}$ is calculated from the given information:

$$
w_{a}=\frac{\dot{W}_{T}}{\dot{m}}=\frac{(3000)(550) / 778}{20,000 / 3600}=381.7 \mathrm{Btu} / \mathrm{lbm}
$$

The efficiency is found, using (6.48), to be

$$
\eta_{T}=\frac{w_{a}}{w_{s}}=\frac{381.7}{535.8}=0.712 \quad \text { or } \quad 71.2 \%
$$

6.20 Calculate the efficiency of the Rankine cycle shown in Fig. 6-12 if the maximum temperature is $700^{\circ} \mathrm{C}$. The pressure is constant in the boiler and condenser.

The isentropic process from 2 to 3 allows us to locate state 3 . Since $P_{2}=10 \mathrm{MPa}$ and $T_{2}=700^{\circ} \mathrm{C}$, we find

$$
s_{3}=s_{2}=7.1696=0.6491+7.5019 x_{3} \quad \therefore x_{3}=0.8692
$$

The enthalpy of state 3 is then $h_{3}=h_{f}+x_{3} h_{f g}=191.8+(0.8692)(2392.8)=2272 \mathrm{~kJ} / \mathrm{kg}$. The turbine output is

$$
w_{T}=-\left(h_{3}-h_{2}\right)=-(2272-3870.5)=1598 \mathrm{~kJ} / \mathrm{kg}
$$

Fig. 6-12

The energy input to the pump is

$$
w_{P}=-\frac{p_{1}-p_{4}}{\rho}=-\frac{10000-10}{1000}=-9.99 \mathrm{~kJ} / \mathrm{kg}
$$

and, since $-w_{P}=h_{1}-h_{4}$,

$$
h_{1}=h_{4}-w_{P}=191.8-(-9.99)=201.8 \mathrm{~kJ} / \mathrm{kg}
$$

The energy input to the boiler is $q_{B}=h_{2}-h_{1}=3870.9-201.8=3669 \mathrm{~kJ} / \mathrm{kg}$, from which

$$
\eta_{\text {cycle }}=\frac{w_{T}+w_{P}}{q_{B}}=\frac{1598-9.99}{3669}=0.433 \text { or } 43.3 \%
$$

## Supplementary Problems

6.21 A Carnot engine extracts 100 kJ of heat from an $800^{\circ} \mathrm{C}$ reservoir and rejects to the surroundings at $20^{\circ} \mathrm{C}$. Calculate the entropy change ( $a$ ) of the reservoir and ( $b$ ) of the surroundings.
Ans. (a) $-0.0932 \mathrm{~kJ} / \mathrm{K} \quad$ (b) $0.0932 \mathrm{~kJ} / \mathrm{K}$
6.22 A Carnot refrigerator removes 200 kJ of heat from a refrigerated space maintained at $-10^{\circ} \mathrm{C}$. Its COP is 10 . Calculate the entropy change $(a)$ of the refrigerated space and $(b)$ of the high-temperature reservoir. Ans. (a) $-0.76 \mathrm{~kJ} / \mathrm{K} \quad$ (b) $0.76 \mathrm{~kJ} / \mathrm{s}$
6.23 A reversible heat pump requires 4 hp while providing $50,000 \mathrm{Btu} / \mathrm{hr}$ to heat a space maintained at $70^{\circ} \mathrm{F}$. Calculate the entropy change of the space and the low-temperature reservoir after 10 min of operation. Ans. $15.72 \mathrm{Btu} /{ }^{\circ} \mathrm{R},-4.02 \mathrm{Btu} /{ }^{\circ} \mathrm{R}$
6.24 Compare the entropy increase of the high-temperature reservoir and the entropy decrease of the specimen of Prob. 5.28. Ans. $5 \mathrm{~kJ} / \mathrm{K},-5 \mathrm{~kJ} / \mathrm{K}$
6.25 Verify that (6.17) results from (6.15) and (6.16).
6.26 A gas of mass 0.2 kg is compressed slowly from 150 kPa and $40^{\circ} \mathrm{C}$ to 600 kPa , in an adiabatic process. Determine the final volume if the gas is $(a)$ air, $(b)$ carbon dioxide, $(c)$ nitrogen, and ( $d$ ) hydrogen.
Ans.
(a) $0.0445 \mathrm{~m}^{3}$
(b) $0.0269 \mathrm{~m}^{3}$
(c) $0.046 \mathrm{~m}^{3}$
(d) $0.246 \mathrm{~m}^{3}$
6.27 Two kg of gas changes state from 120 kPa and $27^{\circ} \mathrm{C}$ to 600 kPa in a rigid container. Calculate the entropy change if the gas is (a) air, (b) carbon dioxide, (c) nitrogen, and (d) hydrogen.
Ans.
(a) $2.31 \mathrm{~kJ} / \mathrm{K}$
(b) $2.1 \mathrm{~kJ} / \mathrm{K}$
(c) $2.4 \mathrm{~kJ} / \mathrm{K}$
(d) $32.4 \mathrm{~kJ} / \mathrm{K}$
6.28 Determine the entropy change of a gas in a rigid container that is heated from the conditions shown in Fig. 6-13 to 100 psia, if the gas is ( $a$ ) air, (b) carbon dioxide, ( $c$ ) nitrogen, and (d) hydrogen. Atmospheric pressure is 13 psia.
Ans. (a) $0.349 \mathrm{Btu} /{ }^{\circ} \mathrm{R}$
(b) $0.485 \mathrm{Btu} /{ }^{\circ} \mathrm{R}$
(c) $0.352 \mathrm{Btu} /{ }^{\circ} \mathrm{R}$
(d) $0.342 \mathrm{Btu} /{ }^{\circ} \mathrm{R}$

Fig. 6-13
6.29 The entropy change in a certain expansion process is $5.2 \mathrm{~kJ} / \mathrm{K}$. The gas, initially at $80 \mathrm{kPa}, 27^{\circ} \mathrm{C}$, and 4 $\mathrm{m}^{3}$ achieves a final temperature of $127^{\circ} \mathrm{C}$. Calculate the final volume if the gas is (a) air, (b) carbon dioxide, ( $c$ ) nitrogen, and ( $d$ ) hydrogen.
Ans. (a) $254 \mathrm{~m}^{3}$
(b) $195 \mathrm{~m}^{3}$
(c) $255 \mathrm{~m}^{3}$
(d) $259 \mathrm{~m}^{3}$
6.30 Nine kJ of heat is added to the cylinder shown in Fig. 6-14. If the initial conditions are 200 kPa and $47^{\circ} \mathrm{C}$, compute the work done and the entropy change for (a) air (b) carbon dioxide, (c) nitrogen, and (d) hydrogen.
Ans.
(a) $35.4 \mathrm{~J}, 15.4 \mathrm{~J} / \mathrm{K}$;
(b) $42 \mathrm{~J}, 16.9 \mathrm{~J} / \mathrm{K}$;
(c) $34 \mathrm{~J}, 15.3 \mathrm{~J} / \mathrm{K}$;
(d) $2.48 \mathrm{~J}, 15.2 \mathrm{~J} / \mathrm{K}$.

Fig. 6-14
6.31 A piston is inserted into a cylinder, causing the pressure to change from 50 to 4000 kPa while the temperature remains constant at $27^{\circ} \mathrm{C}$. To accomplish this, heat transfer must occur. Determine the heat transfer and the entropy change, if the working substance is (a) air, (b) carbon dioxide, ( $c$ ) nitrogen, and (d) hydrogen.
Ans. (a) $-377 \mathrm{~kJ} / \mathrm{kg},-1.26 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}$;
(b) $-248 \mathrm{~kJ} / \mathrm{kg},-0.828 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}$;
(c) $-390 \mathrm{~kJ} / \mathrm{kg},-1.30 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}$;
(d) $-5420 \mathrm{~kJ} / \mathrm{kg},-18.1 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}$
6.32 The temperature of a gas changes from $60^{\circ} \mathrm{F}$ to $900^{\circ} \mathrm{F}$ while the pressure remains constant at 16 psia. Compute the heat transfer and the entropy change if the gas is ( $a$ ) air, ( $b$ ) carbon dioxide, ( $c$ ) nitrogen, and ( $d$ ) hydrogen.
Ans. (a) $202 \mathrm{Btu} / \mathrm{lbm}, 0.24 \mathrm{Btu} / \mathrm{lbm}^{\circ}{ }^{\circ} \mathrm{R}$;
(b) $170 \mathrm{Btu} / \mathrm{lbm}, 0.202 \mathrm{Btu} / \mathrm{lbm}^{\circ}{ }^{\circ} \mathrm{R}$;
(c) $208 \mathrm{Btu} / \mathrm{lbm}, 0.248 \mathrm{Btu} / \mathrm{lbm}-{ }^{\circ} \mathrm{R}$;
(d) $2870 \mathrm{Btu} / \mathrm{lbm}, 3.42 \mathrm{Btu} / \mathrm{lbm}-{ }^{\circ} \mathrm{R}$
6.33 A rigid, insulated $4-\mathrm{m}^{3}$ volume is divided in half by a membrane. One chamber is pressurized with air to 100 kPa and the other is completely evacuated. The membrane is ruptured and after a period of time equilibrium is restored. What is the entropy change? Ans. $0.473 \mathrm{~kJ} / \mathrm{K}$
6.34 Four hundred kJ of paddle-wheel work is transferred to air in a rigid, insulated $2-\mathrm{m}^{3}$ volume, initially at 100 kPa and $57^{\circ} \mathrm{C}$. Calculate the entropy change if the working substance is ( $a$ ) air, (b) carbon dioxide, (c) nitrogen, and (d) hydrogen.
Ans.
(a) $0.889 \mathrm{~kJ} / \mathrm{K}$
(b) $0.914 \mathrm{~kJ} / \mathrm{K}$
(c) $0.891 \mathrm{~kJ} / \mathrm{K}$
(d) $0.886 \mathrm{~kJ} / \mathrm{K}$
6.35 A torque of $40 \mathrm{~N} \cdot \mathrm{~m}$ is needed to rotate a shaft at $40 \mathrm{rad} / \mathrm{s}$. It is attached to a paddle wheel located in a rigid $2-\mathrm{m}^{3}$ volume. Initially the temperature is $47^{\circ} \mathrm{C}$ and the pressure is 200 kPa ; if the paddle wheel rotates for 10 min and 500 kJ of heat is transferred to the air in the volume, determine the entropy increase ( $a$ ) assuming constant specific heats and ( $b$ ) using the gas table.
Ans. (a) $2.81 \mathrm{~kJ} / \mathrm{K} \quad$ (b) $2.83 \mathrm{~kJ} / \mathrm{K}$
6.36 Two lb of air is contained in an insulated piston-cylinder arrangement. The air is compressed from 16 psia and $60^{\circ} \mathrm{F}$ by applying $2 \times 10^{5} \mathrm{ft}$-lbf of work. Compute the final pressure and temperature, (a) assuming constant specific heats and (b) using the gas table.
Ans. (a) $366 \mathrm{psia}, 812{ }^{\circ} \mathrm{F}$; (b) $362 \mathrm{psia}, 785^{\circ} \mathrm{F}$
6.37 A piston-cylinder arrangement is used to compress 0.2 kg of air isentropically from initial conditions of 120 kPa and $27^{\circ} \mathrm{C}$ to 2000 kPa . Calculate the work necessary, ( $a$ ) assuming constant specific heats and (b) using the gas table.

Ans. (a) -53.1 kJ
(b) -53.4 kJ
6.38 Four kg of air expands in an insulated cylinder from 500 kPa and $227^{\circ} \mathrm{C}$ to 20 kPa . What is the work output ( $a$ ) assuming constant specific heats and (b) using the gas table?
Ans. (a) 863 kJ (b) 864 kJ
6.39 Steam, at a quality of 85 percent, is expanded in a cylinder at a constant pressure of 800 kPa by adding $2000 \mathrm{~kJ} / \mathrm{kg}$ of heat. Compute the entropy increase and the final temperature.
Ans. $2.95 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}, 934^{\circ} \mathrm{C}$
6.40 Two lb of steam, initially at a quality of 40 percent and a pressure of 600 psia , is expanded in a cylinder at constant temperature until the pressure is halved. Determine the entropy change and the heat transfer. Ans. 1.158 Btu $/{ }^{\circ} \mathrm{R}$, 983 Btu
6.41 0.1 kg water is expanded in a cylinder at a constant pressure of 4 MPa from saturated liquid until the temperature is $600^{\circ} \mathrm{C}$. Calculate the work necessary and the entropy change.
Ans. $39 \mathrm{~kJ}, 0.457 \mathrm{~kJ} / \mathrm{K}$
6.42 Two kg of steam at $100^{\circ} \mathrm{C}$ is contained in a $3.4-\mathrm{m}^{3}$ cylinder. If the steam undergoes an isentropic expansion to 20 kPa , determine the work output. Ans. 442 kJ
6.43 Five kg of steam contained in a $2-\mathrm{m}^{3}$ cylinder at 40 kPa is compressed isentropically to 5000 kPa . What is the work needed? Ans. 185 kJ
6.44 Ten lb of water at 14.7 psia is heated at constant pressure from $40^{\circ} \mathrm{F}$ to saturated vapor. Compute the heat transfer necessary and the entropy change. Ans. 11,420 Btu, 17.4 Btu/ ${ }^{\circ} \mathrm{R}$
6.45 Five kg of ice at $-20^{\circ} \mathrm{C}$ is mixed with water initially at $20^{\circ} \mathrm{C}$. If there is no significant heat transfer from the container, determine the final temperature and the net entropy change if the initial mass of water is (a) 10 kg and (b) 40 kg . Ans. (a) $0^{\circ} \mathrm{C}, 0.135 \mathrm{~kJ} / \mathrm{K}$; (b) $10.6^{\circ} \mathrm{C}, 1.93 \mathrm{~kJ} / \mathrm{K}$
6.46 A Carnot engine operates with steam on the cycle shown in Fig. 6-15. What is the thermal efficiency? If the work output is $300 \mathrm{~kJ} / \mathrm{kg}$, what is the quality of state 1? Ans. $48.9 \%, 0.563$

Fig. 6-15
6.47 The steam in a Carnot engine is compressed adiabatically from 20 kPa to 800 kPa . The heat addition results in saturated vapor. If the quality at the end of the heat rejection is 15 percent, calculate the net work per cycle and the thermal efficiency. Ans. $433 \mathrm{~kJ} / \mathrm{kg}, 24.9 \%$
6.48 A Carnot engine which operates with steam has a pressure of 8 psia and a quality of 20 percent at the beginning of the adiabatic compression process. If the thermal efficiency is 40 percent and the adiabatic expansion process begins with a saturated vapor, determine the heat added. Ans. $769 \mathrm{Btu} / \mathrm{lbm}$

Fig. 6-16
6.49 A Carnot engine operates at 4000 cycles per minute with 0.02 kg of steam, as shown in Fig. 6-16. If the quality of state 4 is 15 percent, (a) What is the power output? (b) what is the quality of state 3 ? Ans. (a) $19.5 \mathrm{~kW} \quad$ (b) 0.678
6.50 For a Carnot engine operating under the conditions of Prob. 5.17, show that the inequality of Clausius is satisfied.
6.51 Using the information given in Prob. 5.22, verify that the inequality of Clausius is satisfied.
6.52 For the steam cycle of Prob, 6.46 show that the inequality of Clausius is satisfied.
6.53 One lb of air is contained in a $6 \mathrm{ft}^{3}$ volume at a pressure of 30 psia. Heat is transferred to the air from a high-temperature reservoir until the temperature is tripled in value while the pressure is held constant. Determine the entropy change of $(a)$ the air, ( $b$ ) the high-temperature reservoir which is at $1000^{\circ} \mathrm{F}$, and (c) the universe. Ans. (a) $0.264 \mathrm{Btu} /{ }^{\circ} \mathrm{R} \quad(b)-0.156 \mathrm{Btu} /{ }^{\circ} \mathrm{R} \quad$ (c) $0.108 \mathrm{Btu} /{ }^{\circ} \mathrm{R}$
6.54 Two kg of air is stored in a rigid volume of $2 \mathrm{~m}^{3}$ with the temperature initially at $300^{\circ} \mathrm{C}$. Heat is transferred from the air until the pressure reaches 120 kPa . Calculate the entropy change of ( $a$ ) the air and ( $b$ ) the universe if the surroundings are at $27^{\circ} \mathrm{C}$. Ans. ( $a$ ) $-0.452 \mathrm{~kJ} / \mathrm{K} \quad$ (b) $0.289 \mathrm{~kJ} / \mathrm{K}$
6.55 Three kg of saturated steam at $200^{\circ} \mathrm{C}$ is cooled at constant pressure until the steam is completcly condensed. What is the net entropy change of the universe if the surroundings are at $20^{\circ} \mathrm{C}$ ?
Ans. $7.56 \mathrm{~kJ} / \mathrm{K}$
6.56 Steam at a quality of 80 percent is contained in a rigid vessel of a volume $400 \mathrm{~cm}^{3}$. The initial pressure is 200 kPa . Energy is added to the steam by heat transfer from a source maintained at $700^{\circ} \mathrm{C}$ until the pressure is 600 kPa . What is the entropy change of the universe? Ans. $0.611 \mathrm{~J} / \mathrm{K}$

The feedwater heater shown in Fig. 6-17 is used to preheat water in a power plant cycle. Saturated water leaves the preheater. Calculate the entropy production if all pressures are 60 psia.
Ans. $0.423 \mathrm{Btu} / \mathrm{sec}^{-}{ }^{\circ} \mathrm{R}$

Fig. 6-17
6.58 Air flows from a tank maintained at 140 kPa and $27^{\circ} \mathrm{C}$ from a 25 -mm-diameter hole. Estimate the mass flux from the hole assuming an isentropic process. Ans. $0.147 \mathrm{~kg} / \mathrm{s}$
6.59 Air flows from a nozzle. The inlet conditions are 130 kPa and $150^{\circ} \mathrm{C}$ with a velocity of $40 \mathrm{~m} / \mathrm{s}$. Assuming an isentropic process, calculate the exit velocity if the exit pressure is 8.5 kPa .
Ans. $309 \mathrm{~m} / \mathrm{s}$
6.60 The gases flowing through a turbine have essentially the same properties as air. The inlet gases are at 800 kPa and $900^{\circ} \mathrm{C}$ and the exit pressure is atmospheric at 90 kPa . Compute the work output assuming an isentropic process if $(a)$ the specific heats are constant and $(b)$ the gas tables are used.
Ans. (a) $545 \mathrm{~kJ} / \mathrm{kg}$
(b) $564 \mathrm{~kJ} / \mathrm{kg}$
6.61 Saturated steam at $300^{\circ} \mathrm{F}$ is compressed to a pressure of 800 psia . The device used for the compression process is well-insulated. Assuming the process to be reversible, calculate the power needed if $6 \mathrm{lbm} / \mathrm{sec}$ of steam is flowing. Ans. 2280 hp
6.62 Every second 3.5 kg of superheated steam flows through the turbine shown in Fig. 6-18. Assuming an isentropic process, calculate the maximum power rating of this turbine. Ans. 3.88 MW

Fig. 6-18
6.63 Two hundred kW is to be produced by a steam turbine. The outlet steam is to be saturated at 80 kPa and the steam entering will be at $600^{\circ} \mathrm{C}$. For an isentropic process determine the mass flux of steam. Ans. $0.198 \mathrm{~kg} / \mathrm{s}$
6.64 A turbine produces 3 MW by extracting energy from 4 kg of steam which flows through the turbine every second. The steam enters at $250^{\circ} \mathrm{C}$ and 1500 kPa and exits as saturated steam at 2 kPa . Calculate the turbine efficiency. Ans. 39.9 percent
6.65 A steam turbine is $85 \%$ efficient. Steam enters at $900^{\circ} \mathrm{F}$ and 300 psia and leaves at 4 psia. (a) How much energy can be produced? ( $b$ ) If 3000 hp must be produced, what must the mass flux be? Ans. (a) $348 \mathrm{Btu} / \mathrm{lbm}$ (b) $6.096 \mathrm{lbm} / \mathrm{sec}$
6.66 Determine the efficiency of an ideal piston engine operating on the Otto cycle shown in Fig. 6-19, if $T_{1}=60^{\circ} \mathrm{C}$ and $T_{3}=1600^{\circ} \mathrm{C}$. Ans. $47.5 \%$

Fig. 6-19
6.67. Calculate the efficiency of the Rankine cycle shown in Fig. 6-20, if $P_{4}=20 \mathrm{kPa}, P_{1}=P_{2}=4 \mathrm{MPa}$, and $T_{2}=600^{\circ} \mathrm{C}$. Ans. $36.3 \%$

Fig. 6-20

Fig. 6-21
6.68 Determine the efficiency of the Rankine cycle shown schematically in Fig. 6-21. Ans. $28 \%$
6.69 For the diesel cycle shown in Fig. 6-22 the compression ratio $v_{1} / v_{2}$ is 15 and the added heat is 1800 kJ per kilogram of air. If $T_{1}=20^{\circ} \mathrm{C}$, calculate the thermal efficiency. Ans. $50.3 \%$

## Reversible Work, Irreversibility, and Availability

### 7.1 BASIC CONCEPTS

Reversible work for a process is defined as the work associated by taking a reversible-process path from state $A$ to state $B$. As stated previously, a reversible process is a process that, having taken place, can be reversed and, having been reversed, leaves no change in either the system or the surroundings. A reversible process must be a quasiequilibrium process and is subject to the following restrictions:

- No friction exists.
- Heat transfer is due only to an infinitesimal temperature difference.
- Unrestrained expansion does not occur.
- There is no mixing.
- There is no turbulence.
- There is no combustion or chemical reaction.

It can be easily shown that the reversible work or the work output from a reversible process going from state $A$ to state $B$ is the maximum work that can be achieved for the state change from $A$ to $B$.

It is of interest to compare the actual work for a process to the reversible work for a process. This comparison is done in two ways. First, a second-law efficiency for a process or a device can be defined as

$$
\begin{array}{ll}
\eta_{\mathrm{II}}=\frac{W_{a}}{W_{\mathrm{rev}}} & \text { (turbine or engine) } \\
\eta_{\mathrm{II}}=\frac{W_{\mathrm{rev}}}{W_{a}} & \text { (pump or compressor) } \tag{7.2}
\end{array}
$$

where $W_{a}$ is the actual work and $W_{\text {rev }}$ is the reversible work for the fictitious reversible process. Second-law efficiency is different from the adiabatic efficiency of a device introduced in Chap. 6. It is generally higher and provides a better comparison to the ideal.

Second, irreversibility is defined as the difference between the reversible work and the actual work for a process, or

$$
\begin{equation*}
I=W_{\mathrm{rev}}-W_{a} \tag{7.3}
\end{equation*}
$$

On a per-unit-mass basis,

$$
\begin{equation*}
i=w_{\text {rev }}-w_{a} \tag{7.4}
\end{equation*}
$$

Both irreversibility and second-law efficiency will allow us to consider how close an actual process or device is to the ideal. Once the irreversibilities for devices in an actual engineering system, such as a steam power cycle, have been calculated, attempts to improve the performance of the system can be guided by attacking the largest irreversibilities. Similarly, since the maximum possible work will be reversible work, irreversibility can be used to evaluate the feasibility of a device. If the irreversibility of a proposed device is less than zero, the device is not feasible. [Section 7.2 develops the concepts of reversible work and irreversibility.]

Availability is defined as the maximum amount of reversible work that can be extracted from a system:

$$
\begin{equation*}
\Psi=\left(W_{\mathrm{rev}}\right)_{\max } \tag{7.5}
\end{equation*}
$$

or, on a per-unit-mass basis,

$$
\begin{equation*}
\psi=\left(w_{\mathrm{rev}}\right)_{\max } \tag{7.6}
\end{equation*}
$$

The maximization in (7.5) and (7.6) is over the reversible path joining the prescribed initial state to a final dead state in which system and surroundings are in equilibrium. [Section 7.3 develops the notion of availability.]

### 7.2 REVERSIBLE WORK AND IRREVERSIBILITY

To obtain expressions for reversible work and irreversibility, we will consider a transient process with specified work output and heat input and a uniform through-flow. We begin by allowing this to be an irreversible process. Consider the control volume shown in Fig. 7-1. The first law for this control volume can be written as

$$
\begin{equation*}
\dot{Q}-\dot{W}_{s}=\left(h_{2}+\frac{V_{2}^{2}}{2}+g z_{2}\right) \dot{m}_{2}-\left(h_{1}+\frac{V_{1}^{2}}{2}+g z_{1}\right) \dot{m}_{1}+\dot{E}_{\mathrm{c} . \mathrm{v}} \tag{7.7}
\end{equation*}
$$

Using (6.47), with $T_{\text {surr }}=T_{0}$ and $\dot{Q}_{\text {surr }}=-\dot{Q}$, we may write the second law as

$$
\begin{equation*}
\dot{S}_{\text {c.v. }}+s_{2} \dot{m}_{2}-s_{1} \dot{m}_{1}-\frac{\dot{Q}}{T_{0}}-\dot{S}_{\mathrm{prod}}=0 \tag{7.8}
\end{equation*}
$$

Eliminate $\dot{Q}$ between (7.7) and (7.8) to obtain

$$
\begin{equation*}
\dot{W}_{s}=-\dot{E}_{\mathrm{c} . \mathrm{v} .}+T_{0} \dot{S}_{\mathrm{c} . \mathrm{v} .}-\left(h_{2}+\frac{V_{2}^{2}}{2}+g z_{2}-T_{0} s_{2}\right) \dot{m}_{2}+\left(h_{1}+\frac{V_{1}^{2}}{2}+g z_{1}-T_{0} s_{1}\right) \dot{m}_{1}-T_{0} \dot{S}_{\mathrm{prod}} \tag{7.9}
\end{equation*}
$$

Since $\dot{S}_{\text {prod }}$ is due to the irreversibilities, the reversible work rate is given by (7.9) when $\dot{S}_{\text {prod }}$ is set equal to zero:

$$
\begin{equation*}
\dot{W}_{\mathrm{rev}}=-\dot{E}_{\mathrm{c} . \mathrm{v} .}+T_{0} \dot{S}_{\mathrm{c} . \mathrm{v} .}-\left(h_{2}+\frac{V_{2}^{2}}{2}+g z_{2}-T_{0} s_{2}\right) \dot{m}_{2}+\left(h_{1}+\frac{V_{1}^{2}}{2}+g z_{1}-T_{0} s_{1}\right) \dot{m}_{1} \tag{7.10}
\end{equation*}
$$

Then a time integration yields

$$
\begin{align*}
W_{\mathrm{rev}}= & {\left[m_{i}\left(u_{i}+\frac{V_{i}^{2}}{2}+g z_{i}-T_{0} s_{i}\right)-m_{f}\left(u_{f}+\frac{V_{f}^{2}}{2}+g z_{f}-T_{0} s_{f}\right)\right]_{\mathrm{c} . \mathrm{v}} } \\
& +m_{1}\left(h_{1}+\frac{V_{1}^{2}}{2}+g z_{1}-T_{0} s_{1}\right)-m_{2}\left(h_{2}+\frac{V_{2}^{2}}{2}+g z_{2}-T_{0} s_{2}\right) \tag{7.11}
\end{align*}
$$

Fig. 7-1
where the subscripts $i$ and $f$ pertain to the initial and final states of the control volume.
The actual work, if not given, can be determined from a first-law analysis [integrate (7.7)]:

$$
\begin{align*}
W_{a}= & {\left[m_{i}\left(u_{i}+\frac{V_{i}^{2}}{2}+g z_{i}\right)-m_{f}\left(u_{f}+\frac{V_{f}^{2}}{2}+g z_{f}\right)\right]_{c . \mathrm{v} .} } \\
& +m_{1}\left(h_{1}+\frac{V_{1}^{2}}{2}+g z_{1}\right)-m_{2}\left(h_{2}+\frac{V_{2}^{2}}{2}+g z_{2}\right)+Q \tag{7.12}
\end{align*}
$$

From (7.3), (7.11), and (7.12),

$$
\begin{equation*}
I=\left(m_{f} T_{0} s_{f}-m_{i} T_{0} s_{i}\right)_{c . v .}+T_{0} m_{2} s_{2}-T_{0} m_{1} s_{1}-Q \tag{7.13}
\end{equation*}
$$

For a steady flow with negligible changes in kinetic and potential energies, we have

$$
\begin{align*}
\dot{W}_{\mathrm{rev}} & =\dot{m}\left[h_{1}-h_{2}+T_{0}\left(s_{2}-s_{1}\right)\right]  \tag{7.14}\\
\dot{I} & =\dot{m} T_{0}\left(s_{2}-s_{1}\right)+Q \tag{7.15}
\end{align*}
$$

It is important to realize that the basic results of this Section-(7.11), (7.12), and (7.13)-also hold for a system, which is nothing other than a control volume for which $m_{1}=m_{2}=0$ (and thus $m_{i}=m_{f}=m$ ). Because time plays no part in the thermodynamics of a system, we generally replace the indices $i$ and $f$ by 1 and 2 .

EXAMPLE 7.1 A steam turbine is supplied with steam at 12 MPa and $700^{\circ} \mathrm{C}$, and exhausts at 0.6 MPa .
(a) Determine the reversible work and irreversibility if the turbine is an ideal turbine.
(b) If the turbine has an adiabatic efficiency of 0.88 , what is the reversible work, irreversibility, and second-law efficiency?
(a) The properties for the inlet state are obtained from the steam tables. Since an ideal turbine is isentropic, $s_{2}=s_{1}=7.0757 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}$. From the steam tables we note that the exit state must be superheated vapor. We interpolate to obtain $T_{2}=225.2^{\circ} \mathrm{C}$ and $h_{2}=2904.1 \mathrm{~kJ} / \mathrm{kg}$. Then, from the first law for a control volume,

$$
w_{a}=h_{1}-h_{2}=3858.4-2904.1=954.3 \mathrm{~kJ} / \mathrm{kg}
$$

From (7.11), neglecting kinetic and potential energies,

$$
w_{\mathrm{rev}}=h_{1}-h_{2}-T_{0}\left(s_{1}-\hat{s}_{2}^{0}\right)=3858.4-2904.1=954.3 \mathrm{~kJ} / \mathrm{kg}
$$

The irreversibility for an ideal turbine is $i=w_{\text {rev }}-w_{a}=954.3-954.3=0 \mathrm{~kJ} / \mathrm{kg}$.
(b) Now let the adiabatic turbine have $\eta_{T}=0.88$. The isentropic or ideal work was calculated in ( $a$ ), so that the actual work is $w_{a}=\eta_{T} w_{\text {ideal }}=(0.88)(954.3)=839.8 \mathrm{~kJ} / \mathrm{kg}$. For this adiabatic process,

$$
h_{2}=h_{1}-w_{a}=3858.4-839.8=3018.6 \mathrm{~kJ} / \mathrm{kg}
$$

From the steam tables we find that the exit state with $P_{2}=0.6 \mathrm{MPa}$ is superheated vapor, with $T_{2}=279.4^{\circ} \mathrm{C}$ and $s_{2}=7.2946 \mathrm{~kJ} / \mathrm{kg}$. Then, assuming $T_{0}=298 \mathrm{~K}$,

$$
w_{\mathrm{rev}}=h_{1}-h_{2}-T_{0}\left(s_{1}-s_{2}\right)=3858.4-3018.6-(298)(7.0757-7.2946)=905 \mathrm{~kJ} / \mathrm{kg}
$$

The second-law efficiency is $\eta_{\mathrm{II}}=w_{a} / w_{\mathrm{rev}}=0.928$, which is greater than the adiabatic efficiency. The irreversibility is

$$
i=w_{\mathrm{rev}}-w_{a}=905.0-839.8=65.2 \mathrm{~kJ} / \mathrm{kg}
$$

EXAMPLE 7.2 Measurements are made on an adiabatic compressor with supply air at 15 psia and $80^{\circ} \mathrm{F}$. The exhaust air is measured at 75 psia and $440^{\circ} \mathrm{F}$. Can these measurements be correct?

For steady flow in the control volume, with $Q=0$, (7.15) becomes

$$
i=T_{0}\left(s_{2}-s_{1}\right)
$$

The entropy change is found, using values from the air tables, to be

$$
s_{2}-s_{1}=\phi_{2}-\phi_{1}-R \ln \frac{P_{2}}{P_{1}}=0.72438-0.60078-\frac{53.3}{778} \ln \frac{75}{15}=0.01334 \mathrm{Btu} / 1 \mathrm{bm}-{ }^{\circ} \mathrm{R}
$$

The irreversibility is then $i=(537)(0.01334)=7.16 \mathrm{Btu} / \mathrm{lbm}$. As this is positive, the measurements can be correct. We assumed $T_{11}$ to be $537^{\circ} \mathrm{R}$.

### 7.3 AVAILABILITY AND EXERGY

According to the discussion in Section 7.1, $\Psi$ is given by (7.11) when the final state ( $f$ ) is identified with the state of the surroundings (0):

$$
\begin{align*}
\Psi= & {\left[m_{i}\left(u_{i}+\frac{V_{i}^{2}}{2}+g z_{i}-T_{10} s_{i}\right)-m_{f}\left(u_{0}+\frac{V_{0}^{2}}{2}+g z_{0}-T_{0} s_{01}\right)\right]_{c . v} } \\
& +m_{1}\left(h_{1}+\frac{V_{1}^{2}}{2}+g z_{1}-T_{0} s_{1}\right)-m_{2}\left(h_{0}+\frac{V_{0}^{2}}{2}+g z_{0}-T_{0} s_{0}\right) \tag{7.16}
\end{align*}
$$

For a steady-flow process (7.16) becomes

$$
\begin{equation*}
\psi=h_{1}-h_{0}+\frac{V_{1}^{2}-V_{0}^{2}}{2}+g\left(z_{1}-z_{0}\right)-T_{0}\left(s_{1}-s_{0}\right) \tag{7.17}
\end{equation*}
$$

In carrying out a second-law analysis, it is often useful to define a new thermodynamic function (analogous to enthalpy), called exergy:

$$
\begin{equation*}
E \equiv h+\frac{V^{2}}{2}+g z-T_{0} s \tag{7.18}
\end{equation*}
$$

Comparing (7.18) to (7.17), we see that $E_{1}-E_{0}=\psi$. We interpret this equation as a work-energy relation: the extractable specific work $\psi$ exactly equals the decrease in useful energy $E$ between the entrance and dead states of the system. More generally, when the system passes from one state to another, specific work in the amount $-\Delta E$ is made available.

Certain engineering devices have useful outputs or inputs that are not in the form of work; a nozzle is an example. Consequently, we generalize the notion of second-law efficiency to that of second-law effectiveness:

$$
\begin{equation*}
\varepsilon_{I I}=\frac{(\text { availability produced })+(\text { work produced })+(\text { adjusted heat produced })}{(\text { availability supplied })+(\text { work used })+(\text { adjusted heat used })} \tag{7.19}
\end{equation*}
$$

Heat to or from a device is "adjusted" in (7.19) on the basis of the temperature $T_{\text {h.r }}$ of the heat reservoir which is interacting with the device:

$$
\begin{equation*}
\text { adjusted heat }=\left(1-\frac{T_{0}}{T_{\mathrm{h} \cdot \mathbf{r} .}}\right) Q \tag{7.20}
\end{equation*}
$$

EXAMPLE 7.3 Which system can do more useful work, 0.1 lbm of $\mathrm{CO}_{2}$ at $440^{\circ} \mathrm{F}$ and 30 psia or 0.1 lbm of $\mathrm{N}_{2}$ at $440^{\circ} \mathrm{F}$ and 30 psia ?

Assuming a dead state at $77^{\circ} \mathrm{F}\left(537^{\circ} \mathrm{R}\right)$ and 14.7 psia, we use Table F-4E to calculate the availability of the $\mathrm{CO}_{2}$ :

$$
\begin{aligned}
\Psi & =m\left[h-h_{10}-T_{00}\left(\phi-\phi_{0}-R \ln \frac{P}{P_{11}}\right)\right] \\
& =\left(\frac{0.1}{44}\right)\left[7597.6-4030.2-537\left(56.070-51.032-1.986 \ln \frac{30}{14.7}\right)\right]=3.77 \mathrm{Btu}
\end{aligned}
$$

Similarly, for the $\mathrm{N}_{2}$,

$$
\begin{aligned}
\Psi & =m\left[h-h_{0}-T_{0}\left(\phi-\phi_{0}-R \ln \frac{P}{P_{0}}\right)\right] \\
& =\left(\frac{0.1}{28}\right)\left[6268.1-3279.5-(537)\left(49.352-45.743-1.986 \ln \frac{30}{14.7}\right)\right]=6.47 \mathrm{Btu}
\end{aligned}
$$

Hence, the $\mathrm{N}_{2}$ can do more uscful work.
EXAMPLE 7.4 How much useful work is wasted in the condenser of a power plant which takes in steam of quality 0.85 and 5 kPa and delivers saturated liquid at the same pressure?

The maximum specific work available at the condenser inlet is $\psi_{1}=h_{1}-h_{0}-T_{0}\left(s_{1}-s_{0}\right)$; at the outlet it is $\psi_{2}=h_{2}-h_{0}-T_{0}\left(s_{2}-s_{0}\right)$. The uscful work wasted is $\psi_{1}-\psi_{2}=h_{1}-h_{2}-T_{4}\left(s_{1}-s_{2}\right)$.

From the steam tables, assuming $T_{0}=298 \mathrm{~K}$ and using the quality to find $h_{1}$ and $s_{1}$, we find

$$
\psi_{1}-\psi_{2}=h_{1}-h_{2}-T_{0}\left(s_{1}-s_{2}\right)=2197.2-136.5-(298)(7.2136-0.4717)=51.6 \mathrm{~kJ} / \mathrm{kg}
$$

EXAMPLE 7.5 Calculate the exergy of steam at $500^{\circ} \mathrm{F}$ and 300 psia. The surroundings are at $76^{\circ} \mathrm{F}$.
From the superheated steam tables, $E=h-T_{0} s=1257.5-(536)(1.5701)=415.9 \mathrm{Btu} / \mathrm{lbm}$.
EXAMPLE 7.6 Determine the second-law effectiveness for an ideal isentropic nozzle. Air enters the nozzle at 1000 K and 0.5 MPa with negligible kinetic energy and exits to a pressure of 0.1 MPa .

Since the process is isentropic, we use the air tables to find

$$
\phi_{2}=\phi_{1}-R \ln \frac{P_{1}}{P_{2}}=2.968-0.286 \ln 5=2.506 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K}
$$

Thus

$$
T_{2}=657.5 \mathrm{~K} \quad h_{2}=667.8 \mathrm{~kJ} / \mathrm{kg} \quad h_{1}=1046.1 \mathrm{~kJ} / \mathrm{kg} \quad h_{0}=298.2 \mathrm{~kJ} / \mathrm{kg}
$$

By the first law,

$$
h_{1}=h_{2}+\frac{V_{2}^{2}}{2} \quad \text { or } \quad V_{2}=\sqrt{2}\left(h_{1}-h_{2}\right)^{0.5}=\sqrt{2}\left[(1046.1-667.8)\left(10^{3}\right)\right]^{1.5}=1230 \mathrm{~m} / \mathrm{s}
$$

To evaluate the second-law effectiveness we need the availability produced:

$$
\begin{aligned}
\psi_{2} & =h_{2}-h_{0}+\frac{V_{2}^{2}}{2}-T_{0}\left(\phi_{2}-\phi_{0}-R \ln \frac{P_{2}}{P_{0}}\right) \\
& =667.8-298.2+\frac{1230^{2}}{(2)(1000)}-(298)[2.506-1.695-(0.287)(0)]=884 \mathrm{~kJ} / \mathrm{kg}
\end{aligned}
$$

where $P_{2}=P_{0}=0.1 \mathrm{MPA}$. The availability supplied is

$$
\psi_{1}=h_{1}-h_{0}-T_{0}\left(\phi_{1}-\phi_{0}-R \ln \frac{P_{1}}{P_{0}}\right)=1046.1-298.2-(298)(2.968-1.695-0.287 \ln 5)=506 \mathrm{~kJ} / \mathrm{kg}
$$

Since there is no work or heat transfer, (7.19) gives

$$
\varepsilon_{11}=\frac{\psi_{2}}{\psi_{1}}=\frac{884}{506}=1.75
$$

Note that second-law effectiveness is not bounded by 1 (much like the COP for a refrigeration cycle).

### 7.4 SECOND-LAW ANALYSIS OF A CYCLE

You may choose to study this section after Chapters 8 and 9 .
In applying second-law concepts to a cycle two approaches may be employed. The first is simply to evaluate the irreversibilities associated with each device or process in the cycle; this will identify sources of large irreversibilities which will adversely affect the efficiency of the cycle. The second is to evaluate $\varepsilon_{\Pi}$ for the whole cycle.

Fig. 7-2

EXAMPLE 7.7 Consider the simple Rankine cycle with steam extraction shown in Fig. 7-2. Calculate the second-law effectiveness for the cycle if the boiler produces steam at 1 MPa and $300^{\circ} \mathrm{C}$ and the turbine exhausts to the condenser at 0.01 MPa . The steam extraction occurs at 0.1 MPa , where 10 percent of the steam is removed. Make-up water is supplied as saturated liquid at the condenser pressure, and saturated liquid leaves the condenser.

We begin by traversing the cycle starting at state 1 :

$$
1 \rightarrow 2 \quad \text { Ideal turbine: } \quad s_{2}=s_{1}=7.1237 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K}
$$

Comparing to $s_{f}$ and $s_{g}$ at 0.1 MPa , we have a two-phase mixture at state 2 with

$$
x_{2}=\frac{s_{2}-s_{f}}{s_{f g}}=0.96
$$

so that $h_{2}=h_{f}+0.96 h_{f g}=2587.3 \mathrm{~kJ} / \mathrm{kg}$.

$$
2 \rightarrow 3 \quad \text { Ideal turbine: } \quad s_{3}=s_{2}=7.1237 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K}
$$

Comparing to $s_{f}$ and $s_{g}$ at 0.01 MPa , we have a two-phase mixture at state 3 with

$$
x_{3}=\frac{s_{3}-s_{f}}{s_{f g}}=0.86
$$

so that $h_{3}=h_{f}+0.86 h_{f g}=2256.9 \mathrm{~kJ} / \mathrm{kg}$. The second-law effectiveness is given by

$$
\varepsilon_{\Pi}=\frac{\Psi_{2}+W_{\text {turb }}}{\Psi_{4}+W_{\text {pump }}+\left[1-\left(T_{0} / T_{1}\right)\right] Q_{\text {boil }}}
$$

The dead state for water is liquid at 100 kPa and $25^{\circ} \mathrm{C}$ :

$$
h_{0}=h_{f}=104.9 \mathrm{~kJ} / \mathrm{kg} \quad s_{0}=s_{f}=0.3672 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K}
$$

Now the various quantities of interest may be calculated, assuming $m_{1}=1 \mathrm{~kg}$ :

$$
\begin{aligned}
\Psi_{2} & =m_{2}\left[h_{2}-h_{0}-T_{0}\left(s_{2}-s_{0}\right)\right]=(0.1)[2587.3-104.9-(298)(7.1237-0.3672)]=46.89 \mathrm{~kJ} \\
W_{\text {turb }} & =m_{1}\left(h_{1}-h_{2}\right)+m_{3}\left(h_{2}-h_{3}\right)=(1.0)(3051.2-2587.3)+(0.9)(2587.3-2256.9)=761.3 \mathrm{~kJ} \\
\Psi_{4} & =m_{4}\left[h_{4}-h_{0}-T_{0}\left(s_{4}-s_{0}\right)\right]=(0.1)[191.8-104.9-(298)(0.6491-0.3671)=0.28 \mathrm{~kJ} \\
W_{\text {pump }} & =m_{1} \frac{\Delta P}{\rho}=(1.0)\left(\frac{1000-10}{1000}\right)=0.99 \mathrm{~kJ} \quad Q_{\text {boil }}=m_{1}\left(h_{1}-h_{6}\right)=(1.0)(3051.2-192.8)=2858 \mathrm{~kJ}
\end{aligned}
$$

whence

$$
\varepsilon_{\Pi}=\frac{46.89+761.3}{0.28+0.99+(1-298 / 573)(2858)}=0.59
$$

EXAMPLE 7.8 Perform an irreversibility calculation for each device in the ideal regenerative gas turbine cycle shown in Fig. 7-3.

Fig. 7-3
The temperatures and pressures shown in Table 7-1 are given; $h$ and $\phi$ are found in the air tables. For each device we will calculate the irreversibility by

$$
i=T_{0}\left(\phi_{1}-\phi_{2}-R \ln \frac{P_{1}}{P_{2}}\right)-q
$$

except for the burner, where we assume the heat transfer to occur at $T_{4}$. The irreversibilities are:
Compressor: 0
Regenerator: 0
Burner: $206.3 \mathrm{~kJ} / \mathrm{kg}$
Turbine: 0

Table 7-1

| State | $T(\mathrm{~K})$ | $P(\mathrm{MPa})$ | $h(\mathrm{~kJ} / \mathrm{kg})$ | $\phi(\mathrm{kJ} / \mathrm{kg} \cdot \mathrm{K})$ |
| :---: | :---: | :---: | :---: | :---: |
| 1 | 294 | 0.1 | 294.2 | 1.682 |
| 2 | 439 | 0.41 | 440.7 | 2.086 |
| 3 | 759 | 0.41 | 777.5 | 2.661 |
| 4 | 1089 | 0.41 | 1148.3 | 2.764 |
| 5 | 759 | 0.1 | 777.5 | 2.661 |
| 6 | 439 | 0.1 | 440.7 | 2.086 |

The only irreversibility is associated with the burner. This suggests that large savings are possible by improving the performance of the burner. However, in attempting such improvement we must bear in mind that much of the irreversibility in the burner arises out of the combustion process, which is essential for the operation of the turbine.

## Solved Problems

7.1 The intake stroke for the cylinder of an internal combustion engine may be considered as a
 transient polytropic process with exponent -0.04 . The initial pressure, temperature, and volume are $13.5 \mathrm{psia}, 560^{\circ} \mathrm{R}$, and $0.0035 \mathrm{ft}^{3}$. Air is supplied at 14.7 psia and $520^{\circ} \mathrm{R}$, and the final volume and temperature are $0.025 \mathrm{ft}^{3}$ and $520^{\circ} \mathrm{R}$. Determine the reversible work and the irreversibility associated with the intake process.

Table 7-2

| Inlet State | Initial State <br> of C.V. | Final State <br> of C.V. |
| :--- | :--- | :--- |
| $T_{1}=520^{\circ} \mathrm{R}$ | $T_{i}=560^{\circ} \mathrm{R}$ | $T_{f}=520^{\circ} \mathrm{R}$ |
| $P_{1}=14.7 \mathrm{psia}$ | $P_{i}=13.5 \mathrm{psia}$ | $u_{j}=88.62 \mathrm{Btu} / \mathrm{lbm}$ |
| $h_{1}=124.27 \mathrm{Btu} / \mathrm{lbm}$ | $u_{i}=95.47 \mathrm{Btu} / \mathrm{bmm}$ | $\phi_{f}=0.5917 \mathrm{Btu} / \mathrm{lbm}-{ }^{\circ} \mathrm{R}$ |
| $\phi_{1}=0.5917 \mathrm{Btu} / \mathrm{lbm}-{ }^{\circ} \mathrm{R}$ | $\phi_{i}=0.6095 \mathrm{Btu} / \mathrm{lbm}-{ }^{\circ} \mathrm{R}$ | $V_{f}=0.025 \mathrm{ft}^{3}$ |
|  | $V_{i}=0.0035 \mathrm{ft}^{3}$ |  |

At the various states either we are given, or the air tables provide, the values shown in Table 7-2. In the initial state,

$$
m_{i}=\frac{P_{i} V_{i}}{R T_{i}}=\frac{(13.5)(144)(0.0035)}{(53.3)(560)}=2.28 \times 10^{-4} \mathrm{lbm}
$$

The final state is produced by a polytropic process, so that

$$
\begin{aligned}
& P_{f}=P_{i}\left(\frac{V_{i}}{V_{f}}\right)^{n}=(13.5)\left(\frac{0.0035}{0.025}\right)^{-0.04}=14.6 \mathrm{psia} \\
& m_{f}=\frac{P_{f} V_{f}}{R T_{f}}=\frac{(14.6)(144)(0.025)}{(53.3)(520)}=1.90 \times 10^{-3} \mathrm{lbm}
\end{aligned}
$$

From conservation of mass, $m_{1}=m_{f}-m_{i}=\left(1.90 \times 10^{3}\right)-\left(2.28 \times 10^{-4}\right)=1.67 \times 10^{-3} \mathrm{lbm}$. Only boundary work is actually performed; for the polytropic process we have

$$
W_{a}=\frac{P_{f} V_{f}-P_{i} V_{i}}{1-n}=\frac{[(14.6)(0.025)-(13.5)(0.0035)](144)}{(1+0.04)(778)}=0.057 \mathrm{Btu}
$$

The reversible work is given by (7.11) (neglect $K E$ and $P E$, as usual):

$$
W_{\mathrm{rev}}=m_{i}\left(u_{i}-T_{0} s_{i}\right)-m_{f}\left(u_{f}-T_{0} s_{f}\right)+m_{1}\left(h_{1}-T_{0} s_{1}\right)
$$

The needed values of $s_{i}$ and $s_{f}$ are obtained from the ideal-gas relation

$$
s=\phi-R \ln \frac{P}{P_{0}}
$$

where $P_{0}$ is some reference pressure. Normally, we do not have to worry about $P_{0}$, since when we consider an entropy change, $P_{0}$ cancels. It can be shown that even for this problem it will cancel, so that

$$
\begin{aligned}
W_{\mathrm{rev}}= & m_{i}\left(u_{i}-T_{0} \phi_{i}+T_{0} R \ln P_{i}\right)-m_{f}\left(u_{f}-T_{0} \phi_{f}+T_{0} R \ln P_{f}\right) \\
& +m_{1}\left(h_{1}-T_{0} \phi_{1}+T_{0} R \ln P_{1}\right)=0.058 \mathrm{Btu}
\end{aligned}
$$

and, finally, $I=W_{\text {rev }}-W_{a}=0.058-0.057=0.001 \mathrm{Btu}$.
7.2 A supply pump for a power plant takes in saturated water at 0.01 MPa and boosts its pressure to 10 MPa . The pump has an adiabatic efficiency of 0.90 . Calculate the irreversibility and second-law efficiency.

At the inlet and exit states either we are given, or the steam tables provide, the values given in Table 7-3.

Table 7-3

| Inlet state 1: saturated liquid phase | Exit state 2: compressed liquid phase |
| :---: | :--- |
| $T=45.8^{\circ} \mathrm{C}$ | $P=10 \mathrm{MPa}$ |
| $P=0.01 \mathrm{MPa}$ |  |
| $h=191.8 \mathrm{~kJ} / \mathrm{kg}$ |  |
| $s=0.6491 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}$ |  |

The actual work is

$$
w_{a}=\frac{w_{\text {ideal }}}{\eta}=-\frac{\Delta P}{\eta \rho}=-\frac{10000-10}{(0.9)(1000)}=-11.1 \mathrm{~kJ} / \mathrm{kg}
$$

Then, by the first law, $h_{2}=-w_{a}+h_{1}=-(-11.1)+191.8=202.9 \mathrm{~kJ} / \mathrm{kg}$. Using this enthalpy, we can interpolate for the entropy from the compressed liquid table and find $s_{2}=0.651 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}$. As in Example 7.2, the irreversibility is given by

$$
i=T_{0}\left(s_{2}-s_{1}\right)=(298)(0.651-0.6491)=0.57 \mathrm{~kJ} / \mathrm{kg}
$$

whence

$$
w_{\mathrm{rev}}=i+w_{a}=0.57+(-11.1)=-10.5 \mathrm{~kJ} / \mathrm{kg} \quad \eta_{\Pi}=\frac{w_{\mathrm{rev}}}{w_{a}}=\frac{-10.5}{-11.1}=0.95
$$

7.3 A power plant utilizes groundwater in a secondary coolant loop. Water enters the loop at $40^{\circ} \mathrm{F}$ and 16 psia and exits at $80^{\circ} \mathrm{F}$ and 15 psia . If the heat transfer in the loop occurs at $100^{\circ} \mathrm{F}$, what is the irreversibility?

Data are presented in Table 7-4. The heat transfer is $q=h_{2}-h_{1}=48.1-8.02=40.1 \mathrm{Btu} / \mathrm{lbm}$. The irreversibility is given by

$$
i=T_{0}\left(s_{2}-s_{1}\right)-q=(560)(0.09332-0.01617)-40.1=3.1 \mathrm{Btu} / \mathrm{lbm}
$$

Table 7-4

| Inlet state 1: compressed liquid phase | Exit state $2:$ compressed liquid phase |
| :---: | :---: |
| $T=40^{\circ} \mathrm{F}$ | $T=80^{\circ}$ |
| $P=16 \mathrm{psia}$ | $P=15 \mathrm{psia}$ |
| $h=8.02 \mathrm{Btu} / \mathrm{lbm}$ | $h=48.1 \mathrm{Btu} / \mathrm{lbm}$ |
| $s=0.01617 \mathrm{Btu} / \mathrm{lbm}-{ }^{\circ} \mathrm{R}$ | $s=0.09332 \mathrm{Btu} / \mathrm{lbm}-{ }^{\circ} \mathrm{R}$ |

7.4 A reservoir of water is perched in the hills overlooking a valley. The water is at $25^{\circ} \mathrm{C}$ and 100 kPa . If the reservoir is 1 km above the valley floor, calculate the availability of the water from the perspective of a farmer living in the valley.

The inlet and exit states are identified as follows:

| Inlet state 1: | $\mathrm{T}=25^{\circ} \mathrm{C}$ | $\mathrm{P}=0.1 \mathrm{MPa}$ | $\mathrm{z}=1 \mathrm{~km}$ |
| :--- | :--- | :--- | :--- |
| Dead state 2: | $\mathrm{T}=25^{\circ} \mathrm{C}$ | $\mathrm{P}=0.1 \mathrm{MPa}$ | $\mathrm{z}=0 \mathrm{~km}$ |

We have assumed that the availability of the water in the reservoir is due entirely to the elevation. Then

$$
\psi=g\left(z_{1}-z_{0}\right)=(9.8)(1-0)=9.8 \mathrm{~kJ} / \mathrm{kg}
$$

7.5 A feedwater heater extracts steam from a turbine at 600 kPa and $250^{\circ} \mathrm{C}$ which it combines with $0.3 \mathrm{~kg} / \mathrm{s}$ of liquid at 600 kPa and $150^{\circ} \mathrm{C}$. The exhaust is saturated liquid at 600 kPa . Determine the second-law effectiveness of the heater.

For data, see Table 7-5. By conservation of mass, $\dot{m}_{3}=\dot{m}_{1}+\dot{m}_{2}$. Then, the first law demands $\dot{m}_{3} h_{3}=\dot{m}_{1} h_{1}+\dot{m}_{2} h_{2}$. Solving simultaneously for $\dot{m}_{1}$ and $\dot{m}_{3}$ :

$$
\dot{m}_{1}=0.00504 \mathrm{~kg} / \mathrm{s} \quad \dot{m}_{3}=0.305 \mathrm{~kg} / \mathrm{s}
$$

The second-law effectiveness is $\varepsilon_{\Pi}=\dot{\Psi}_{3} /\left(\dot{\Psi}_{1}+\dot{\Psi}_{2}\right)$. Taking the dead state as liquid water at $25^{\circ} \mathrm{C}$ and 100 kPa , we have

$$
h_{0}=105 \mathrm{~kJ} / \mathrm{kg} \quad s_{0}=0.3672 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K}
$$

Table 7-5

| Inlet state $1:$ <br> superheated vapor | Inlet state $2:$ <br> compressed liquid | Exit state 3: <br> saturated liquid |
| :--- | :--- | :--- |
| $T=250^{\circ} \mathrm{C}$ | $T=150^{\circ} \mathrm{C}$ | $P=0.6 \mathrm{MPa}$ |
| $P=0.6 \mathrm{MPa}$ | $P=0.6 \mathrm{MPa}$ | $T=158.9^{\circ} \mathrm{C}$ |
| $h=2957.2$ | $h=632.2 \mathrm{~kJ} / \mathrm{kg}$ | $h=670.6 \mathrm{~kJ} / \mathrm{kg}$ |
| $s=7.1824 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}$ | $s=1.8422 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}$ | $s=1.9316 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}$ |

Then

$$
\begin{aligned}
& \dot{\Psi}_{3}=\dot{m}\left[h_{3}-h_{0}-T_{0}\left(s_{3}-s_{0}\right)\right]=(0.305)[670.6-105-298(1.9316-0.3672)]=30.33 \mathrm{~kW} \\
& \dot{\Psi}_{1}=\dot{m}_{1}\left[h_{1}-h_{0}-T_{0}\left(s_{1}-s_{0}\right)\right]=(0.00504)[2957.2-105-298(7.1824-0.3672)]=4.14 \mathrm{~kW} \\
& \dot{\Psi}_{2}=\dot{m}_{2}\left[h_{2}-h_{0}-T_{0}\left(s_{2}-s_{0}\right)\right]=(0.30)[632.2-105-298(1.8422-0.3672)]=23.63 \mathrm{~kW} \\
& \text { and }
\end{aligned}
$$

$$
\varepsilon_{\mathrm{II}}=\frac{30.33}{4.14+23.63}=1.09
$$

7.6 Consider the ideal refrigeration cycle shown in Fig. 7-4 which utilizes Freon 12. The condenser operates at 130 psia while the evaporator operates at 20 psia . Calculate the second-law effectiveness for the cycle.

Fig. $7-4$

The given values and the Freon 12 tables in Appendix D allow us to set up Table 7-6.
Table 7-6

| State | $T\left({ }^{\circ} \mathrm{F}\right)$ | $P(\mathrm{psia})$ | $h(\mathrm{Btu} / \mathrm{lbm})$ | $s\left(\mathrm{Btu} / \mathrm{lbm}-{ }^{\circ} \mathrm{R}\right)$ |
| :---: | :---: | :---: | :---: | :---: |
| 1 (Saturated | 104.4 | 140 | 32.15 | 0.0651 |
| liquid phase) | -8.13 | 20 |  | 0.1697 |
| 2 (Two-phase) | -8.13 | 20 | 76.4 |  |
| (Saturated <br> vapor phase) |  | 140 |  |  |
| 4 (Superheated |  |  |  |  |
| phase) |  |  |  |  |

Now, traversing the cycle, the enthalpy remains constant across a valve, so that $h_{2}=h_{1}=30.84$ Btu/lbm. State 2 is two-phase, so that

$$
x=\frac{h_{2}-h_{f}}{h_{g}-h_{f}}=\frac{32.15-6.77}{76.4-6.77}=0.364
$$

and

$$
s_{2}=s_{4}+x\left(s_{k}-s_{f}\right)=0.0155+(0.364)(0.1697-0.0155)=0.0716 \mathrm{Btu} / \mathrm{Ibm}-{ }^{\circ} \mathrm{R}
$$

State 4 results from an isentropic compression. At $P_{4}=140 \mathrm{psia}$ and $s_{4}=0.1697 \mathrm{Btu} / \mathrm{lbm}-{ }^{\circ} \mathrm{R}$, we interpolate to find $h_{4}=91.24 \mathrm{Btu} / \mathrm{lbm}$. We now calculate the second-law effectiveness for the cycle:

$$
\begin{aligned}
\text { availability produced } & =\left(1-\frac{T_{0}}{T_{3}}\right) Q_{L}=\left(1-\frac{536}{452}\right)(30.84-76.4)=8.46 \mathrm{Btu} / \mathrm{lbm} \\
\text { work used }=W_{\mathrm{comp}} & =h_{4}-h_{3}=91.2-76.4=14.8 \mathrm{Btu} / \mathrm{lbm} \\
\varepsilon_{11} & =\frac{8.46}{14.8}=0.572
\end{aligned}
$$

## Supplementary Problems

7.7 Steam enters a turbine at 6 MPa and $500^{\circ} \mathrm{C}$ and exits at 100 kPa and $150^{\circ} \mathrm{C}$. Determine (a) the reversible work and (b) the irreversibility of the process. Ans. (a) $864.2 \mathrm{~kJ} / \mathrm{kg}$ (b) $218.5 \mathrm{~kJ} / \mathrm{kg}$
7.8 The inlet conditions to an adiabatic steam turbine are 800 psia and $700^{\circ} \mathrm{F}$. At the exit the pressure is 30 psia and the steam has a quality of 93 percent. Determine ( $a$ ) the irreversibility, ( $b$ ) the reversible work, and (c) the adiabatic efficiency for the turbine.
Ans. (a) $17.67 \mathrm{Btu} / \mathrm{lbm} \quad$ (b) $257.6 \mathrm{Btu} / \mathrm{lbm} \quad$ (c) $85.1 \%$
7.9 A steam turbine with an isentropic efficiency of 85 percent operates between steam pressures of 1500 and 100 psia. If the inlet steam is at $1000^{\circ} \mathrm{F}$, determine the actual work and the second-law efficiency of the turbine. Ans. $259 \mathrm{Btu} / \mathrm{lbm}, 94.2 \%$
7.10 What does irreversibility imply about an adiabatic steam turbine which operates with inlet steam at 10 MPa and $700^{\circ} \mathrm{C}$ and exhausts at 0.2 MPa with a quality of 90 percent?
Ans. $i=-179 \mathrm{~kJ} / \mathrm{kg} \quad$ (impossible)
7.11 A designer of gas turbines claims to have developed a turbine which will take hot combustion gases (having the properties of air) at 80 psia and $2500^{\circ} \mathrm{R}$ and exhaust at 14.7 psia and $1200^{\circ} \mathrm{R}$. What is the minimum amount of heat transfer which must occur for this turbine to be feasible?
Ans. $\quad$-44.3 Btu/lbm
7.12 Determine the availability of water in a hot water tank at 100 kPa and $95^{\circ} \mathrm{C}$. Ans. $29.8 \mathrm{~kJ} / \mathrm{kg}$
7.13 What is the availability of a $2-\mathrm{in}^{3}$ ice cube at $10^{\circ} \mathrm{F}$ and 14.7 psia ? Ans. 2.54 Btu
7.14 Ideally, which fluid can do more work: air at 600 psia and $600^{\circ} \mathrm{F}$ or steam at 600 psia and $600^{\circ} \mathrm{F}$ ? Ans. Stcam (471 Btu/lbm vs. 77.3 Btu/lbm)
7.15 A piston-cylinder system with air undergoes a polytropic compression with $n=1.1$ from $75^{\circ} \mathrm{F}, 15 \mathrm{psia}$, and 0.2 liter to 0.04 liter. Determine ( $a$ ) actual work, ( $b$ ) heat transfer, ( $c$ ) reversible work, and (d) irreversibility.
$\begin{array}{lllll}\text { Ans. (a) }-26.64 \mathrm{ft}-\mathrm{lbf} & \text { (b) }-0.0257 \mathrm{Btu} & \text { (c) }-25.09 \mathrm{ft}-\mathrm{lbf} & \text { (d) } 1.55 \mathrm{ft}-\mathrm{lbf}\end{array}$
7.16 Methane gas at 800 K and 3 MPa is contained in a piston-cylinder system. The system is allowed to expand to 0.1 MPa in a polytropic process with $n=2.3$. What is the second-law efficiency of the process? Ans. 65.0\%
7.17 Argon is contained in a sealed tank of 10 liters at 400 psia and $50^{\circ} \mathrm{F}$. What is the maximum work the argon can do on carth at $536^{\circ} \mathrm{R}$ ? Ans. 89.4 Btu
7.18 A rigid tank initially contains 0.5 lbm of Freon 12 as saturated liquid at 30 psia . It is then allowed to come to equilibrium with its surroundings at $70^{\circ} \mathrm{F}$. Determine ( $a$ ) the final state of the refrigerant and (b) the irreversibility. Ans. (a) compressed liquid (b) 0.463 Btu
7.19 Air enters a compressor at 100 kPa and 295 K and exits at 700 kPa and 530 K with $40 \mathrm{~kJ} / \mathrm{kg}$ of heat transfer to the surroundings. Determine ( $a$ ) reversible work, ( $b$ ) irreversibility, and ( $c$ ) second-law efficiency for the compressor. Ans. (a) $-227 \mathrm{~kJ} / \mathrm{kg}$ (b) $48.2 \mathrm{~kJ} / \mathrm{kg} \quad$ (c) $82.5 \%$
7.20 A compressor with an adiabatic efficiency of 90 percent intakes air at $500^{\circ} \mathrm{R}$ and 15 psia and exhausts at 120 psia. Determine ( $a$ ) the actual work and ( $b$ ) the reversible work associated with this compressor.
Ans. (a) $-108.2 \mathrm{Btu} / \mathrm{lbm} \quad$ (b) $-102.3 \mathrm{Btu} / \mathrm{lbm}$
7.21 The evaporator for an air-conditioning system is a heat exchanger. Freon 12 enters at $0.05 \mathrm{~kg} / \mathrm{s}$ and $-20^{\circ} \mathrm{C}$ as saturated liquid and leaves as saturated vapor. Air enters at $34^{\circ} \mathrm{C}$ and leaves at $18^{\circ} \mathrm{C}$. (a) What is the mass flow rate of air? (b) What is the irreversibility rate of the evaporator.
Ans. (a) $0.502 \mathrm{~kg} / \mathrm{s} \quad$ (b) 1.449 kW
7.22 A direct contact heat exchanger serves as the condenser for a steam power plant. Steam with quality of 50 percent at 100 kPa flows into the mixing tank at $2 \mathrm{~kg} / \mathrm{s}$. Groundwater at $10^{\circ} \mathrm{C}$ and 100 kPa is available to produce saturated liquid flowing out of the mixing tank. The mixing tank is well-insulated. Determine ( $a$ ) the mass flow rate of groundwater required and ( $b$ ) the irreversibility rate.
Ans. (a) $6.00 \mathrm{~kg} / \mathrm{s} \quad$ (b) 650 kW
7.23 Steam is throttled across an adiabatic valve from 250 psia and $450^{\circ} \mathrm{F}$ to 60 psia. Determine (a) the reversible work and ( $b$ ) the irreversibility. Ans. ( $a$ ) $40,800 \mathrm{ft}-\mathrm{lbf} / \mathrm{lbm} \quad$ (b) $40,800 \mathrm{ft}-\mathrm{lbf} / \mathrm{lbm}$
7.24 It has been proposed to utilize a nozzle in conjunction with a wind turbine system. Air enters the adiabatic nozzle at $9 \mathrm{~m} / \mathrm{s}, 300 \mathrm{~K}$, and 120 kPa and exits at $100 \mathrm{~m} / \mathrm{s}$ and 100 kPa . Determine (a) the irreversibility and (b) the reversible work. Ans. (a) $10.58 \mathrm{~kJ} / \mathrm{kg} \quad$ (b) $15.58 \mathrm{~kJ} / \mathrm{kg}$
7.25 In the burner for a gas turbine system $0.2 \mathrm{lbm} / \mathrm{sec}$ of air at 20 psia and $900^{\circ} \mathrm{R}$ is heated to $2150^{\circ} \mathrm{R}$ in a constant-pressure process while hot combustion gases (assumed to be air) are cooled from $3000^{\circ} \mathrm{R}$ to $2400^{\circ} \mathrm{R}$. What is the irreversibility rate of this process? Ans. $11.3 \mathrm{Btu} / \mathrm{sec}$
7.26 Saturated water enters an adiabatic pump at 10 kPa and exits at 1 MPa . If the pump has an adiabatic efficiency of 95 percent, determine ( $a$ ) the reversible work and ( $b$ ) the second-law efficiency.
Ans. (a) $-0.105 \mathrm{~kJ} / \mathrm{kg} \quad$ (b) $10.0 \%$
7.27 The pressure of water is increased, by the use of a pump, from 14 to 40 psia. A rise in the water temperature from $60^{\circ} \mathrm{F}$ to $60.1^{\circ} \mathrm{F}$ is observed. Determine ( $a$ ) the irreversibility, ( $b$ ) the reversible work, and (c) the adiabatic efficiency of the pump. Ans. (a) $80.2 \mathrm{ft}-\mathrm{lbf} / \mathrm{lbm} \quad$ (b) $-57.6 \mathrm{ft}-\mathrm{lbf} / \mathrm{lbm}$ (c) $43.5 \%$
7.28 Air at $2200^{\circ} \mathrm{R}$ and 40 psia enters a gas turbine with an adiabatic efficiency of 75 percent and exhausts at 14.7 psia. Determine ( $a$ ) the availability of the exhaust air and ( $b$ ) the reversible work.

Ans. (a) $168 \mathrm{Btu} / \mathrm{lbm}$ (b) $109 \mathrm{Btu} / \mathrm{lbm}$

## Power and Refrigeration Vapor Cycles

### 8.1 INTRODUCTION

The ideal Carnot cycle is used as a model to compare all real and all other ideal cycles against. The efficiency of a Carnot power cycle is the maximum possible for any power cycle; it is given by

$$
\begin{equation*}
\eta=1-\frac{T_{L}}{T_{H}} \tag{8.1}
\end{equation*}
$$

Note that the efficiency is increased by raising the temperature $T_{H}$ at which heat is added or by lowering the temperature $T_{L}$ at which heat is rejected. We will observe that this carries over to real cycles: the cycle efficiency can be maximized by using the highest maximum temperature and the lowest minimum temperature.

We will first discuss vapor cycles that are used to generate power, then vapor cycles that are used to refrigerate or heat a space. Chapter 9 will examine gas cycles with both power and refrigeration applications.

### 8.2 THE RANKINE CYCLE

The first class of power cycles that we consider are those utilized by the electric power generating industry, namely, power cycles that operate in such a way that the working fluid changes phase from a liquid to a vapor. The simplest vapor power cycle is called the Rankine cycle, shown schematically in Fig. 8-1a. A major feature of such a cycle is that the pump requires very little work to deliver high-pressure water to the boiler. A possible disadvantage is that the expansion process in the turbine usually enters the quality region, resulting in the formation of liquid droplets that may damage the turbine blades.

The Rankine cycle is an idealized cycle in which losses in each of the four components are neglected. The losses usually are quite small and will be neglected completely in our initial analysis. The Rankine cycle is composed of the four ideal processes shown on the T-s diagram in Fig. 8-1b:
$\mathbf{1} \boldsymbol{\rightarrow 2}$ : $\quad$ Isentropic compression in a pump
$\mathbf{2} \rightarrow \mathbf{3}$ : Constant-pressure heat addition in a boiler
$3 \rightarrow 4: \quad$ Isentropic expansion in a turbine
$4 \rightarrow$ 1: Constant-pressure heat extraction in a condenser
If we neglect kinetic energy and potential energy changes, the net work output is the area under the $T$-s diagram, represented by area $1-2-3-4-1$; this is true since the first law requires that $W_{\text {net }}=Q_{\text {net }}$. The heat transfer to the working substance is represented by area $a-2-3-b-a$. Thus, the thermal efficiency $\eta$ of the Rankine cycle is

$$
\begin{equation*}
\eta=\frac{\text { area } 1-2-3-4-1}{\text { area } a-2-3-b-a} \tag{8.2}
\end{equation*}
$$

that is, the desired output divided by the energy input (the purchased energy). Obviously, the thermal efficiency can be improved by increasing the numerator or by decreasing the denominator. This can be done by increasing the pump outlet pressure $P_{2}$, increasing the boiler outlet temperature $T_{3}$, or decreasing the turbine outlet pressure $P_{4}$.

Note that the efficiency of the Rankine cycle is less than that of a Carnot cycle operating between the high temperature $T_{3}$ and the low temperature $T_{1}$ since most of the heat transfer from a high-temperature reservoir occurs across large temperature differences.

Fig. 8-1

It is possible for the efficiency of a Rankine cycle to be equal to that of a Carnot cycle if the cycle is designed to operate as shown in Fig. 8-2a. However, the pump would be required to pump a mixture of liquid and vapor, a rather difficult and work-consuming task compared to pumping all liquid. In addition, the condensation of liquid droplets in the turbine would result in severe damage. To avoid the damage from droplets, one could propose superheating the steam at constant temperature, as shown in Fig. 8-2b. This, however, requires that the pressure for the constant-temperature superheated portion of the process decrease from the saturated vapor point to state 3 . To achieve such a decrease, the flow in the boiler pipes would have to be accelerated, a task that would require pipes of decreasing diameter. This would be expensive, should it even be attempted. Thus it is proposed that $P_{2}$ and $T_{3}$ be quite large ( $T_{3}$ being limited by the temperature-resistance characteristics of the pipe metal, typically about $600^{\circ} \mathrm{C}$ ). (See Fig. $8-2 \mathrm{c}$ ). It is also proposed that the condenser outlet pressure be very low (it can be quite close to absolute zero). This would, however, result in state 4 being in the quality region (a quality of 90 percent is too low) causing water droplets to form. To avoid this problem it is necessary to reheat the steam, as will be discussed in the following section.

Fig. 8-2

By Section 4.8 and Fig. 8-1b,

$$
\begin{equation*}
q_{B}=h_{3}-h_{2} \quad w_{P}=v_{1}\left(P_{2}-P_{1}\right) \quad q_{C}=h_{4}-h_{1} \quad w_{T}=h_{3}-h_{4} \tag{8.3}
\end{equation*}
$$

where $w_{P}$ and $q_{C}$ are expressed as positive quantities. In terms of the above, the thermal efficiency is

$$
\begin{equation*}
\eta=\frac{w_{T}-w_{P}}{q_{B}} \tag{8.4}
\end{equation*}
$$

The pump work is usually quite small, however, compared to the turbine work and can most often be
neglected. With this approximation there results

$$
\begin{equation*}
\eta=\frac{w_{T}}{q_{B}} \tag{8.5}
\end{equation*}
$$

This is the relation used for the thermal efficiency of the Rankine cycle.
EXAMPLE 8.1 A steam power plant is proposed to operate between the pressures of 10 kPa and 2 MPa with a maximum temperature of $400^{\circ} \mathrm{C}$, as shown in Fig. 8-3. What is the maximum efficiency possible from the power cycle?

Fig. 8-3

Let us include the pump work in the calculation and show that it is negligible. Also, we will assume a unit mass of working fluid since we are only interested in the efficiency. The pump work is [see (4.71) with $v=1 / \rho$ ]

$$
w_{P}=v_{1}\left(P_{2}-P_{1}\right)=(0.001)(2000-10)=1.99 \mathrm{~kJ} / \mathrm{kg}
$$

Using (4.67) we find that $h_{2}=h_{1}+w_{\text {in }}=191.8+1.99=194 \mathrm{~kJ} / \mathrm{kg}$. The heat input is found using $q_{B}=h_{3}-$ $h_{2}=3248-194=3054 \mathrm{~kJ} / \mathrm{kg}$. To locate state 4 we recognize that $s_{4}=s_{3}=7.1279$. Hence,

$$
s_{4}=s_{f}+x_{4} s_{f g} \quad \therefore 7.1279=0.6491+7.5019 x_{4}
$$

giving the quality of state 4 as $x_{4}=0.8636$. This allows us to find $h_{4}$ to be

$$
h_{4}=192+(0.8636)(2393)=2259 \mathrm{~kJ} / \mathrm{kg}
$$

The work output from the turbine is

$$
w_{T}=h_{3}-h_{4}=3248-2259=989 \mathrm{~kJ} / \mathrm{kg}
$$

Consequently, the efficiency is

$$
\eta=\frac{w_{T}-w_{P}}{q_{B}}=\frac{989-2}{3054}=0.3232 \text { or } 32.32 \%
$$

Obviously, the work required in the pumping process is negligible, being only 0.2 percent of the turbine work. In engineering applications we often neglect quantities that have an influence of less than 3 percent, since invariably there is some quantity in the calculations that is known to only $\pm 3$ percent; for example, the mass flux, the dimensions of a pipe, or the density of the fluid.

### 8.3 RANKINE CYCLE EFFICIENCY

The efficiency of the Rankine cycle can be improved by increasing the boiler pressure while maintaining the maximum temperature and the minimum pressure. The net increase in work output is the crosshatched area minus the dotted area of Fig. 8-4a, a relatively small change; the added heat, however, decreases by the dotted area minus the crosshatched area of Fig. 8-4b. This is obviously a significant decrease, and it leads to a significant increase in efficiency. Example 8.2 illustrates this effect. The disadvantage of raising the boiler pressure is that the quality of the steam exiting the turbine may become too low (less than 90 percent), resulting in severe water droplet damage to the turbine blades and impaired turbine efficiency.

Fig. 8-4

Increasing the maximum temperature also results in an improvement in thermal efficiency of the Rankine cycle. In Fig. 8-5a the net work is increased by the crosshatched area and the heat input is increased by the sum of the crosshatched area and the dotted area, a smaller percentage increase than the work increase. Since the numerator of (8.5) realizes a larger percentage increase than the denominator, there will be a resulting increase in efficiency. This will be illustrated in Example 8.3. Of course, metallurgical considerations limit the maximum temperature which can be attained in the boiler. Temperatures up to about $600^{\circ} \mathrm{C}$ are allowable. Another advantage of raising the boiler temperature is that the quality of state 4 is obviously increased; this reduces water droplet formation in the turbine.

A decrease in condenser pressure, illustrated in Fig. 8-5b, will also result in increased Rankine cycle efficiency. The net work will increase a significant amount, represented by the crosshatched area, and the heat input will increase a slight amount because state $1^{\prime}$ will move to a slightly lower entropy than that of state 1 ; this will result in an increase in the Rankine cycle efficiency. The low pressure is limited by the heat transfer process that occurs in the condenser. The heat is rejected by transferring heat to cooling water or to air which enters the condenser at about $20^{\circ} \mathrm{C}$; the heat transfer process requires a temperature differential between the cooling water and the steam of at least $10^{\circ} \mathrm{C}$. Hence, a temperature of at least $30^{\circ} \mathrm{C}$ is required in the condenser; this corresponds to a minimum condenser pressure (see the saturated steam tables) of approximately 4 kPa abs. This is, of course, dependent on the temperature of the cooling and the temperature differential required in the heat exchanger.

Fig. 8-5

EXAMPLE 8.2 Increase the boiler pressure of Example 8.1 to 4 MPa while maintaining the maximum temperature and the minimum pressure. Calculate the percentage increase in the thermal efficiency.

Neglecting the work of the pump, the enthalpy $h_{2}$ remains unchanged: $h_{2}=192 \mathrm{~kJ} / \mathrm{kg}$. At $400^{\circ} \mathrm{C}$ and 4 MPa the enthalpy and entropy are $s_{3}=6.7698 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}$ and $h_{3}=3214 \mathrm{~kJ} / \mathrm{kg}$. State 4 is in the quality region. Using $s_{4}=s_{3}$, the quality is found to be

$$
x_{4}=\frac{s_{4}-s_{f}}{s_{f g}}=\frac{6.7698-0.6491}{7.5019}=0.8159
$$

Observe that the moisture content has increased to 18.4 percent, an undesirable result. The enthalpy of state 4 is then

$$
h_{4}=h_{f}+x_{4} h_{f g}=192+(0.8159)(2393)=2144 \mathrm{~kJ} / \mathrm{kg}
$$

The heat addition is $q_{B}=h_{3}-h_{2}=3214-192=3022 \mathrm{~kJ} / \mathrm{kg}$ and the turbine work output is

$$
w_{T}=h_{3}-h_{4}=3214-2144=1070 \mathrm{~kJ} / \mathrm{kg}
$$

Finally, the thermal efficiency is

$$
\eta=\frac{1070}{3022}=0.3541
$$

The percentage increase in efficiency from that of Example 8.1 is

$$
\% \text { increase }=\left(\frac{0.3541-0.3232}{0.3232}\right)(100)=9.55 \%
$$

EXAMPLE 8.3 Increase the maximum temperature in the cycle of Example 8.1 to $600^{\circ} \mathrm{C}$, while maintaining the boiler pressure and condenser pressure, and determine the percentage increase in thermal efficiency.

At $600^{\circ} \mathrm{C}$ and 2 MPa the enthalpy and entropy are $h_{3}=3690 \mathrm{~kJ} / \mathrm{kg}$ and $s_{3}=7.7032 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}$. State 4 remains in the quality region and, using $s_{4}=s_{3}$, we have

$$
x_{4}=\frac{7.7032-0.6491}{7.5019}=0.9403
$$

Note here that the moisture content has been decreased to 6.0 percent, a desirable result. The enthalpy of state 4 is now found to be $h_{4}=192+(9.9403)(2393)=2442 \mathrm{~kJ} / \mathrm{kg}$. This allows us to calculate the thermal efficiency as

$$
\eta=\frac{w_{T}}{q_{B}}=\frac{h_{3}-h_{4}}{h_{3}-h_{2}}=\frac{3690-2442}{3690-192}=0.3568
$$

where $h_{2}$ is taken from Example 8.1. The percentage increase is

$$
\% \text { increase }=\left(\frac{0.3568-0.3232}{0.3232}\right)(100)=10.4 \%
$$

In addition to a significant increase in cfficiency, note that the quality of the steam exiting the turbine exceeds $90 \%$, an improved value.

EXAMPLE 8.4 Decrease the condenser pressure of Example 8.1 to 4 kPa while maintaining the boiler pressure and maximum temperature, and determine the percentage increase in thermal efficiency.

The enthalpies $h_{2}=192 \mathrm{~kJ} / \mathrm{kg}$ and $h_{3}=3248 \mathrm{~kJ} / \mathrm{kg}$ remain as stated in Example 8.1. Using $s_{3}=s_{4}=$ 7.1279 , with $P_{4}=4 \mathrm{kPa}$, we find the quality to be

$$
x_{4}=\frac{s_{4}-s_{f}}{s_{f g}}=\frac{7.1279-0.4225}{8.0529}=0.8327
$$

Note that the moisture content of 16.7 percent is quite high. The enthalpy of state 4 is $h_{4}=121$ $+(0.8327)(2433)=2147 \mathrm{~kJ} / \mathrm{kg}$. The thermal efficiency is then

$$
\eta=\frac{h_{3}-h_{4}}{h_{3}-h_{2}}=\frac{3248-2147}{3248-192}=0.3603
$$

The percentage increase is found to be

$$
\% \text { increase }=\left(\frac{0.3603-0.3232}{0.3232}\right)(100)=11.5 \%
$$

### 8.4 THE REHEAT CYCLE

It is apparent from the previous section that when operating a Rankine cycle with a high boiler pressure or a low condenser pressure it is difficult to prevent liquid droplets from forming in the low-pressure portion of the turbine. Since most metals cannot withstand temperatures above about $600^{\circ} \mathrm{C}$, the reheat cycle is often used to prevent liquid droplet formation: the steam passing through the turbine is reheated at some intermediate pressure, thereby raising the temperature to state 5 in the $T$-s diagram of Fig. 8-6. The steam then passes through the low-pressure section of the turbine and enters the condenser at state 6 . This controls or completely eliminates the moisture problem in the turbine. Often the turbine is separated into a high-pressure turbine and a low-pressure turbine. The reheat cycle does not significantly influence the thermal efficiency of the cycle, but it does result in a significant additional work output, represented in the figure by area $4-5-6-4^{\prime}-4$. The reheat cycle demands a significant investment in additional equipment, and the use of such equipment must be economically justified by the increased work output.

Fig. 8-6
EXAMPLE 8.5 High-pressure steam enters a turbine at 600 psia and $1000^{\circ} \mathrm{F}$. It is reheated at a pressure of 40 psia to $600^{\circ} \mathrm{F}$ and then expanded to 2 psia . Determine the cycle efficiency. See Fig. 8-6.

At 2 psia saturated water has an enthalpy of (refer to Table C-2E) $h_{1} \simeq h_{2}=94 \mathrm{Btu} / \mathrm{lbm}$. From Table C-3E we find $h_{3}=1.518 \mathrm{Btu} / \mathrm{lbm}$ and $s_{3}=1.716 \mathrm{Btu} / \mathrm{lbm}-{ }^{\circ} \mathrm{R}$. Setting $s_{4}=s_{3}$, we interpolate, obtaining

$$
h_{4}=\left(\frac{1.716-1.712}{1.737-1.712}\right)(1217-1197)+1197=1200 \mathrm{Btu} / \mathrm{lbm}
$$

At 40 psia and $600^{\circ} \mathrm{F}$ we have

$$
h_{5}=1333 \mathrm{Btu} / \mathrm{lbm} \quad \text { and } \quad s_{5}=1.862 \mathrm{Btu} / \mathrm{lbm}-{ }^{\circ} \mathrm{R}
$$

In the quality region use $s_{6}=s_{5}$ and find

$$
x_{6}=\frac{1.862-0.175}{1.745}=0.9668
$$

Thus, $h_{0}=94+(0.9668)(1022)=1082 \mathrm{Btu} / \mathrm{lbm}$. The energy input and output are

$$
\begin{aligned}
& q_{B}=\left(h_{5}-h_{4}\right)+\left(h_{3}-h_{2}\right)=1333-1200+1518-94=1557 \mathrm{Btu} / \mathrm{lbm} \\
& w_{T}=\left(h_{5}-h_{6}\right)+\left(h_{3}-h_{4}\right)=1333-1082+1518-1200=569 \mathrm{Btu} / \mathrm{lbm}
\end{aligned}
$$

The thermal efficiency is then calculated to be

$$
\eta=\frac{w_{T}}{q_{B}}=\frac{569}{1557}=0.365 \quad \text { or } \quad 36.5 \%
$$

### 8.5 THE REGENERATIVE CYCLE

In the conventional Rankine cycle, as well as in the reheat cycle, a considerable percentage of the total energy input is used to heat the high-pressure water from $T_{2}$ to its saturation temperature. The crosshatched area in Fig. 8-7a represents this necessary energy. To reduce this energy, the water could be preheated before it enters the boiler by intercepting some of the steam as it expands in the turbine

Fig. 8-7
(for example, at state 5 of Fig. $8-7 b$ ) and mixing it with the water as it exits the first of the pumps, thereby preheating the water from $T_{2}$ to $T_{6}$. This would avoid the necessity of condensing all the steam, thereby reducing the amount of energy lost from the condenser. (Note that the use of cooling towers would allow smaller towers for a given energy output.) A cycle which utilizes this type of heating is a regenerative cycle, and the process is referred to as regeneration. A schematic representation of the major elements of such a cycle is shown in Fig. 8-8. The water entering the boiler is often referred to as feedwater, and the device used to mix the extracted steam and the condenser water is called a feedwater heater. When the condensate is mixed directly with the steam, it is done so in an open feedwater heater, as sketched in Fig. 8-8.

Fig. 8-8
In analyzing a regenerative cycle we must consider a control volume surrounding the feedwater heater, see Fig. 8-9. A mass balance would result in

$$
\begin{equation*}
\dot{m}_{6}=\dot{m}_{5}+\dot{m}_{2} \tag{8.6}
\end{equation*}
$$

An energy balance, assuming an insulated heater, neglecting kinetic and potential energy changes, gives

$$
\begin{equation*}
\dot{m}_{6} h_{6}=\dot{m}_{5} h_{5}+\dot{m}_{2} h_{2} \tag{8.7}
\end{equation*}
$$

Combining the above two equations gives

$$
\begin{equation*}
\dot{m}_{5}=\frac{h_{6}-h_{2}}{h_{5}-h_{2}} \dot{m}_{6} \tag{8.8}
\end{equation*}
$$

Fig. 8-9
A closed feedwater heater, which can be designed into a system using only one main pump, is also a possibility. Figure $8-10$ is a schematic diagram of a system using a closed feedwater heater. The disadvantages of such a system are that it is more expensive and its heat transfer characteristics are not as desirable as heat transfer in which the steam and water are simply mixed, as in the open heater.

Fig. 8-10
The closed feedwater heater is a heat exchanger in which the water passes through in tubes and the steam surrounds the tubes, condensing on the outer surfaces. The condensate thus formed, at temperature $T_{6}$, is pumped with a small condensate pump into the main feedwater line, as shown, or it passes through a trap (a device that permits only liquid to pass through) and is fed back to the condenser or back to a lower-pressure feedwater heater. A mass and energy balance are also required when analyzing a closed feedwater heater; if pump energy requirement is neglected in the analysis, the same relationship [see (8.8)] results.

The pressure at which the steam should be extracted from the turbine is approximated as follows. For one heater the steam should be extracted at the point that allows the exiting feedwater temperature $T_{6}$ to be midway between the saturated steam temperature in the boiler and the condenser temperature. For several heaters the temperature difference should be divided as equally as possible.

Obviously, if one feedwater heater improves thermal efficiency, two should improve it more. This is, in fact, true, but two heaters cost more initially and are more expensive to maintain. With a large number of heaters it is possible to approach the Carnot efficiency but at an unjustifiably high cost. Small power plants may have two heaters; large power plants, as many as six.

The regenerative cycle is afflicted by the moisture problem in the low-pressure portions of the turbine; hence, it is not uncommon to combine a reheat cycle and a regenerative cycle, thereby avoiding the moisture problem and increasing the thermal efficiency. A possible combination cycle is shown in Fig. 8-11. Ideal efficiencies significantly higher than for nonregenerative cycles can be realized with this combination cycle.

Fig. 8-11
A final word about efficiency. We calculate the efficiency of a cycle using the turbine work output as the desired output and consider the rejected heat from the condenser as lost energy. There are special situations where a power plant can be located strategically so that the rejected steam can be utilized to heat or cool buildings or the steam can be used in various industrial processes. This is often referred to as cogeneration. Often one-half of the rejected heat can be effectively used, almost doubling the "efficiency" of a power plant. Steam or hot water cannot be transported very far; thus, the power plant must be located very close to an industrial area or a densely populated area. A college campus is an obvious candidate for cogeneration, as are most large industrial concerns.

EXAMPLE 8.6 The high-temperature situation of Example 8.3 is to be modified by inserting an open feedwater heater such that the extraction pressure is 200 kPa . Determine the percentage increase in thermal efficiency.

Refer to the $T-s$ diagram of Fig. $8-7 b$ and to Fig. 8-8. We have from Example 8.3 and the steam tables

$$
h_{1} \simeq h_{2}=192 \mathrm{~kJ} / \mathrm{kg} \quad h_{6} \simeq h_{7}=505 \mathrm{~kJ} / \mathrm{kg} \quad h_{3}=3690 \mathrm{~kJ} / \mathrm{kg} \quad h_{4}=2442 \mathrm{~kJ} / \mathrm{kg}
$$

Now, locate state 5 . Using $s_{5}=s_{3}=7.7032 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}$, we interpolate and find, at 200 kPa ,

$$
h_{5}=\left(\frac{7.7032-7.5074}{7.7094-7.5074}\right)(2971-2870)+2870=2968 \mathrm{~kJ} / \mathrm{kg}
$$

We now apply conservation of mass and the first law to a control volume surrounding the feedwater heater. We have, using $m_{6}=1 \mathrm{~kg}$, since we are only interested in efficiency [see ( 8.8 )],

$$
m_{5}=\frac{505-192}{2968-192}=0.1128 \mathrm{~kg} \quad \text { and } \quad m_{2}=0.8872 \mathrm{~kg}
$$

The work output from the turbine is

$$
w_{T}=h_{3}-h_{5}+\left(h_{5}-h_{4}\right) m_{2}=3690-2968+(2968-2442)(0.8872)=1189 \mathrm{~kJ} / \mathrm{kg}
$$

The energy input to the boiler is $q_{B}=h_{3}-h_{7}=3690-505=3185 \mathrm{~kJ} / \mathrm{kg}$. The thermal efficiency is calculated to be

$$
\eta=\frac{1189}{3185}=0.3733
$$

The increase in efficiency is

$$
\% \text { increase }=\left(\frac{0.3733-0.3568}{0.3568}\right)(100)=4.62 \%
$$

EXAMPLE 8.7 An open feedwater heater is added to the reheat cycle of Example 8.5. Steam is extracted where the reheater interrupts the turbine flow. Determine the efficiency of this reheat-regeneration cycle.

A $T$-s diagram (Fig. $8-12 a$ ) is sketched to aid in the calculations. From the steam tables or from Example 8.5,

$$
\begin{array}{ll}
h_{1}=h_{2}=94 \mathrm{Btu} / \mathrm{lbm} & h_{7}=h_{y}=236 \mathrm{Btu} / \mathrm{lbm} \quad h_{3}=1518 \mathrm{Btu} / \mathrm{lbm} \\
h_{5}=1333 \mathrm{Btu} / \mathrm{lbm} & h_{0}=1082 \mathrm{Btu} / \mathrm{lbm} \quad h_{4}=1200 \mathrm{Btu} / \mathrm{lbm}
\end{array}
$$

Continuity and the first law applied to the heater give [see (8.8)]

$$
m_{4}=\frac{h_{8}-h_{2}}{h_{4}-h_{2}}=\frac{236-94}{1200-94}=0.128 \mathrm{lbm} \quad \text { and } \quad m_{2}=0.872 \mathrm{lbm}
$$

The turbine work output is then

$$
w_{T}=h_{3}-h_{+}+\left(h_{s}-h_{6}\right) m_{2}=1518-1200+(1333-1082)(0.872)=537 \mathrm{Btu} / \mathrm{lbm}
$$

The energy input is $q_{B}=h_{3}-h_{8}=1518-236+(1333-1200)(0.872)=1398 \mathrm{Btu} / \mathrm{lbm}$. The efficiency is calculated to be

$$
\eta=\frac{537}{1398}=0.384 \quad \text { or } \quad 38.4 \%
$$

Note the significant improvement in cycle efficiency. (5.2\%)

Fig. 8-12

### 8.6 THE SUPERCRITICAL RANKINE CYCLE

The Rankine cycle and variations of the Rankine cycle presented thus far have involved heat addition during the vaporization process; this heat transfer process occurs at a relatively low temperature, say $250^{\circ} \mathrm{C}$, at a pressure of 4 MPa , yet the hot gases surrounding the boiler after combustion are around $2500^{\circ} \mathrm{C}$. This large temperature difference makes the heat transfer process quite irreversible; recall that to approach reversibility the heat transfer process must occur over a small temperature difference. Hence, to improve the plant efficiency it is desirable to increase the temperature at which the heat transfer takes place. This will, of course, also improve the cycle efficiency since the area representing work will be increased. To get closer to the Carnot cycle efficiency, the temperature of the working fluid should be as near the temperature of the hot gases as possible. The supercritical Rankin cycle accomplishes this, as sketched on the $T$-s diagram in Fig. 8-13a. Note that the quality region is never entered during the heat-addition process. At these high pressures the pipes and associated fluid handling equipment must be quite massive, capable of
resisting the large pressure forces. The added cost of this more massive structure must be justified by the increase in efficiency and power output.

If the high-pressure superheated steam is expanded isentropically (insulated and without losses) through the turbine to a relatively low condenser pressure, it is obvious that a Rankine cycle will result in too high a moisture content in the low-pressure portion of the turbine. To eliminate this problem two reheat stages may be employed, and to maximize the cycle efficiency several regenerative stages may be utilized. Figure $8-13 b$ shows six regenerative stages and two reheat stages. Example 8.8 illustrates a cycle with two reheat and two regenerative stages.

Fig. 8-13

EXAMPLE 8.8 A supercritical reheat-regeneration cycle is proposed to operate as shown in the $T$-s diagram in Fig. 8-14, with two reheat stages and two open feedwater heaters. Determine the maximum possible cycle efficiency.

The enthalpies are found from the steam tables to be

$$
\begin{gathered}
h_{1} \simeq h_{2}=192 \mathrm{~kJ} / \mathrm{kg} \quad h_{4} \cong h_{5}=1087 \mathrm{~kJ} / \mathrm{kg} \quad h_{8}=3674 \mathrm{~kJ} / \mathrm{kg} \\
h_{3}=505=\mathrm{kJ} / \mathrm{kg} \quad h_{6}=3444 \mathrm{~kJ} / \mathrm{kg} \quad h_{10}=3174 \mathrm{~kJ} / \mathrm{kg} \\
s_{6}=s_{7}=6.2339 \quad \therefore h_{7}\left(\frac{6.2339-6.0709}{6.3622-6.0709}\right)(2961-2801)+2801=2891 \mathrm{~kJ} / \mathrm{kg} \quad s_{8}=s_{9}=7.3696 \\
\therefore h_{9}=\left(\frac{7.3696-7.2803}{7.5074-7.2803}\right)(2870-2769)+2769=2809 \mathrm{~kJ} / \mathrm{kg} \quad s_{10}=s_{11}=8.0636 \\
\therefore x_{11}=\frac{8.0636-0.6491}{7.5019}=0.9883 \quad \therefore h_{11}=192+(0.9883)(2393)=2557 \mathrm{~kJ} / \mathrm{kg}
\end{gathered}
$$

Next, we apply the first law to each of the two heaters. Assume that $\dot{m}=1 \mathrm{~kg} / \mathrm{s}$. The other mass fluxes are shown on the $T$-s diagram in Fig. 8-15. We find, from the first law applied to the high-pressure heater,

$$
h_{5}=h_{7} \dot{m}_{7}+\left(1-\dot{m}_{7}\right) h_{3} \quad \therefore \dot{m}_{7}=\frac{h_{5}-h_{3}}{h_{7}-h_{3}}=\frac{1087-505}{2891-505}=0.2439 \mathrm{~kg} / \mathrm{s}
$$

From the first law applied to the low-pressure heater, we find

$$
\begin{aligned}
\left(1-\dot{m}_{7}\right) h_{3} & =\dot{m}_{9} h_{9}+\left(1-\dot{m}_{7}-\dot{m}_{9}\right) h_{2} \\
\therefore \dot{m}_{9} & =\frac{\left(1-\dot{m}_{7}\right) h_{3}-h_{2}+\dot{m}_{7} h_{2}}{h_{9}-h_{2}}=\frac{(1-0.2439)(505)-192+(0.2439)(192)}{2809-192}=0.0904 \mathrm{~kg} / \mathrm{s}
\end{aligned}
$$

The power from the turbine is calculated to be

$$
\begin{aligned}
\dot{W}_{T} & =(1)\left(h_{6}-h_{7}\right)+\left(1-\dot{m}_{7}\right)\left(h_{8}-h_{9}\right)+\left(1-\dot{m}_{7}-\dot{m}_{9}\right)\left(h_{111}-h_{11}\right) \\
& =3444-2891+(0.7561)(3674-2809)+(0.6657)(3174-2557)=1609 \mathrm{~kW}
\end{aligned}
$$

Fig. 8-14

Fig. 8-15

The boiler energy input is

$$
\begin{aligned}
\dot{Q}_{B} & =(1)\left(h_{6}-h_{5}\right)+\left(1-\dot{m}_{7}\right)\left(h_{8}-h_{7}\right)+\left(1-\dot{m}_{7}-\dot{m}_{9}\right)\left(h_{10}-h_{9}\right) \\
& =3444-1087+(0.7561)(3674-2891)+(0.6657)(3174-2809)=3192 \mathrm{~kW}
\end{aligned}
$$

The cycle efficiency is faitly high at

$$
\eta=\frac{1609}{3192}=0.504 \quad \text { or } \quad 50.4 \%
$$

This higher efficiency results from the extremely high pressure of 30 MPa during the heat addition process. The associated savings must justify the increased costs of the massive equipment needed in a high-pressure system. Note: the fact that state 11 is in the quality region is not of concern since $x_{11}$ is quite close to unity. As the next section demonstrates, losses will increase the entropy of state 11 , with the result that state 11 will actually be in the superheated region.

### 8.7 EFFECT OF LOSSES ON POWER CYCLE EFFICIENCY

The preceding sections dealt with ideal cycles assuming no pressure drop through the pipes in the boiler, no losses as the superheated steam passes over the blades in the turbine, no subcooling of the water leaving the condenser, and no pump losses during the compression process. The losses in the combustion process and the inefficiencies in the subsequent heat transfer to the fluid in the pipes of the boiler are not included here; those losses, which are in the neighborhood of 15 percent of the input energy in the coal or oil, would be included in the overall plant efficiency.

There is actually only one substantial loss that must be accounted for when we calculate the actual cycle efficiency: the loss that occurs when the steam is expanded through the rows of turbine blades in the turbine. As the steam passes over a turbine blade, there is friction on the blade and the steam may separate from the rear portion of the blade. In addition, heat transfer from the turbine may occur, although this is usually quite small. These losses result in a turbine efficiency of 80 to 89 percent. Turbine efficiency is defined as

$$
\begin{equation*}
\eta_{T}=\frac{w_{a}}{w_{s}} \tag{8.9}
\end{equation*}
$$

where $w_{a}$ is the actual work and $w_{s}$ is the isentropic work.
The definition of pump efficiency, with pump work taken into account, is

$$
\begin{equation*}
\eta_{P}=\frac{w_{s}}{w_{a}} \tag{8.10}
\end{equation*}
$$

where the isentropic work input is obviously less than the actual input.
There is a substantial loss in pressure, probably 10 to 20 percent, as the fluid flows from the pump exit through the boiler to the turbine inlet. The loss can be overcome by simply increasing the exit
pressure from the pump. This does require more pump work, but the pump work is still less than 1 percent of the turbine output and is thus negligible. Consequently, we ignore the boiler pipe losses.

The condenser can be designed to operate such that the exiting water is very close to the saturated liquid condition. This will minimize the condenser losses so that they can also be neglected. The resulting actual Rankine cycle is shown on the $T$-s diagram in Fig. 8-16; the only significant loss is the turbine loss. Note the increase in entropy of state 4 as compared to state 3 . Also, note the desirable effect of the decreased moisture content of state 4 ; in fact, state 4 may even move into the superheated region, as shown.

Fig. 8-16

EXAMPLE 8.9 A Rankine cycle operates between pressures of 2 MPa and 10 kPa with a maximum temperature of $600^{\circ} \mathrm{C}$. If the insulated turbine has an efficiency of 80 percent, calculate the cycle efficiency and the temperature of steam at the turbine outlet.

From the steam tables we find $h_{1} \simeq h_{2}=192 \mathrm{~kJ} / \mathrm{kg}, h_{3}=3690 \mathrm{~kJ} / \mathrm{kg}$, and $s_{3}=7.7032 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}$. Setting $s_{4^{\prime}}=s_{3}$ we find the quality and enthalpy of state $4^{\prime}$ (see Fig. 8-16) to be

$$
x_{4^{\prime}}=\frac{7.7032-0.6491}{7.5019}=0.9403 \quad \therefore h_{4^{\prime}}=192+(0.9403)(2393)=2442 \mathrm{~kJ} / \mathrm{kg}
$$

From the definition of turbine efficiency,

$$
0.8=\frac{w_{a}}{3690-2442} \quad w_{a}=998 \mathrm{~kJ} / \mathrm{kg}
$$

The cycle efficiency is then

$$
\eta=\frac{w_{a}}{q_{B}}=\frac{998}{3690-192}=0.285 \quad \text { or } \quad 28.5 \%
$$

Note the substantial reduction from the ideal cycle efficiency of 35.7 percent as calculated in Example 8.3.
If we neglect kinetic and potential energy changes, the adiabatic process from state 3 to state 4 allows us to write

$$
w_{a}=h_{3}-h_{4} \quad 998=3690-h_{4} \quad h_{4}=2692 \mathrm{~kJ} / \mathrm{kg}
$$

At 10 kPa we find that state 4 is in the superheated region. The temperature is interpolated to be

$$
T_{4}=\left(\frac{2692-2688}{2783-2688}\right)(150-100)+100=102^{\circ} \mathrm{C}
$$

Obviously, the moisture problem has been eliminated by the losses in the turbine; the losses tend to act as a small reheater.

### 8.8 THE VAPOR REFRIGERATION CYCLE

It is possible to extract heat from a space by operating a vapor cycle, similar to the Rankine cycle, in reverse. Work input is, of course, required in the operation of such a cycle, as shown in Fig. 8-17a.

(a)

Fig. 8-17

The work is input by a compressor that increases the pressure, and thereby the temperature, through an isentropic compression process in the ideal cycle. The working fluid (often Freon 12) then enters a condenser in which heat is extracted, resulting in saturated liquid. The pressure is then reduced in an expansion process so that the fluid can be evaporated with the addition of heat from the refrigerated space.

The most efficient cycle, a Carnot cycle, is shown in Fig. 8-17b. There are, however, two major drawbacks when an attempt is made to put such a cycle into actual operation. First, it is not advisable to compress the mixture of liquid and vapor as represented by state 1 in Fig. 8-17b since the liquid droplets would cause excessive wear; in addition, equilibrium between the liquid phase and the vapor phase is difficult to maintain in such a process. Hence, in the ideal refrigeration cycle a saturated vapor state is assumed at the end of the evaporation process; this allows superheated vapor to exist in the compressor, as shown by process 1-2 in Fig. 8-17c. Second, it would be quite expensive to construct a device to be used in the expansion process that would be nearly isentropic (no losses allowed). It is much simpler to reduce the pressure irreversibly by using an expansion valve which employs a throttling process in which enthalpy remains constant, as shown by the dotted line in Fig. 8-17c. Even though this expansion process is characterized by losses, it is considered to be part of the "ideal" vapor refrigeration cycle. Because the expansion process is a nonequilibrium process, the area under the $T$-s diagram does not represent the net work input.

The performance of the refrigeration cycle, when used as a refrigerator, is measured by

$$
\begin{equation*}
\mathrm{COP}=\frac{\dot{Q}_{\text {in }}}{\dot{W}_{\text {in }}} \tag{8.11}
\end{equation*}
$$

When the cycle is used as a heat pump, the performance is measured by

$$
\begin{equation*}
\mathrm{COP}=\frac{\dot{\underline{Q}}_{\text {out }}}{\dot{W}_{\text {in }}} \tag{8.12}
\end{equation*}
$$

We do not calculate the efficiency of a refrigeration cycle since the efficiency is not of particular interest. What is of interest is the ratio of the output energy to the input energy. The coefficient of performance can attain values of perhaps 5 for properly designed heat pumps and 4 for refrigerators.

The condensation and evaporation temperatures, and hence the pressures, are established by the particular situation that motivates the design of the refrigeration unit. For example, in a home refrigerator that is designed to cool the freezer space to $-18^{\circ} \mathrm{C}\left(0^{\circ} \mathrm{F}\right)$ it is necessary to design the evaporator to operate at approximately $-25^{\circ} \mathrm{C}$ to allow for effective heat transfer between the space and the cooling coils. The refrigerant condenses by transferring heat to air maintained at about $20^{\circ} \mathrm{C}$; consequently, to allow for effective heat transfer from the coils that transport the refrigerant, the refrigerant must be maintained at a temperature of at least $28^{\circ} \mathrm{C}$. This is shown in Fig. 8-18.

Fig. 8-18

To accomplish refrigeration for most spaces, it is necessary that the evaporation temperature be quite low, in the neighborhood of $-25^{\circ} \mathrm{C}$, perhaps. This, of course, rules out water as a possible refrigerant. Two common refrigerants in use today are ammonia $\left(\mathrm{NH}_{3}\right)$ and Freon $12\left(\mathrm{CCl}_{2} \mathrm{~F}_{2}\right)$. The thermodynamic properties of Freon 12 are presented in Appendix D; of ammonia, in Appendix E. The selection of a refrigerant depends on the two design temperatures shown in Fig. 8-18. For example, temperatures well below $-100^{\circ} \mathrm{C}$ are required to liquefy many gases. Obviously, neither ammonia nor Freon 12 may be used at such low temperatures since they do not exist in a liquid form below $-100^{\circ} \mathrm{C}$. Also, it is desirable to operate a refrigeration cycle such that the low pressure is above atmospheric pressure, thereby avoiding air contamination should a leak occur. In addition, for most applications the refrigerant must be nontoxic, stable, and relatively inexpensive.

Deviations from the ideal vapor refrigeration cycle are shown on the T-s diagram of Fig. 8-19b. These include:

Pressure drops due to friction in connecting pipes.
Heat transfer occurs from or to the refrigerant through the pipes connecting the components.
Pressure drops occur through the condenser and evaporator tubes.
Heat transfer occurs from the compressor.
Frictional effects and flow separation occur on the compressor blades.
The vapor entering the compressor may be slightly superheated.
The temperature of the liquid exiting the condenser may be below the saturation temperature.

(a)

(b)

Fig. 8-19

Some of these effects are small and can be neglected, depending on the location of the components and whether the components and pipes are insulated. Also, not all of the effects are undesirable; the subcooling of the condensate in the condenser allows state 4 in Fig. 8-17c to move to the left, thereby increasing the refrigerant effect. Example 8.11 illustrates the difference between an ideal refrigeration cycle and an actual refrigeration cycle.

A "ton" of refrigeration is supposedly the heat rate necessary to melt a ton of ice in 24 hours. By definition, 1 ton of refrigeration equals $3.52 \mathrm{~kW}(12,000 \mathrm{Btu} / \mathrm{hr})$.

EXAMPLE 8.10 Freon 12 is used in an ideal vapor refrigeration cycle operating between saturation temperatures of $-20^{\circ} \mathrm{C}$ in the evaporator and $41.64^{\circ} \mathrm{C}$ in the condenser. Calculate the rate of refrigeration, the coefficient of performance, and the rating in horsepower per ton if the refrigerant flows at $0.6 \mathrm{~kg} / \mathrm{s}$. Also, determine the coefficient of performance if the cycle is operated as a heat pump.

The T-s diagram in Fig. 8-20 is drawn as an aid in the solution. The enthalpy of each state is needed. From Appendix D we find that $h_{1}=178.6 \mathrm{~kJ} / \mathrm{kg}, h_{3}=h_{4}=76.3 \mathrm{~kJ} / \mathrm{kg}$, and $s_{1}=0.7082 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}$. Using $s_{1}=s_{2}$, we interpolate at a pressure of 1.0 MPa , which is the pressure associated with the saturation temperature of $41.64^{\circ} \mathrm{C}$, and find that

$$
h_{2}=\left(\frac{0.7082-0.7021}{0.7254-0.7021}\right)(217.8-210.2)+210.2=212.2 \mathrm{~kJ} / \mathrm{kg}
$$

The rate of refrigeration is measured by the heat transfer rate needed in the evaporation process, namely,

$$
\dot{Q}_{E}=\dot{m}\left(h_{1}-h_{4}\right)=(0.6)(178.6-76.3)=61.4 \mathrm{~kW}
$$

Fig. 8-20

The power needed to operate the compressor is

$$
\dot{W}_{C}=\dot{m}\left(h_{2}-h_{1}\right)=(0.6)(212.2-178.6)=20.2 \mathrm{~kW}
$$

The coefficient of performance is then calculated to be COP $=61.4 / 20.2=3.04$.
The horsepower per ton of refrigeration is determined, with the appropriate conversion of units, as follows:

$$
\mathrm{Hp} / \mathrm{ton}=\frac{20.2 / 0.746}{61.4 / 3.52}=1.55
$$

If the above cycle were operated as a heat pump, the coefficient of performance would be

$$
\mathrm{COP}=\frac{h_{2}-h_{3}}{h_{2}-h_{1}}=\frac{212.2-76.3}{212.2-178.6}=4.04
$$

Obviously, the COP for a heat pump is greater than the COP for a refrigerator, since $\dot{Q}_{\text {out }}$ must always be greater than $\dot{Q}_{\text {in }}$. Note, however, that the heat pump in this problem heats the space with 4 times the energy input to the device.

EXAMPLE 8.11 The ideal refrigeration cycle of Example 8.10 is used in the operation of an actual refrigerator. It experiences the following real effects:

The refrigerant leaving the evaporator is superheated to $-10^{\circ} \mathrm{C}$.
The refrigerant leaving the condenser is subcooled to $40^{\circ} \mathrm{C}$.
The compressor is 80 percent efficient.
Calculate the actual rate of refrigeration and the coefficient of performance.
From Appendix D we find, using $T_{3}=40^{\circ} \mathrm{C}$, that $h_{3}=h_{4}=74.5 \mathrm{~kJ} / \mathrm{kg}$. Also, from Table D-1 we observe that $P_{1}=0.15 \mathrm{MPa}$. From Table D-3, at $P_{1}=0.15 \mathrm{MPa}$ and $T_{1}=-10{ }^{\circ} \mathrm{C}$,

$$
h_{1}=185 \mathrm{~kJ} / \mathrm{kg} \quad s_{1}=0.732 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K}
$$

If the compressor were isentropic, then, with $s_{2^{\prime}}=s_{1}$ and $P_{2}=1.0 \mathrm{MPa}$,

$$
h_{2^{\prime}}=\left(\frac{0.732-0.7254}{0.7476-0.7254}\right)(225.3-217.8)+218=220 \mathrm{~kJ} / \mathrm{kg}
$$

From the definition of efficiency, $\eta=w_{s} / w_{a}$, we have

$$
0.8=\frac{h_{2^{\prime}}-h_{1}}{h_{2}-h_{1}}=\frac{220-185}{h_{2}-185} \quad \therefore h_{2}=229 \mathrm{~kJ} / \mathrm{kg}
$$

The rate of refrigeration is $\dot{Q}_{E}=(0.6)(185-74.5)=66.3 \mathrm{~kW}$. Note that the real effects have actually increased the capability to refrigerate a space. The coefficient of performance becomes

$$
\mathrm{COP}=\frac{66.3}{(0.6)(229-185)}=2.51
$$

The decrease in the COP occurs because the power input to the compressor has increased substantially.

### 8.9 THE MULTISTAGE VAPOR REFRIGERATION CYCLE

In Example 8.11 the subcooling of the condensate leaving the condenser resulted in increased refrigeration. Subcooling is an important consideration in designing a refrigeration system. It can be accomplished either by designing a larger condenser or by designing a heat exchanger that uses the refrigerant from the evaporator as the coolant.

Another technique that can result in increased refrigeration is to place two refrigeration cycles in series (a two-stage cycle), operating as shown in Fig. 8-21a; the increased refrigeration is shown in Fig. $8-21 b$. This two-stage cycle has the added advantage that the power required to compress the refrigerant is substantially reduced. Note that the high-temperature refrigerant leaving the low-

(a)

(b)

Fig. 8-21
pressure stage compressor is used to evaporate the refrigerant in the high-pressure stage. This requires a heat exchanger, and, of course, two expansion valves and two compressors. The additional costs of this added equipment must be justified by improved performance. For extremely low refrigeration temperatures several stages may be justified.

The optimal value for the intermediate pressure $P_{i}$ is given by

$$
\begin{equation*}
P_{i}=\left(P_{H} P_{L}\right)^{1 / 2} \tag{8.13}
\end{equation*}
$$

where $P_{H}$ and $P_{L}$ are the respective high and low absolute pressures, shown in Fig. 8-21b. In this discussion the same refrigerant is assumed in both systems; if different refrigerants are used, then the appropriate $T$-s diagram must be used for each fluid.

To determine the relationship between the mass fluxes of the two systems we simply apply the first law (an energy balance) to the heat exchanger. This gives

$$
\begin{equation*}
\dot{m}_{H}\left(h_{5}-h_{8}\right)=\dot{m}_{L}\left(h_{2}-h_{3}\right) \tag{8.14}
\end{equation*}
$$

where $\dot{m}_{H}$ is the mass flux of the refrigerant in the high-pressure system and $\dot{m}_{L}$ is the refrigerant mass flux in the low-pressure system. This gives

$$
\begin{equation*}
\frac{\dot{m}_{H}}{\dot{m}_{L}}=\frac{h_{2}-h_{3}}{h_{5}-h_{8}} \tag{8.15}
\end{equation*}
$$

The low-pressure system actually performs the desired refrigeration. Thus, in the design process, it is this system that allows us to determine $\dot{m}_{l}$. If $X$ tons $=3.52 X$ kilowatts of refrigeration is required, then

$$
\begin{equation*}
\dot{m}_{L}\left(h_{1}-h_{4}\right)=3.52 X \tag{8.16}
\end{equation*}
$$

The mass flux is

$$
\begin{equation*}
\dot{m}_{L}=\frac{3.52 X}{h_{1}-h_{4}} \tag{8.17}
\end{equation*}
$$

EXAMPLE 8.12 A two-stage cycle replaces the refrigeration cycle of Example 8.10. Determine the rate of refrigeration and the coefficient of performance and compare with those of Example 8.10 . Use $\dot{m}_{L}=0.6 \mathrm{~kg} / \mathrm{s}$.

Refer to Fig. 8-21 for the various state designations. Using $T_{1}=-20^{\circ} \mathrm{C}$, we find $P_{L}=151 \mathrm{kPa}$. Also, $P_{H}=1000 \mathrm{kPa}$. Then, (8.13) results in

$$
P_{i}=\left(P_{L} P_{H}\right)^{1 / 2}=[(151)(1000)]^{1 / 2}=389 \mathrm{kPa}
$$

From Appendix D we find

$$
\begin{aligned}
& h_{1}=178.6 \mathrm{~kJ} / \mathrm{kg} \quad s_{1}=s_{2}=0.7082 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K} \quad h_{7}=h_{8}=76.3 \mathrm{~kJ} / \mathrm{kg} \\
& h_{3}=h_{4}=\left(\frac{389-320}{400-320}\right)(43.6-37.1)+37.1=42.7 \mathrm{~kJ} / \mathrm{kg} \\
& s_{5}=s_{6}=\left(\frac{389-320}{400-320}\right)(0.6928-0.6960)+0.6960=0.6932 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K} \\
& h_{5}=\left(\frac{389-320}{400-320}\right)(190.97-188.0)+188.0=190.6 \mathrm{~kJ} / \mathrm{kg}
\end{aligned}
$$

At $P_{i}=389 \mathrm{kPa}$ we interpolate and obtain

$$
\begin{array}{lll}
T=10^{\circ} \mathrm{C} & s=0.6993 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K} & h=193.8 \mathrm{~kJ} / \mathrm{kg} \\
T=20^{\circ} \mathrm{C} & s=0.7226 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K} & h=200.3 \mathrm{~kJ} / \mathrm{kg}
\end{array}
$$

This gives

$$
h_{2}=\left(\frac{0.7082-0.6993}{0.7226-0.6993}\right)(200.3-193.8)+193.8=196.3 \mathrm{~kJ} / \mathrm{kg}
$$

Also, extrapolating, we find

$$
h_{6}=\left(\frac{0.6932-0.7021}{0.7254-0.7021}\right)(217.8-210.2)+210.2=207.3 \mathrm{~kJ} / \mathrm{kg}
$$

From the above, $\dot{Q}_{E}=\dot{m}_{L}\left(h_{1}-h_{4}\right)=(0.6)(178.6-42.7)=81.5 \mathrm{~kW}$. This compares with a value of 61.4 kW from the simple refrigeration cycle of Example 8.10. That represents a 32.9 percent increase in the rate of refrigeration. The mass flux in the high-pressure stage is found from (8.15) to be

$$
\dot{m}_{H}=\dot{m}_{L} \frac{h_{2}-h_{3}}{h_{5}-h_{8}}=(0.6)\left(\frac{196.4-42.7}{190.6-76.3}\right)=0.807 \mathrm{~kg} / \mathrm{s}
$$

The power input to the compressors is

$$
\dot{W}_{\mathrm{in}}=\dot{m}_{L}\left(h_{2}-h_{1}\right)+\dot{m}_{H}\left(h_{6}-h_{5}\right)=(0.6)(196.3-178.6)+(0.807)(207.3-190.6)=24.1 \mathrm{~kW}
$$

The coefficient of performance is now calculated to be

$$
\mathrm{COP}=\frac{\dot{Q}_{E}}{\dot{W}_{\mathrm{in}}}=\frac{81.5}{24.1}=3.38
$$

This compares with a value of 3.04 from the refrigeration cycle of Example 8.10 , a 11.5 percent increase. The advantages of using two stages is obvious when considering the increased refrigeration and performance; the equipment is much more expensive, however, and must be justified economically.

### 8.10 THE HEAT PUMP

The heat pump utilizes the vapor refrigeration cycle discussed in Sec. 8.8. It can be used to heat a house in cool weather or cool a house in warm weather, as shown schematically in Fig. 8-22. Note that in the heating mode the house gains heat from the condenser, whereas in the cooling mode the house loses heat to the evaporator. This is possible since the evaporator and the condenser are similar heat exchangers. In an actual situation, valving is used to perform the desired switching of the heat exchangers.

The heat pump system is sized to meet the heating load or the cooling load, whichever is greater. In southern areas where the cooling loads are extremely large, the system may be oversized for the

Fig. 8-22
small heating demand of a chilly night; an air conditioner with an auxiliary heating system may be advisable in those cases. In a northern area where the large heating load demands a relatively large heat pump, the cooling load on a warm day may be too low for effective use of the heat pump; the large cooling capacity would quickly reduce the temperature of the house without a simultaneous reduction in the humidity, a necessary feature of any cooling system. In that case, a furnace which provides the heating with an auxiliary cooling system is usually advisable. Or, the heat pump could be designed based on the cooling load, with an auxiliary heater for times of heavy heating demands.

EXAMPLE 8.13 A heat pump using Freon 12 is proposed for heating a home that requires a maximum heating load of 300 kW . The evaporator operates at $-10^{\circ} \mathrm{C}$ and the condenser at 900 kPa . Assume an ideal cycle.
(a) Determine the COP.
(b) Determine the cost of electricity at $\$ 0.07 / \mathrm{kWh}$.
(c) Compare the Freon 12 system with the cost of operating a furnace using natural gas at $\$ 0.50$ /therm if there are $100000 \mathrm{~kJ} /$ therm of natural gas.
(a) The $T$-s diagram (Fig. 8-23) is sketched for reference. From Appendix D we find $h_{1}=183.1 \mathrm{~kJ} / \mathrm{kg}$, $s_{1}=s_{2}=0.7014 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}$, and $h_{3}=h_{4}=71.9 \mathrm{~kJ} / \mathrm{kg}$. Interpolating, there results

$$
h_{2}=\left(\frac{0.7014-0.6982}{0.7131-0.6982}\right)(211.8-204.2)+204.2=205.8 \mathrm{~kJ} / \mathrm{kg}
$$

Fig. 8-23

The heat rejected by the condenser is

$$
\dot{Q}_{C}=\dot{m}\left(h_{2}-h_{3}\right) \quad 300=\dot{m}(205.8-71.9)
$$

This gives the refrigerant mass flux as $\dot{m}=2.24 \mathrm{~kg} / \mathrm{s}$. The required power by the compressor is then $\dot{W}_{\text {in }}=\dot{m}\left(h_{2}-h_{1}\right)=(2.24)(205.8-183.1)=50.8 \mathrm{~kW}$. This results in a coefficient of performance of

$$
\mathrm{COP}=\frac{\dot{Q}_{C}}{\dot{W}_{\mathrm{in}}}=\frac{300}{50.8}=5.91
$$

(b) Cost of electricity $(50.8 \mathrm{~kW})(\$ 0.07 / \mathrm{kWh})=\$ 3.56 / \mathrm{h}$
(c) Assuming the furnace to be ideal, that is, it converts all of the energy of the gas into usable heat, we have

$$
\text { Cost of gas }=\left[\frac{(300)(3600)}{100000}\right](0.50)=\$ 5.40 / \mathrm{h}
$$

### 8.11 THE ABSORPTION REFRIGERATION CYCLE

In the refrigeration systems discussed thus far the power input needed to operate the compressor is relatively large since the refrigerant moving through the compressor is in the vapor state and has a very large specific volume when compared with that of a liquid. We can markedly reduce this power if we increase the pressure with a pump operating with a liquid. Such a refrigeration cycle exists; it is the absorption refrigeration cycle, shown schematically in Fig. 8-24. Note that the compressor of the conventional refrigeration cycle has been replaced with the several pieces of equipment shown on the right of the cycle. The absorber, the pump, the heat exchanger, and the generator are the major additional components that replace the compressor.

Saturated, low-pressure refrigerant vapor leaves the evaporator and enters the absorber where it is absorbed into the weak carrier solution. Heat is released in this absorption process, and to aid the

Fig. 8-24
process the temperature is maintained at a relatively low value by removing heat $\dot{Q}_{A}$. The much stronger liquid solution leaves the absorber and is pumped to the higher condenser pressure, requiring very little pump power. It passes through a heat exchanger, which increases its temperature, and enters the generator where the added heat boils off the refrigerant which then passes on to the condenser. The remaining weak carrier solution is then returned from the generator to the absorber to be recharged with refrigerant; on its way to the absorber the temperature of the carrier solution is reduced in the heat exchanger and its pressure is reduced with a regulating valve.

The primary disadvantage of the absorption cycle is that a relatively high-temperature energy source must be available to supply the heat transfer $Q_{C}$; this is typically supplied by a source that would otherwise be wasted, such as rejected steam from a power plant. The additional heat $\dot{Q}_{G}$ must be inexpensive, or the additional cost of the extra equipment cannot be justified.

For applications in which the refrigerated space is maintained at temperatures below $0^{\circ} \mathrm{C}$, the refrigerant is normally ammonia and the carrier is water. For air-conditioning applications the refrigerant can be water and the carrier either lithium bromide or lithium chloride. With water as the refrigerant a vacuum of 0.001 MPa must be maintained in the evaporator and absorber to allow for an evaporator temperature of $7{ }^{\circ} \mathrm{C}$. Since the evaporator temperature must be about $10^{\circ} \mathrm{C}$ below the temperature of the air that is cooling the space, such a low pressure is not unreasonable.

To analyze the absorption cycle we must know the amount of refrigerant contained in a mixture, both in liquid form and in vapor form. This can be found with the aid of an equilibrium chart, such as that for an ammonia-water mixture. At a given temperature and pressure the equilibrium diagram displays the following properties:

1. The concentration fraction $x^{\prime}$ of liquid ammonia:

$$
\begin{equation*}
x^{\prime}=\frac{\text { mass of liquid } \mathrm{NH}_{3}}{\text { mass of mixture }} \tag{8.18}
\end{equation*}
$$

2. The concentration fraction $x^{\prime \prime}$ of vapor ammonia:

$$
\begin{equation*}
x^{\prime \prime}=\frac{\text { mass of vapor } \mathrm{NH}_{3}}{\text { mass of mixture }} \tag{8.19}
\end{equation*}
$$

3. The enthalpy $h_{L}$ of the liquid mixture.
4. The enthalpy $h_{c}$ of the ammonia vapor.

These various properties are illustrated by Fig. 8-25.

Fig. 8-25
Finally, in the absorber and the generator two streams enter and one stream leaves. To determine the properties of the leaving stream, it is necessary to use a mass balance and an energy balance on each device; mass balances on both the refrigerant and the mixture are necessary.

## Solved Problems

8.1 A steam power plant is designed to operate on a Rankine cycle with a condenser outlet temperature of $80^{\circ} \mathrm{C}$ and boiler outlet temperature of $500^{\circ} \mathrm{C}$. If the pump outlet pressure is 2 MPa , calculate the maximum possible thermal efficiency of the cycle. Compare with the efficiency of a Carnot engine operating between the same temperature limits.

To calculate the thermal efficiency we must determine the turbine work and the boiler heat transfer. The turbine work is found as follows (refer to Fig. 8-1):

$$
\begin{array}{ll}
\text { At state 3: } & h_{3}=3468 \mathrm{~kg} / \mathrm{kg} \quad s_{3}=7.432 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K} \\
\text { At state 4: } & s_{4}=s_{3}=7.432=1.075+6.538 x_{4}
\end{array}
$$

Thus $x_{4}=0.9723, h_{4}=335+(0.9723)(2309)=2580 \mathrm{~kJ} / \mathrm{kg}$, and $w_{T}=h_{3}-h_{4}=3468-2580=888$ $\mathrm{kJ} / \mathrm{kg}$. The boiler heat, assuming that $h_{2}=h_{1}$ (the pump work is negligible), is $q_{B}=h_{3}-h_{2}=$ $3468-335=3133 \mathrm{~kJ} / \mathrm{kg}$. The cycle efficiency is then

$$
\eta=\frac{w_{T}}{q_{B}}=\frac{888}{3133}=0.283 \quad \text { or } 28.3 \%
$$

The efficiency of a Carnot cycle operating between the high and low temperatures of this cycle is

$$
\eta=1-\frac{T_{L}}{T_{H}}=1-\frac{353}{773}=0.543 \quad \text { or } 54.3 \%
$$

8.2 For the ideal Rankine cycle shown in Fig. 8-26 determine the mass flow rate of steam and the cycle efficiency.

The turbine output is shown to be 20 MW . Referring to Fig. 8-1, we find

$$
\begin{aligned}
h_{3} & =3422 \mathrm{~kJ} / \mathrm{kg}, \quad s_{3}=6.881 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K} \quad s_{4}=s_{3}=6.881=0.649+7.502 x_{4} \\
\therefore x_{4} & =0.8307 \quad \therefore h_{4}=192+(0.8307)(2393)=2180 \mathrm{~kJ} / \mathrm{kg}
\end{aligned}
$$

The mass flux is now calculated to be

$$
\dot{m}=\frac{\dot{W}_{T}}{w_{T}}=\frac{\dot{W}_{T}}{h_{3}-h_{4}}=\frac{20000}{3422-2180}=16.1 \mathrm{~kg} / \mathrm{s}
$$

Fig. 8-26

The boiler heat transfer, neglecting the pump work so that $h_{2} \cong h_{1}$, is

$$
q_{B}=h_{3}-h_{2}=3422-192=3230 \mathrm{~kJ} / \mathrm{kg}
$$

The cycle efficiency is found to be

$$
\eta=\frac{\dot{W}_{T}}{\dot{Q}_{B}}=\frac{\dot{W}_{T}}{\dot{m} q_{B}}=\frac{20000}{(16.1)(3230)}=0.385 \text { or } 38.5 \%
$$

8.3 A solar bank of collectors with an area of $8000 \mathrm{ft}^{2}$ supplies energy to the boiler of a Rankine cycle power plant. At peak load the collectors provide $200 \mathrm{Btu} / \mathrm{ft}^{2}$-hr to the working fluid. The Freon 12 working fluid leaves the boiler at 300 psia and $240^{\circ} \mathrm{F}$ and enters the pump at $100^{\circ} \mathrm{F}$. Determine $(a)$ the pump work, $(b)$ the cycle efficiency, $(c)$ the mass flux of the Freon 12 , and ( $d$ ) the maximum power output.
(a) The pump work requirement for this ideal cycle is (refer to Fig. 8-1)

$$
w_{P}=\left(P_{2}-P_{1}\right) t=[(300-131.9)(144)](0.01269)=307.2 \mathrm{ft}-\mathrm{lbf} / \mathrm{lbm} \quad \text { or } 0.395 \mathrm{Btu} / \mathrm{lbm}
$$

(b) To calculate the thermal efficiency we must know the boiler heat input. It is $q_{B}=h_{3}-h_{2}=$ $107.1-(31.1+0.395)=75.6 \mathrm{Btu} / \mathrm{lbm}$, where the enthalpy at the pump outlet, state 2 , is the inlet enthalpy $h_{1}$ plus $w_{P}$.

We must also calculate the turbine work output. To locate state 4 we use the entropy as follows: $s_{3}=s_{4}=0.1842 \mathrm{Btu} / \mathrm{lbm}-{ }^{\circ} \mathrm{R}$. This is in the superheated region. Interpolating for the state at $P_{4}=131.9$ psia and $s_{4}=0.1842$, we find that $h_{4}=99.5 \mathrm{Btu} / \mathrm{lbm}$. This result requires a double interpolation, so care must be taken. The turbine work is thus

$$
w_{T}=h_{3}-h_{4}=107.1-99.5=7.6 \mathrm{Btu} / \mathrm{lbm}
$$

The cycle efficiency is

$$
\eta=\frac{w_{T}-w_{P}}{q_{B}}=\frac{7.6-0.4}{75.6}=0.095 \text { or } 9.5 \%
$$

(c) To find the mass flux, we use the total heat flux input from the collectors. $\dot{Q}_{B}=(200)(8000)=$ $\dot{m} q_{B}=\dot{m}(75.6)$. This results in $\dot{m}=21,160 \mathrm{lbm} / \mathrm{hr}$ or $5.88 \mathrm{lbm} / \mathrm{sec}$.
(d) The maximum power output is $\dot{W}_{T}=\dot{m} w_{T}=(21,160)(7.6)=161,000 \mathrm{Btu} / \mathrm{hr}$ or 63.3 hp . We have used the conversion $2545 \mathrm{Btu} / \mathrm{hr}=1 \mathrm{hp}$.
8.4 The steam of a Rankine cycle, operating between 4 MPa and 10 kPa , is reheated at 400 kPa to $400^{\circ} \mathrm{C}$. Determine the cycle efficiency if the maximum temperature is $600^{\circ} \mathrm{C}$.

Referring to Fig. 8-6, we find from the steam tables the following:

$$
\begin{array}{rlrl}
h_{2} & \cong h_{1} & =191.8 \mathrm{~kJ} / \mathrm{kg}, & h_{3}=3674.4 \mathrm{~kJ} / \mathrm{kg}, \quad h_{5}=3273.4 \mathrm{~kJ} / \mathrm{kg}, \\
s_{4} & =s_{3}=7.369 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K} \quad & s_{6}=s_{5}=7.899 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K}
\end{array}
$$

For the two isentropic processes we calculate the following:

$$
\left.\begin{array}{l}
s_{4}=7.369 \\
P_{4}=400 \mathrm{kPa}
\end{array}\right\} \quad \text { Interpolate }: h_{4}=2960 \mathrm{~kJ} / \mathrm{kg}
$$

$s_{6}=7.898=0.649+7.501 x_{6} \quad \therefore x_{6}=0.9664 \quad \therefore h_{6}=191.8+0.9664 \times 2392.8=2504 \mathrm{~kJ} / \mathrm{kg}$
The heat transfer to the boiler is

$$
q_{B}=h_{3}-h_{2}+h_{5}-h_{4}=3674-192+3273-2960=3795 \mathrm{~kJ} / \mathrm{kg}
$$

The work output from the turbine is

$$
w_{T}=h_{3}-h_{4}+h_{5}-h_{6}=3674-2960+3273-2504=1483 \mathrm{~kJ} / \mathrm{kg}
$$

The cycle efficiency is finally calculated to be

$$
\eta=\frac{w_{T}}{q_{B}}=\frac{1483}{3795}=0.391 \quad \text { or } 39.1 \%
$$

8.5 An ideal reheat Rankine cycle operates between 8 MPa and 4 kPa with a maximum temperature of $600^{\circ} \mathrm{C}$ (Fig. 8-27). Two reheat stages, each with a maximum temperature of $600^{\circ} \mathrm{C}$, are to be added at 1 MPa and 100 kPa . Calculate the resulting cycle efficiency.

From the steam tables we find

$$
\begin{array}{lccc}
h_{1} \cong h_{2}=121.5 \mathrm{~kJ} / \mathrm{kg} & h_{3}=3642 \mathrm{~kJ} / \mathrm{kg} \quad h_{5}=3698 \mathrm{~kJ} / \mathrm{kg} \quad h_{7}=3705 \mathrm{~kJ} / \mathrm{kg} \\
s_{3}=s_{4}=7.021 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K} & s_{5}=s_{6}=8.030 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K} \quad s_{7}=s_{8}=9.098 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K}
\end{array}
$$

We interpolate at each of the superheated states 4,6 , and 8 :

$$
\begin{aligned}
& \left.\left.\begin{array}{l}
s_{4}=7.021 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K} \\
P_{4}=1 \mathrm{MPa}
\end{array}\right\} \quad \therefore h_{4}=2995 \mathrm{~kJ} / \mathrm{kg} \quad \begin{array}{l}
s_{6}=8.030 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K} \\
P_{6}=100 \mathrm{kPa}
\end{array}\right\} \therefore h_{6}=2972 \mathrm{~kJ} / \mathrm{kg} \\
& \left.\begin{array}{l}
s_{8}=9.098 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K} \\
P_{8}=4 \mathrm{kPa}
\end{array}\right\} \quad \therefore h_{8}=2762 \mathrm{~kJ} / \mathrm{kg}
\end{aligned}
$$

The boiler heat transfer is

$$
q_{B}=h_{3}-h_{2}+h_{5}-h_{4}+h_{7}-h_{6}=3642-122+3698-2995+3705-2972=4956 \mathrm{~kJ} / \mathrm{kg}
$$

The turbine work is

$$
w_{T}=h_{3}-h_{4}+h_{5}-h_{6}+h_{7}-h_{8}=3642-2995+3698-2972+3705-2762=2316 \mathrm{~kJ} / \mathrm{kg}
$$

The cycle efficiency is then calculated to be

$$
\eta=\frac{w_{T}}{q_{B}}=\frac{2316}{4956}=0.467 \text { or } 46.7 \%
$$

Fig. 8-27
8.6 The condenser pressure of a regenerative cycle is 3 kPa and the feedwater pump provides a pressure of 6 MPa to the boiler. Calculate the cycle efficiency if one open feedwater heater is to be used. The maximum temperature is $600^{\circ} \mathrm{C}$.

The pressure at which the steam passing through the turbine is intercepted is estimated by selecting a saturation temperature half way between the boiler saturation temperature and the condenser saturation temperature; i.e., referring to Fig. $8-7, T_{0}=\left(\frac{1}{2}\right)(275.6+24.1)=149.8^{\circ} \mathrm{C}$. The closest
pressure entry to this saturation temperature is at 400 kPa . Hence, this is the selected pressure for the feedwater heater. Using the steam tables, we find

$$
\begin{array}{lc}
h_{2} \cong h_{1}=101 \mathrm{~kJ} / \mathrm{kg} & h_{7} \cong h_{6}=604.3 \mathrm{~kJ} / \mathrm{kg} \\
h_{3}=3658.4 \mathrm{~kJ} / \mathrm{kg} & s_{3}=s_{4}=s_{5}=7.168 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K}
\end{array}
$$

For the isentropic processes we find

$$
\left.\begin{array}{l}
s_{5}=7.168 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K} \\
P_{5}=0.4 \mathrm{MPa}
\end{array}\right\} \quad \therefore h_{5}=2859 \mathrm{~kJ} / \mathrm{kg}
$$

$$
s_{4}=7.168=0.3545+8.2231 x_{4} \quad \therefore x_{4}=0.8286 \quad \therefore h_{4}=101+(0.8286)(2444.5)=2126 \mathrm{~kJ} / \mathrm{kg}
$$

If we assume $\dot{m}_{6}=1 \mathrm{~kg} / \mathrm{s}$, we find from (8.8) that

$$
\dot{m}_{5}=\frac{h_{6}-h_{2}}{h_{5}-h_{2}} \dot{m}_{6}=\left(\frac{640-101}{2859-101}\right)(1)=0.195 \mathrm{~kg} / \mathrm{s}
$$

Then we have:

$$
\begin{aligned}
& \dot{m}_{2}=\dot{m}_{6}-\dot{m}_{5}=1-0.195=0.805 \mathrm{~kg} / \mathrm{s} \\
& \dot{Q}_{B}=\dot{m}_{6}\left(h_{3}-h_{7}\right)=(1)(3658-604)=3054 \mathrm{~kW} \\
& \dot{W}_{T}=\dot{m}_{6}\left(h_{3}-h_{5}\right)+\dot{m}_{2}\left(h_{5}-h_{4}\right)=(1)(3658-2859)+(0.805)(2859-2126)=1389 \mathrm{~kW}
\end{aligned}
$$

The cycle efficiency is finally calculated to be

$$
\eta=\frac{\dot{W}_{T}}{\dot{Q}_{B}}=\frac{1389}{3054}=0.455 \quad \text { or } 45.5 \%
$$

8.7 For the regenerative cycle shown in Fig. 8-28 determine the thermal efficiency, the mass flux of steam, and the ratio of rejected heat to added heat. Neglect pump work.

Referring to Fig. 8-7b to identify the states and using the steam tables, we find

$$
h_{2} \cong h_{1}=191.8 \mathrm{~kJ} / \mathrm{kg} \quad h_{6} \cong h_{7}=762.8 \mathrm{~kJ} / \mathrm{kg} \quad h_{3}=3625.3 \mathrm{~kJ} / \mathrm{kg}
$$

The enthalpies of states 4 and 5 are determined by assuming an isentropic process as follows:

$$
\left.\begin{array}{rl}
s_{5}=s_{3}=6.904 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K} \\
P_{5}=1 \mathrm{MPa}
\end{array}\right\} \quad \therefore h_{5}=2932 \mathrm{~kJ} / \mathrm{kg} ~\left(\begin{array}{l} 
\\
s_{4}=s_{3}=6.904=0.6491+7.5019 x_{4} \quad \therefore x_{4}=0.8338 \\
\therefore h_{4}=191.8+(0.8338)(2392.8)=2187 \mathrm{~kJ} / \mathrm{kg}
\end{array}\right.
$$

Fig. 8-28

An energy balance on the heater, which is assumed insulated, is $\dot{m}_{5}\left(h_{5}-h_{6}\right)=\dot{m}_{2}\left(h_{7}-h_{2}\right)$. A mass balance provides (see Fig. $8-10$ ) $\dot{m}_{7}=\dot{m}_{5}+\dot{m}_{2}$. Assuming $\dot{m}_{7}=1 \mathrm{~kg} / \mathrm{s}$, the above two equations are combined to give

$$
\dot{m}_{2}=\frac{h_{5}-h_{6}}{h_{7}-h_{2}+h_{5}-h_{6}}=\frac{2932-763}{763-192+2932-763}=0.792 \mathrm{~kg} / \mathrm{s}
$$

We then have $\dot{m}_{5}=1-\dot{m}_{2}=1-0.792=0.208 \mathrm{~kg} / \mathrm{s}$. The turbine power (with $\dot{m}_{7}=1 \mathrm{~kg} / \mathrm{s}$ ) can now be calculated to be

$$
\dot{W}_{T}=\dot{m}_{7}\left(h_{3}-h_{5}\right)+\dot{m}_{2}\left(h_{5}-h_{4}\right)=(1.0)(3625-2932)+(0.792)(2932-2187)=1283 \mathrm{~kW}
$$

The boiler heat rate is

$$
\dot{Q}_{B}=\dot{m}_{7}\left(h_{3}-h_{7}\right)=(1.0)(3625-763)=2862 \mathrm{~kW}
$$

The cycle efficiency is calculated to be

$$
\eta=\frac{\dot{W}_{T}}{\dot{Q}_{B}}=\frac{1283}{2862}=0.448 \quad \text { or } 44.8 \%
$$

The mass flux of steam is found as

$$
\dot{m}_{7}=\frac{\dot{W}_{T}}{\left(\dot{W}_{T}\right)_{\text {with } \dot{m}_{7}=1}}=\frac{20}{1.283}=15.59 \mathrm{~kg} / \mathrm{s}
$$

The ratio of rejected heat to added heat is

$$
\frac{\dot{Q}_{C}}{\dot{Q}_{B}}=\frac{\dot{Q}_{B}-\dot{W}_{T}}{\dot{Q}_{B}}=1-\frac{\dot{W}_{T}}{\dot{Q}_{B}}=1-\frac{1283}{2862}=0.552
$$

8.8 A power plant operates on a reheat-regenerative cycle in which steam at $1000^{\circ} \mathrm{F}$ and 2000 psia enters the turbine. It is reheated at a pressure of 400 psia to $800^{\circ} \mathrm{F}$ and has two open feedwater heaters, one using extracted steam at 400 psia and the other using extracted steam at 80 psia. Determine the thermal efficiency if the condenser operates at 2 psia .

Refer to the T-s diagram of Fig. 8-11 to identify the various states. The pump power requirements are negligible. From the steam tables the enthalpies are

$$
\begin{array}{lll}
h_{2} \cong h_{1}=94 \mathrm{Btu} / \mathrm{lbm} & h_{3}=282 \mathrm{Btu} / \mathrm{lbm} & h_{5}=424 \mathrm{Btu} / \mathrm{lbm} \\
h_{6}=1474 \mathrm{Btu} / \mathrm{lbm} & h_{8}=1417 \mathrm{Btu} / \mathrm{lbm} &
\end{array}
$$

The enthalpies of state 7,9 , and 10 are found assuming isentropic processes as follows:

$$
\left.\begin{array}{rl}
s_{7}= & s_{6}=1.560 \mathrm{Btu} / \mathrm{lbm}-{ }^{\circ} \mathrm{R} \\
P_{7} & =400 \mathrm{psia}
\end{array}\right\} \quad \therefore h_{7}=1277 \mathrm{Btu} / \mathrm{lbm}
$$

Using an energy balance on each heater [see (8.8)], we find, assuming $\dot{m}_{5}=1 \mathrm{lbm} / \mathrm{sec}$,

$$
\begin{aligned}
& \dot{m}_{7}=\frac{h_{5}-h_{3}}{h_{7}-h_{3}}(1)=\frac{424-282}{1277-282}=0.1427 \mathrm{lbm} / \mathrm{sec} \\
& \dot{m}_{9}=\frac{h_{3}-h_{2}}{h_{9}-h_{2}}\left(1-\dot{m}_{7}\right)=\left(\frac{282-94}{1235-94}\right)(1-0.1427)=0.1413 \mathrm{lbm} / \mathrm{sec}
\end{aligned}
$$

A mass balance gives $\dot{m}_{2}=1-\dot{m}_{7}-\dot{m}_{9}=1-0.1427-0.1413=0.716 \mathrm{lbm} / \mathrm{sec}$; now

$$
\begin{aligned}
\dot{Q}_{B} & =(1)\left(h_{6}-h_{5}\right)+\left(1-\dot{m}_{7}\right)\left(h_{8}-h_{7}\right)=1474-424+(1-0.1427)(1417-1277)=1170 \mathrm{Btu} / \mathrm{sec} \\
\dot{W}_{T} & =(1)\left(h_{6}-h_{7}\right)+\left(1-\dot{m}_{7}\right)\left(h_{8}-h_{9}\right)+\dot{m}_{2}\left(h_{9}-h_{10}\right) \\
& =1474-1277+(1-0.1427)(1417-1235)+(0.716)(1235-978)=537 \mathrm{Btu} / \mathrm{sec} \\
\eta & =\frac{\dot{W}_{T}}{\dot{Q}_{B}}=\frac{537}{1170}=0.459 \text { or } 45.9 \%
\end{aligned}
$$

8.9 The turbine of Prob. 8.2 is 87 percent efficient. Determine the mass flow rate and the cycle efficiency with $\dot{W}_{T}=20 \mathrm{MW}$.

Referring to Fig. 8-16 and using the steam tables; we find the following enthalpies:

$$
\begin{aligned}
h_{3} & =3422 \mathrm{~kJ} / \mathrm{kg} \quad h_{2} \cong h_{1}=192 \mathrm{~kJ} / \mathrm{kg} \quad s_{4^{\prime}}=s_{3}=6.881=0.649+7.502 x_{4^{\prime}} \\
\therefore x_{4^{\prime}} & =0.8307 \quad \therefore h_{4^{\prime}}=192+(0.8307)(2393)=2180 \mathrm{~kJ} / \mathrm{kg}
\end{aligned}
$$

The calculation is completed as follows:

$$
\begin{aligned}
w_{s} & =h_{3}-h_{4^{\prime}}=3422-2180=1242 \mathrm{~kJ} / \mathrm{kg} \\
w_{a} & =\eta_{T} w_{s}=(0.87)(1242)=1081 \mathrm{~kJ} / \mathrm{kg} \\
\dot{m} & =\frac{\dot{W}_{T}}{w_{a}}=\frac{20000}{1081}=18.5 \mathrm{~kg} / \mathrm{s} \\
\eta & =\frac{\dot{W}_{T}}{\dot{Q}_{B}}=\frac{\dot{W}_{T}}{\dot{m}\left(h_{3}-h_{2}\right)}=\frac{20000}{(18.5)(3422-192)}=0.317 \quad \text { or } 31.7 \%
\end{aligned}
$$

8.10 The turbine of a Rankine cycle operating between 4 MPa and 10 kPa is 84 percent efficient. If the steam is reheated at 400 kPa to $400^{\circ} \mathrm{C}$, determine the cycle efficiency. The maximum temperature is $600^{\circ} \mathrm{C}$. Also, calculate the mass flux of condenser cooling water if it increases $10^{\circ} \mathrm{C}$ as it passes through the condenser when the cycle mass flux of steam is $10 \mathrm{~kg} / \mathrm{s}$.

Referring to Figs. 8-6 and 8-16 and using the steam tables, we find the following enthalpies:

$$
\begin{aligned}
h_{2} \cong & h_{1}=192 \mathrm{~kJ} / \mathrm{kg} \quad h_{3}=3674 \mathrm{~kJ} / \mathrm{kg} \quad h_{5}=3273 \mathrm{~kJ} / \mathrm{kg} \\
s_{4^{\prime}}= & s_{3}=7.369 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K} \\
& P_{4}=400 \mathrm{kPa} \quad \therefore h_{4^{\prime}}=2960 \mathrm{~kJ} / \mathrm{kg} \\
s_{6^{\prime}}= & s_{5}=7.899=0.649+7.501 x_{6^{\prime}} \quad \therefore x_{6^{\prime}}=0.9665 \\
\therefore h_{6^{\prime}}= & 192+(0.9665)(2393)=2505 \mathrm{~kJ} / \mathrm{kg}
\end{aligned}
$$

We find the actual work from the turbine to be

$$
w_{T}=\eta_{T}\left(h_{3}-h_{4^{\prime}}\right)+\eta_{T}\left(h_{5}-h_{6^{\prime}}\right)=(0.84)(3674-2960)+(0.84)(3273-2505)=1247 \mathrm{~kJ} / \mathrm{kg}
$$

To find the boiler heat requirement, we must calculate the actual $h_{4}$ :

$$
\eta_{T}=\frac{w_{a}}{w_{s}}=\frac{h_{3}-h_{4}}{h_{3}-h_{4^{\prime}}} \quad 0.84=\frac{3674-h_{4}}{3674-2960} \quad h_{4}=3074 \mathrm{~kJ} / \mathrm{kg}
$$

Then

$$
\begin{aligned}
q_{B} & =h_{3}-h_{2}+h_{5}-h_{4}=3674-192+3273-3074=3681 \mathrm{~kJ} / \mathrm{kg} \\
\eta & =\frac{w_{T}}{q_{B}}=\frac{1247}{3681}=0.339 \text { or } 33.9 \%
\end{aligned}
$$

To find the heat rejected by the condenser we must determine the actual $h_{6}$ :

$$
\eta_{T}=\frac{w_{a}}{w_{s}}=\frac{h_{5}-h_{6}}{h_{5}-h_{6^{\prime}}} \quad 0.84=\frac{3273-h_{6}}{3273-2505} \quad h_{6}=2628 \mathrm{~kJ} / \mathrm{kg}
$$

Thus $\dot{Q}_{C}=\dot{m}\left(h_{6}-h_{1}\right)=(10)(2628-192)=24.36 \mathrm{MW}$. Because this heat is carried away by the cooling water,

$$
\dot{Q}_{w}=\dot{m}_{w} c_{p} \Delta T_{w} \quad 24360=\dot{m}_{w}(4.18)(10) \quad \dot{m}_{w}=583 \mathrm{~kg} / \mathrm{s}
$$

8.11 An ideal refrigeration cycle uses ammonia as the working fluid between saturation temperatures of $-40^{\circ} \mathrm{F}$ and $50^{\circ} \mathrm{F}$. If the refrigerant mass flux is $2.0 \mathrm{lbm} / \mathrm{sec}$, determine the rate of refrigeration and the coefficient of performance.

Referring to Fig. 8-17c, we find from Appendix E that

$$
h_{1}=597.6 \mathrm{Btu} / \mathrm{lbm} \quad h_{3}=h_{4}=97.9 \mathrm{Btu} / \mathrm{lbm} \quad s_{1}=1.4242 \mathrm{Btu} / \mathrm{lbm}-{ }^{\circ} \mathrm{R}
$$

Recognizing that the ammonia is compressed isentropically in the ideal cycle, state 2 is located as follows:

$$
\left.\begin{array}{rl}
s_{2}=s_{1} & =1.4242 \mathrm{Btu} / \mathrm{lbm}^{\circ} \mathrm{R} \\
P_{2} & =89.2 \mathrm{psia}
\end{array}\right\} \quad \therefore h_{2}=732 \mathrm{Btu} / \mathrm{lbm}
$$

where $P_{2}$ is the saturation pressure at $50^{\circ} \mathrm{F}$. We can now calculate the desired information:

$$
\begin{aligned}
\dot{Q}_{E} & =\dot{m}\left(h_{1}-h_{4}\right)=(2)(597.6-97.9)=999 \mathrm{Btu} / \mathrm{sec}(300 \text { tons }) \\
\dot{W}_{\text {in }} & =\dot{m}\left(h_{2}-h_{1}\right)=(2)(732-597.6)=269 \mathrm{Btu} / \mathrm{sec} \\
\mathrm{COP} & =\frac{\dot{Q}_{E}}{\dot{W}_{\text {in }}}=\frac{999}{269}=3.71
\end{aligned}
$$

8.12 Freon 12 is compressed from 200 kPa to 1.0 MPa in an 80 percent efficient compressor (Fig. $8-29$ ). The condenser exiting temperature is $40^{\circ} \mathrm{C}$. Calculate the COP and the refrigerant mass flux for 100 tons ( 352 kW ) of refrigeration.

From the Freon 12 table we find that

$$
h_{1}=182.07 \mathrm{~kJ} / \mathrm{kg} \quad h_{3}=h_{4}=74.53 \mathrm{~kJ} / \mathrm{kg} \quad s_{1}=0.7035 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K}
$$

State $2^{\prime}$ is located, assuming an isentropic process, as follows:

$$
\left.\begin{array}{rl}
s_{2^{\prime}}=s_{1} & =0.7035 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K} \\
P_{2} & =1.0 \mathrm{MPa}
\end{array}\right\} \quad \therefore h_{2^{\prime}}=210.6 \mathrm{~kJ} / \mathrm{kg}
$$

The efficiency of the compressor allows us to determine the actual compressor work. It is

$$
w_{a}=\frac{w_{s}}{\eta_{c}}=\frac{h_{2^{\prime}}-h_{1}}{\eta_{c}}=\frac{210.6-182.07}{0.8}=35.7 \mathrm{~kJ} / \mathrm{kg}
$$

The cycle COP is calculated to be

$$
\mathrm{COP}=\frac{h_{1}-h_{4}}{w_{a}}=\frac{182.07-74.53}{35.7}=3.01
$$

The mass flux of refrigerant is found from $\dot{Q}_{E}$ :

$$
\dot{Q}_{E}=\dot{m}\left(h_{1}-h_{4}\right) \quad 352=\dot{m}(182.07-74.53) \quad \dot{m}=3.27 \mathrm{~kg} / \mathrm{s}
$$

Fig. 8-29
8.13 A two-stage refrigeration system operates between high and low pressures of 1.6 MPa and 100 kPa , respectively. If the mass flux of Freon 12 in the low-pressure stage is $0.6 \mathrm{~kg} / \mathrm{s}$, find ( $a$ ) the tons of refrigeration, $(b)$ the coefficient of performance, and (c) the mass flux of cooling water used to cool the Freon 12 in the condenser if $\Delta T_{w}=15^{\circ} \mathrm{C}$.

The intermediate pressure is $P_{i}=\left(P_{H} P_{L}\right)^{1 / 2}=[(1.6)(0.1)]^{1 / 2}=0.4 \mathrm{MPa}$. Referring to Fig. 8-21, the Freon 12 tables provide us with

$$
\begin{array}{llr}
h_{1}=174.15 \mathrm{~kJ} / \mathrm{kg} & h_{5}=190.97 \mathrm{~kJ} / \mathrm{kg} & h_{7}=h_{8}=98.19 \mathrm{~kJ} / \mathrm{kg} \\
h_{3}=h_{4}=43.64 \mathrm{~kJ} / \mathrm{kg} & s_{1}=0.7171 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K} & s_{5}=0.6928 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K}
\end{array}
$$

Assuming the compressors to be isentropic, the enthalpies of states 2 and 6 are found by extrapolation as follows:

$$
\left.\begin{array}{rl}
s_{2}= & s_{1}=0.7171 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K} \\
& P_{2}=0.4 \mathrm{MPa}
\end{array}\right\} \quad h_{2}=198 \mathrm{~kJ} / \mathrm{kg}
$$

The mass flux of the Freon 12 in the high-pressure stage is

$$
\dot{m}_{H}=\dot{m}_{L} \frac{h_{2}-h_{3}}{h_{S}-h_{8}}=(0.6)\left(\frac{198-43.64}{190.97-98.19}\right)=0.998 \mathrm{~kg} / \mathrm{s}
$$

(a) $\dot{Q}_{E}=\dot{m}_{L}\left(h_{1}-h_{4}\right)=(0.6)(174.15-43.64)=78.3 \mathrm{~kW}=22.2$ tons
(b) $\quad \dot{W}_{m}=\dot{m}_{L}\left(h_{2}-h_{1}\right)+\dot{m}_{H}\left(h_{6}-h_{5}\right)=(0.6)(198-174.15)+(0.998)(215-190.97)=38.3 \mathrm{~kW}$ $\mathrm{COP}=\frac{\dot{Q}_{t}}{\dot{W}_{m i}}=\frac{78.3}{38.3}=2.04$
(c) Cooling water is used to cool the Freon 12 in the condenser. As energy balance on the condenser provides

$$
\dot{m}_{w} c_{p} \Delta T_{H}=\dot{m}_{H}\left(h_{b}-h_{7}\right) \quad \dot{m}_{*}=\frac{(0.998)(215-98.19)}{(4.18)(15)}=1.86 \mathrm{~kg} / \mathrm{s}
$$

8.14 A heat pump uses groundwater at $12^{\circ} \mathrm{C}$ as an energy source. If the energy delivered by the heat pump is to be $60 \mathrm{MJ} / \mathrm{h}$, estimate the minimum mass flux of groundwater if the compressor operates with Freon 12 between pressures of 100 kPa and 1.0 MPa . Also, calculate the minimum compressor horsepower.

Referring to Fig. 8-17c, the Freon 12 table provides

$$
h_{1}=174.15 \mathrm{~kJ} / \mathrm{kg} \quad h_{3}=h_{4}=76.26 \mathrm{~kJ} / \mathrm{kg} \quad s_{1}=0.7171 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K}
$$

State 2 is located assuming an isentropic process as follows:

$$
\left.\begin{array}{rl}
s_{2}=s_{1} & =0.7171 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K} \\
P_{2} & =1.0 \mathrm{MPa}
\end{array}\right\} \quad \therefore h_{2}=215 \mathrm{~kJ} / \mathrm{kg}
$$

The condenser delivers $60 \mathrm{MJ} / \mathrm{h}$ of heat; thus,

$$
\dot{Q}_{C}=\dot{m}_{\mathrm{F} 12}\left(h_{2}-h_{3}\right) \quad \frac{60000}{3600}=\dot{m}_{\mathrm{F} 12}(215-76.26) \quad \therefore \dot{m}_{F 12}=0.120 \mathrm{~kg} / \mathrm{s}
$$

The minimum mass flux of groundwater results if the water enters the evaporator at $12^{\circ} \mathrm{C}$ and leaves at $0^{\circ} \mathrm{C}$ (the freezing point of water). Also, we have assumed an ideal cycle, providing us with a minimum mass flux. An energy balance on the evaporator demands that the energy given by the Freon 12 be lost by the groundwater:

$$
\begin{aligned}
\dot{m}_{F 12}\left(h_{1}-h_{4}\right) & =\dot{m}_{\text {water }} c_{p}, \Delta T_{\text {water }} \quad(0.120)(174.15-76.26)=\dot{m}_{\text {water }}(4.18)(12-0) \\
\dot{m}_{\text {water }} & =0.234 \mathrm{~kg} / \mathrm{s}
\end{aligned}
$$

Finally, the minimum compressor power is

$$
\dot{W}_{i n}=\dot{m}_{F 12}\left(h_{2}-h_{1}\right)=(0.120)(215-174.15)=4.90 \mathrm{~kW}=6.57 \mathrm{hp}
$$

## Supplementary Problems

8.15 A power plant operating on an ideal Rankine cycle has steam entering the turbine at $500^{\circ} \mathrm{C}$ and 2 MPa . If the steam enters the pump at 10 kPa , calculate ( $a$ ) the thermal efficiency with pump work included. (b) the thermal efficiency neglecting pump work, and (c) the percentage error in efficiency neglecting pump work. Ans. (a) $33.9 \%$ (b) $34.0 \%$ (c) $0.29 \%$
8.16 An ideal Rankine cycle operates between temperatures of $500^{\circ} \mathrm{C}$ and $60^{\circ} \mathrm{C}$. Determine the cycle efficiency and the quality of the turbine outlet steam if the pump outlet pressure is (a) 2 MPa , (b) 6 MPa , and (c) $10 \mathrm{MPa} . \quad$ Ans. (a) $31.6 \%, 0.932$ (b) $36.4 \%, 0.855 \quad$ (c) $38.5 \%, 0.815$
8.17 The influence of maximum temperature on the efficiency of a Rankine cycle is desired. Holding the maximum and minimum pressures constant at 1000 psia and 2 psia, respectively, what is the thermal efficiency if the boiler outlet steam temperature is $(a) 800^{\circ} \mathrm{F},(b) 1000^{\circ} \mathrm{F}$, and (c) $1200^{\circ} \mathrm{F}$ ?
Ans.
(a) $37.0 \%$
(b) $38.7 \%$
(c) $40.4 \%$
8.18 A power plant is to be operated on an ideal Rankine cycle with the superheated steam exiting the boiler at 4 MPa and $500^{\circ} \mathrm{C}$. Calculate the thermal efficiency and the quality at the turbine outlet if the condenser pressure is (a) $20 \mathrm{kPa},(b) 10 \mathrm{kPa}$, and (c) 8 kPa .
Ans. (a) $34.7 \%, 0.884$
(b) $36.3 \%, 0.865$
(c) $37.5 \%, 0.851$
8.19 A power plant operates on a Rankine cycle between temperatures of $600^{\circ} \mathrm{C}$ and $40^{\circ} \mathrm{C}$. The maximum pressure is 8 MPa and the turbine output is 20 MW . Determine the minimum mass flow rate of cooling water through the condenser if a maximum temperature differential of $10^{\circ} \mathrm{C}$ is allowed.
Ans. $664 \mathrm{~kg} / \mathrm{s}$
8.20 Oil, with a heating value of $30 \mathrm{MJ} / \mathrm{kg}$, is used in the boiler shown schematically in Fig. 8-30. If 85 percent of the energy is transferred to the working fluid, how much oil is needed per hour?
Ans. $13480 \mathrm{~kg} / \mathrm{h}$

Fig. 8-30
8.21 Hot geyser water at $95^{\circ} \mathrm{C}$ is available to supply energy to the boiler of a Rankine cycle power plant. Freon 12 is the working fluid. The maximum possible mass flux of hot water is $2.0 \mathrm{~kg} / \mathrm{s}$. The Freon 12 exits the boiler as saturated vapor at $80^{\circ} \mathrm{C}$, and the condenser temperature is $40^{\circ} \mathrm{C}$. Calculate ( $a$ ) pump work rate, ( $b$ ) the thermal efficiency, and (c) the maximum possible power output. Assume that the hot water can equal the Freon 12 temperature as it leaves the boiler.
$\begin{array}{lll}\text { Ans. (a) } 1.07 \mathrm{~kW} & \text { (b) } 9.8 \% & \text { (c) } 13.2 \mathrm{~kW}\end{array}$
8.22 Coal, with a heating value of $2500 \mathrm{Btu} / \mathrm{lbm}$, is used to provide energy to the working fluid in a boiler which is 85 percent efficient. Determine the minimum mass flux of coal, in $\mathrm{lbm} / \mathrm{hr}$, that would be necessary for the turbine output to be 100 MW . The pump reccives water at 2 psia , in the simple Rankine cycle, and delivers it to the boiler at 2000 psia. Superheated steam is to leave the boiler at $1000^{\circ} \mathrm{F}$. Ans. $217,000 \mathrm{lbm} / \mathrm{hr}$

Fig. 8-31
8.23 For the ideal reheat cycle shown in Fig. 8-31, calculate the thermal efficiency and the pump mass flux. Ans. $38.4 \%, 44.9 \mathrm{~kg} / \mathrm{s}$
8.24 The steam passing through the turbine of the power cycle of Prob. 8.15 is reheated at 100 kPa to $400{ }^{\circ} \mathrm{C}$. Find the thermal efficiency. Ans. $34.2 \%$
8.25 The steam passing through the turbine of Prob. 8.16 b is reheated to $300^{\circ} \mathrm{C}$ at an extraction pressure of (a) $100 \mathrm{kPa},(b) 400 \mathrm{kPa}$ and ( $c$ ) 600 kPa . Calculate the thermal efficiency.
Ans. (a) $34.1 \%$
(b) $36.0 \%$
(c) $36.3 \%$
8.26 The power cycle of Prob. $8.17 b$ is proposed for reheat. Calculate the thermal efficiency if the steam is reheated to $1000^{\circ} \mathrm{F}$ after being extracted at a pressure of (a) 400 psia , (b) 200 psia and (c) 100 psia . Ans. (a) $40.2 \%, \quad$ (b) $40.6 \% \quad$ (c) $40.4 \%$
8.27 The steam passing through the turbine of Problem 8.20 is reheated at 600 kPa to $400^{\circ} \mathrm{C}$ and at 50 kPa to $400^{\circ} \mathrm{C}$. ( $a$ ) What is the resulting thermal efficiency? ( $b$ ) Calculate the oil needed per hour for the same power output of the turbine of Problem 8.20.
$\begin{array}{ll}\text { Ans. (a) } 40.3 \% & \text { (b) } 14000 \mathrm{~kg} / \mathrm{h}\end{array}$
8.28 For the ideal reheat cycle shown in Fig. 8-32, find ( $a$ ) the thermal efficiency and ( $b$ ) the mass flux of steam. Ans. (a) $42.0 \% \quad$ (b) $27.3 \mathrm{~kg} / \mathrm{s}$

Fig. 8-32
8.29 An open feedwater heater is to be designed for the power cycle of Prob. 8.15 by extracting steam from the turbine at 400 kPa . Determine the thermal efficiency of the ideal regenerative cycle.
Ans. $35.6 \%$
8.30 A portion of the steam passing through the turbine of Prob. 8.16 b is extracted and fed into an open feedwater heater. Calculate the thermal efficiency if it is extracted at a pressure of (a) 600 kPa , $\begin{array}{lllll}\text { (b) } 800 \mathrm{kPa} \text {, and (c) } 1000 \mathrm{kPa} \text {. Ans. (a) } 38.7 \% & \text { (b) } 38.8 \% & \text { (c) } 38.7 \%\end{array}$
8.31 An open feedwater heater extracts steam from the turbine of Prob. $8.17(b)$ at 100 psia. Determine the thermal efficiency if the superheated steam enters the turbine at (a) $700^{\circ} \mathrm{F}$, (b) $800^{\circ} \mathrm{F}$, and (c) $1000^{\circ} \mathrm{F}$. $\begin{array}{llll}\text { Ans. (a) } 38.9 \% & \text { (b) } 39.6 \% & \text { (c) } 41.2 \%\end{array}$
8.32 A closed feedwater heater extracts steam from the turbine of Prob. $8.16 b$ at 800 kPa . What is the thermal efficiency of the resulting ideal regenerative cycle? Ans. $38.8 \%$
8.33 Part of the steam passing through the turbine of Prob. 8.20 is extracted at 1000 kPa and fed into a closed feedwater heater. Calculate ( $a$ ) the thermal efficiency and ( $b$ ) the mass flux of oil for the same power output. Ans. (a) $44.8 \% \quad$ (b) $12600 \mathrm{~kg} / \mathrm{h}$
8.34 To avoid a moisture problem in the turbine of Prob. 8.19 the steam is extracted at 600 kPa and reheated to $400^{\circ} \mathrm{C}$, and an open feedwater heater, using extracted steam at the same pressure, is inserted into the cycle. What is the resulting thermal efficiency and the mass flux of water flowing through the feedwater pump? Ans. $44.7 \%, 13.59 \mathrm{~kg} / \mathrm{s}$
8.35 For the ideal reheat-regenerative cycle shown in Fig. 8-33 calculate ( $a$ ) the thermal efficiency, (b) the mass flux of water fed to the boiler, and (c) the mass flux of condenser cooling water.
Ans. (a) $47.2 \%$
(b) $67.8 \mathrm{~kg} / \mathrm{s}$
(c) $2680 \mathrm{~kg} / \mathrm{s}$

Fig. 8-33
8.36 A power plant is to operate on a supercritical steam cycle with reheat and regeneration. The steam leaves the boiler at 4000 psia and $1000^{\circ} \mathrm{F}$. It is extracted from the turbine at 400 psia ; part enters an open feedwater heater and the remainder is reheated to $800^{\circ} \mathrm{F}$. The condenser pressure is 2 psia. Assuming an ideal cycle, calculate the thermal efficiency. Ans. $46.6 \%$
8.37 For the steam power cycle, operating as shown in the T-s diagram of Fig. 8-34 two open feedwater heaters are employed. Calculate the thermal efficiency. Ans. 50.5\%

Fig. 8-34
8.38 Determine the cycle thermal efficiency if the turbine is 85 percent efficient in (a) Prob. 8.15, (b) Prob. 8.16a, (c) Prob. 8.17(b), and (d) Prob. 8.19.
Ans. (a) $28.8 \%$
(b) $26.9 \%$
(c) $32.9 \%$
(d) $35.6 \%$
8.39 If the turbine of Prob. 8.20 is 80 percent efficient, determine the mass flux of oil needed to maintain the same power output. Ans. $16850 \mathrm{~kg} / \mathrm{h}$
8.40 Assume a turbine efficiency of 85 percent for Prob. 8.21 and calculate the thermal efficiency and the expected power output. Ans. $8.2 \%, 11.2 \mathrm{~W}$
8.41 For the simple Rankine cycle shown in Fig. 8-35 the turbine efficiency is 85 percent. Determine ( $a$ ) the thermal efficiency, ( $b$ ) the mass flux of steam, ( $c$ ) the diameter of the inlet pipe to the turbine if a maximum velocity of $100 \mathrm{~m} / \mathrm{s}$ is allowed, and ( $d$ ) the mass flux of condenser cooling water.
Ans. (a) $38.4 \%$
(b) $29.6 \mathrm{~kg} / \mathrm{s}$
(c) 16.1 cm
(d) $1480 \mathrm{~kg} / \mathrm{s}$

Fig. 8-35
8.42 The actual turbine of Prob. 8.23 has an efficiency of 85 percent in the high-pressure side of the turbine and $80 \%$ in the low-pressure side. Calculate the cycle thermal efficiency and the pump mass flux for the same power output. Ans. $34.0 \%, 54.6 \mathrm{~kg} / \mathrm{s}$
8.43 Calculate the cycle thermal efficiency if the turbine is 85 percent efficient for the cycle of Prob. 8.28.

Ans. $35.7 \%$
8.44 Calculate the cycle thermal efficiency if the turbine is 87 percent for the cycle of (a) Prob. 8.29, (b) Prob. $8.31 b$ and (c) Prob. 8.32. Ans. (a) $31.0 \% ~(b) 34.5 \% ~(c) ~ 33.8 \% ~$
8.45 Determine the thermal efficiency for the cycle shown in Fig. $8-36$ if the turbine is 85 percent efficient. Ans. $29.0 \%$

Fig. 8-36
8.46 If the turbine of Prob. 8.36 is 85 percent efficient, what is the thermal efficiency of the cycle?

Ans. $40.9 \%$
8.47 An ideal vapor refrigeration cycle utilizes Freon 12 as the working fluid between saturation temperatures of $-30^{\circ} \mathrm{C}$ and $40^{\circ} \mathrm{C}$. For a flow of $0.6 \mathrm{~kg} / \mathrm{s}$, determine ( $a$ ) the rate of refrigeration, $(b)$ the coefficient of performance, and (c) the coefficient of performance if used as a heat pump.
Ans.
(a) 59.8 kW
(b) 2.50
(c) 3.50
8.48 Freon 12 is used in an ideal refrigeration cycle between pressures of 120 and 1000 kPa . If the compressor requires 10 hp , calculate ( $a$ ) the rate of refrigeration, $(b)$ the coefficient of performance, and (c) the $\begin{array}{llllll}\text { coefficient of performance if used as a heat pump. Ans. (a) } 19.8 \mathrm{~kW} & \text { (b) } 2.65 & \text { (c) } 3.65\end{array}$
8.49 An ideal refrigeration cycle using Freon 12 produces 10 tons of refrigeration. If it operates between saturation temperatures of $-10^{\circ} \mathrm{F}$ and $120^{\circ} \mathrm{F}$, determine ( $a$ ) the COP ( $b$ ) the power input needed for the compressor, and (c) the volume rate of flow into the compressor.
Ans. (a) 2.39
(b) 19.7 hp
(c) $1.64 \mathrm{ft}^{3} / \mathrm{sec}$
8.50 Use ammonia as the working fluid and rework Prob. 8.49.

Ans. $2.54,18.5 \mathrm{hp}, 0.892 \mathrm{ft}^{3} / \mathrm{sec}$
8.51 For 20 tons of refrigeration calculate the minimum work input to the compressor for the cycle shown in Fig. 8-37 if the working fluid is (a) Freon $12,(b)$ ammonia, and (c) water.
Ans. (a) 31.6 kW
(b) 22.9 kW
(c) 19.4 kW

Fig. 8-37
8.52 The turbine shown in Fig. 8-38 produces just enough power to operate the compressor. The Freon 12 is mixed in the condenser and is then separated into mass fluxes $\dot{m}_{p}$ and $\dot{m}_{r}$. Determine $\dot{m}_{p} / \dot{m}_{r}$ and $\dot{Q}_{B} / \dot{Q}_{E} . \quad$ Ans. 1.51, 2.49

Fig. 8-38
8.53 Assume that the refrigerant leaving the condenser of Prob. 8.47 is subcooled to $35^{\circ} \mathrm{C}$. Calculate the coefficient of performance. Ans. 2.62
8.54 The compressor of a refrigeration cycle accepts Freon 12 as saturated vapor at 200 kPa and compresses it to 1200 kPa ; it is 80 percent efficient. The Freon 12 leaves the condenser at $40^{\circ} \mathrm{C}$. Determine ( $a$ ) the COP and (b) the mass flux of Freon 12 for 10 tons of refrigeration. Ans. (a) 2.70 (b) $0.327 \mathrm{~kg} / \mathrm{s}$
8.55 Freon 12 enters a compressor at 15 psia and $0^{\circ} \mathrm{F}$ and leaves at 180 psia and $200^{\circ} \mathrm{F}$. If it exits the condenser as saturated liquid and the system produces 12 tons of refrigeration, calculate ( $a$ ) the COP, (b) the mass flux of refrigerant, ( $c$ ) the power input to the compressor, ( $d$ ) the compressor efficiency, and ( $e$ ) the volume rate of flow entering the compressor.
Ans. (a) 1.62
(b) $0.976 \mathrm{lbm} / \mathrm{sec}$
(c) 35.1 hp
(d) $79.5 \%$
(e) $2.56 \mathrm{ft}^{3} / \mathrm{sec}$
8.56 A refrigeration cycle circulates $0.2 \mathrm{~kg} / \mathrm{s}$ of Freon 12 . Saturated vapor enters the compressor at 140 kPa and leaves at 1200 kPa and $80^{\circ} \mathrm{C}$. The temperature at the condenser exit is $45^{\circ} \mathrm{C}$. Determine ( $a$ ) the COP, ( $b$ ) the tons of refrigeration, ( $c$ ) the required power input, ( $d$ ) the efficiency of the compressor, and ( $e$ ) the mass flux of condenser cooling water if a temperature rise of $10^{\circ} \mathrm{C}$ is allowed.
Ans. (a) 1.87
(b) 5.58 tons
(c) 10.5 kW
(d) $73 \%$
(e) $0.721 \mathrm{~kg} / \mathrm{s}$
8.57 A refrigeration cycle utilizes a compressor which is 80 percent efficient; it accepts Freon 12 as saturated vapor at $-25^{\circ} \mathrm{C}$. The liquid leaving the condenser is at 800 kPa and $30^{\circ} \mathrm{C}$. For a mass flux of $0.1 \mathrm{~kg} / \mathrm{s}$ calculate ( $a$ ) the COP, ( $b$ ) the tons of refrigeration, and ( $c$ ) the mass flux of condenser cooling water for a temperature rise of $10^{\circ} \mathrm{C}$

Ans. (a) 2.73
(b) 3.18 tons
(c) $0.366 \mathrm{~kg} / \mathrm{s}$
8.58 The refrigeration cycle of Prob. 8.48 is replaced with an ideal two-stage cycle with an intermediate pressure of 320 kPa . If 10 tons of refrigeration is produced, calculate the mass fluxes in both loops and the COP. Ans. $0.253 \mathrm{~kg} / \mathrm{s}, 0.362 \mathrm{~kg} / \mathrm{s}, 2.79$
8.59 An ideal two-stage with an intermediate temperature of $50^{\circ} \mathrm{F}$ replaces the refrigeration cycle of Prob. 8.49. Determine the COP and the necessary power input. Ans. $2.83,16.7 \mathrm{hp}$
(a) For a 20 -ton refrigeration cycle like that shown in Fig. 8-39, operating with Freon 12 between pressures of 1000 and 160 kPa , determine the maximum coefficient of performance and the minimum power input. (b) Determine the maximum COP and the minimum power input for a single-stage system operating between the same pressures.

Ans. (a) $3.65,19.3 \mathrm{~kW}$;
(b) $3.26,22.3 \mathrm{~kW}$

Fig. 8-39
8.61 A two-stage refrigeration system using Freon 12 operates between pressures of 1.0 MPa and 90 kPa with a mass flux of $0.5 \mathrm{~kg} / \mathrm{s}$ in the high-pressure stage. Assuming ideal cycles, calculate (a) the tons of refrigeration, ( $b$ ) the power input, ( $c$ ) the rating in compressor horsepower per ton of refrigeration, and (d) the mass flux of condenser cooling water if a $20^{\circ} \mathrm{C}$ temperature rise is allowed.
Ans. (a) 13.7 tons
(b) 18.0 kW
(c) $1.76 \mathrm{hp} / \mathrm{ton}$
(d) $0.791 \mathrm{~kg} / \mathrm{s}$
8.62 A heat pump using Freon 12 as the refrigerant provides $80 \mathrm{MJ} / \mathrm{h}$ to a building. The cycle operates between pressures of 1000 and 200 kPa . Assuming an ideal cycle, determine ( $a$ ) the COP, (b) the compressor horsepower, and (c) the volume flow rate into the compressor.
Ans.
(a) 4.70
(b) 6.20 hp
(c) $0.0138 \mathrm{~m}^{3} / \mathrm{s}$
8.63 A home heating system uses a heat pump with Freon 12 as the refrigerant. The maximum heating load results when the temperature of $1000 \mathrm{ft}^{3} / \mathrm{min}$ of circulation air is raised $45^{\circ} \mathrm{F}$. If the compressor increases the pressure from 30 to 160 psia , calculate ( $a$ ) the COP, ( $b$ ) the compressor power needs, and (c) the mass flux of Freon 12. Assume an ideal cycle.
Ans. (a) 4.24
(b) 4.91 hp
(c) $0.257 \mathrm{lbm} / \mathrm{sec}$

# Power and Refrigeration Gas Cycles 

### 9.1 INTRODUCTION

Several cycles utilize a gas as the working substance, the most common being the Otto cycle and the diesel cycle used in internal combustion engines. The word "cycle" used in reference to an internal combustion engine is technically incorrect since the working fluid does not undergo a thermodynamic cycle; air enters the engine, mixes with a fuel, undergoes combustion, and exits the engine as exhaust gases. This is often referred to as an open cycle, but we should keep in mind that a thermodynamic cycle does not really occur; the engine itself operates in what we could call a mechanical cycle. We do, however, analyze an internal combustion engine as though the working fluid operated on a cycle; it is an approximation that allows us to predict influences of engine design on such quantities as efficiency and fuel consumption.

### 9.2 GAS COMPRESSORS

We have already utilized the gas compressor in the refrigeration cycles discussed earlier and have noted that the control volume energy equation relates the power input to the enthalpy change as follows:

$$
\begin{equation*}
\dot{W}_{\text {comp }}=\dot{m}\left(h_{e}-h_{i}\right) \tag{9.1}
\end{equation*}
$$

where $h_{e}$ and $h_{i}$ are the exit and inlet enthalpies, respectively. In this form we model the compressor as a fixed volume into which and from which a gas flows; we assume that negligible heat transfer occurs from the compressor and ignore the difference between inlet and outlet kinetic and potential energy changes.

There are three general types of compressors: reciprocating, centrifugal, and axial-flow. Reciprocating compressors are especially useful for producing high pressures, but are limited to relatively low flow rates; upper limits of about 200 MPa with inlet flow rates of $160 \mathrm{~m}^{3} / \mathrm{min}$ are achievable with a two-stage unit. For high flow rates with relatively low pressure rise, a centrifugal or axial-flow compressor would be selected; a pressure rise of several MPa for an inlet flow rate of over 10000 $\mathrm{m}^{3} / \mathrm{min}$ is possible.

## The Reciprocating Compressor

A sketch of the cylinder of a reciprocating compressor is shown in Fig. 9-1. The intake and exhaust valves are closed when state 1 is reached, as shown on the $P-v$ diagram of Fig. 9-2a. An isentropic compression follows as the piston travels inward until the maximum pressure at state 2 is reached. The exhaust valve then opens and the piston continues its inward motion while the air is exhausted until state 3 is reached at top dead center. The exhaust valve then closes and the piston begins its outward motion with an isentropic expansion process until state 4 is reached. At this point the intake value opens and the piston moves outward during the intake process until the cycle is completed.

During actual operation the $P-v$ diagram would more likely resemble that of Fig. 9-2b. Intake and exhaust valves do not open and close instantaneously, the airflow around the valves results in pressure gradients during the intake and exhaust strokes, losses occur due to the valves, and some heat transfer may take place. The ideal cycle does, however, allow us to predict the influence of proposed design changes on work requirements, maximum pressure, flow rate, and other quantities of interest.

The effectiveness of a compressor is partially measured by the volumetric efficiency, which is defined as the volume of gas drawn into the cylinder divided by the displacement volume. That is,

Fig. 9-1

(a) The ideal cycle

(b) The actual cycle

Fig. 9-2
referring to Fig. 9-2,

$$
\begin{equation*}
\eta_{\mathrm{vol}}=\frac{V_{1}-V_{4}}{V_{1}-V_{3}} \tag{9.2}
\end{equation*}
$$

The higher the volumetric efficiency the greater the volume of air drawn in as a percentage of the displacement volume. This can be increased if the clearance volume $V_{3}$ is decreased.

To improve the performance of the reciprocating compressor, we can remove heat from the compressor during the compression process $1 \rightarrow 2$. The effect of this is displayed in Fig. 9-3, where a polytropic process is shown. The temperature of state $2^{\prime}$ would be significantly lower than that of state

Fig. 9-3

2 and the work requirement for the complete cycle would be less since the area under the $P-v$ diagram would decrease. To analyze this situation let us return to the control volume inlet-outlet description, as used with (9.1). The required work is, for an adiabatic compressor,

$$
\begin{equation*}
w_{\text {comp }}=h_{2}-h_{1}=c_{p}\left(T_{2}-T_{1}\right) \tag{9.3}
\end{equation*}
$$

assuming an ideal gas with constant specific heat. For an isentropic compression between inlet and outlet we know that

$$
\begin{equation*}
T_{2}=T_{1}\left(\frac{P_{2}}{P_{1}}\right)^{(k-1) / k} \tag{9.4}
\end{equation*}
$$

This allows the work to be expressed as, using $c_{p}$ given in (4.30),

$$
\begin{equation*}
w_{\text {comp }}=\frac{k R}{k-1} T_{1}\left[\left(\frac{P_{2}}{P_{1}}\right)^{(k-1) / k}-1\right] \tag{9.5}
\end{equation*}
$$

For a polytropic process we simply replace $k$ with $n$ and obtain

$$
\begin{equation*}
w_{\text {comp }}=\frac{n R}{n-1} T_{1}\left[\left(\frac{P_{2}}{P_{1}}\right)^{(n-1) / n}-1\right] \tag{9.6}
\end{equation*}
$$

The heat transfer is then found from the first law.
By external cooling, with a water jacket surrounding the compressor, the value of $n$ for air can be reduced to about 1.35 . This reduction from 1.4 is difficult since heat transfer must occur from the rapidly moving air through the compressor casing to the cooling water, or from fins. This is an ineffective process, and multistage compressors with interstage cooling are often a desirable alternative. With a single stage and with a high $P_{2}$ the outlet temperature $T_{2}$ would be too high even if $n$ could be reduced to, say, 1.3.

Consider a two-stage compressor with a single intercooler, as shown in Fig. 9-4a. The compression processes are assumed to be isentropic and are shown in the $T-s$ and $P-v$ diagrams of Fig. 9-4b.

(b)

Fig. 9-4

Referring to (9.5), the work is written as

$$
\begin{equation*}
w_{\mathrm{comp}}=c_{p} T_{1}\left[\left(\frac{P_{2}}{P_{1}}\right)^{(k-1) / k}-1\right]+c_{p} T_{3}\left[\left(\frac{P_{4}}{P_{3}}\right)^{(k-1) / k}-1\right]=c_{p} T_{1}\left[\left(\frac{P_{2}}{P_{1}}\right)^{(k-1) / k}+\left(\frac{P_{4}}{P_{2}}\right)^{(k-1) / k}-2\right] \tag{9.7}
\end{equation*}
$$

where we have used $P_{2}=P_{3}$ and $T_{1}=T_{3}$, for an ideal intercooler. To determine the intercooler pressure $P_{2}$ that minimizes the work, we let $\partial w_{\text {comp }} / \partial P_{2}=0$. This gives

$$
\begin{equation*}
P_{2}=\left(P_{1} P_{4}\right)^{1 / 2} \quad \text { or } \quad \frac{P_{2}}{P_{1}}=\frac{P_{4}}{P_{3}} \tag{9.8}
\end{equation*}
$$

That is, the pressure ratio is the same across each stage. If three stages were used, the same analysis would lead to a low-pressure intercooler pressure of

$$
\begin{equation*}
P_{2}=\left(P_{1}^{2} P_{6}\right)^{1 / 3} \tag{9.9}
\end{equation*}
$$

and a high-pressure intercooler pressure of

$$
\begin{equation*}
P_{4}=\left(P_{1} P_{6}^{2}\right)^{1 / 3} \tag{9.10}
\end{equation*}
$$

where $P_{6}$ is the highest pressure. This is also equivalent to equal pressure ratios across each stage. Additional stages may be necessary for extremely high outlet pressures; an equal pressure ratio across each stage would yield the minimum work for the ideal compressor.

## Centrifugal and Axial-Flow Compressors

A centrifugal compressor is sketched in Fig. 9-5. Air enters along the axis of the compressor and is forced to move outward along the rotating impeller vanes due to the effects of centrifugal forces. This results in an increased pressure from the axis to the edge of the rotating impeller. The diffuser section results in a further increase in the pressure as the velocity is reduced due to the increasing area in each subsection of the diffuser. Depending on the desired pressure-speed characteristics, the rotating impeller can be fitted with radial impeller vanes, as shown; with backward-curved vanes; or with forward-curved vanes.

Fig. 9-5

Fig. 9-6

An axial-flow compressor is illustrated in Fig. 9-6. It is similar in appearance to the steam turbine used in the Rankine power cycle. Several stages of blades are needed to provide the desired pressure rise, with a relatively small rise occurring over each stage. Each stage has a stator, a series of blades that are attached to the stationary housing, and a rotor. All the rotors are attached to a common rotating shaft which utilizes the power input to the compressor. The specially designed airfoil-type blades require extreme precision in manufacturing and installation to yield the maximum possible pressure rise while avoiding flow separation. The area through which the air passes decreases slightly as the pressure rises due to the increased density in the higher-pressure air. In fluid mechanics the velocity and pressure at each stage can be analyzed; in thermodynamics we are concerned only with inlet and outlet conditions.

EXAMPLE 9.1 A reciprocating compressor is to deliver $20 \mathrm{~kg} / \mathrm{min}$ of air at 1600 kPa . It receives atmospheric air at $20^{\circ} \mathrm{C}$. Calculate the required power if the compressor is assumed to be 90 percent efficient. No cooling is assumed.

The efficiency of the compressor is defined as

$$
\eta=\frac{\text { isentropic work }}{\text { actual work }}=\frac{h_{2^{\prime}}-h_{1}}{h_{2}-h_{1}}
$$

where state 2 identifies the actual state reached and state $2^{\prime}$ is the ideal state that could be reached with no losses. Let us find the temperature $T_{2^{\prime}}$ first. It is

$$
T_{2^{\prime}}=T_{1}\left(\frac{P_{2}}{P_{1}}\right)^{(k-1) / k}=(293)\left(\frac{1600}{100}\right)^{(1.4-1) / 1.4}=647 \mathrm{~K}
$$

Using the efficiency, we have

$$
\eta=\frac{c_{p}\left(T_{2^{\prime}}-T_{1}\right)}{c_{p}\left(T_{2}-T_{1}\right)} \quad \text { or } \quad T_{2}=T_{1}+\frac{1}{\eta}\left(T_{2^{\prime}}-T_{1}\right)=293+\left(\frac{1}{0.9}\right)(647-293)=686 \mathrm{~K}
$$

The power required to drive the adiabatic compressor (no cooling) is then

$$
\dot{W}_{\mathrm{comp}}=\dot{m}\left(h_{2}-h_{1}\right)=\dot{m} c_{p}\left(T_{2}-T_{1}\right)=\left(\frac{20}{60}\right)(1.006)(686-293)=131.9 \mathrm{~kW}
$$

EXAMPLE 9.2 Suppose that, for the compressor of Example 9.1, it is decided that because $T_{2}$ is too high, two stages with an intercooler are necessary. Determine the power requirement for the proposed two-stage adiabatic compressor. Assume 90 percent efficiency for each stage.

The intercooler pressure for minimum power input is given by (9.8) as $P_{2}=\sqrt{P_{1} P_{4}}=\sqrt{(100)(1600)}=400$ kPa . This results in a temperature entering the intercooler of

$$
T_{2^{\prime}}=T_{1}\left(\frac{P_{2}}{P_{1}}\right)^{(1.4-1) / 1.4}=293\left(\frac{400}{100}\right)^{0.2857}=435 \mathrm{~K}
$$

Since $T_{3}=T_{1}$ and $P_{4} / P_{3}=P_{2} / P_{1}$, we also have $T_{4^{\prime}}=(293)(400 / 100)^{0.2857}=435 \mathrm{~K}$. Considering the efficiency of each stage allows us to find

$$
T_{2}=T_{1}+\frac{1}{\eta}\left(T_{2^{\prime}}-T_{1}\right)=293+\left(\frac{1}{0.9}\right)(435-293)=451 \mathrm{~K}
$$

This will also be the exiting temperature $T_{4^{\prime}}$. Note the large reduction from the single-stage temperature of 686 K . Assuming no heat transfer in the compressor stages, the power necessary to drive the compressor is

$$
\dot{W}_{\mathrm{comp}}=\dot{m} c_{p}\left(T_{2}-T_{1}\right)+\dot{m} c_{p}\left(T_{4}-T_{3}\right)=\left(\frac{20}{60}\right) \times(1.00)(451-293)+\left(\frac{20}{60}\right)(1.00)(451-293)=105 \mathrm{~kW}
$$

This is a 20 percent reduction in the power requirement.

### 9.3 THE AIR-STANDARD CYCLE

In this section we introduce engines that utilize a gas as the working fluid. Spark-ignition engines that burn gasoline and compression-ignition (diesel) engines that burn fuel oil are the two most common engines of this type.

The operation of a gas engine can be analyzed by assuming that the working fluid does indeed go through a complete thermodynamic cycle. The cycle is often called an air-standard cycle. All the air-standard cycles we will consider have certain features in common:

Air is the working fluid throughout the entire cycle. The mass of the small quantity of injected fuel is negligible.
There is no inlet process or exhaust process.
The combustion process is replaced by a heat transfer process with energy transferred from an external source.
The exhaust process, used to restore the air to its original state, is replaced with a constant-volume process transferring heat to the surroundings; no work is accomplished with a constant-volume process.
All processes are assumed to be in quasiequilibrium.
The air is assumed to be an ideal gas with constant specific heats.
A number of the engines we will consider make use of a closed system with a piston-cylinder arrangement, as shown in Fig. 9-7. The cycle shown on the $P-v$ and $T-s$ diagrams in the figure is representative. The diameter of the piston is called the bore, and the distance the piston travels in one direction is the stroke. When the piston is at top dead center (TDC), the volume occupied by the air in the cylinder is at a minimum; this volume is the clearance volume. When the piston moves to bottom dead center ( $B D C$ ), the air occupies the maximum volume. The difference between the maximum volume and the clearance volume is the displacement volume. The clearance volume is often implicitly presented as the percent clearance $c$, the ratio of the clearance volume to the displacement volume. The compression ratio $r$ is defined to be the ratio of the volume occupied by the air at BDC to the volume occupied by the air at TDC, that is, referring to Fig. 9-7,

$$
\begin{equation*}
r=\frac{V_{1}}{V_{2}} \tag{9.11}
\end{equation*}
$$

The mean effective pressure (MEP) is another quantity that is often used when rating pistoncylinder engines; it is the pressure that, if acting on the piston during the power stroke, would produce an amount of work equal to that actually done during the entire cycle. Thus,

$$
\begin{equation*}
W_{\mathrm{cycle}}=(\mathrm{MEP})\left(V_{\mathrm{BDC}}-V_{\mathrm{TDC}}\right) \tag{9.12}
\end{equation*}
$$

In Fig. 9-7 this means that the enclosed area of the actual cycle is equal to the area under the MEP dotted line.

Fig. 9-7

EXAMPLE 9.3 An engine operates with air on the cycle shown in Fig. 9-7 with isentropic processes $1 \rightarrow 2$ and $3 \rightarrow 4$. If the compression ratio is 12 , the minimum pressure is 200 kPa , and the maximum pressure is 10 MPa determine ( $a$ ) the percent clearance and ( $b$ ) the MEP.
(a) The percent clearance is given by

$$
c=\frac{V_{2}}{V_{1}-V_{2}}(100)
$$

But the compression ratio is $r=V_{1} / V_{2}=12$. Thus,

$$
c=\frac{V_{2}}{12 V_{2}-V_{2}}(100)=\frac{100}{11}=9.09 \%
$$

(b) To determine the MEP we must calculate the area under the $P-V$ diagram; this is equivalent to calculating the work. The work from $3 \rightarrow 4$ is, using $P V^{k}=C$,

$$
W_{3-4}=\int P d V=C \int \frac{d V}{V^{k}}=\frac{C}{1-k}\left(V_{4}^{1-k}-V_{3}^{1-k}\right)=\frac{P_{4} V_{4}-P_{3} V_{3}}{1-k}
$$

where $C=P_{4} V_{4}^{k}=P_{3} V_{3}^{k}$. But we know that $V_{4} / V_{3}=12$, so

$$
W_{3-4}=\frac{V_{3}}{1-k}\left(12 P_{4}-P_{3}\right)
$$

Likewise, the work from $1 \rightarrow 2$ is

$$
W_{1-2}=\frac{V_{2}}{1-k}\left(P_{2}-12 P_{1}\right)
$$

Since no work occurs in the two constant-volume processes, we find, using $V_{2}=V_{3}$,

$$
W_{\text {cycle }}=\frac{V_{2}}{1-k}\left(12 P_{4}-P_{3}+P_{2}-12 P_{1}\right)
$$

The pressures $P_{2}$ and $P_{4}$ are found as follows:

$$
P_{2}=P_{1}\left(\frac{V_{1}}{V_{2}}\right)^{k}=(200)(12)^{1.4}=1665 \mathrm{kPa} \quad P_{4}=P_{3}\left(\frac{V_{3}}{V_{4}}\right)^{k}=(10000)\left(\frac{1}{12}\right)^{1.4}=308 \mathrm{kPa}
$$

whence

$$
W_{\text {cycle }}=\frac{V_{2}}{-0.4}[(12)(308)-10000+1665-(12)(200)]=20070 V_{2}
$$

But $W_{\text {cycle }}=(\operatorname{MEP})\left(V_{1}-V_{2}\right)=(\operatorname{MEP})\left(12 V_{2}-V_{2}\right)$; equating the two expressions yields

$$
\mathrm{MEP}=\frac{20070}{11}=1824 \mathrm{kPa}
$$

### 9.4 THE CARNOT CYCLE

This ideal cycle was treated in detail in Chapter 5. Recall that the thermal efficiency of a Carnot engine,

$$
\begin{equation*}
\eta_{\mathrm{carnot}}=1-\frac{T_{L}}{T_{H}} \tag{9.13}
\end{equation*}
$$

exceeds that of any real engine operating between the given temperatures.

### 9.5 THE OTTO CYCLE

The four processes that form the cycle are displayed in the $T-s$ and $P-V$ diagrams of Fig. 9-8. The piston starts at state 1 at BDC and compresses the air until it reaches TDC at state 2 . Combustion then occurs, resulting in a sudden jump in pressure to state 3 while the volume remains constant (this

Fig. 9-8
combustion process is simulated with a quasiequilibrium heat addition process). The process that follows is the power stroke as the air (simulating the combustion products) expands isentropically to state 4 . In the final process heat transfer to the surroundings occurs and the cycle is completed.

The thermal efficiency of the Otto cycle is found from

$$
\begin{equation*}
\eta=\frac{\dot{W}_{\text {net }}}{\dot{Q}_{\text {in }}}=\frac{\dot{Q}_{\text {in }}-\dot{Q}_{\text {out }}}{\dot{Q}_{\text {in }}}=1-\frac{\dot{Q}_{\text {out }}}{\dot{Q}_{\text {in }}} \tag{9.14}
\end{equation*}
$$

Noting that the two heat transfer processes occur during constant-volume processes, for which the work is zero, there results

$$
\begin{equation*}
\dot{Q}_{\mathrm{in}}=\dot{m} c_{r}\left(T_{3}-T_{2}\right) \quad \dot{Q}_{\mathrm{out}}=\dot{m} c_{r}\left(T_{4}-T_{1}\right) \tag{9.15}
\end{equation*}
$$

where we have assumed each quantity to be positive. Then

$$
\begin{equation*}
\eta=1-\frac{T_{4}-T_{1}}{T_{3}-T_{2}} \tag{9.16}
\end{equation*}
$$

This can be written as

$$
\begin{equation*}
\eta=1-\frac{T_{1}}{T_{2}} \frac{T_{4} / T_{1}-1}{T_{3} / T_{2}-1} \tag{9.17}
\end{equation*}
$$

For the isentropic processes we have

$$
\begin{equation*}
\frac{T_{2}}{T_{1}}=\left(\frac{V_{1}}{V_{2}}\right)^{k-1} \quad \text { and } \quad \frac{T_{3}}{T_{4}}=\left(\frac{V_{4}}{V_{3}}\right)^{k-1} \tag{9.18}
\end{equation*}
$$

But, using $V_{1}=V_{4}$ and $V_{3}=V_{2}$, we see that

$$
\begin{equation*}
\frac{T_{2}}{T_{1}}=\frac{T_{3}}{T_{4}} \tag{9.19}
\end{equation*}
$$

Thus, (9.17) gives the thermal efficiency as

$$
\begin{equation*}
\eta=1-\frac{T_{1}}{T_{2}}=1-\left(\frac{V_{2}}{V_{1}}\right)^{k-1}=1-\frac{1}{r^{k-1}} \tag{9.20}
\end{equation*}
$$

We see, then, that the thermal efficiency in this idealized cycle is dependent only on the compression ratio $r$ : the higher the compression ratio, the higher the thermal efficiency.

EXAMPLE 9.4 A spark-ignition engine is proposed to have a compression ratio of 10 while operating with a low temperature of $200^{\circ} \mathrm{C}$ and a low pressure of 200 kPa . If the work output is to be $1000 \mathrm{~kJ} / \mathrm{kg}$, calculate the maximum possible thermal efficiency and compare with that of a Carnot cycle. Also calculate the MEP.

The Otto cycle provides the model for this engine. The maximum possible thermal efficiency for the engine would be

$$
\eta=1-\frac{1}{r^{k-1}}=1-\frac{1}{(10)^{0.4}}=0.602 \text { or } 60.2 \%
$$

Since process $1 \rightarrow 2$ is isentropic, we find that

$$
T_{2}=T_{1}\left(\frac{v_{1}}{v_{2}}\right)^{k-1}=(473)(10)^{0.4}=1188 \mathrm{~K}
$$

The net work for the cycle is given by

$$
\begin{aligned}
& w_{\text {net }}=w_{1-2}+\psi_{2-3}^{0}+w_{3-4}+\psi_{4-1}^{0}=c_{1}\left(T_{1}-T_{2}\right)+c_{1}\left(T_{3}-T_{4}\right) \quad \text { or } \\
& 1000=(0.717)\left(473-1188+T_{3}-T_{4}\right)
\end{aligned}
$$

But, for the isentropic process $3 \rightarrow 4$,

$$
T_{3}=T_{4}\left(\frac{v_{4}}{v_{3}}\right)^{k-1}=\left(T_{4}\right)(10)^{0.4}=2.512 T_{4}
$$

Solving the last two equations simultaneously, we find $T_{3}=3508 \mathrm{~K}$ and $T_{4}=1397 \mathrm{~K}$, so that

$$
\eta_{\text {carnot }}=1-\frac{T_{L}}{T_{H}}=1-\frac{473}{3508}=0.865 \text { or } 86.5 \%
$$

The Otto cycle efficiency is less than that of a Carnot cycle operating between the limiting temperatures because the heat transfer processes in the Otto cycle are not isothermal.

The MEP is found by using the equation

$$
\boldsymbol{w}_{\text {net }}=(\mathrm{MEP})\left(v_{1}-v_{2}\right)
$$

We have

$$
v_{1}=\frac{R T_{1}}{P_{1}}=\frac{(0.287)(473)}{200}=0.6788 \mathrm{~m}^{3} / \mathrm{kg} \quad \text { and } \quad v_{2}=\frac{r_{1}}{10}
$$

Thus

$$
\text { MEP }=\frac{w_{\text {net }}}{v_{1}-v_{2}}=\frac{1000}{(0.9)(0.6788)}=1640 \mathrm{kPa}
$$

### 9.6 THE DIESEL CYCLE

If the compression ratio is large enough, the temperature of the air in the cylinder when the piston approaches TDC will exceed the ignition temperature of diesel fuel. This will occur if the compression ratio is about 14 or greater. No external spark is needed; the diesel fuel is simply injected into the cylinder and combustion occurs because of the high temperature of the compressed air. This type of engine is referred to as a compression-ignition engine. The ideal cycle used to model the compression-ignition engine is the diesel cycle, shown in Fig. 9-9. The difference between this cycle and the Otto cycle is that, in the diesel cycle, the heat is added during a constant-pressure process.

Fig. 9-9

The cycle begins with the piston at BDC, state 1 ; compression of the air occurs isentropically to state 2 at TDC; heat addition takes place (this models the injection and combustion of fuel) at constant pressure until state 3 is reached; expansion occurs isentropically to state 4 at BDC; constant volume heat rejection completes the cycle and returns the air to the original state. Note that the power stroke includes the heat addition process and the expansion process.

The thermal efficiency of the diesel cycle is expressed as

$$
\begin{equation*}
\eta=\frac{\dot{W}_{\text {net }}}{\dot{Q}_{\text {in }}}=1-\frac{\dot{Q}_{\text {out }}}{\dot{Q}_{\text {in }}} \tag{9.21}
\end{equation*}
$$

For the constant-volume process and the constant-pressure process

$$
\begin{equation*}
\dot{Q}_{\text {out }}=\dot{m} c_{v}\left(T_{4}-T_{1}\right) \quad \dot{Q}_{\text {in }}=\dot{m} c_{p}\left(T_{3}-T_{2}\right) \tag{9.22}
\end{equation*}
$$

The efficiency is then

$$
\begin{equation*}
\eta=1-\frac{c_{l}\left(T_{4}-T_{1}\right)}{c_{p}\left(T_{3}-T_{2}\right)}=1-\frac{T_{4}-T_{1}}{k\left(T_{3}-T_{2}\right)} \tag{9.23}
\end{equation*}
$$

This can be put in the form

$$
\begin{equation*}
\eta=1-\frac{T_{1}}{k T_{2}} \frac{T_{4} / T_{1}-1}{T_{3} / T_{2}-1} \tag{9.24}
\end{equation*}
$$

This expression for the thermal efficiency is often written in terms of the compression ratio $r$ and the cutoff ratio $r_{c}$ which is defined as $V_{3} / V_{2}$; there results

$$
\begin{equation*}
\eta=1-\frac{1}{r^{k-1}} \frac{r_{c}^{k}-1}{k\left(r_{c}-1\right)} \tag{9.25}
\end{equation*}
$$

From this expression we see that, for a given compression ratio $r$, the efficiency of the diesel cycle is less than that of an Otto cycle. For example, if $r=10$ and $r_{c}=2$, the Otto cycle efficiency is 60.2 percent and the diesel cycle efficiency is 53.4 percent. As $r_{c}$ increases, the diesel cycle efficiency decreases. In practice, however, a compression ratio of 20 or so can be achieved in a diesel engine; using $r=20$ and $r_{c}=2$, we would find $\eta=64.7$ percent. Thus, because of the higher compression ratios, a diesel engine typically operates at a higher efficiency than a gasoline engine.

The decrease in diesel cycle efficiency with an increase in $r_{c}$ can also be observed by considering the T-s diagram shown in Fig. 9-10. If we increase $r_{c}$, the end of the heat input process moves to state $3^{\prime}$. The increased work output is then represented by area $3-3^{\prime}-4^{\prime}-4-3$. The heat input increases considerably, as represented by area $3-3^{\prime}-a-b-3$. The net effect is a decrease in cycle efficiency, caused

Fig. 9-10
obviously by the convergence of the constant-pressure and constant-volume lines on the $T$-s diagram. For the Otto cycle note that two constant-volume lines diverge, thereby giving an increase in cycle efficiency with increasing $T_{3}$.

EXAMPLE 9.5 A diesel cycle, with a compression ratio of 18 operates on air with a low pressure of 200 kPa and a low temperature $200^{\circ} \mathrm{C}$. If the work output is $1000 \mathrm{~kJ} / \mathrm{kg}$, determine the thermal efficiency and the MEP. Also, compare with the efficiency of an Otto cycle operating with the same maximum pressure.

The cutoff ratio $r_{c}$ is found first. We have

$$
v_{1}=\frac{R T_{1}}{P_{1}}=\frac{(0.287)(473)}{200}=0.6788 \mathrm{~m}^{3} / \mathrm{kg} \quad \text { and } \quad v_{2}=v_{1} / 18=0.03771 \mathrm{~m}^{3} / \mathrm{kg}
$$

Since process $1 \rightarrow 2$ is isentropic, we find

$$
T_{2}=T_{1}\left(\frac{v_{1}}{v_{2}}\right)^{k-1}=(473)(18)^{0.4}=1503 \mathrm{~K} \quad \text { and } \quad P_{2}=P_{1}\left(\frac{v_{1}}{v_{2}}\right)^{k}=(200)(18)^{1.4}=11.44 \mathrm{MPa}
$$

The work for the cycle is given by

$$
\begin{aligned}
& w_{\text {net }}=q_{\text {net }}=q_{2-3}+q_{4-1}=c_{p}\left(T_{3}-T_{2}\right)+c_{\nu}\left(T_{1}-T_{4}\right) \\
& 1000=(1.00)\left(T_{3}-1503\right)+(0.717)\left(473-T_{4}\right)
\end{aligned}
$$

For the isentropic process $3 \rightarrow 4$ and the constant-pressure process $2 \rightarrow 3$, we have

$$
T_{4}=T_{3}\left(\frac{v_{3}}{v_{4}}\right)^{k-1}=T_{3}\left(\frac{v_{3}}{0.6788}\right)^{0.4} \quad \frac{T_{3}}{v_{3}}=\frac{T_{2}}{v_{2}}=\frac{1503}{0.03771}=39860
$$

The last three equations can be combined to yield

$$
1000=(1.00)\left(39860 v_{3}-1503\right)+(0.717)\left(473-46540 v_{3}^{1.4}\right)
$$

This equation is solved by trial and error to give

$$
v_{3}=0.0773 \mathrm{~m}^{3} / \mathrm{kg} \quad \therefore T_{3}=3080 \mathrm{~K} \quad T_{4}=1290 \mathrm{~K}
$$

This gives the cutoff ratio as $r_{c}=v_{3} / v_{2}=2.05$. The thermal efficiency is now calculated as

$$
\eta=1-\frac{1}{r^{k-1}} \frac{r_{c}^{k}-1}{k\left(r_{c}-1\right)}=1-\frac{1}{(18)^{0.4}} \frac{(2.05)^{1.4}-1}{(1.4)(2.05-1)}=0.629 \quad \text { or } \quad 62.9 \%
$$

Also, MEP $=w_{\text {net }} /\left(v_{1}-v_{2}\right)=1000 /(0.6788-0.0377)=641 \mathrm{kPa}$.
For the comparison Otto cycle,

$$
r_{\text {otto }}=v_{1} / v_{3}=\frac{0.6788}{0.0773}=8.78 \quad \eta_{\text {otto }}=1-\frac{1}{r^{k-1}}=0.581 \quad \text { or } 58.1 \%
$$

### 9.7. THE DUAL CYCLE

An ideal cycle that better approximates the actual performance of a compression-ignition engine is the dual cycle, in which the combustion process is modeled by two heat-addition processes: a constant-volume process and a constant-pressure process, as shown in Fig. 9-11. The thermal efficiency is found from

$$
\begin{equation*}
\eta=1-\frac{\dot{Q}_{\text {out }}}{\dot{Q}_{\text {in }}} \tag{9.26}
\end{equation*}
$$

Fig. 9-11
where

$$
\begin{equation*}
\dot{Q}_{\mathrm{out}}=\dot{m} c_{l}\left(T_{5}-T_{1}\right) \quad \dot{Q}_{\mathrm{in}}=\dot{m} c_{c}\left(T_{3}-T_{2}\right)+\dot{m} c_{p}\left(T_{4}-T_{3}\right) \tag{9.27}
\end{equation*}
$$

Hence, we have

$$
\begin{equation*}
\eta=1-\frac{T_{5}-T_{1}}{T_{3}-T_{2}+k\left(T_{4}-T_{3}\right)} \tag{9.28}
\end{equation*}
$$

If we define the pressure ratio $r_{p}=P_{3} / P_{2}$, the thermal efficiency can be expressed as

$$
\begin{equation*}
\eta=1-\frac{1}{r^{k-1}} \frac{r_{p} r_{c}^{k}-1}{k r_{p}\left(r_{c}-1\right)+r_{p}-1} \tag{9.29}
\end{equation*}
$$

If we let $r_{p}=1$, the diesel cycle efficiency results; if we let $r_{c}=1$, the Otto cycle efficiency results. If $r_{p}>1$, the thermal efficiency will be less than the Otto cycle efficiency but greater than the diesel cycle efficiency.

EXAMPLE 9.6 A dual cycle, which operates on air with a compression ratio of 16 , has a low pressure of 200 kPa and a low temperature of $200^{\circ} \mathrm{C}$. If the cutoff ratio is 2 and the pressure ratio is 1.3 , calculate the thermal efficiency, the heat input, the work output, and the MEP.

By (9.29),

$$
\eta=1-\frac{1}{(16)^{0.4}} \frac{(1.3)(2)^{1.4}-1}{(1.4)(1.3)(2-1)+1.3-1}=0.622 \text { or } 62.2 \%
$$

The heat input is found from $\boldsymbol{q}_{\text {in }}=c_{t}\left(T_{3}-T_{2}\right)+c_{p}\left(T_{4}-T_{3}\right)$, where

$$
\begin{gathered}
T_{2}=T_{1}\left(\frac{v_{1}}{v_{2}}\right)^{k-1}=(473)(16)^{0.4}=1434 \mathrm{~K} \quad T_{3}=T_{2} \frac{P_{3}}{P_{2}}=(1434)(1.3)=1864 \mathrm{~K} \\
T_{4}=T_{3} \frac{v_{4}}{v_{3}}=(1864)(2)=3728 \mathrm{~K}
\end{gathered}
$$

Thus, $q_{\text {in }}=(0.717)(1864-1434)+(1.00)(3728-1864)=2172 \mathrm{~kJ} / \mathrm{kg}$. The work output is found from

$$
w_{\text {out }}=\eta q_{\text {in }}=(0.622)(2172)=1350 \mathrm{~kJ} / \mathrm{kg}
$$

Finally, since

$$
\iota_{1}=\frac{R T_{1}}{P_{1}}=\frac{(0.287)(473)}{200}=0.6788 \mathrm{~m}^{3} / \mathrm{kg}
$$

we have

$$
\text { MEP }=\frac{w_{\text {out }}}{c_{1}\left(1-\tau_{2} / v_{1}\right)}=\frac{1350}{(0.6788)(15 / 16)}=2120 \mathrm{kPa}
$$

### 9.8 THE STIRLING AND ERICSSON CYCLES

The Stirling and Ericsson cycles, although not extensively used to model actual engines, are presented to illustrate the effective use of a regenerator, a heat exchanger which utilizes waste heat. A schematic diagram is shown in Fig. 9-12. Note that for both the constant-volume processes of the Stirling cycle (Fig. 9-13) and the constant-pressure processes of the Ericsson cycle (Fig. 9-14) the heat transfer $q_{2-3}$ required by the gas is equal in magnitude to the heat transfer $q_{4-1}$ discharged by the gas.

Fig. 9-12

Fig. 9-13 Stirling cycle

Fig. 9-14 Ericsson cycle

This suggests the use of a regenerator that will, internally to the cycle, transfer the otherwise wasted heat from the air during the process $4 \rightarrow 1$ to the air during the process $2 \rightarrow 3$. The net result of this is that the thermal efficiency of each of the two ideal cycles shown equals that of a Carnot cycle operating between the same two temperatures. This is obvious because the heat transfer in and out of each cycle occurs at constant temperature. Thus, the thermal efficiency is

$$
\begin{equation*}
\eta=1-\frac{T_{L}}{T_{H}} \tag{9.30}
\end{equation*}
$$

Note that the heat transfer (the purchased energy) needed for the turbine can be supplied from outside an actual engine, that is, external combustion. Such external combustion engines have lower emissions but have not proved to be competitive with the Otto and diesel cycle engines because of problems inherent in the regenerator design and the isothermal compressor and turbine.

EXAMPLE 9.7 A Stirling cycle operates on air with a compression ratio of 10 . If the low pressure is 30 psia, the low temperature is $200^{\circ} \mathrm{F}$, and the high temperature is $1000^{\circ} \mathrm{F}$, calculate the work output and the heat input.

For the Stirling cycle the work output is

$$
w_{\text {out }}=w_{3-4}+w_{1-2}=R T_{3} \ln \frac{v_{4}}{v_{3}}+R T_{1} \ln \frac{v_{2}}{v_{1}}=(53.3)(1460 \ln 10+660 \ln 0.1)=98,180 \mathrm{ft}-\mathrm{lbf} / \mathrm{lbm}
$$

where we have used (4.36) for the isothermal process. Consequently,

$$
\eta=1-\frac{T_{L}}{T_{H}}=1-\frac{660}{1460}=0.548 \quad q_{\text {in }}=\frac{w_{\text {out }}}{\eta}=\frac{98,180 / 778}{0.548}=230 \mathrm{Btu} / \mathrm{lbm}
$$

EXAMPLE 9.8 An Ericsson cycle operates on air with a compression ratio of 10 . For a low pressure of 200 kPa , a low $100^{\circ} \mathrm{C}$, and a high temperature of $600^{\circ} \mathrm{C}$, calculate the work output and the heat input.

For the Ericsson cycle the work output is

$$
w_{\text {out }}=w_{1-2}+w_{2-3}+w_{3-4}+w_{4-1}=R T_{1} \ln \frac{v_{2}}{v_{1}}+P_{2}\left(v_{3}-v_{2}\right)+R \mathrm{~T}_{3} \ln \frac{v_{4}}{v_{3}}+P_{1}\left(v_{1}-v_{4}\right)
$$

We must calculate $P_{2}, v_{1}, v_{2}$, and $v_{4}$. We know

$$
v_{1}=\frac{R T_{1}}{P_{1}}=\frac{(0.287)(373)}{200}=0.5353 \mathrm{~m}^{3} / \mathrm{kg}
$$

For the constant-pressure process $4 \rightarrow 1$,

$$
\frac{T_{4}}{v_{4}}=\frac{T_{1}}{v_{1}} \quad \frac{873}{v_{4}}=\frac{373}{0.5353} \quad v_{4}=1.253 \mathrm{~m}^{3} / \mathrm{kg}
$$

From the definition of the compression ratio, $v_{4} / v_{2}=10$, giving $v_{2}=0.1253 \mathrm{~m}^{3} / \mathrm{kg}$. Using the ideal-gas law, we have

$$
P_{3}=P_{2}=\frac{R T_{2}}{v_{2}}=\frac{(0.287)(373)}{0.1253}=854.4 \mathrm{kPa}
$$

The final necessary property is $v_{3}=R T_{3} / P_{3}=(0.287)(873) / 854.4=0.2932 \mathrm{~m}^{3} / \mathrm{kg}$. The expression for work output gives

$$
\begin{aligned}
w_{\text {out }}= & (0.287)(373) \ln \frac{0.1253}{0.5353}+(854.4)(0.2932-0.1253) \\
& +0.287 \times 873 \ln \frac{1.253}{0.2932}+(200)(0.5353-1.253)=208 \mathrm{~kJ} / \mathrm{kg}
\end{aligned}
$$

Finally,

$$
\eta=1-\frac{T_{L}}{T_{H}}=1-\frac{378}{873}=0.573 \quad q_{\text {in }}=\frac{w_{\text {out }}}{\eta}=\frac{208}{0.573}=364 \mathrm{~kJ} / \mathrm{kg}
$$

### 9.9 THE BRAYTON CYCLE

The gas turbine is another mechanical system that produces power. It may operate on an open cycle when used as a tank engine or truck engine, or on a closed cycle when used in a nuclear power plant. In open cycle operation, air enters the compressor, passes through a constant-pressure combustion chamber, passes through a turbine, and then exits as products of combustion to the atmosphere, as shown in Fig. 9-15a. In closed cycle operation the combustion chamber is replaced with a heat exchanger in which energy enters the cycle from some exterior source; an additional heat exchanger transfers heat from the cycle so that the air is returned to its initial state, as shown in Fig. 9-15b.

The ideal cycle used to model the gas turbine is the Brayton cycle. It utilizes isentropic compression and expansion, as indicated in Fig. 9-16. The efficiency of such a cycle is given by

$$
\begin{equation*}
\eta=1-\frac{\dot{Q}_{\text {out }}}{\dot{Q}_{\text {in }}}=1-\frac{c_{p}\left(T_{4}-T_{1}\right)}{c_{p}\left(T_{3}-T_{2}\right)}=1-\frac{T_{1}}{T_{2}} \frac{T_{4} / T_{1}-1}{T_{3} / T_{2}-1} \tag{9.31}
\end{equation*}
$$

Using the isentropic relations

$$
\begin{equation*}
\frac{P_{2}}{P_{1}}=\left(\frac{T_{2}}{T_{1}}\right)^{k /(k-1)} \quad \frac{P_{3}}{P_{4}}=\left(\frac{T_{3}}{T_{4}}\right)^{k /(k-1)} \tag{9.32}
\end{equation*}
$$

Fig. 9-15

Fig. 9-16
and observing that $P_{2}=P_{3}$ and $P_{1}=P_{4}$, we see that

$$
\begin{equation*}
\frac{T_{2}}{T_{1}}=\frac{T_{3}}{T_{4}} \quad \text { or } \quad \frac{T_{4}}{T_{1}}=\frac{T_{3}}{T_{2}} \tag{9.33}
\end{equation*}
$$

Hence, the thermal efficiency can be written as

$$
\begin{equation*}
\eta=1-\frac{T_{1}}{T_{2}}=1-\left(\frac{P_{1}}{P_{2}}\right)^{(k-1) / k} \tag{9.34}
\end{equation*}
$$

In terms of the pressure ratio $r_{p}=P_{2} / P_{1}$ the thermal efficiency is

$$
\begin{equation*}
\eta=1-r_{p}^{(1-k) / k} \tag{9.35}
\end{equation*}
$$

Of course, this expression for thermal efficiency was obtained using constant specific heats. For more accurate calculations the gas tables should be used.

In an actual gas turbine the compressor and the turbine are not isentropic; some losses do occur. These losses, usually in the neighborhood of 15 percent, significantly reduce the efficiency of the gas turbine engine.

Another important feature of the gas turbine that seriously limits thermal efficiency is the high work requirement of the compressor, measured by the back work ratio $\dot{W}_{\text {comp }} / \dot{W}_{\text {turb }}$. The compressor may require up to 80 percent of the turbine's output (a back work ratio of 0.8 ), leaving only 20 percent for net work output. This relatively high limit is experienced when the efficiencies of the compressor and turbine are too low. Solved problems illustrate this point.

EXAMPLE 9.9 Air enters the compressor of a gas turbine at 100 kPa and $25^{\circ} \mathrm{C}$. For a pressure ratio of 5 and a maximum temperature of $850^{\circ} \mathrm{C}$ determine the back work ratio and the thermal efficiency using the Brayton cycle.

To find the back work ratio we observe that

$$
\frac{w_{\text {comp }}}{w_{\text {turb }}}=\frac{c_{p}\left(T_{2}-T_{1}\right)}{c_{p}\left(T_{3}-T_{4}\right)}=\frac{T_{2}-T_{1}}{T_{3}-T_{4}}
$$

The temperatures are $T_{1}=298 \mathrm{~K}, T_{3}=1123 \mathrm{~K}$, and

$$
T_{2}=T_{1}\left(\frac{P_{2}}{P_{1}}\right)^{(k-1) / k}=(298)(5)^{0.2857}=472.0 \mathrm{~K} \quad T_{4}=T_{3}\left(\frac{P_{4}}{P_{5}}\right)^{(k-1) / k}=(1123)\left(\frac{1}{5}\right)^{0.2857}=709.1 \mathrm{~K}
$$

The back work ratio is then

$$
\frac{w_{\text {comp }}}{w_{\text {turb }}}=\frac{472.0-298}{1123-709}=0.420 \text { or } 42.0 \%
$$

The thermal efficiency is $\eta=1-r^{(1-k) / k}=1-(5)^{-0.2857}=0.369(36.9 \%)$.
EXAMPLE 9.10 Assume the compressor and the gas turbine in Example 9.9 both have an efficiency of 80 percent. Using the Brayton cycle determine the back work ratio and the thermal efficiency.

We can calculate the quantities asked for if we determine $w_{\text {comp }}, w_{\text {turb }}$, and $q_{i n}$. The compressor work is

$$
w_{\text {comp }}=\frac{w_{\text {comp }, s}}{\eta_{\text {comp }}}=\frac{c_{P}}{\eta_{\text {comp }}}\left(T_{2^{\prime}}-T_{1}\right)
$$

where $w_{\text {comp.s }}$ is the isentropic work. $T_{2}$, is the temperature of state $2^{\prime}$ assuming an isentropic process; state 2 is the actual state. We then have, using $T_{2}=T_{2}$ from Example 9.9,

$$
w_{\text {cump }}=\left(\frac{1.00}{0.8}\right)(472-298)=217.5 \mathrm{~kJ} / \mathrm{kg}
$$

Likewise, there results $w_{\text {turb }}=\eta_{\text {turt }} w_{\text {turb. } s}=\eta_{\text {turb }} c_{p}\left(T_{3}-T_{4}\right)=(0.8)(1.00)(1123-709.1)=331.1 \mathrm{~kJ} / \mathrm{kg}$, where $T_{4}$ is $T_{4}$ as calculated in Example 9.9. State 4 is the actual state and state $4^{\prime}$ is the isentropic state. The back work ratio is then

$$
\frac{w_{\text {comp }}}{w_{\text {turb }}}=\frac{217.5}{331.1}=0.657 \quad \text { or } 65.7 \%
$$

The heat transfer input necessary in this cycle is $q_{\text {in }}=h_{3}-h_{2}=c_{p}\left(T_{3}-T_{2}\right)$, where $T_{2}$ is the actual temperature of the air leaving the compressor. It is found by returning to the compressor:

$$
w_{\text {comp }}=c_{p}\left(T_{2}-T_{1}\right) \quad 217.5=(1.00)\left(T_{2}-298\right) \quad \therefore T_{2}=515.5 \mathrm{~K}
$$

Thus, $q_{\text {in }}=(1.00)(1123-515.5)=607.5 \mathrm{~kJ} / \mathrm{kg}$. The thermal efficiency of the cycle can then be written as

$$
\eta=\frac{w_{\text {net }}}{q_{\text {in }}}=\frac{w_{\text {turb }}-w_{\text {comp }}}{q_{\text {in }}}=\frac{331.1-217.5}{607.5}=0.187 \text { or } 18.7 \%
$$

### 9.10 THE REGENERATIVE GAS-TURBINE CYCLE

The heat transfer from the simple gas-turbine cycle of the previous section is simply lost to the surroundings-either directly, with the products of combustion, or from a heat exchanger. Some of this exit energy can be utilized since the temperature of the flow exiting the turbine is greater than the temperature of the flow entering the compressor. A counterflow heat exchanger, a regenerator, is used to transfer some of this energy to the air leaving the compressor, as shown in Fig. 9-17. For an ideal regenerator the exit temperature $T_{3}$ would equal the entering temperature $T_{5}$; and, similarly, $T_{2}$ would equal $T_{6}$. Since less energy is rejected from the cycle, the thermal efficiency is expected to increase. It is given by

$$
\begin{equation*}
\eta=\frac{w_{\text {turt }}-w_{\text {comp }}}{q_{\text {in }}} \tag{9.36}
\end{equation*}
$$

Using the first law, expressions for $q_{\text {in }}$ and $w_{\text {turb }}$ are found to be

$$
\begin{equation*}
q_{\text {in }}=c_{p}\left(T_{4}-T_{3}\right) \quad w_{\text {turb }}=c_{p}\left(T_{4}-T_{5}\right) \tag{9.37}
\end{equation*}
$$

Fig. 9-17

Hence, for the ideal regenerator in which $T_{3}=T_{5}, q_{\text {in }}=w_{\text {turb }}$ and the thermal efficiency can be written as

$$
\begin{equation*}
\eta=1-\frac{w_{\text {comp }}}{w_{\text {turt }}}=1-\frac{T_{2}-T_{1}}{T_{4}-T_{5}}=1-\frac{T_{1}}{T_{4}} \frac{T_{2} / T_{1}-1}{1-T_{5} / T_{4}} \tag{9.38}
\end{equation*}
$$

Using the appropriate isentropic relation, this can be written in the form

$$
\begin{equation*}
\eta=1-\frac{T_{1}}{T_{4}} \frac{\left(P_{2} / P_{1}\right)^{(k-1) / k}-1}{1-\left(P_{1} / P_{2}\right)^{(k-1) / k}}=1-\frac{T_{1}}{T_{4}} r_{p}^{(k-1) / k} \tag{9.39}
\end{equation*}
$$

Note that this expression for thermal efficiency is quite different from that for the Brayton cycle. For a given pressure ratio, the efficiency increases as the ratio of minimum to maximum temperature decreases. But, perhaps more surprisingly, as the pressure ratio increases the efficiency decreases, an effect opposite to that of the Brayton cycle. Hence it is not surprising that for a given regenerative cycle temperature ratio, there is a particular pressure ratio for which the efficiency of the Brayton cycle will equal the efficiency of the regenerative cycle. This is shown for a temperature ratio of 0.25 in Fig. 9-18.

Fig. 9-18
In practice the temperature of the air leaving the regenerator at state 3 must be less than the temperature of the air entering at state 5 . Also, $T_{6}>T_{2}$. The effectiveness, or efficiency, of a regenerator is measured by

$$
\begin{equation*}
\eta_{\mathrm{reg}}=\frac{h_{3}-h_{2}}{h_{5}-h_{2}} \tag{9.40}
\end{equation*}
$$

This is equivalent to

$$
\begin{equation*}
\eta_{\mathrm{reg}}=\frac{T_{3}-T_{2}}{T_{5}-T_{2}} \tag{9.41}
\end{equation*}
$$

if we assume an ideal gas with constant specific heats. Obviously, for the ideal regenerator $T_{3}=T_{5}$ and $\eta_{\text {reg }}=1$. Regenerator efficiencies exceeding 80 percent are common.

EXAMPLE 9.11 Add an ideal regenerator to the gas-turbine cycle of Example 9.9 and calculate the thermal efficiency and the back work ratio.

The thermal efficiency is found using (9.39):

$$
\eta=1-\frac{T_{1}}{T_{4}}\left(\frac{P_{2}}{P_{1}}\right)^{(k-1) / k}=1-\left(\frac{298}{1123}\right)(5)^{0.2857}=0.580 \quad \text { or } 58.0 \%
$$

This represents a 57 percent increase in efficiency, a rather large effect. Note that, for the information given, the back work ratio does not change; hence, $w_{\text {comp }} / w_{\text {turb }}=0.420$.

### 9.11 THE INTERCOOLING, REHEAT, REGENERATIVE GAS-TURBINE CYCLE

In addition to the regenerator of the previous section there are two other common techniques for increasing the thermal efficiency of the gas turbine cycle. First, an intercooler can be inserted into the compression process; air is compressed to an intermediate pressure, cooled in an intercooler, and then compressed to the final pressure. This reduces the work required for the compressor, as was discussed in Sec. 9.2, and it reduces the maximum temperature reached in the cycle. The intermediate pressure is determined by equating the pressure ratio for each stage of compression; that is, referring to Fig. 9.19 [see (9.8)],

$$
\begin{equation*}
\frac{P_{2}}{P_{1}}=\frac{P_{4}}{P_{3}} \tag{9.42}
\end{equation*}
$$

Fig. 9-19
The second technique for increasing thermal efficiency is to use a second combustor, called a reheater. The intermediate pressure is determined as in the compressor; we again require that the ratios be equal; that is,

$$
\begin{equation*}
\frac{P_{6}}{P_{7}}=\frac{P_{8}}{P_{9}} \tag{9.43}
\end{equation*}
$$

Since $P_{9}=P_{1}$ and $P_{6}=P_{4}$, we see that the intermediate turbine pressure is equal to the intermediate compressor pressure for our ideal-gas turbine.

Finally, we should note that intercooling and reheating are never used without regeneration. In fact, if regeneration is not employed, intercooling and reheating reduce the efficiency of a gas-turbine cycle.

EXAMPLE 9.12 Add an ideal intercooler, reheater, and regenerator to the gas-turbine cycle of Example 9.9 and calculate the thermal efficiency. Keep all given quantities the same.

The intermediate pressure is found to be $P_{2}=\sqrt{P_{1} P_{4}}=\sqrt{(100)(500)}=223.6 \mathrm{kPa}$. Hence, for the ideal isentropic process,

$$
T_{2}=T_{1}\left(\frac{P_{2}}{P_{1}}\right)^{(k-1) / k}=(298)\left(\frac{223.6}{100}\right)^{0.2857}=375.0 \mathrm{~K}
$$

The maximum temperature $T_{6}=T_{8}=1123 \mathrm{~K}$. Using $P_{7}=P_{2}$ and $P_{6}=P_{4}$, we have

$$
T_{7}=T_{6}\left(\frac{P_{7}}{P_{6}}\right)^{(k-1) / k}=(1123)\left(\frac{223.6}{500}\right)^{0.2857}=892.3 \mathrm{~K}
$$

Now all the temperatures in the cycle are known and the thermal efficiency can be calculated as

$$
\begin{aligned}
\eta & =\frac{w_{\text {out }}}{q_{\text {in }}}=\frac{w_{\text {turb }}-w_{\text {comp }}}{q_{C}+q_{R}}=\frac{c_{p}\left(T_{6}-T_{7}\right)+c_{p}\left(T_{8}-T_{9}\right)-c_{p}\left(T_{2}-T_{1}\right)-c_{p}\left(T_{4}-T_{3}\right)}{c_{p}\left(T_{6}-T_{5}\right)+c_{p}\left(T_{8}-T_{7}\right)} \\
& =\frac{230.7+230.7-77.0-77.0}{230.7+230.7}=0.666 \text { or } 66.6 \%
\end{aligned}
$$

This represents a 14.9 percent increase over the cycle of Example 9.11 with only a regenerator, and an 80.5 percent increase over the simple gas-turbine cycle. Obviously, losses in the additional components must be considered for any actual situation.

### 9.12 THE TURBOJET ENGINE

The turbojet engines of modern commercial aircraft utilize gas-turbine cycles as the basis for their operation. Rather than producing power, however, the turbine is sized to provide just enough power to drive the compressor. The energy that remains is used to increase the kinetic energy of the exiting exhaust gases by passing the gases through an exhaust nozzle thereby providing thrust to the aircraft. Assuming that all of the air entering the engine passes through the turbine and out the exhaust nozzle, as shown in Fig. 9-20, the net thrust on the aircraft due to one engine is

$$
\begin{equation*}
\text { thrust }=\dot{m}\left(V_{5}-V_{1}\right) \tag{9.44}
\end{equation*}
$$

Fig. 9-20
where $\dot{m}$ is the mass flux of air passing through the engine. The mass flux of fuel is assumed to be negligibly small. In our ideal engine we assume that the pressures at section 1 and section 5 are equal to atmospheric pressure and that the velocity at section 1 is equal to the aircraft speed. A solved problem will illustrate the calculations for this application.

EXAMPLE 9.13 A turbojet engine inlets $100 \mathrm{lbm} / \mathrm{sec}$ of air at 5 psia and $-50^{\circ} \mathrm{F}$ with a velocity of $600 \mathrm{ft} / \mathrm{sec}$. The compressor discharge pressure is 50 psia and the turbine inlet temperature is $2000^{\circ} \mathrm{F}$. Calculate the thrust and the horsepower developed by the engine.

To calculate the thrust we must first calculate the exit velocity. To do this we must know the temperatures $T_{4}$ and $T_{5}$ exiting the turbine and the nozzle, respectively. Then the energy equation can be applied across the nozzle as

$$
\begin{aligned}
& \text { neglect } \\
& \frac{V_{4}}{2}+h_{4}=\frac{V_{5}^{2}}{2}+h_{5} \quad \text { or } \quad V_{5}^{2}=2 c_{p}\left(T_{4}-T_{5}\right)
\end{aligned}
$$

Let us find the temperatures $T_{4}$ and $T_{5}$. The temperature $T_{2}$ is found to be (using $T_{1}=410^{\circ} \mathrm{R}$ )

$$
T_{2}=T_{1}\left(\frac{P_{2}}{P_{1}}\right)^{(k-1) / k}=(410)\left(\frac{50}{5}\right)^{0.2857}=791.6^{\circ} \mathrm{R}
$$

Since the work from the turbine equals the work required by the compressor, we have $h_{2}-h_{1}=h_{3}-h_{4}$ or $T_{3}-T_{4}=T_{2}-T_{1}$. Thus, $T_{4}=2460-(791.6-410)=2078^{\circ} \mathrm{R}$. The isentropic expansion through the turbine yields

$$
P_{4}=P_{3}\left(\frac{T_{4}}{T_{3}}\right)^{k /(k-1)}=(50)\left(\frac{2078}{2460}\right)^{3.5}=27.70 \mathrm{psia}
$$

The temperature $T_{5}$ at the nozzle exit where $P_{5}=5$ psia is found, assuming isentropic nozzle expansion, to be

$$
T_{5}=T_{4}\left(\frac{P_{5}}{P_{4}}\right)^{(k-1) / k}=(2078)\left(\frac{5}{27.7}\right)^{0.2857}=1274^{\circ} \mathrm{R}
$$

The energy equation then gives

$$
V_{5}=\left[2 c_{p}\left(T_{4}-T_{5}\right)\right]^{1 / 2}=[(2)(0.24)(778)(32.2)(2078-1274)]^{1 / 2}=3109 \mathrm{ft} / \mathrm{sec}
$$

[Note: We use $c_{p}=\left(0.24 \mathrm{Btu} / \mathrm{lbm}-{ }^{\circ} \mathrm{R}\right) \times(778 \mathrm{ft}-\mathrm{lbf} / \mathrm{Btu}) \times\left(32.2 \mathrm{lbm}-\mathrm{ft} / \mathrm{lbf}-\mathrm{sec}^{2}\right)$. This provides the appropriate units for $c_{p}$.]

The thrust is: thrust $=\dot{m}\left(V_{5}-V_{1}\right)=(100 / 32.2)(3109-600)=7790 \mathrm{lbf}$. The horsepower is

$$
\mathrm{hp}=\frac{(\text { thrust })(\text { velocity })}{550}=\frac{(7790)(600)}{550}=8500 \mathrm{hp}
$$

where we have used the conversion $550 \mathrm{ft}-\mathrm{lbf} / \mathrm{sec}=1 \mathrm{hp}$.

### 9.13 THE COMBINED BRAYTON-RANKINE CYCLE

The Brayton cycle efficiency is quite low primarily because a substantial amount of the energy input is exhausted to the surroundings. This exhausted energy is usually at a relatively high temperature and thus it can be used effectively to produce power. One possible application is the combined Brayton-Rankine cycle in which the high-temperature exhaust gases exiting the gas turbine are used to supply energy to the boiler of the Rankine cycle, as illustrated in Fig. 9-21. Note that the temperature $T_{9}$ of the Brayton cycle gases exiting the boiler is less than the temperature $T_{3}$ of the Rankine cycle steam exiting the boiler; this is possible in the counterflow heat exchanger, the boiler.

Fig. 9-21

To relate the air mass flux $\dot{m}_{a}$ of the Brayton cycle to the steam mass flux $\dot{m}_{s}$ of the Rankine cycle, we use an energy balance in the boiler; it gives (see Fig. 9-21),

$$
\begin{equation*}
\dot{m}_{a}\left(h_{8}-h_{9}\right)=\dot{m}_{s}\left(h_{3}-h_{2}\right) \tag{9.45}
\end{equation*}
$$

assuming no additional energy addition in the boiler, which would be possible with an oil burner, for example.

The cycle efficiency would be found by considering the purchased energy as $\dot{Q}_{\text {in }}$, the energy input in the combustor. The output is the sum of the net output $\dot{W}_{\mathrm{GT}}$ from the gas turbine and the output $\dot{W}_{\mathrm{ST}}$ from the steam turbine. The combined cycle efficiency is thus given by

$$
\begin{equation*}
\eta=\frac{\dot{W}_{\mathrm{GT}}+\dot{W}_{\mathrm{ST}}}{\dot{Q}_{\text {in }}} \tag{9.46}
\end{equation*}
$$

An example will illustrate the increase in efficiency of such a combined cycle.
EXAMPLE 9.14 A simple steam power plant operates between pressures of 10 kPa and 4 MPa with a maximum temperature of $400^{\circ} \mathrm{C}$. The power output from the steam turbine is 100 MW . A gas turbine provides the energy to the boiler; it accepts air at 100 kPa and $25^{\circ} \mathrm{C}$, has a pressure ratio of 5 , and a maximum temperature of $850^{\circ} \mathrm{C}$. The exhaust gases exit the boiler at 350 K . Determine the thermal efficiency of the combined Brayton-Rankine cycle.

If we neglect the work of the pump, the enthalpy remains unchanged across the pump. Hence, $h_{2}=h_{1}=192$ $\mathrm{kJ} / \mathrm{kg}$. At $400^{\circ} \mathrm{C}$ and 4 MPa we have $h_{3}=3214 \mathrm{~kJ} / \mathrm{kg}$ and $s_{3}=6.7698 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}$. State 4 is located by noting that $s_{4}=s_{3}$ so that the quality is

$$
x_{4}=\frac{s_{4}-s_{f}}{s_{f 8}}=\frac{6.798-0.6491}{7.5019}=0.8159
$$

Thus, $h_{4}=h_{f}+x_{4} h_{f g}=192+(0.8159)(2393)=2144 \mathrm{~kJ} / \mathrm{kg}$. The steam mass flux is found using the turbine output as follows:

$$
\dot{w}_{\text {ST }}=\dot{m}_{s}\left(h_{3}-h_{4}\right) \quad 100000=\dot{m}_{s}(3214-2144) \quad \dot{m}_{s}=93.46 \mathrm{~kg} / \mathrm{s}
$$

Considering the gas-turbine cycle,

$$
T_{6}=T_{5}\left(\frac{P_{6}}{P_{5}}\right)^{(k-1) / k}=(298)(5)^{0.2857}=472.0 \mathrm{~K}
$$

Also,

$$
T_{8}=T_{7}\left(\frac{P_{8}}{P_{7}}\right)^{(k-1) / k}=(1123)\left(\frac{1}{5}\right)^{0.2857}=709.1 \mathrm{~K}
$$

Thus we have, for the boiler,

$$
\begin{aligned}
\dot{m}_{s}\left(h_{3}-h_{2}\right) & =\dot{m}_{a} c_{\rho}\left(T_{8}-T_{9}\right) \quad(93.46)(3214-192)=\left(\dot{m}_{a}\right)(1.00)(709.1-350) \\
\dot{m}_{a} & =786.5 \mathrm{~kg} / \mathrm{s}
\end{aligned}
$$

The output of the gas turbine is (note that this is not $\dot{w}_{\mathrm{Gr}}$ )

$$
\dot{W}_{\text {turb }}=\dot{m}_{a} c_{p}\left(T_{7}-T_{8}\right)=(786.5)(1.00)(1123-709.1)=325.5 \mathrm{MW}
$$

The energy needed by the compressor is

$$
\dot{W}_{\text {comp }}=\dot{m}_{a} c_{p}\left(T_{6}-T_{5}\right)=(786.5)(1.00)(472-298)=136.9 \mathrm{MW}
$$

Hence, the net gas turbine output is $\dot{W}_{\text {GT }}=\dot{W}_{\text {turb }}-\dot{W}_{\text {comp }}=325.5-136.9=188.6 \mathrm{MW}$. The energy input by the combustor is

$$
\dot{Q}_{\text {in }}=\dot{m}_{a} c_{p}\left(T_{7}-T_{6}\right)=(786.5)(1.00)(1123-472)=512 \mathrm{MW}
$$

The above calculations allow us to determine the combined cycle efficiency as

$$
\eta=\frac{\dot{W}_{\mathrm{ST}}+\dot{W}_{\mathrm{GT}}}{\dot{Q}_{\mathrm{in}}}=\frac{100+188.6}{512}=0.564 \text { or } 56.4 \%
$$

Note that this efficiency is 59.3 percent higher than the Rankine cycle (see Example 8.2 ) and 52.8 percent higher than the Brayton cycle (see Example 9.9). Cycle efficiency could be increased even more by using steam reheaters, steam regenerators, gas intercoolers, and gas reheaters.

### 9.14. THE GAS REFRIGERATION CYCLE

If the flow of the gas is reversed in the Brayton cycle of Sec. 9.9, the gas undergoes an isentropic expansion process as it flows through the turbine, resulting in a substantial reduction in temperature, as shown in Fig. 9-22. The gas with low turbine exit temperature can be used to refrigerate a space to temperature $T_{2}$ by extracting heat at rate $\dot{Q}_{\mathrm{in}}$ from the refrigerated space.

Figure 9-22 illustrates a closed refrigeration cycle. (An open cycle system is used in aircraft; air is extracted from the atmosphere at state 2 and inserted into the passenger compartment at state 1 . This provides both fresh air and cooling.) An additional heat exchanger may be used, like the regenerator of the Brayton power cycle, to provide an even lower turbine exit temperature, as illustrated in Fig. $9-23$. The gas does not enter the expansion process (the turbine) at state 5 ; rather, it passes through an internal heat exchanger (it does not exchange heat with the surroundings). This allows the temperature of the gas entering the turbine to be much lower than that of Fig. 9-22. The temperature $T_{1}$ after the expansion is so low that gas liquefication is possible. It should be noted, however, that the coefficient of performance is actually reduced by the inclusion of an internal heat exchanger.

Fig. 9-22

A reminder: when the purpose of a thermodynamic cycle is to cool a space, we do not define a cycle's efficiency; rather, we define its coefficient of performance:

$$
\begin{equation*}
\mathrm{COP}=\frac{\text { desired effect }}{\text { energy that costs }}=\frac{\dot{Q}_{\text {in }}}{\dot{W}_{\text {in }}} \tag{9.47}
\end{equation*}
$$

where $\dot{W}_{\text {in }}=\dot{m}\left(w_{\text {comp }}-w_{\text {turb }}\right)$.
EXAMPLE 9.15 Air enters the compressor of a simple gas refrigeration cycle at $-10^{\circ} \mathrm{C}$ and 100 kPa . For a compression ratio of 10 and a turbine inlet temperature of $30^{\circ} \mathrm{C}$ calculate the minimum cycle temperature and the coefficient of performance.

Assuming isentropic compression and expansion processes we find

$$
\begin{aligned}
& T_{3}=T_{2}\left(\frac{P_{3}}{P_{2}}\right)^{(k-1) / k}=(263)(10)^{0.2857}=508 \mathrm{~K} \\
& T_{1}=T_{4}\left(\frac{P_{1}}{P_{4}}\right)^{(k-1) / k}=(303)\left(\frac{1}{10}\right)^{0.2857}=157 \mathrm{~K}=-116^{\circ} \mathrm{C}
\end{aligned}
$$

The COP is now calculated as follows:

$$
\begin{aligned}
q_{\text {in }} & =c_{p}\left(T_{2}-T_{1}\right)=(1.00)(263-157)=106 \mathrm{~kJ} / \mathrm{kg} \\
w_{\text {comp }} & =c_{p}\left(T_{3}-T_{2}\right)=(1.00)(508-263)=245 \mathrm{~kJ} / \mathrm{kg} \\
w_{\text {turb }} & =c_{p}\left(T_{4}-T_{1}\right)=(1.00)(303-157)=146 \mathrm{~kJ} / \mathrm{kg} \\
\therefore \mathrm{COP} & =\frac{q_{\text {in }}}{w_{\text {comp }}-w_{\text {turb }}}=\frac{106}{245-146}=1.07
\end{aligned}
$$

This coefficient of performance is quite low when compared with that of a vapor refrigeration cycle. Thus gas refrigeration cycles are usual only for special applications.

EXAMPLE 9.16 Use the given information for the compressor of the refrigeration cycle of Example 9.15 but add an ideal internal heat exchanger, a regenerator, as illustrated in Fig. 9-23, so that the air temperature entering the turbine is $-40^{\circ} \mathrm{C}$. Calculate the minimum cycle temperature and the cocfficient of performance.

Fig. 9-23
Assuming isentropic compression we again have $T_{4}=T_{3}\left(P_{4} / P_{3}\right)^{(k-1) / k}=(263)(10)^{0.2857}=508 \mathrm{~K}$. For an ideal internal heat exchanger we would have $T_{5}=T_{3}=263 \mathrm{~K}$ and $T_{6}=T_{2}=233 \mathrm{~K}$. The minimum cycle temperature is

$$
T_{1}=T_{6}\left(\frac{P_{1}}{P_{6}}\right)^{(k-1) / k}=(233)\left(\frac{1}{10}\right)^{0.2657}=121 \mathrm{~K}=-152^{\circ} \mathrm{C}
$$

For the COP:

$$
\begin{aligned}
q_{\text {in }} & =c_{p}\left(T_{2}-T_{1}\right)=(1.00)(233-121)=112 \mathrm{~kJ} / \mathrm{kg} \\
w_{\text {comp }} & =c_{p}\left(T_{4}-T_{3}\right)=(1.00)(508-263)=245 \mathrm{~kJ} / \mathrm{kg} \\
w_{\text {turb }} & =c_{p}\left(T_{6}-T_{1}\right)=(1.00)(233-121)=112 \mathrm{~kJ} / \mathrm{kg} \\
\therefore \mathrm{COP} & =\frac{q_{\text {in }}}{w_{\text {comp }}-w_{\text {turb }}}=\frac{112}{245-112}=0.842
\end{aligned}
$$

Obviously, the COP is lower than that of the cycle with no internal heat exchanger. The objective is not to increase the COP but to provide extremely low refrigeration temperatures.

## Solved Problems

9.1 An adiabatic compressor receives $20 \mathrm{~m}^{3} / \mathrm{min}$ of air from the atmosphere at $20^{\circ} \mathrm{C}$ and compresses it to 10 MPa . Calculate the minimum power requirement.

An isentropic compression requires the minimum power input for an adiabatic compressor. The outlet temperature for such a process is

$$
T_{2}=T_{1}\left(\frac{P_{2}}{P_{1}}\right)^{(k-1) / k}=(293)\left(\frac{10000}{100}\right)^{0.2857}=1092 \mathrm{~K}
$$

To find the mass flux, we must know the density. It is $\rho=P / R T=100 /(0.287)(293)=1.189 \mathrm{~kg} / \mathrm{m}^{3}$. The mass flux is then (the flow rate is given) $\dot{m}=\rho(A V)=(1.189)(20 / 60)=0.3963 \mathrm{~kg} / \mathrm{s}$. The minimum power requirement is now calculated to be

$$
\dot{W}_{\text {comp }}=\dot{m}\left(h_{2}-h_{1}\right)=\dot{m} c_{p}\left(T_{2}-T_{1}\right)=(0.3963)(1.00)(1092-293)=317 \mathrm{~kW}
$$

9.2 A compressor receives $4 \mathrm{~kg} / \mathrm{s}$ of $20^{\circ} \mathrm{C}$ air from the atmosphere and delivers it at a pressure of 18 MPa . If the compression process can be approximated by a polytropic process with $n=1.3$, calculate the power requirement and the rate of heat transfer.

The power requirement is [see (9.6)]

$$
\dot{W}_{\mathrm{comp}}=\dot{m} \frac{n R}{n-1} T_{1}\left[\left(\frac{P_{2}}{P_{1}}\right)^{(n-1) / n}-1\right]=(4) \frac{(1.3)(0.287)}{1.3-1}(293)\left[\left(\frac{18000}{100}\right)^{0.3 / 1.3}-1\right]=3374 \mathrm{~kW}
$$

The first law for the control volume [see (4.66)] surrounding the compressor provides us with

$$
\begin{aligned}
\dot{Q} & =\dot{m} \Delta h+\dot{W}_{\mathrm{comp}}=\dot{m} c_{p}\left(T_{2}-T_{1}\right)+\dot{W}_{\mathrm{comp}}=\dot{m} c_{p} T_{1}\left[\left(\frac{P_{2}}{P_{1}}\right)^{(n-1) / n}-1\right]+\dot{W}_{\text {comp }} \\
& =(4)(1.00)(293)\left[\left(\frac{18000}{100}\right)^{0.3 / 1.3}-1\right]-3374=-661 \mathrm{~kW}
\end{aligned}
$$

In the above, we have used the compressor power as negative since it is a power input. The expression of (9.6) is the magnitude of the power with the minus sign suppressed, but when the first law is used we must be careful with the signs. The negative sign on the heat transfer means that heat is leaving the control volume.
9.3 An adiabatic compressor is supplied with $2 \mathrm{~kg} / \mathrm{s}$ of atmospheric air at $15^{\circ} \mathrm{C}$ and delivers it at 5 MPa . Calculate the efficiency and power input if the exiting temperature is $700^{\circ} \mathrm{C}$.

Assuming an isentropic process and an inlet temperature of $15^{\circ} \mathrm{C}$, the exit temperature, would be

$$
T_{z^{\prime}}=T_{1}\left(\frac{P_{2}}{P_{1}}\right)^{(k-1) / k}=(288)\left(\frac{5000}{100}\right)^{0.2857}=880.6 \mathrm{~K}
$$

The efficiency is then

$$
\eta=\frac{w_{s}}{w_{a}}=\frac{c_{p}\left(T_{2^{\prime}}-T_{1}\right)}{c_{p}\left(T_{2}-T_{1}\right)}=\frac{880.6-288}{973-288}=0.865 \quad \text { or } 86.5 \%
$$

The power input is $\dot{W}_{\text {comp }}=\dot{m} c_{p}\left(T_{2}-T_{1}\right)=(2)(1.00)(973-288)=1370 \mathrm{~kW}$.
9.4 An ideal compressor is to compress $20 \mathrm{lbm} / \mathrm{min}$ of atmospheric air at $70^{\circ} \mathrm{F}$ at 1500 psia . Calculate the power requirement for ( $a$ ) one stage, ( $b$ ) two stages, and ( $c$ ) three stages.
(a) For a single stage, the exit temperature is

$$
T_{2}=T_{1}\left(\frac{P_{2}}{P_{1}}\right)^{(k-1) / k}=(530)\left(\frac{1500}{14.7}\right)^{0.2857}=1987^{\circ} \mathrm{R}
$$

The required power is

$$
\dot{W}_{\text {comp }}=\dot{m} c_{p}\left(T_{2}-T_{1}\right)=\left(\frac{20}{60}\right)[(0.24)(778)](1987-530)=90,680 \mathrm{ft}-\mathrm{lbf} / \mathrm{sec} \text { or } 164.9 \mathrm{hp}
$$

(b) With two stages, the intercooler pressure is $P_{2}=\left(P_{1} P_{4}\right)^{1 / 2}=[(14.7)(1500)]^{1 / 2}=148.5 \mathrm{psia}$. The intercooler inlet and exit temperatures are (see Fig. 9-4)

$$
\begin{aligned}
& T_{2}=T_{1}\left(\frac{P_{2}}{P_{1}}\right)^{(k-1) / k}=530\left(\frac{148.5}{14.7}\right)^{0.2857}=1026^{\circ} \mathrm{R} \\
& T_{4}=T_{3}\left(\frac{P_{4}}{P_{3}}\right)^{(k-1) / k}=530\left(\frac{1500}{148.5}\right)^{0.2857}=1026^{\circ} \mathrm{R}
\end{aligned}
$$

The power required for this two-stage compressor is

$$
\begin{aligned}
\dot{W}_{\text {comp }} & =\dot{m} c_{p}\left(T_{2}-T_{1}\right)+\dot{m} c_{p}\left(T_{4}-T_{3}\right) \\
& =\left(\frac{20}{60}\right)[(0.24)(778)](1026-530+1026-530)=61,740 \mathrm{ft}-\mathrm{lbf} / \mathrm{sec}
\end{aligned}
$$

or 112.3 hp . This represents a 31.9 percent reduction compared to the single-stage compressor.
(c) For three stages, we have, using (9.9) and (9.10),

$$
\begin{aligned}
& P_{2}=\left(P_{1}^{2} P_{5}\right)^{1 / 3}=\left[(14.7)^{2}(1500)\right]^{1 / 3}=68.69 \mathrm{psia} \\
& P_{4}=\left(P_{1} P_{6}^{2}\right)^{1 / 3}=\left[(14.7)(1500)^{2}\right]^{1 / 3}=321.0 \mathrm{psia}
\end{aligned}
$$

The high temperature and power requirement are then

$$
\begin{aligned}
T_{2} & =T_{4}=T_{6}=T_{1}\left(\frac{P_{2}}{P_{1}}\right)^{(k-1) / k}=(530)\left(\frac{68.69}{14.7}\right)^{0.2857}=823.3^{\circ} \mathrm{R} \\
\dot{W}_{\text {comp }} & =3 \dot{m} c_{p}\left(T_{2}-T_{1}\right)=(3)\left(\frac{20}{60}\right)[(0.24)(778)](823.3-530)=54,770 \mathrm{ft}-\mathrm{lbf} / \mathrm{sec}
\end{aligned}
$$

or 99.6 hp . This represents a 39.6 percent reduction compared to the single-stage compressor.
9.5 The calculations in Prob. 9.4 were made assuming constant specific heats. Recalculate the power requirements for ( $a$ ) and ( $b$ ) using the more accurate air tables (Appendix F).
(a) For one stage, the exit temperature is found using $P_{r}$. At stage $T_{1}=530^{\circ} \mathrm{R}: h_{1}=126.7 \mathrm{Btu} / \mathrm{lbm}$, $\left(P_{r}\right)_{1}=1.300$. Then,

$$
\left(P_{r}\right)_{2}=\left(P_{r}\right)_{1} \frac{P_{2}}{P_{1}}=(1.300)\left(\frac{1500}{14.7}\right)=132.7
$$

This provides us with $T_{2}=1870^{\circ} \mathrm{R}$ and $h_{2}=469.0 \mathrm{Btu} / \mathrm{lbm}$. The power requirement is

$$
\dot{W}_{\text {comp }}=\dot{m}\left(h_{2}-h_{1}\right)=\left(\frac{20}{60}\right)(469-126.7)(778)=88,760 \mathrm{ft}-\mathrm{lbf} / \mathrm{sec} \text { or } 161.4 \mathrm{hp}
$$

(b) With two stages, the intercooler pressure remains at 148.5 psia. The intercooler inlet condition is found as follows:

$$
\left(P_{r}\right)_{2}=\left(P_{r}\right)_{1} \frac{P_{2}}{P_{1}}=(1.300)\left(\frac{148.5}{14.7}\right)=13.13
$$

whence $T_{2}=1018^{\circ} \mathrm{R}$ and $h_{2}=245.5 \mathrm{Btu} / \mathrm{lbm}$. These also represent the compressor exit (see Fig. 9-4), so that

$$
\begin{aligned}
\dot{W}_{\text {comp }} & =\dot{m}\left(h_{2}-h_{1}\right)+\dot{m}\left(h_{4}-h_{3}\right) \\
& =\left(\frac{20}{60}\right)(245.5-126.7+245.5-126.7)(778)=61,620 \mathrm{ft}-\mathrm{bf} / \mathrm{sec}
\end{aligned}
$$

or 112.0 hp . Obviously, the assumption of constant specific heats is quite acceptable. The single-stage calculation represents an error of only 2 percent.
9.6 A Carnot engine operates on air between high and low pressures of 3 MPa and 100 kPa with a low temperature of $20^{\circ} \mathrm{C}$. For a compression ratio of 15 , calculate the thermal efficiency, the MEP, and the work output.

The specific volume at TDC (see Fig. 6-1) is $v_{1}=R T_{1} / P_{1}=(0.287)(293) / 100=0.8409 \mathrm{~m}^{3} / \mathrm{kg}$. For a compression ratio of 15 (we imagine the Carnot engine to have a piston-cylinder arrangement), the specific volume at BDC is

$$
v_{3}=\frac{v_{1}}{15}=\frac{0.8409}{15}=0.05606 \mathrm{~m}^{3} / \mathrm{kg}
$$

The high temperature is then $T_{3}=P_{3} v_{3} / R=(3000)(0.05606) / 0.287=586.0 \mathrm{~K}$.
The cycle efficiency is calculated to be $\eta=1-T_{L} / T_{H}=1-293 / 586=0.500$. To find the work output, we must calculate the specific volume of state 2 as follows:

$$
\begin{array}{ll}
P_{2} v_{2}=P_{1} v_{1}=(100)(0.8409)=84.09 & P_{2} v_{2}^{1.4}=P_{3} v_{3}^{1.4}=(3000)(0.05606)^{1.4}=53.12 \\
\therefore v_{2}=0.3171 \mathrm{~m}^{3} / \mathrm{kg}
\end{array}
$$

The entropy change $\left(s_{2}-s_{1}\right)$ is then

$$
\Delta s=c_{v} \ln 1+R \ln \frac{v_{2}}{v_{1}}=0+0.287 \ln \frac{0.3171}{0.8409}=-0.2799 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K}
$$

The work output is now found to be $w_{\text {net }}=\Delta T|\Delta s|=(586-293)(0.2799)=82.0 \mathrm{~kJ} / \mathrm{kg}$. Finally,

$$
w_{\text {net }}=(\mathrm{MEP})\left(v_{1}-v_{2}\right) \quad 82.0=(\mathrm{MEP})(0.8409-0.3171) \quad \mathrm{MEP}=156.5 \mathrm{kPa}
$$

9.7 An inventor proposes a reciprocating engine with a compression ratio of 10 , operating on $1.6 \mathrm{~kg} / \mathrm{s}$ of atmospheric air at $20^{\circ} \mathrm{C}$, that produces 50 hp . After combustion the temperature is $400^{\circ} \mathrm{C}$. Is the proposed engine feasible?

We will consider a Carnot engine operating between the same pressure and temperature limits; this will establish the ideal situation without reference to the details of the proposed engine. The specific volume at state 1 (see Fig. 6-1) is

$$
v_{1}=\frac{R T_{1}}{P_{1}}=\frac{(0.287)(293)}{100}=0.8409 \mathrm{~m}^{3} / \mathrm{kg}
$$

For a compression ratio of 10 , the minimum specific volume must be $v_{3}=v_{1} / 10=0.8409 / 10=0.08409$. The specific heat at state 2 is now found by considering the isothermal process from 1 to 2 and the isentropic process from 2 to 3 :

$$
\begin{aligned}
& P_{2} v_{2}=P_{1} v_{1}=100 \times 0.8409=84.09 \quad P_{2} c_{2}^{k}=\frac{0.287(673)}{0.08409}(0.08409)^{1.4}=71.75 \\
& \therefore v_{2}=0.6725 \mathrm{~m}^{3} / \mathrm{kg}
\end{aligned}
$$

The change in entropy is

$$
\Delta s=R \ln \frac{v_{2}}{v_{1}}=0.287 \ln \frac{0.6725}{0.8409}=-0.0641 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K}
$$

The work output is then $w_{\text {nct }}=\Delta T|\Delta \mathrm{~s}|=(400-20)(0.0641)=24.4 \mathrm{~kJ} / \mathrm{kg}$. The power output is

$$
\dot{W}=\dot{m} w_{\text {net }}=(1.6)(24.4)=39.0 \mathrm{~kW} \quad \text { or } 52.2 \mathrm{hp}
$$

The maximum possible power output is 52.2 hp ; the inventor's claims of 50 hp is highly unlikely, though not impossible.
9.8 A six-cylinder engine with a compression ratio of 8 and a total volume at TDC of 600 mL intakes atmospheric air at $20^{\circ} \mathrm{C}$. The maximum temperature during a cycle is $1500^{\circ} \mathrm{C}$.
Assuming an Otto cycle, calculate ( $a$ ) the heat supplied per cycle, ( $b$ ) the thermal efficiency, and (c) the power output for 4000 rpm .
(a) The compression ratio of 8 allows us to calculate $T_{2}$ (see Fig. 9-8):

$$
T_{2}=T_{1}\left(\frac{V_{1}}{V_{2}}\right)^{k-1}=(293)(8)^{0.4}=673.1 \mathrm{~K}
$$

The heat supplied is then $q_{\text {in }}=c_{1}\left(T_{3}-T_{2}\right)=(0.717)(1773-673.1)=788.6 \mathrm{~kJ} / \mathrm{kg}$. The mass of air in the six cylinders is

$$
m=\frac{P_{1} V_{1}}{R T_{1}}=\frac{(100)\left(600 \times 10^{-6}\right)}{(0.287)(293)}=0.004281 \mathrm{~kg}
$$

The heat supplied per cycle is $Q_{\text {in }}=m q_{\text {in }}=(0.004281)(788.6)=3.376 \mathrm{~kJ}$.
(b) $\eta=1-r^{1-k}=1-8^{-0.4}=0.5647$ or $56.5 \%$.
(c) $W_{\text {out }}=\eta Q_{\text {in }}=(0.5647)(3.376)=1.906 \mathrm{~kJ}$.

For the idealized Otto cycle, we assume that one cycle occurs each revolution. Consequently,

$$
\dot{W}_{\text {out }}=\left(W_{\text {out }}\right)(\text { cycles per second })=(1.906)(4000 / 60)=127 \mathrm{~kW} \text { or } 170 \mathrm{hp}
$$

9.9 A diesel engine intakes atmospheric air at $60^{\circ} \mathrm{F}$ and adds $800 \mathrm{Btu} / \mathrm{lbm}$ of energy. If the maximum pressure is 1200 psia calculate ( $a$ ) the cutoff ratio, ( $b$ ) the thermal efficiency, and (c) the power output for an airflow of $0.2 \mathrm{lbm} / \mathrm{sec}$.
(a) The compression process is isentropic. The temperature at state 2 (see Fig. 9-9) is calculated to be

$$
T_{2}=T_{1}\left(\frac{P_{2}}{P_{1}}\right)^{(k-1) / k}=(520)\left(\frac{1200}{14.7}\right)^{0.2857}=1829^{\circ} \mathrm{R}
$$

The temperature at state 3 is found from the first law as follows:

$$
q_{\text {in }}=c_{p}\left(T_{3}-T_{2}\right) \quad 800=(0.24)\left(T_{3}-1829\right) \quad \therefore T_{3}=5162^{\circ} \mathrm{R}
$$

The specific volumes of the three states are

$$
\begin{aligned}
& v_{1}=\frac{R T_{1}}{P_{1}}=\frac{(53.3)(520)}{(14.7)(144)}=13.09 \mathrm{ft}^{3} / \mathrm{lbm} \quad v_{2}=\frac{R T_{2}}{P_{2}}=\frac{(53.3)(1829)}{(1200)(144)}=0.5642 \mathrm{ft}^{3} / \mathrm{lbm} \\
& v_{3}=\frac{R T_{3}}{P_{3}}=\frac{(53.3)(5162)}{(1200)(144)}=1.592 \mathrm{ft}^{3} / \mathrm{lbm}
\end{aligned}
$$

The cutoff ratio is then $r_{c}=v_{3} / v_{2}=1.592 / 0.5642=2.822$.
(b) The compression ratio is $r=v_{1} / v_{2}=13.09 / 0.5642=23.20$. The thermal efficiency can now be calculated, using (9.25):

$$
\eta=1-\frac{1}{r^{k-1}} \frac{r_{c}^{k}-1}{k\left(r_{c}-1\right)}=1-\frac{1}{(23.2)^{0.4}} \frac{(2.822)^{1.4}-1}{(1.4)(2.822-1)}=0.6351 \quad \text { or } 63.51 \%
$$

(c) $\dot{W}_{\text {out }}=\eta \dot{Q}_{\text {in }}=\eta \dot{m} q_{\text {in }}=[(0.6351)(0.2)(800)](778)=79,060 \mathrm{ft}-\mathrm{lbf} / \mathrm{sec}$ or 143.7 hp .
9.10 A dual cycle is used to model a piston engine. The engine intakes atmospheric air at $20^{\circ} \mathrm{C}$, compresses it to 10 MPa , and then combustion increases the pressure to 20 MPa . For a cutoff ratio of 2 , calculate the cycle efficiency and the power output for an airflow of $0.1 \mathrm{~kg} / \mathrm{s}$.

The pressure ratio (refer to Fig. 9-11) is $r_{p}=P_{3} / P_{2}=20 / 10=2$. The temperature after the isentropic compression is

$$
T_{2}=T_{1}\left(\frac{P_{2}}{P_{1}}\right)^{(k-1) / k}=(293)\left(\frac{10000}{100}\right)^{0.2857}=1092 \mathrm{~K}
$$

The specific volumes are

$$
v_{1}=\frac{R T_{1}}{P_{1}}=\frac{(0.287)(293)}{100}=0.8409 \mathrm{~m}^{3} / \mathrm{kg} \quad v_{2}=\frac{R T_{2}}{P_{2}}=\frac{(0.287)(1092)}{10000}=0.03134 \mathrm{~m}^{3} / \mathrm{kg}
$$

The compression ratio is then $r=v_{1} / v_{2}=0.8409 / 0.03134=26.83$. This allows us to calculate the thermal efficiency:

$$
\eta=1-\frac{1}{r^{k-1}} \frac{r_{p} r_{c}^{k-1}-1}{k r_{p}\left(r_{c}-1\right)+r_{p}-1}=1-\frac{1}{(26.83)^{0.4}} \frac{(2)(2)^{0.4}-1}{(1.4)(2)(2-1)+2-1}=0.8843
$$

To find the heat input, the temperatures of states 3 and 4 must be known. For the constant-volume heat addition,

$$
\frac{T_{3}}{P_{3}}=\frac{T_{2}}{P_{2}} \quad \therefore T_{3}=T_{2} \frac{P_{3}}{P_{2}}=(1092)(2)=2184 \mathrm{~K}
$$

For the constant-pressure heat addition,

$$
\frac{T_{3}}{v_{3}}=\frac{T_{4}}{v_{4}} \quad \therefore T_{4}=T_{3} \frac{v_{4}}{v_{3}}=(2184)(2)=4368 \mathrm{~K}
$$

The heat input is then

$$
q_{\text {in }}=c_{v}\left(T_{3}-T_{2}\right)+c_{p}\left(T_{4}-T_{3}\right)=(0.717)(2184-1092)+(1.00)(4368-2184)=2967 \mathrm{~kJ} / \mathrm{kg}
$$

so that

$$
w_{\text {out }}=\eta q_{\text {in }}=(0.8843)(2967)=2624 \mathrm{~kJ} / \mathrm{kg}
$$

The power output is $\dot{W}_{\text {out }}=\dot{m} w_{\text {out }}=(0.1)(2624)=262.4 \mathrm{~kW}$.
9.11 Air at 90 kPa and $15^{\circ} \mathrm{C}$ is supplied to an ideal cycle at intake. If the compression ratio is 10 and the heat supplied is $300 \mathrm{~kJ} / \mathrm{kg}$, calculate the efficiency and the maximum temperature for (a) a Stirling cycle, and (b) an Ericsson cycle.
(a) For the constant-temperature process, the heat transfer equals the work. Referring to Fig. 9-13, the first law gives

$$
q_{\text {out }}=w_{1-2}=R T_{1} \ln \frac{v_{1}}{v_{2}}=(0.287)(288) \ln 10=190.3 \mathrm{~kJ} / \mathrm{kg}
$$

The work output for the cycle is then $w_{\text {out }}=q_{\text {in }}-q_{\text {out }}=300-190.3=109.7 \mathrm{~kJ} / \mathrm{kg}$. The efficiency is

$$
\eta=\frac{w_{\text {out }}}{q_{\text {in }}}=\frac{109.7}{300}=0.366
$$

The high temperature is found from

$$
\eta=1-\frac{T_{L}}{T_{H}} \quad \therefore T_{H}=\frac{T_{L}}{1-\eta}=\frac{288}{1-0.366}=454 \mathrm{~K}
$$

(b) For the Ericsson cycle of Fig. 9-14, the compression ratio is $v_{4} / v_{2}$. The constant-temperature heat addition $3 \rightarrow 4$ provides

$$
q_{\text {in }}=w_{3-4}=R T_{4} \ln \frac{v_{4}}{v_{3}} \quad \therefore 300=(0.287) T_{4} \ln \frac{v_{4}}{v_{3}}
$$

The constant-pressure process $2 \rightarrow 3$ allows

$$
\frac{T_{3}}{v_{3}}=\frac{T_{2}}{v_{2}}=\frac{288}{v_{4} / 10}
$$

The constant-pressure process $4 \rightarrow 1$ demands

$$
\frac{T_{4}}{v_{4}}=\frac{T_{1}}{v_{1}}=\frac{P_{1}}{R}=\frac{90}{0.287}=313.6
$$

Recognizing that $T_{3}=T_{4}$, the above can be combined to give

$$
300=(0.287)\left(313.6 v_{4}\right) \ln \frac{v_{4}}{v_{3}} \quad v_{3}=0.1089 v_{4}^{2}
$$

The above two equations are solved simultaneously by trial and error to give

$$
v_{4}=3.94 \mathrm{~m}^{3} / \mathrm{kg} \quad v_{3}=1.69 \mathrm{~m}^{3} / \mathrm{kg}
$$

Thus, from the compression ratio, $v_{2}=v_{4} / 10=0.394 \mathrm{~m}^{3} / \mathrm{kg}$. The specific volume of state 1 is

$$
v_{1}=\frac{R T}{P_{1}}=\frac{(0.287)(288)}{90}=0.9184 \mathrm{~m}^{3} / \mathrm{kg}
$$

The heat rejected is then

$$
q_{\text {out }}=R T_{1} \ln \frac{v_{1}}{v_{2}}=(0.287)(288) \ln \frac{0.9184}{0.394}=70.0 \mathrm{~kJ} / \mathrm{kg}
$$

The net work for the cycle is $w_{\text {out }}=q_{\text {in }}-q_{\text {out }}=300-70.0=230 \mathrm{~kJ} / \mathrm{kg}$. The efficiency is then $\eta=w_{\text {out }} / q_{\text {in }}=230 / 300=0.767$. This allows us to calculate the high temperature:

$$
\eta=1-\frac{T_{L}}{T_{H}} \quad 0.767=1-\frac{288}{T_{H}} \quad \therefore T_{H}=1240 \mathrm{~K}
$$

9.12 A gas-turbine power plant is to produce 800 kW of power by compressing atmospheric air at $20^{\circ} \mathrm{C}$ to 800 kPa . If the maximum temperature is $800^{\circ} \mathrm{C}$, calculate the minimum mass flux of the air.

The cycle is modeled as an ideal Brayton cycle. The cycle efficiency is given by (9.35):

$$
\eta=1-r_{p}^{(1-k) / k}=1-\left(\frac{800}{100}\right)^{-0.4 / 1.4}=0.4479
$$

The energy added in the combustor is (see Fig. 9-15) $\dot{Q}_{\text {in }}=\dot{W}_{\text {out }} / \eta=800 / 0.4479=1786 \mathrm{~kW}$. The temperature into the combustor is

$$
T_{2}=T_{1}\left(\frac{P_{2}}{P_{1}}\right)^{(k-1) / k}=(293)\left(\frac{800}{100}\right)^{0.2857}=530.7 \mathrm{~K}
$$

With a combustor outlet temperature of 1073 K , the mass flux follows from a combustor energy balance:

$$
\dot{Q}_{\mathrm{in}}=\dot{m} c_{p}\left(T_{3}-T_{2}\right) \quad 1786=(\dot{m})(1.00)(1073-530.7) \quad \therefore \dot{m}=3.293 \mathrm{~kg} / \mathrm{s}
$$

This represents a minimum, since losses have not been included.
9.13 If the efficiency of the turbine of Prob. 9.12 is 85 percent and that of the compressor is 80 percent, calculate the mass flux of air needed, keeping the other quantities unchanged. Also calculate the cycle efficiency.

The compressor work, using $T_{2^{\prime}}=530.7$ from Prob. 9.12, is

$$
w_{\mathrm{comp}}=\frac{w_{\mathrm{comp}, \mathrm{~s}}}{\eta_{\mathrm{comp}}}=\frac{1}{\eta_{\mathrm{comp}}} c_{p}\left(T_{2^{\prime}}-T_{1}\right)=\left(\frac{1}{0.8}\right)(1.00)(530.7-293)=297.1 \mathrm{~kJ} / \mathrm{kg}
$$

The temperature of state $4^{\prime}$, assuming an isentropic process, is

$$
T_{4^{\prime}}=T_{3}\left(\frac{P_{4}}{P_{3}}\right)^{(k-1) / k}=(1073)\left(\frac{100}{800}\right)^{0.2857}=592.4 \mathrm{~K}
$$

The turbine work is then

$$
w_{\text {turb }}=\eta_{\text {turb }} w_{\text {turb }, s}=\eta_{\text {turb }} c_{p}\left(T_{4^{\prime}}-T_{3}\right)=(0.85)(1.00)(592.4-1073)=408.5 \mathrm{~kJ} / \mathrm{kg}
$$

The work output is then $w_{\text {out }}=w_{\text {turb }}-w_{\text {comp }}=408.5-297.1=111.4 \mathrm{~kJ} / \mathrm{kg}$. This allows us to determine the mass flux:

$$
\dot{W}_{\mathrm{out} 1}=\dot{m} w_{\mathrm{out}} \quad 800=(\dot{m})(111.4) \quad \therefore \dot{m}=7.18 \mathrm{~kg} / \mathrm{s}
$$

To calculate the cycle efficiency, we find the actual temperature $T_{2}$. It follows from an energy balance on the actual compressor:

$$
w_{\text {comp }}=c_{p}\left(T_{2}-T_{1}\right) \quad 297.1=(1.00)\left(T_{2}-293\right) \quad \therefore T_{2}=590.1 \mathrm{~K}
$$

The combustor rate of heat input is thus $\dot{Q}_{\text {in }}=\dot{m}\left(T_{3}-T_{2}\right)=(7.18)(1073-590.1)=3467 \mathrm{~kW}$. The efficiency follows as

$$
\eta=\frac{\dot{W}_{\text {out }}}{\dot{Q}_{\text {in }}}=\frac{800}{3467}=0.2307
$$

Note the sensitivity of the mass flux and the cycle efficiency to the compressor and turbine efficiency.
9.14 Assuming the ideal-gas turbine and regenerator shown in Fig. 9-24, find $\dot{Q}_{\text {in }}$ and the back work ratio.

Fig. 9-24
The cycle efficiency is (see Fig. 9-17)

$$
\eta=1-\frac{T_{1}}{T_{4}} r_{p}^{(k-1) / k}=1-\left(\frac{540}{1660}\right)\left(\frac{75}{14.7}\right)^{0.2857}=0.4818
$$

The rate of energy input to the combustor is

$$
\dot{Q}_{\text {in }}=\frac{\dot{W}_{\text {out }}}{\eta}=\frac{(800)(550 / 778)}{0.4818}=1174 \mathrm{Btu} / \mathrm{sec}
$$

The compressor outlet temperature is

$$
T_{2}=T_{1}\left(\frac{P_{2}}{P_{1}}\right)^{(k-1) / k}=(540)\left(\frac{75}{14.7}\right)^{0.2857}=860.2^{\circ} \mathrm{R}
$$

The turbine outlet temperature is

$$
T_{4}=T_{3}\left(\frac{P_{4}}{P_{3}}\right)^{(k-1) / k}=(1660)\left(\frac{14.7}{75}\right)^{0.2857}=1042^{\circ} \mathrm{R}
$$

The turbine and compressor work are then

$$
\begin{gathered}
w_{\text {comp }}=c_{p}\left(T_{2}-T_{1}\right)=(1.00)(860.2-540)=320.2 \mathrm{Btu} / \mathrm{lbm} \\
w_{\text {turb }}=c_{p}\left(T_{3}-T_{4}\right)=(1.00)(1660-1042)=618 \mathrm{Btu} / \mathrm{lbm}
\end{gathered}
$$

The back work ratio is then $w_{\text {comp }} / w_{\text {turb }}=320.2 / 618=0.518$.
9.15 To Prob. 9.14 add an intercooler and a reheater. Calculate the ideal cycle efficiency and the back work ratio.

The intercooler pressure is (see Fig. 9-19), $P_{2}=\sqrt{P_{1} P_{4}}=\sqrt{(14.7)(75)}=33.2 \mathrm{psia}$. The temperatures $T_{2}$ and $T_{4}$ are

$$
T_{4}=T_{2}=T_{1}\left(\frac{P_{2}}{P_{1}}\right)^{(k-1) / k}=(540)\left(\frac{33.2}{14.7}\right)^{0.2857}=681.5^{\circ} \mathrm{R}
$$

Using $P_{7}=P_{2}$ and $P_{6}=P_{4}$, there results

$$
T_{9}=T_{7}=T_{6}\left(\frac{P_{7}}{P_{6}}\right)^{(k-1) / k}=(1660)\left(\frac{33.2}{75}\right)^{0.2857}=1315^{\circ} \mathrm{R}
$$

The work output of the turbine and input to the compressor are

$$
\begin{aligned}
& w_{\text {turb }}=c_{p}\left(T_{8}-T_{9}\right)+c_{p}\left(T_{6}-T_{7}\right)=(0.24)(778)(1660-1315)(2)=128,800 \mathrm{ft}-\mathrm{lbf} / \mathrm{lbm} \\
& w_{\text {comp }}=c_{p}\left(T_{4}-T_{3}\right)+c_{p}\left(T_{2}-T_{1}\right)=(0.24)(778)(681.5-540)(2)=52,840 \mathrm{ft}-\mathrm{lbf} / \mathrm{lbm}
\end{aligned}
$$

The heat inputs to the combustor and the reheater are

$$
\begin{gathered}
q_{\text {comb }}=c_{p}\left(T_{6}-T_{5}\right)=(0.24)(1660-1315)=82.8 \mathrm{Btu} / \mathrm{lbm} \\
q_{\text {reheater }}=c_{p}\left(T_{8}-T_{7}\right)=(0.24)(1660-1315)=82.8 \mathrm{Btu} / \mathrm{lbm}
\end{gathered}
$$

The cycle efficiency is now calculated to be

$$
\eta=\frac{w_{\text {out }}}{q_{\text {in }}}=\frac{w_{\text {turb }}-w_{\text {comp }}}{q_{\text {comb }}+q_{\text {reheater }}}=\frac{(128,800-52,840) / 778}{82.8+82.8}=0.590
$$

The back work ratio is $w_{\text {comp }} / w_{\text {turb }}=52,840 / 128,800=0.410$
9.16 A turbojet aircraft flies at a speed of $300 \mathrm{~m} / \mathrm{s}$ at an elevation of 10000 m . If the compression ratio is 10 , the turbine inlet temperature is $1000^{\circ} \mathrm{C}$, and the mass flux of air is $30 \mathrm{~kg} / \mathrm{s}$, calculate the maximum thrust possible from this engine. Also, calculate the rate of fuel consumption if the heating value of the fuel is $8400 \mathrm{~kJ} / \mathrm{kg}$.

The inlet temperature and pressure are found from Table B-1 to be (see Fig. 9-20)

$$
T_{1}=223.3 \mathrm{~K} \quad P_{1}=0.2615 \quad P_{0}=26.15 \mathrm{kPa}
$$

The temperature exiting the compressor is

$$
T_{2}=T_{1}\left(\frac{P_{2}}{P_{1}}\right)^{(k-1) / k}=(223.3)(10)^{0.2857}=431.1 \mathrm{~K}
$$

Since the turbine drives the compressor, the two works are equal so that

$$
c_{p}\left(T_{2}-T_{1}\right)=c_{p}\left(T_{3}-T_{4}\right) \quad \therefore T_{3}-T_{4}=T_{2}-T_{1}
$$

Since $T_{3}=1273$, we can find $T_{4}$ as $T_{4}=T_{3}+T_{1}-T_{2}=1273+223.3-431.1=1065.2 \mathrm{~K}$. We can now calculate the pressure at the turbine exit to be, using $P_{3}=P_{2}=261.5 \mathrm{kPa}$,

$$
P_{4}=P_{3}\left(\frac{T_{4}}{T_{3}}\right)^{k /(k-1)}=(261.5)\left(\frac{1065.2}{1273}\right)^{3.5}=140.1 \mathrm{kPa}
$$

The temperature at the nozzle exit, assuming an isentropic expansion, is

$$
T_{5}=T_{4}\left(\frac{P_{5}}{P_{4}}\right)^{(k-1) / k}=(1065.2)\left(\frac{26.15}{140.1}\right)^{0.2857}=659.4 \mathrm{~K}
$$

The energy equation provides us with the exit velocity $V_{5}=\left[2 c_{p}\left(T_{4}-T_{5}\right)\right]^{1 / 2}=[(2)(1000)$ $(1065.2-659.4)]^{1 / 2}=901 \mathrm{~m} / \mathrm{s}$, where $c_{p}=1000 \mathrm{~J} / \mathrm{kg} \cdot \mathrm{K}$ must be used in the expression. The thrust can now be calculated as

$$
\text { thrust }=\dot{m}\left(V_{5}-V_{1}\right)=(30)(901-300)=18030 \mathrm{~N}
$$

This represents a maximum since a cycle composed of ideal processes was used.
The heat transfer rate in the burner is $\dot{Q}=\dot{m} c_{p}\left(T_{3}-T_{2}\right)=(30)(1.00)(1273-431.1)=25.26 \mathrm{MW}$. This requires that the mass flux of fuel $\dot{m}_{f}$ be

$$
8400 \dot{m}_{f}=25260 \quad \therefore \dot{m}_{f}=3.01 \mathrm{~kg} / \mathrm{s}
$$

9.17 A gas-turbine cycle inlets $20 \mathrm{~kg} / \mathrm{s}$ of atmospheric air at $15^{\circ} \mathrm{C}$, compresses it to 1200 kPa , and heats it to $1200^{\circ} \mathrm{C}$ in a combustor. The gases leaving the turbine heat the steam of a Rankine cycle to $350^{\circ} \mathrm{C}$ and exit the heat exchanger (boiler) at $100^{\circ} \mathrm{C}$. The pump of the Rankine cycle operates between 10 kPa and 6 MPa . Calculate the maximum power output of the combined cycle and the combined cycle efficiency.

The temperature of gases leaving the gas turbine is (see Fig. 9-21)

$$
T_{8}=T_{7}\left(\frac{P_{8}}{P_{7}}\right)^{(k-1) / k}=(1473)\left(\frac{100}{1200}\right)^{0.2857}=724.2 \mathrm{~K}
$$

This temperature of the air exiting the compressor is

$$
T_{6}=T_{5}\left(\frac{P_{6}}{P_{5}}\right)^{(k-1) / k}=(288)\left(\frac{1200}{100}\right)^{0.2857}=585.8 \mathrm{~K}
$$

The net power output of the gas turbine is then

$$
\begin{aligned}
\dot{W}_{\mathrm{GT}} & =\dot{W}_{\text {turb }}-\dot{W}_{\text {comp }}=\dot{m} c_{p}\left(T_{7}-T_{8}\right)-\dot{m} c_{p}\left(T_{6}-T_{5}\right) \\
& =(20)(1.00)(1473-724.2-585.8+288)=9018 \mathrm{~kW}
\end{aligned}
$$

The temperature exiting the condenser of the Rankine cycle is $45.8^{\circ} \mathrm{C}$. An energy balance on the boiler heat exchanger allows us to find the mass flux $\dot{m}_{s}$ of the steam:

$$
\begin{aligned}
\dot{m}_{a} c_{p}\left(T_{8}-T_{9}\right) & =\dot{m}_{s}\left(h_{3}-h_{2}\right) \quad(20)(1.00)(724.2-100)=\dot{m}_{s}(3043-191.8) \\
\dot{m}_{s} & =3.379 \mathrm{~kg} / \mathrm{s}
\end{aligned}
$$

The isentropic process $3 \rightarrow 4$ allows $h_{4}$ to be found:

$$
\begin{aligned}
s_{4} & =s_{3}=6.3342=0.6491+7.5019 x_{4} \quad \therefore x_{4}=0.7578 \\
\therefore h_{4} & =191.8+(0.7578)(2392.8)=2005 \mathrm{~kJ} / \mathrm{kg}
\end{aligned}
$$

The steam turbine output is $\dot{W}_{\mathrm{ST}}=\dot{m}\left(h_{3}-h_{4}\right)=(3.379)(3043-2005)=3507 \mathrm{~kW}$. The maximum power output (we have assumed ideal processes in the cycles) is, finally,

$$
\dot{W}_{\text {out }}=\dot{W}_{\mathrm{GT}}+\dot{W}_{\mathrm{ST}}=9018+3507=12525 \mathrm{~kW} \text { or } 12.5 \mathrm{MW}
$$

The energy input to this combined cycle is $\dot{Q}_{\text {in }}=\dot{m}_{a} c_{p}\left(T_{7}-T_{6}\right)=(20)(1.00)(1473-585.8)=17.74$ MW. The cycle efficiency is then

$$
\eta=\frac{\dot{W}_{\text {out }}}{\dot{Q}_{\text {in }}}=\frac{12.5}{17.74}=0.70
$$

9.18 A simple gas cycle produces 10 tons of refrigeration by compressing air from 200 kPa to 2 MPa . If the maximum and minimum temperatures are $300^{\circ} \mathrm{C}$ and $-90^{\circ} \mathrm{C}$, respectively, find the compressor power and the cycle COP. The compressor is 82 percent efficient and the turbine is 87 percent efficient.

The ideal compressor inlet temperature (see Fig. 9-22) is $T_{2}=T_{3}\left(P_{2} / P_{3}\right)^{(k-1) / k}=$ $(573)(200 / 2000)^{0.2857}=296.8 \mathrm{~K}$. Because the compressor is 82 percent efficient, the actual inlet temperature $T_{2}$ is found as follows:

$$
\eta_{\mathrm{comp}}=\frac{w_{s}}{w_{a}}=\frac{c_{p}\left(T_{3}-T_{2^{\prime}}\right)}{c_{p}\left(T_{3}-T_{2}\right)} \quad \therefore T_{2}=\left(\frac{1}{0.82}\right)[(0.82)(573)-573+296.8]=236.2 \mathrm{~K}
$$

The low-temperature heat exchanger produces 10 tons $=35.2 \mathrm{~kW}$ of refrigeration:

$$
\dot{Q}_{\text {in }}=\dot{m} c_{p}\left(T_{2}-T_{1}\right) \quad 35.2=\dot{m}(1.00)(236.2-183) \quad \therefore \dot{m}=0.662 \mathrm{~kg} / \mathrm{s}
$$

The compressor power is then $\dot{W}_{\text {comp }}=\dot{m} c_{p}\left(T_{3}-T_{2}\right)=(0.662)(1.00)(573-236.2)=223 \mathrm{~kW}$. The turbine produces power to help drive the compressor. The ideal turbine inlet temperature is

$$
T_{4^{\prime}}=T_{1}\left(\frac{P_{4}}{P_{1}}\right)^{(k-1) / k}=(183)\left(\frac{2000}{200}\right)^{0.2857}=353.3 \mathrm{~K}
$$

The turbine power output is $\dot{W}_{\text {turb }}=\dot{m} \eta_{\text {turb }} c_{p}\left(T_{4^{\prime}}-T_{1}\right)=(0.662)(0.87 \times 1.00)(353.3-183)=98.1 \mathrm{~kW}$. The cycle COP is now calculated to be

$$
\mathrm{COP}=\frac{\dot{Q}_{\text {in }}}{\dot{W}_{\text {net }}}=\frac{(10)(3.52)}{223-98.1}=0.282
$$

9.19 Air enters the compressor of a gas refrigeration cycle at $-10^{\circ} \mathrm{C}$ and is compressed from 200 kPa to 800 kPa . The high-pressure air is then cooled to $0^{\circ} \mathrm{C}$ by transferring energy to the surroundings and then to $-30^{\circ} \mathrm{C}$ with an internal heat exchanger before it enters the turbine. Calculate the minimum possible temperature of the air leaving the turbine, the coefficient of performance, and the mass flux for 8 tons of refrigeration. Assume ideal components.

Refer to Fig. 9-23 for designation of states. The temperature at the compressor outlet is

$$
T_{4}=T_{3}\left(\frac{P_{4}}{P_{3}}\right)^{(k-1) / k}=(283)\left(\frac{800}{200}\right)^{0.2857}=420.5 \mathrm{~K}
$$

The minimum temperature at the turbine outlet follows from an isentropic process:

$$
T_{1}=T_{6}\left(\frac{P_{1}}{P_{6}}\right)^{(k-1) / k}=(243)\left(\frac{200}{800}\right)^{0.2857}=163.5 \mathrm{~K}
$$

The coefficient of performance is calculated as follows:

$$
\begin{aligned}
q_{\text {in }} & =c_{p}\left(T_{2}-T_{1}\right)=(1.00)(243-163.5)=79.5 \mathrm{~kJ} / \mathrm{kg} \\
w_{\text {comp }} & =c_{p}\left(T_{4}-T_{3}\right)=(1.00)(420.5-283)=137.5 \mathrm{~kJ} / \mathrm{kg} \\
w_{\text {turb }} & =c_{p}\left(T_{6}-T_{1}\right)=(1.00)(243-163.5)=79.5 \mathrm{~kJ} / \mathrm{kg} \\
\therefore \mathrm{COP} & =\frac{q_{\text {in }}}{w_{\text {comp }}-w_{\text {turb }}}=\frac{79.5}{137.5-79.5}=1.37
\end{aligned}
$$

We find the mass flux as follows:

$$
\dot{Q}_{\mathrm{in}}=\dot{m} q_{\mathrm{in}} \quad(8)(3.52)=(\dot{m})(79.5) \quad \dot{m}=0.354 \mathrm{~kg} / \mathrm{s}
$$

## Supplementary Problems

9.20 An ideal compressor receives $100 \mathrm{~m}^{3} / \mathrm{min}$ of atmospheric air at $10^{\circ} \mathrm{C}$ and delivers it at 20 MPa . Determine the mass flux and the power required. Ans. $2.05 \mathrm{~kg} / \mathrm{s}, 2058 \mathrm{~kW}$
9.21 A adiabatic compressor receives $1.5 \mathrm{~kg} / \mathrm{s}$ of atmospheric air at $25^{\circ} \mathrm{C}$ and delivers it at 4 MPa . Calculate the required power and the exiting temperature if the efficiency is assumed to be (a) 100 percent, and
(b) 80 percent.
Ans. (a) $835 \mathrm{~kW}, 582^{\circ} \mathrm{C}$
(b) $1044 \mathrm{~kW}, 721^{\circ} \mathrm{C}$
9.22 An adiabatic compressor receives atmospheric air at $60^{\circ} \mathrm{F}$ at a flow rate of $4000 \mathrm{ft}^{3} / \mathrm{min}$ and delivers it at 10,000 psia. Calculate the power requirement assuming a compressor efficiency of (a) 100 percent and (b) 82 percent. Ans. (a) $4895 \mathrm{hp} \quad$ (b) 5970 hp
9.23 A compressor delivers $2 \mathrm{~kg} / \mathrm{s}$ of air at 2 MPa having received it from the atmosphere at $20^{\circ} \mathrm{C}$. Determine the required power input and the rate of heat removed if the compression process is polytropic with (a) $n=1.4$, (b) $n=1.3$, (c) $n=1.2$, and (d) $n=1.0$.
Ans. (a) $797 \mathrm{~kW}, 0$
(b) $726 \mathrm{~kW}, 142 \mathrm{~kW}$
(c) $653 \mathrm{~kW}, 274 \mathrm{~kW}$
(d) $504 \mathrm{~kW}, 504 \mathrm{~kW}$
9.24 The heat transfer from a compressor is one-fifth the work input. If the compressor receives atmospheric air at $20^{\circ} \mathrm{C}$ and delivers it at 4 MPa , determine the polytropic exponent assuming an ideal compressor. Ans. 1.298
9.25 The maximum temperature in the compressor of Prob. $9.22(a)$ is too high. To reduce it, several stages are suggested. Calculate the maximum temperature and the isentropic power requirement assuming (a) two stages and (b) three stages. Ans. (a) $860^{\circ} \mathrm{F}, 2766 \mathrm{hp} \quad$ (b) $507.8^{\circ} \mathrm{F}, 2322 \mathrm{hp}$
9.26 A compressor receives $0.4 \mathrm{lbm} / \mathrm{sec}$ of air at 12 psia and $50^{\circ} \mathrm{F}$ and delivers it at 500 psia. For an 85 percent efficient compressor calculate the power requirement assuming ( $a$ ) one stage, and ( $b$ ) two stages. Ans. (a) 155 hp (b) 115 hp
9.27 Rather than assuming constant specific heats, use the air tables (Appendix F) and rework (a) Prob. 9.20 and (b) Prob. 9.22(a). Compute the percentage error for the constant specific heat assumption.
Ans.
(a) $2003 \mathrm{~kW}, 2.8 \%$
(b) $4610 \mathrm{hp}, 6.2 \%$
9.28 A three-stage compressor receives $2 \mathrm{~kg} / \mathrm{s}$ of air at 95 kPa and $22^{\circ} \mathrm{C}$ and delivers it at 4 MPa . For an ideal compressor calculate ( $a$ ) the intercooler pressures, ( $b$ ) the temperatures at each state, ( $c$ ) the power required, and ( $d$ ) the intercooler heat transfer rates.
Ans. (a) $330 \mathrm{kPa}, 1150 \mathrm{kPa}$
(b) $148^{\circ} \mathrm{C}, 22^{\circ} \mathrm{C}$
(c) 756 kW
(d) 252 kW
9.29 An engine with a bore and a stroke of $0.2 \times 0.2 \mathrm{~m}$ and a clearance of 5 percent experiences a minimum pressure of 120 kPa and a maximum pressure of 12 MPa . If it operates with air on the cycle of Fig. 9-7, determine ( $a$ ) the displacement volume, ( $b$ ) the compression ratio, and ( $c$ ) the MEP.
Ans. (a) 6.28 liters
(b) 20
(c) 245 kPa
9.30 An air-standard cycle operates in a piston-cylinder arrangement with the following four processes: $1 \rightarrow 2$ -isentropic compression from 100 kPa and $15^{\circ} \mathrm{C}$ to $2 \mathrm{MPa} ; 2 \rightarrow 3$-constant-pressurc heat addition to $1200^{\circ} \mathrm{C} ; 3 \rightarrow 4$-isentropic expansion; and $4 \rightarrow 1$-constant-volume heat rejection.
(a) Show the cycle on $P-t$ and $T \cdot s$ diagrams, ( $b$ ) calculate the heat addition and (c) calculate the cycle efficiency. Ans. (b) $522 \mathrm{~kJ} / \mathrm{kg} \quad$ (c) $22.3 \%$
9.31 An air-standard cycle operates in a piston-cylinder arrangement with the following four processes: $1 \rightarrow 2$ -constant-temperature compression from 12 psia and $70^{\circ} \mathrm{F}$ to 400 psia; $2 \rightarrow 3$-constant-pressure expansion to $1400^{\circ} \mathrm{F} ; 3 \rightarrow 4$-isentropic expansion; and $4 \rightarrow 1$-constant-volume process.
(a) Show the cycle on $P-r$ and $T-s$ diagrams, ( $b$ ) calculate the work output, and (c) calculate the cycle efficiency. Ans. (b) $118,700 \mathrm{ft}-\mathrm{lbf} / \mathrm{lbm} \quad$ (c) $47.8 \%$
9.32 A Carnot piston engine operates with air between $20^{\circ} \mathrm{C}$ and $600^{\circ} \mathrm{C}$ with a low pressure of 100 kPa . If it is to deliver $800 \mathrm{~kJ} / \mathrm{kg}$ of work calculate ( $a$ ) the thermal efficiency, ( $b$ ) the compression ratio, and ( $c$ ) the MEP. See Fig. 6-1. Ans. (a) $54.7 \%$ (b) $1873 \quad$ (c) 952 kPa
9.33 A Carnot engine operates on air as shown in Fig. 9-25. Find (a) the power output, (b) the thermal efficiency, and (c) the MEP. See Fig. 6-1. Ans. (a) $207 \mathrm{~kW} \quad$ (b) $45.4 \% \quad$ (c) 146.6 kPa

Fig. 9-25
9.34 A Carnot engine has heat addition during the combustion process of $4000 \mathrm{Btu} / \mathrm{sec}$. If the temperature limits are $1200^{\circ} \mathrm{F}$ and $30^{\circ} \mathrm{F}$, with high and low pressures of 1500 psia and 10 psia , determine the mass flux of air and the MEP. Sce Fig. 6-1. Ans. $67.4 \mathrm{lbm} / \mathrm{sec}, 12.5 \mathrm{psia}$
9.35 A Carnot engine operates between the temperatures of $100^{\circ} \mathrm{C}$ and $600^{\circ} \mathrm{C}$ with pressure limits of 150 kPa and 10 MPa . Calculate the mass flux of air if the rejected heat flux is (a) 100 kW , (b) 400 kW , and (c) 2 MW . Sce Fig. 6-1. Ans. (a) $1.23 \mathrm{~kg} / \mathrm{s} \quad$ (b) $0.328 \mathrm{~kg} / \mathrm{s} \quad$ (c) $0.0655 \mathrm{~kg} / \mathrm{s}$
9.36 A piston engine with a $0.2 \times 0.2 \mathrm{~m}$ bore and stroke is modeled as a Carnot engine. It operates on 0.5 $\mathrm{kg} / \mathrm{s}$ of air between temperatures of $20^{\circ} \mathrm{C}$ and $500^{\circ} \mathrm{C}$ with a low pressure of 85 kPa and a clearance of 2 percent. Find ( $a$ ) the power delivered, ( $b$ ) the compression ratio, ( $c$ ) the MEP, and ( $d$ ) the volume at top dead center. See Fig. 6-1. Ans. (a) $104 \mathrm{~kW} \quad$ (b) $51.0 \quad$ (c) $214 \mathrm{kPa} \quad$ (d) 0.1257 liter
9.37 A spark-ignition engine operates on an Otto cycle with a compression ratio of 9 and temperature limits of $30^{\circ} \mathrm{C}$ and $1000^{\circ} \mathrm{C}$. If the power output is 500 kW , calculate the thermal cfficiency and the mass flux of air. Ans. $58.5 \%, 2.19 \mathrm{~kg} / \mathrm{s}$
9.38 An Otto cycle operates with air entering the compression process at 15 psia and $90^{\circ} \mathrm{F}$. If $600 \mathrm{Btu} / \mathrm{lbm}$ of energy is added during combustion and the compression ratio is 10 , determine the work output and the MEP. Ans. 281,000 ft-lbf/ $\mathrm{lbm}, 160 \mathrm{psia}$
9.39 The maximum allowable pressure in an Otto cycle is 8 MPa . Conditions at the beginning of the air compression are 85 kPa and $22^{\circ} \mathrm{C}$. Calculate the required heat addition and the MEP, if the compression ratio is 8 . Ans. $2000 \mathrm{~kJ} / \mathrm{kg}, 1300 \mathrm{kPa}$
9.40 A maximum temperature of $1600^{\circ} \mathrm{C}$ is possible in an Otto cycle in which air enters the compression process at 85 kPa and $30^{\circ} \mathrm{C}$. Find the heat addition and the MEP, if the compression ratio is 6 .
Ans. $898 \mathrm{~kJ} / \mathrm{kg}, 539 \mathrm{kPa}$
9.41 If the Otto cycle shown in Fig. 9-26 operates on air, calculate the thermal efficiency and the MEP. Ans. $57.5 \%, 383 \mathrm{kPa}$

Fig. 9 -26
9.42 A spark-ignition engine with a compression ratio of 8 operates on an Otto cycle using air with a low temperature of $60^{\circ} \mathrm{F}$ and a low pressure of 14.7 psia . If the energy addition during combustion is 800 Btu/lbm, determine ( $a$ ) the work output and ( $b$ ) the maximum pressure.
Ans. (a) $352,000 \mathrm{ft}-\mathrm{lbf} / \mathrm{lbm}$ (b) 1330 psia
9.43 Use the air tables (Appendix F) to solve (a) Prob. 9.38 and (b) Prob. 9.41. Do not assume constant specific heats. Ans. (a) $254,000 \mathrm{ft}-\mathrm{lbf} / \mathrm{lbm}, 144 \mathrm{psia} \quad$ (b) $54.3 \%, 423 \mathrm{kPa}$
9.44 A diesel engine is designed to operate with a compression ratio of 16 and air entering the compression stroke at 110 kPa and $20^{\circ} \mathrm{C}$. If the energy added during combustion is $1800 \mathrm{~kJ} / \mathrm{kg}$, calculate ( $a$ ) the cutoff ratio, $(b)$ the thermal efficiency, and $(c)$ the MEP.
Ans. (a) 3.03
(b) $56.8 \%$
(c) 1430 kPa
9.45 A diesel cycle operates on air which enters the compression process at 85 kPa and $30^{\circ} \mathrm{C}$. If the compression ratio is 16 , the power output is 500 hp , and the maximum temperature is $2000^{\circ} \mathrm{C}$, calculate ( $a$ ) the cutoff ratio, ( $b$ ) the thermal efficiency, and ( $c$ ) the mass flux of air.
Ans. (a) 2.47
(b) $59.2 \%$
(c) $0.465 \mathrm{~kg} / \mathrm{s}$
9.46 Air enters the compression process of a diesel cycle at 120 kPa and $15^{\circ} \mathrm{C}$. The pressure after compression is 8 MPa and $1500 \mathrm{~kJ} / \mathrm{kg}$ is added during combustion. What are ( $a$ ) the cutoff ratio, $(b)$ the thermal efficiency, and (c) the MEP?

Ans. (a) 2.57
(b) $62.3 \%$
(c) 1430 kPa
9.47 For the cycle shown in Fig. $9-27$ find the thermal efficiency and the work output.

Ans. $67 \%, 205,000 \mathrm{ft}-\mathrm{lbf} / \mathrm{lbm}$

Fig. 9-27
9.48 A diesel engine has a $0.6 \times 1.2 \mathrm{~m}$ bore and stroke and operates with 5 percent clearance. For a power output of 5000 hp calculate the compression ratio and the rate of heat input if the cutoff ratio is 2.5 . Ans. $21,5890 \mathrm{~kW}$
9.49 Use the air tables (Appendix F) to solve (a) Prob. 9.44 and (b) Prob. 9.47. Do not assume constant specific heats. Ans. (a) $2.76,50.6 \%, 1270 \mathrm{kPa}$ (b) $62.2 \%, 240,000 \mathrm{ft}-\mathrm{lbf} / \mathrm{lbm}$
9.50 A dual cycle with $r=18, r_{c}=2$, and $r_{p}=1.2$ operates on $0.5 \mathrm{~kg} / \mathrm{s}$ of air at 100 kPa and $20^{\circ} \mathrm{C}$ at the beginning of the compression process. Calculate ( $a$ ) the thermal efficiency, ( $b$ ) the energy input, and $\begin{array}{llll}\text { (c) the power output. Ans. (a) } 63.7 \% & \text { (b) } 1250 \mathrm{~kJ} / \mathrm{kg} & \text { (c) } 534 \mathrm{hp}\end{array}$
9.51 A compression-ignition engine operates on a dual cycle by receiving air at the beginning of the compression process at 80 kPa and $20^{\circ} \mathrm{C}$ and compressing it to 60 MPa . If $1800 \mathrm{~kJ} / \mathrm{kg}$ of energy is added during the combustion process, with one-third of it added at constant volume, determine ( $a$ ) the thermal efficiency, ( $b$ ) the work output, and ( $c$ ) the MEP.
Ans. (a) $81.2 \%$
(b) $1460 \mathrm{~kJ} / \mathrm{kg}$
(c) 1410 kPa
9.52 An ideal cycle operates on air with a compression ratio of 12 . The low pressure is 100 kPa and the low temperature is $30^{\circ} \mathrm{C}$. If the maximum temperature is $1500^{\circ} \mathrm{C}$, calculate the work output and the heat input for ( $a$ ) a Stirling cycle and ( $b$ ) an Ericsson cycle.
Ans. (a) $1048 \mathrm{~kJ} / \mathrm{kg}, 1264 \mathrm{~kJ} / \mathrm{kg} \quad$ (b) $303 \mathrm{~kJ} / \mathrm{kg}, 366 \mathrm{~kJ} / \mathrm{kg}$
9.53 An ideal cycle is to produce a power output of 100 hp while operating on $1.2 \mathrm{lbm} / \mathrm{sec}$ of air at 14.7 psia and $70^{\circ} \mathrm{F}$ at the beginning of the compression process. If the compression ratio is 10 , what is the maximum temperature and the energy input for ( $a$ ) a Stirling cycle and ( $b$ ) an Ericsson cycle?
Ans. (a) $443^{\circ} \mathrm{F}, 142.5 \mathrm{Btu} / \mathrm{lbm} \quad$ (b) $605^{\circ} \mathrm{F}, 117 \mathrm{Btu} / \mathrm{lbm}$
9.54 Calculate the work output and thermal efficiency for the cycles shown in Fig. 9-28a and $b$. Air is the operating fluid. Ans. (a) $831 \mathrm{~kJ} / \mathrm{kg}, 60 \%$ (b) $1840 \mathrm{~kJ} / \mathrm{kg}, 80 \%$

Fig. 9-28
9.55 Air enters the compressor of a gas turbine at 85 kPa and $0^{\circ} \mathrm{C}$. If the pressure ratio is 6 and the maximum temperature is $1000^{\circ} \mathrm{C}$, find ( $a$ ) the thermal efficiency and ( $b$ ) the back work ratio for the associated Brayton cycle. Ans. (a) $40.1 \% \quad$ (b) 0.358
9.56 Three kg of air enters the compressor of a gas turbine each second at 100 kPa and $10^{\circ} \mathrm{C}$. If the pressure ratio is 5 and the maximum temperature is $800^{\circ} \mathrm{C}$, determine ( $a$ ) the horsepower output, (b) the back work ratio, and (c) the thermal efficiency for the associated Brayton cycle.
Ans. (a) 927 hp (b) 0.418 (c) $36.9 \%$
9.57 Determine the compressor outlet pressure that will result in maximum work output for a Brayton cycle in which the compressor inlet air conditions are 14.7 psia and $65^{\circ} \mathrm{F}$ and the maximum temperature is $1500^{\circ} \mathrm{F}$. Ans. 147 psia
9.58 Air enters the compressor of a Brayton cycle at 80 kPa and $30^{\circ} \mathrm{C}$ and compresses it to 500 kPa . If 1800 $\mathrm{kJ} / \mathrm{kg}$ of energy is added in the combustor, calculate $(a)$ the compressor work requirement, $(b)$ the net turbinc output, and (c) the back work ratio. Ans. (a) $208 \mathrm{~kJ} / \mathrm{kg}$ (b) $734 \mathrm{~kJ} / \mathrm{kg} \quad$ (c) 0.221
9.59 Find the back work ratio and the horsepower output of the cycle shown in Fig. 9-29.

Ans. $0.365,799 \mathrm{hp}$

Fig. 9-29
9.60 Calculate the thermal efficiency and the back work ratio of the gas turbine of Prob. 9.55 if the respective compressor and turbine efficiencies are ( $a$ ) $80 \%, 80 \%$, and ( $b$ ) $83 \%, 86 \%$.
Ans. (a) 0.559, 23.3\%
(b) $0.502,28.1 \%$
9.61 Determine the efficiency of the compressor and turbine (the efficiencics are equal) that would result in a zero thermal efficiency for the gas turbine of Prob. 9.55. Ans. $59.8 \%$
9.62 Calculate the thermal efficiency and the back work ratio of the Brayton cycle of Prob. 9.58 if the compressor and turbine efficiencies are ( $a$ ) $83 \%, 83 \%$ and $(b) 81 \%, 88 \%$.
$\begin{array}{lll}\text { Ans. (a) } 30.3 \%, 0.315 & \text { (b) } 32.8 \%, 0.304\end{array}$
9.63 Determine the efficiency of the compressor and turbine (the efficiencies are equal) of the Brayton cycle of Prob. 9.58 that would result in no net work output. Ans. $43.7 \%$
9.64 The efficiency of the turbine of Prob. 9.59 is 83 percent. What compressor efficiency would reduce the Brayton cycle thermal efficiency to zero? Ans. $44 \%$
9.65 Use the air tables to find the thermal efficiency and the back work ratio for (a) Prob. 9.55, (b) Prob. 9.58. and (c) Prob. 9.59. Do not assume constant specific heats.
Ans. (a) 38.1\%, 0.346
(b) $37.1 \%, 0.240$
(c) $34.8 \%, 0.355$
9.66 A regenerator is installed in the gas turbine of Prob. 9.58. Determine the cycle efficiency if its effectiveness is (a) 100 percent and (b) 80 percent. Ans. (a) $88.4 \%$ (b) $70.3 \%$
9.67 For the ideal-gas turbine with regenerator shown in Fig. 9-30 find $\dot{W}_{\text {out }}$ and the back work ratio. Ans. $899 \mathrm{~kW}, 0.432$.

Air

Fig. 9 -30
9.68 Assume that the efficiencies of the compressor and turbine of Prob. 9.67 are 83 percent and 86 percent. respectively, and that the effectiveness of the regenerator is 90 percent. Determine the power output and the back work ratio. Ans. $540 \mathrm{~kW}, 0.604$
9.69 Temperatures for the ideal regenerative gas-turbine cycle of Fig. 9-17 are $T_{1}=60^{\circ} \mathrm{F}, T_{2}=500^{\circ} \mathrm{F}$, $T_{3}=700^{\circ} \mathrm{F}$, and $T_{4}=1600^{\circ} \mathrm{F}$. Calculate the thermal efficiency and the back work ratio if air is the working fluid. Ans. $51.1 \%, 0.489$
9.70 Air enters a two-stage compressor of a gas turbine at 100 kPa and $20^{\circ} \mathrm{C}$ and is compressed to 600 kPa . The inlet temperature to the two-stage turbine is $1000^{\circ} \mathrm{C}$ and a regenerator is also used. Calculate ( $a$ ) the work output, ( $b$ ) the thermal efficiency, and ( $c$ ) the back work ratio assuming an ideal cycle.
Ans.
(a) $171 \mathrm{~kJ} / \mathrm{kg}$
(b) $70.3 \%$
(c) 0.297
9.71 One stage of intercooling, one stage of reheat, and regeneration are added to the gas turbine of Prob. 9.59. Calculate ( $a$ ) the power output, ( $b$ ) the thermal efficiency, and ( $c$ ) the back work ratio assuming an ideal cycle. Ans. (a) $997 \mathrm{hp} \quad$ (b) $71 \%$ (c) 0.29
9.72 (a) For the ideal components shown in Fig. 9-31 calculate the thermal efficiency. (b) For the same components, with an air mass flux of $2 \mathrm{~kg} / \mathrm{s}$, determine $\dot{W}_{\text {out }}, \dot{Q}_{C}, \dot{Q}_{R}$, and $\dot{Q}_{\text {out }}$. Ans. (a) $80.3 \% \quad$ (b) $1792 \mathrm{~kW}, 2232 \mathrm{~kW}, 220 \mathrm{~kW}, 1116 \mathrm{~kW}$

Fig. 9-31
9.73 A turbojet engine inlets $70 \mathrm{~kg} / \mathrm{s}$ of air at an altitude of 10 km while traveling at $300 \mathrm{~m} / \mathrm{s}$. The compressor provides a pressure ratio of 9 and the turbine inlet temperature is $1000{ }^{\circ} \mathrm{C}$. What is the maximum thrust and horsepower that can be expected from this engine? Ans. $41.5 \mathrm{kN}, 16700 \mathrm{hp}$
9.74 Rework Prob. 9.73 with realistic efficiencies of 85 percent and 89 percent in the compressor and turbine, respectively. Assume the nozzle to be 97 percent efficient. Ans. $35.5 \mathrm{kN}, 14300 \mathrm{hp}$
9.75 An aircraft with two turbojet engines requires a thrust of 4300 lbf for cruise conditions of $800 \mathrm{ft} / \mathrm{sec}$. If each engine has a mass flux of $30 \mathrm{lbm} / \mathrm{sec}$ of air, calculate the pressure ratio if the maximum temperature is $2000{ }^{\circ} \mathrm{F}$. The aircraft flies at an altitude of $30,000 \mathrm{ft}$. Ans. 10
9.76 Calculate the thermal efficiency of the combined cycle shown in Fig. 9-32. Ans. $56 \%$

Fig. 9.32
9.77 A gas-turbine cycle intakes $50 \mathrm{~kg} / \mathrm{s}$ of air at 100 kPa and $20^{\circ} \mathrm{C}$. It compresses it by a factor of 6 and the combustor heats it to $900^{\circ} \mathrm{C}$. It then enters the boiler of a simple Rankine cycle power plant that operates on steam between 8 kPa and 4 MPa . The heat exchanger-boiler outlets steam at $400^{\circ} \mathrm{C}$ and exhaust gases at $300^{\circ} \mathrm{C}$. Determine the total power output and the overall cycle efficiency.
Ans. 16 MW, 47\%
9.78 The compressor and turbine of the gas cycle of Prob. 9.77 are 85 percent efficient and the steam turbine is 87 percent efficient. Calculate the combined cycle power output and efficiency.
Ans. 11.6 MW, 35.8\%
9.79 Air flows at the rate of $2.0 \mathrm{~kg} / \mathrm{s}$ through the compressor of an ideal gas refrigeration cycle where the pressure increases to 500 kPa from 100 kPa . The maximum and minimum cycle temperatures are $300^{\circ} \mathrm{C}$ and $-20^{\circ} \mathrm{C}$, respectively. Calculate the COP and the power needed to drive the compressor.
Ans. $\quad 1.73,169 \mathrm{hp}$
9.80 Rework Prob. 9.79 assuming the efficiencies of the compressor and turbine are 84 percent and 88 percent, respectively. Ans. $0.57,324 \mathrm{hp}$
9.81 An ideal internal heat exchanger is added to the cycle of Prob. 9.79 (see Fig. 9-23) so that the low temperature is reduced to $-60^{\circ} \mathrm{C}$ while the maximum temperature remains at $300^{\circ} \mathrm{C}$. Determine the COP and the compressor power requirement. Ans. 1.43, 233 hp
9.82 What is the COP for the ideal air cycle shown in Fig. 9-33 if it is (a) used to refrigerate a space, and $\begin{array}{lll}\text { (b) used to heat a space? Ans. (a) } 1.28 & \text { (b) } 2.28\end{array}$

Fig. 9-33
9.83 Assuming the compressor and turbine of Prob. 9.82 are each 87 percent efficient and the effectiveness of the internal heat exchanger is 90 percent, rework the problem. Ans. (a) 0.83 (b) 1.72

## Chapter 10

## Thermodynamic Relations

### 10.1 THREE DIFFERENTIAL RELATIONSHIPS

Let us consider a variable $z$ which is a function of $x$ and $y$. Then we may write

$$
\begin{equation*}
z=f(x, y) \quad d z=\left(\frac{\partial z}{\partial x}\right)_{y} d x+\left(\frac{\partial z}{\partial y}\right)_{x} d y \tag{10.1}
\end{equation*}
$$

This relationship is an exact mathematical formulation for the differential $z$. Let us write $d z$ in the form

$$
\begin{equation*}
d z=M d x+N d y \tag{10.2}
\end{equation*}
$$

where

$$
\begin{equation*}
M=\left(\frac{\partial z}{\partial x}\right)_{y} \quad N=\left(\frac{\partial z}{\partial y}\right)_{x} \tag{10.3}
\end{equation*}
$$

If we have exact differentials (and we will when dealing with thermodynamic properties), then we have the first important relationship:

$$
\begin{equation*}
\left(\frac{\partial M}{\partial y}\right)_{x}=\left(\frac{\partial N}{\partial x}\right)_{y} \tag{10.4}
\end{equation*}
$$

This is proved by substituting in for $M$ and $N$ from our previous equations:

$$
\begin{equation*}
\frac{\partial^{2} z}{\partial y \partial x}=\frac{\partial^{2} z}{\partial x \partial y} \tag{10.5}
\end{equation*}
$$

which is true providing the order of differentiation makes no difference in the result, which it does not for the functions of interest in our study of thermodynamics.

To find our second important relationship, first consider that $x$ is a function of $y$ and $z$, that is, $x=f(y, z)$. Then we may write

$$
\begin{equation*}
d x=\left(\frac{\partial x}{\partial y}\right)_{z} d y+\left(\frac{\partial x}{\partial z}\right)_{y} d z \tag{10.6}
\end{equation*}
$$

Substituting for $d z$ from (10.1), we have

$$
\begin{equation*}
d x=\left(\frac{\partial x}{\partial y}\right)_{z} d y+\left(\frac{\partial x}{\partial z}\right)_{y}\left[\left(\frac{\partial z}{\partial x}\right)_{y} d x+\left(\frac{\partial z}{\partial y}\right)_{x} d y\right] \tag{10.7}
\end{equation*}
$$

or, rearranging,

$$
\begin{equation*}
0=\left[1-\left(\frac{\partial x}{\partial z}\right)_{y}\left(\frac{\partial z}{\partial x}\right)_{y}\right] d x-\left[\left(\frac{\partial x}{\partial z}\right)_{y}\left(\frac{\partial z}{\partial y}\right)_{x}+\left(\frac{\partial x}{\partial z}\right)_{z}\right] d y \tag{10.8}
\end{equation*}
$$

The two independent variables $x$ and $y$ can be varied independently; i.e., we can fix $x$ and vary $y$, or fix $y$ and vary $x$. If we fix $x$, then $d x=0$; hence the bracketed coefficient of $d y$ must be zero. If we fix $y$, then $d y=0$ and the bracketed coefficient of $d x$ is zero. Consequently,

$$
\begin{equation*}
1-\left(\frac{\partial x}{\partial z}\right)_{y}\left(\frac{\partial z}{\partial x}\right)_{y}=0 \tag{10.9}
\end{equation*}
$$

and

$$
\begin{equation*}
\left(\frac{\partial x}{\partial z}\right)_{y}\left(\frac{\partial z}{\partial y}\right)_{x}+\left(\frac{\partial x}{\partial y}\right)_{z}=0 \tag{10.10}
\end{equation*}
$$

The first equation gives

$$
\begin{equation*}
\left(\frac{\partial x}{\partial z}\right)_{y}\left(\frac{\partial z}{\partial x}\right)_{y}=1 \tag{10.11}
\end{equation*}
$$

which leads to our second important relationship:

$$
\begin{equation*}
\left(\frac{\partial x}{\partial z}\right)_{y}=\frac{1}{(\partial z / \partial x)_{y}} \tag{10.12}
\end{equation*}
$$

Now rewrite (10.10) as

$$
\begin{equation*}
\left(\frac{\partial x}{\partial z}\right)_{y}\left(\frac{\partial z}{\partial y}\right)_{x}=-\left(\frac{\partial x}{\partial y}\right)_{z} \tag{10.13}
\end{equation*}
$$

Dividing through by $(\partial x / \partial y)_{z}$ and using (10.12),

$$
\begin{equation*}
\left[\left(\frac{\partial x}{\partial y}\right)_{z}\right]^{-1}=\left(\frac{\partial y}{\partial x}\right)_{z} \tag{10.14}
\end{equation*}
$$

we obtain the cyclic formula

$$
\begin{equation*}
\left(\frac{\partial x}{\partial z}\right)_{y}\left(\frac{\partial z}{\partial y}\right)_{x}\left(\frac{\partial y}{\partial x}\right)_{z}=-1 \tag{10.15}
\end{equation*}
$$

EXAMPLE 10.1 Estimate the change in the specific volume of air, assuming an ideal gas, using the differential form for $d v$, if the temperature and pressure change from $25^{\circ} \mathrm{C}$ and 122 kPa to $29^{\circ} \mathrm{C}$ and 120 kPa . Compare with the change calculated directly from the ideal-gas law.

Using $v=R T / P$, we find

$$
d v=\left(\frac{\partial v}{\partial T}\right)_{P} d T+\left(\frac{\partial v}{\partial P}\right)_{T} d P=\frac{R}{P} d T-\frac{R T}{P^{2}} d P=\left(\frac{0.287}{121}\right)(4)-\frac{(0.287)(300)}{(121)^{2}}(-2)=0.02125 \mathrm{~m}^{3} / \mathrm{kg}
$$

where we have used average values for $P$ and $T$.
The ideal-gas law provides

$$
\Delta v=\frac{R T_{2}}{P_{2}}-\frac{R T_{1}}{P_{1}}=\frac{(0.287)(302)}{120}-\frac{(0.287)(298)}{122}=0.02125 \mathrm{~m}^{3} / \mathrm{kg}
$$

Obviously the change in state of $4^{\circ} \mathrm{C}$ and -2 kPa is sufficiently small that the differential change du approximates the actual change $\Delta v$.

### 10.2 THE MAXWELL RELATIONS

For small (differential) changes in the internal energy and the enthalpy of a simple compressible system, we may write the differential forms of the first law as

$$
\begin{align*}
d u & =T d s-P d v  \tag{10.16}\\
d h & =T d s+v d P \tag{10.17}
\end{align*}
$$

We introduce two other properties: the Helmholtz function $a$ and the Gibbs function $g$ :

$$
\begin{align*}
& a=u-T s  \tag{10.18}\\
& g=h-T s \tag{10.19}
\end{align*}
$$

In differential form, using (10.16) and (10.17), we can write

$$
\begin{align*}
d a & =-P d v-s d T  \tag{10.20}\\
d g & =v d P-s d T \tag{10.21}
\end{align*}
$$

Applying our first important relationship from calculus [see (10.4)] to the four exact differentials
above, we obtain the Maxwell relations:

$$
\begin{align*}
& \left(\frac{\partial T}{\partial v}\right)_{s}=-\left(\frac{\partial P}{\partial s}\right)_{v}  \tag{10.22}\\
& \left(\frac{\partial T}{\partial P}\right)_{s}=\left(\frac{\partial v}{\partial s}\right)_{P}  \tag{10.23}\\
& \left(\frac{\partial P}{\partial T}\right)_{V}=\left(\frac{\partial s}{\partial v}\right)_{T}  \tag{10.24}\\
& \left(\frac{\partial v}{\partial T}\right)_{P}=-\left(\frac{\partial s}{\partial P}\right)_{T} \tag{10.25}
\end{align*}
$$

Through the Maxwell relations changes in entropy (an immeasurable quantity) can be expressed in terms of changes in $v, T$, and $P$ (measurable quantities). By extension, the same can be done for internal energy and enthalpy (see Sec. 10.4).

EXAMPLE 10.2 Assuming that $h=h(s, P)$, what two differential relationships does this imply? Verify one of the relationships using the steam tables at $400^{\circ} \mathrm{C}$ and 4 MPa .

If $h=h(s, P)$ we can write

$$
d h=\left(\frac{\partial h}{\partial s}\right)_{P} d s+\left(\frac{\partial h}{\partial P}\right)_{s} d P
$$

But the first law can be written as [see (10.17)] $d h=T d s+v d P$. Equating coefficients of $d s$ and $d P$, there results

$$
T=\left(\frac{\partial h}{\partial s}\right)_{P} \quad \varepsilon=\left(\frac{\partial h}{\partial P}\right)_{s}
$$

Let's verify the constant-pressure relationships. At $P=4 \mathrm{MPa}$ and using central differences (use entries on either side of the desired state) at $T=400^{\circ} \mathrm{C}$, we have from the superheat table

$$
\left(\frac{\partial h}{\partial s}\right)_{P}=\frac{3330-3092}{6.937-6.583}=672 \mathrm{~K} \text { or } 399^{\circ} \mathrm{C}
$$

This compares favorably with the specified temperature of $400^{\circ} \mathrm{C}$.

### 10.3 THE CLAPEYRON EQUATION

We may use the Maxwell relations in a variety of ways. For example, (10.24) allows us to express the quantity $h_{f g}$ (the enthalpy of vaporization) using $P, v$, and $T$ data alone. Suppose we desire $h_{f g}$ at the point ( $t_{0}, T_{0}$ ) of Fig. $10-1$. Since the temperature remains constant during the phase change, we

Fig. 10-1
can write

$$
\begin{equation*}
\left(\frac{\partial s}{\partial \nu}\right)_{T=T_{0}}=\frac{s_{g}-s_{f}}{v_{g}-v_{f}} \tag{10.26}
\end{equation*}
$$

Consequently, (10.24) gives

$$
\begin{equation*}
\left(\frac{\partial P}{\partial T}\right)_{c=v_{0}}=\frac{s_{f g}}{v_{f g}} \tag{10.27}
\end{equation*}
$$

But, we can integrate (10.17), knowing that $P$ and $T$ are constant during a phase change:

$$
\begin{equation*}
\int d h=\int T_{0} d s-\int v d P^{0} \quad \text { or } \quad h_{f g}=T_{0} s_{f g} \tag{10.28}
\end{equation*}
$$

This is substituted into (10.27) to give the Clapeyron equation:

$$
\begin{equation*}
\left(\frac{\partial P}{\partial T}\right)_{r=c_{0}}=\frac{h_{f g}}{T_{0} v_{f g}} \quad \text { or } \quad h_{f g}=T_{0} l_{f g}\left(\frac{\partial P}{\partial T}\right)_{l=r_{0}} \tag{10.29}
\end{equation*}
$$

The partial derivative $(\partial P / \partial T)_{c=v_{0}}$ can be evaluated from the saturated-state tables, using the central-difference approximation

$$
\begin{equation*}
\left(\frac{\partial P}{\partial T}\right)_{v=v_{0}} \cong \frac{P_{2}-P_{1}}{T_{2}-T_{1}} \tag{10.30}
\end{equation*}
$$

where $T_{2}$ and $T_{1}$ are selected at equal intervals above and below $T_{0}$. (See Example 10.3.)
For relatively low pressures, the Clapeyron equation can be modified when $v_{g} \gg v_{f}$. We may treat the saturated vapor as an ideal gas, so that

$$
\begin{equation*}
v_{f g}=v_{g}-v_{f} \cong v_{g}=\frac{R T}{P} \tag{10.31}
\end{equation*}
$$

Then (10.29) becomes (dropping the subscript 0 )

$$
\begin{equation*}
\left(\frac{\partial P}{\partial T}\right)_{v}=\frac{P h_{f g}}{R T^{2}} \tag{10.32}
\end{equation*}
$$

This is often referred to as the Clausius-Clapeyron equation. It may also be used for the sublimation process involving a solid to vapor phase change.

During a phase change, the pressure depends only on the temperature; hence, we may use an ordinary derivative so that

$$
\begin{equation*}
\left(\frac{\partial P}{\partial T}\right)_{c}=\left(\frac{d P}{d T}\right)_{\mathrm{sat}} \tag{10.33}
\end{equation*}
$$

Then (10.32) can be rearranged as

$$
\begin{equation*}
\left(\frac{d P}{P}\right)_{\mathrm{sat}}=\frac{h_{f g}}{R}\left(\frac{d T}{T^{2}}\right)_{\mathrm{sat}} \tag{10.34}
\end{equation*}
$$

This is integrated between two saturation states to yield

$$
\begin{equation*}
\ln \left(\frac{P_{2}}{P_{1}}\right)_{\mathrm{sat}} \cong \frac{h_{f g}}{R}\left(\frac{1}{T_{1}}-\frac{1}{T_{2}}\right)_{\mathrm{sat}} \tag{10.35}
\end{equation*}
$$

where we have assumed $h_{f g}$ to be constant between state 1 and state 2 (hence the "approximately equal to" symbol). Relationship (10.35) may be used to approximate the pressure or temperature below the limits of tabulated values (see Example 10.4).

EXAMPLE 10.3 Predict the value for the enthalpy of vaporization for water at $200^{\circ} \mathrm{C}$ assuming steam to be an ideal gas. Calculate the percent error.

At $200^{\circ} \mathrm{C}$ and 155.4 kPa the specific volume of the saturated steam is, in the ideal-gas approximation, $v_{g}=R T / P=(0.462)(473) / 155=0.1406 \mathrm{~m}^{3} / \mathrm{kg}$. For liquid water the density is approximately $1000 \mathrm{~kg} / \mathrm{m}^{3}$ so
that $v_{f} \cong 0.001 \mathrm{~m}^{3} / \mathrm{kg}$ (or we can use $v_{f}$ from the steam table). Hence we find

$$
h_{f g}=T v_{f s}\left(\frac{\partial P}{\partial T}\right)_{v}=(473)(0.1406-0.001)\left(\frac{1906-1254}{210-190}\right)=2153 \mathrm{~kJ} / \mathrm{kg}
$$

This compares with $h_{f g}=1941 \mathrm{~kJ} / \mathrm{kg}$ from the steam tables, the error being

$$
\% \text { error }=\left(\frac{2153-1941}{1941}\right)(100)=10.9 \%
$$

This error is due to the inaccuracy of the value for $v_{g}$.
EXAMPLE 10.4 Suppose the steam tables started at $P_{\text {sat }}=2 \mathrm{kPa}\left(T_{\text {sat }}=17.5^{\circ} \mathrm{C}\right)$ and we desired $T_{\text {sat }}$ at $P_{\text {sat }}=1 \mathrm{kPa}$. Predict $T_{\text {sat }}$ and compare with the value from the steam tables.

Since the pressure is quite low, we will assume that $v_{g} \gg v_{f}$ and that $v_{g}$ is given by the ideal-gas law. Using values for $h_{f g}$ at $P_{\text {sat }}=4 \mathrm{kPa}, 3 \mathrm{kPa}$, and 2 kPa we assume that at $P_{\text {sat }}=1 \mathrm{kPa}, h_{f g}=2480 \mathrm{~kJ} / \mathrm{kg}$. Then (10.35) provides us with

$$
\ln \left(\frac{P_{2}}{P_{1}}\right)_{\text {sat }}=\frac{h_{f g}}{R}\left(\frac{1}{T_{1}}-\frac{1}{T_{2}}\right)_{\text {sat }} \quad \ln \left(\frac{1}{2}\right)=\left(\frac{2480}{0.462}\right)\left(\frac{1}{290.5}-\frac{1}{T_{2}}\right) \quad \therefore T_{2}=280 \mathrm{~K} \text { or } 7.0^{\circ} \mathrm{C}
$$

This is very close to the valuc of $6.98^{\circ} \mathrm{C}$ from the steam tables.

### 10.4 FURTHER CONSEQUENCES OF THE MAXWELL RELATIONS

## Internal Energy

Considering the internal energy to be a function of $T$ and $v$, we can write

$$
\begin{equation*}
d u=\left(\frac{\partial u}{\partial T}\right)_{v} d T+\left(\frac{\partial u}{\partial v}\right)_{T} d v=c_{v} d T+\left(\frac{\partial u}{\partial v}\right)_{T} d v \tag{10.36}
\end{equation*}
$$

where we have used the definition $c_{v}=(\partial u / \partial T)_{i}$. The differential form of the first law is

$$
\begin{equation*}
d u=T d s-P d v \tag{10.37}
\end{equation*}
$$

Assuming $s=f(T, v)$, the above relationship can be written as

$$
\begin{equation*}
d u=T\left[\left(\frac{\partial s}{\partial T}\right)_{r} d T+\left(\frac{\partial s}{\partial v}\right)_{T} d v\right]-P d v=T\left(\frac{\partial s}{\partial T}\right)_{c} d T+\left[T\left(\frac{\partial s}{\partial v}\right)_{T}-P\right] d v \tag{10.38}
\end{equation*}
$$

When this expression for $d u$ is equated to that of (10.36), one obtains

$$
\begin{align*}
c_{r} & =T\left(\frac{\partial s}{\partial T}\right)_{c}  \tag{10.39}\\
\left(\frac{\partial u}{\partial v}\right)_{T} & =T\left(\frac{\partial s}{\partial v}\right)_{T}-P=T\left(\frac{\partial P}{\partial T}\right)_{v}-P \tag{10.40}
\end{align*}
$$

where we have used the Maxwell relation (10.24). We can now relate $d u$ to the properties $P, v, T$, and $c_{i}$. by substituting (10.40) into (10.36):

$$
\begin{equation*}
d u=c_{\imath} d T+\left[T\left(\frac{\partial P}{\partial T}\right)_{v}-P\right] d v \tag{10.41}
\end{equation*}
$$

This can be integrated to provide $\left(u_{2}-u_{1}\right)$ if we have an equation of state that provides the relationship between $P, v$, and $T$ so that $(\partial P / \partial T)_{v}$ is known.

## Enthalpy

Considering enthalpy to be a function of $T$ and $P$, steps similar to those above result in

$$
\begin{align*}
c_{p} & =T\left(\frac{\partial s}{\partial T}\right)_{P}  \tag{10.42}\\
d h & =c_{p} d T+\left[v-T\left(\frac{\partial v}{\partial T}\right)_{P}\right] d P \tag{10.43}
\end{align*}
$$

which can be integrated to give ( $h_{2}-h_{1}$ ) if an equation of state is known.

Since we know that $h=u+P v$, we have

$$
\begin{equation*}
h_{2}-h_{1}=u_{2}-u_{1}+P_{2} v_{2}-P_{1} v_{1} \tag{10.44}
\end{equation*}
$$

Hence, if we know $P=f(T, v)$, we can find ( $u_{2}-u_{1}$ ) from (10.41) and ( $h_{2}-h_{1}$ ) from (10.44). If we know $v=f(P, T)$, we can find $\left(h_{2}-h_{1}\right)$ from (10.43) and ( $u_{2}-u_{1}$ ) from (10.44). In the first case we know $P$ explicitly as a function of $T$ and $v$; in the second case we know $c$ explicitly as a function of $P$ and $T$. For an ideal gas, $P v=R T$ so that the bracketed quantities in (10.41) and (10.43) are zero, as we have assumed earlier in our study of an ideal gas in which $u=u(T)$ and $h=h(T)$. For a nonideal gas an equation of state will be provided so that one of the bracketed quantities can be evaluated.

## Entropy

Finally, let us find an expression for $d s$. Consider $s=s(T, v)$. Then, using (10.39) and (10.24), we have

$$
\begin{equation*}
d s=\left(\frac{\partial s}{\partial T}\right)_{v} d T+\left(\frac{\partial s}{\partial v}\right)_{T} d v=\frac{c_{v}}{T} d T+\left(\frac{\partial P}{\partial T}\right)_{r} d v \tag{10.45}
\end{equation*}
$$

Alternatively, we can let $s=s(T, P)$. Then, using (10.42) and (10.25), we find

$$
\begin{equation*}
d s=\frac{c_{p}}{T} d T-\left(\frac{\partial v}{\partial T}\right)_{P} d P \tag{10.46}
\end{equation*}
$$

These two equations can be integrated to yield

$$
\begin{equation*}
s_{2}-s_{1}=\int_{T_{1}}^{T_{2}} \frac{c_{v}}{T} d T+\int_{v_{1}}^{v_{2}}\left(\frac{\partial P}{\partial T}\right)_{v} d v=\int_{T_{1}}^{T_{2}} \frac{c_{p}}{T} d T-\int_{P_{1}}^{P_{2}}\left(\frac{\partial v}{\partial T}\right)_{P} d P \tag{10.47}
\end{equation*}
$$

For an ideal gas these equations simplify to the equations of Chap. 7. See Sec. 10.7 for actual calculations involving real gases.

EXAMPLE 10.5 Derive an expression for the enthalpy change in an isothermal process of a gas for which the equation of state is $P=R T /(v-b)-\left(a / v^{2}\right)$.

Since $P$ is given explicitly, we find an expression for $\Delta u$ and then use (10.44). For a process in which $d T=0$, (10.41) provides

$$
\Delta u=\int_{c_{1}}^{c_{2}}\left[T\left(\frac{\partial P}{\partial T}\right)_{c}-P\right] d v=\int_{c_{1}}^{v_{2}}\left(\frac{T R}{v-b}-\frac{R T}{v-b}+\frac{a}{v^{2}}\right) d v=-a\left(\frac{1}{c_{2}}-\frac{1}{v_{1}}\right)
$$

The expression for $\Delta h$ is then

$$
h_{2}-h_{1}=\Delta u+P_{2} v_{2}-P_{1} v_{1}=a\left(\frac{1}{v_{1}}-\frac{1}{v_{2}}\right)+P_{2} v_{2}-P_{1} v_{1}
$$

EXAMPLE 10.6 We know that $c_{p}=A+B T$ along a low-pressure isobar $P=P^{*}$. If the equation of state is $P=R T /(v-b)-\left(a / v^{2}\right)$ find an expression for $\Delta s$.

Since we know $P$ explicitly, we use (10.47) to find $\Delta s$ :

$$
\Delta s=\int_{T_{1}}^{T_{2}} \frac{c_{v}}{T} d T+\int_{v_{1}}^{v_{2}}\left(\frac{\partial P}{\partial T}\right)_{c} d v
$$

Our expression for $c_{p}$ holds only along $P=P^{*}$. Rather than integrating directly from 1 to 2 , as shown in Fig. 10-2, we proceed isothermally from 1 to $1^{*}$, then along $P=P^{*}$ from $1^{*}$ to $2^{*}$, and finally isothermally from

Fig. 10-2
$2^{*}$ to 2 . This results in

$$
\begin{aligned}
\Delta s & =-\int_{c_{1}}^{l^{*}}\left(\frac{\partial P}{\partial T}\right)_{r} d v+\int_{T_{1}^{*}}^{T_{2}^{*}} \frac{c_{P}}{T} d T+\int_{c_{2}^{*}}^{c_{2}}\left(\frac{\partial P}{\partial T}\right)_{i} d v \\
& =-\int_{t_{1}}^{c_{1}^{*}} \frac{R}{v-b} d v+\int_{T_{1}^{*}}^{T_{2}^{*}}\left(\frac{A}{T}+B\right) d T+\int_{c^{*}}^{c_{2}} \frac{R}{v-b} d v \\
& =R \ln \frac{l_{1}-b}{l_{1}^{*}-b}+A \ln \frac{T_{2}}{T_{1}}+B\left(T_{2}-T_{1}\right)+R \ln \frac{v_{2}-b}{l_{2}^{*}-b}
\end{aligned}
$$

We could calculate a numerical value for $\Delta s$ if the initial and final states, $A, B, P^{*}, a$, and $b$ were provided for a particular gas.

### 10.5 RELATIONSHIPS INVOLVING SPECIFIC HEATS

If we can relate the specific heats to $P, \nu$, and $T$, we will have completed our objective of relating the "hidden" thermodynamic quantities to the three measurable properties.

The exact differential $d s=M d T+N d P$ was written in (10.46) as

$$
\begin{equation*}
d s=\frac{c_{p}}{T} d T-\left(\frac{\partial \nu}{\partial T}\right)_{p} d P \tag{10.48}
\end{equation*}
$$

Using (10.4), we can write

$$
\begin{equation*}
\left[\frac{\partial}{\partial P}\left(c_{p} / T\right)\right]_{T}=-\left[\frac{\partial}{\partial T}\left(\frac{\partial v}{\partial T}\right)_{P}\right]_{P} \tag{10.49}
\end{equation*}
$$

or, rearranging,

$$
\begin{equation*}
\left(\frac{\partial c_{p}}{\partial P}\right)_{T}=-T\left(\frac{\partial^{2} v}{\partial T^{2}}\right)_{P} \tag{10.50}
\end{equation*}
$$

If we start with (10.45), we obtain

$$
\begin{equation*}
\left[\frac{\partial}{\partial U^{\prime}}\left(c_{v} / T\right)\right]_{T}=\left[\frac{\partial}{\partial T}\left(\frac{\partial P}{\partial T}\right)_{v}\right]_{V} \tag{10.51}
\end{equation*}
$$

resulting in

$$
\begin{equation*}
\left(\frac{\partial c_{i}}{\partial v^{2}}\right)_{T}=T\left(\frac{\partial^{2} P}{\partial T^{2}}\right)_{V} \tag{10.52}
\end{equation*}
$$

Consequently, knowing an equation of state, the quantities $\left(\partial c_{p} / \partial P\right)_{T}$ and $\left(\partial c_{t} / \partial l\right)_{T}$ can be found for an isothermal process.

A third useful relation can be found by equating (10.48) and (10.45):

$$
\begin{equation*}
\frac{c_{p}}{T} d T-\left(\frac{\partial v}{\partial T}\right)_{P} d P=\frac{c_{v}}{T} d T+\left(\frac{\partial P}{\partial T}\right)_{v} d v \tag{10.53}
\end{equation*}
$$

so that

$$
\begin{equation*}
d T=\frac{T(\partial v / \partial T)_{P}}{c_{p}-c_{v}} d P+\frac{T(\partial P / \partial T)_{i}}{c_{p}-c_{c}} d v \tag{10.54}
\end{equation*}
$$

But, since $T=T(P, v)$, we can write

$$
\begin{equation*}
d T=\left(\frac{\partial T}{\partial P}\right)_{v} d P+\left(\frac{\partial T}{\partial v}\right)_{P} d v \tag{10.55}
\end{equation*}
$$

Equating the coefficients of $d P$ in the above two expressions for $d T$ gives

$$
\begin{equation*}
c_{p}-c_{v}=T\left(\frac{\partial v}{\partial T}\right)_{P}\left(\frac{\partial P}{\partial T}\right)_{V}=-T\left(\frac{\partial v}{\partial T}\right)_{P}^{2}\left(\frac{\partial P}{\partial v}\right)_{T} \tag{10.56}
\end{equation*}
$$

where we have used both (10.12) and (10.15). The same relationship would have resulted had we equated the coefficients of $d v$ in (10.54) and (10.55). We can draw three important conclusions from (10.56):

1. $c_{p}=c_{c}$ for a truly incompressible substance ( $v=$ const.). Since $(\partial c / \partial T)_{P}$ is quite small for a liquid or solid, we usually assume that $c_{p} \cong c_{l}$.
2. $c_{p} \rightarrow c_{v}$ as $T \rightarrow 0$ (absolute zero).
3. $c_{p} \geqslant c_{c}$ since $(\partial P / \partial u)_{T}<0$ for all known substances.

Equation (10.56) can be written in terms of the volume expansicity

$$
\begin{equation*}
\beta=\frac{1}{v}\left(\frac{\partial v}{\partial T}\right)_{P} \tag{10.57}
\end{equation*}
$$

and the bulk modulus

$$
\begin{equation*}
B=-v\left(\frac{\partial P}{\partial v}\right)_{T} \tag{10.58}
\end{equation*}
$$

as

$$
\begin{equation*}
c_{p}-c_{i}=\iota T \beta^{2} B \tag{10.59}
\end{equation*}
$$

Values for $\beta$ and $B$ can be found in handbooks of material properties.
EXAMPLE 10.7 Find an expression for $c_{p}-c_{r}$ if the equation of state is $P=R T /(c-b)-\left(a / r^{2}\right)$.
Equation (10.56) provides us with

$$
c_{p}-c_{r}=T\left(\frac{\partial U}{\partial T}\right)_{P}\left(\frac{\partial P}{\partial T}\right)_{l}
$$

Our given equation of state can be written as
so that

$$
T=\frac{1}{R}\left[P(v-b)+\frac{a}{v^{2}}(v-b)\right]
$$

Hence

$$
(\partial T / \partial v)_{P}=\left(P-a / v^{2}+2 a b / v^{3}\right) / R=1 /(\partial v / \partial T)_{P}
$$

This reduces to $c_{p}-c_{r}=R$ if $a=b=0$, the ideal-gas relationship.
EXAMPLE 10.8 Calculate the entropy change of a $10-\mathrm{kg}$ block of copper if the pressure changes from 100 kPa to 50 MPa while the temperature remains constant. Use $\beta=5 \times 10^{-5} \mathrm{~K}^{-1}$ and $\rho=8770 \mathrm{~kg} / \mathrm{m}^{3}$.

Using one of Maxwell's equations and (10.57), the entropy differential is

$$
d s=\left(\frac{\partial s}{\partial P}\right)_{T} d P+\left(\frac{\partial s}{\partial T}\right)_{P} d \Delta T^{(0)}=-\left(\frac{\partial \nu}{\partial T}\right)_{P} d P=-i \cdot \beta d P
$$

Assuming $c$ and $\beta$ to be relatively constant over this pressure range, the entropy change is

$$
s_{2}-s_{1}=-\frac{1}{\rho} \beta\left(P_{2}-P_{1}\right)=-\frac{1}{8770}\left(5 \times 10^{-.5}\right)\left[(50-0.1) \times 10^{6}\right]=-0.285 \mathrm{~J} / \mathrm{kg} \cdot \mathrm{~K}
$$

If we had considered the copper to be incompressible ( $d v=0$ ) the entropy change would be zero, as observed from (10.47). The entropy change in this example results from the small change in volume of the copper.

### 10.6 THE JOULE-THOMSON COEFFICIENT

When a fluid passes through a throttling device (a valve, a porous plug, a capillary tube, or an orifice) the enthalpy remains constant, the result of the first law. In the refrigeration cycle such a device was used to provide a sudden drop in the temperature. A drop does not always occur: the temperature may remain constant or the temperature may increase. Which situation occurs depends on the value of the Joule-Thomson coefficient,

$$
\begin{equation*}
\mu_{j} \equiv\left(\frac{\partial T}{\partial P}\right)_{h} \tag{10.60}
\end{equation*}
$$

If $\mu_{j}$ is positive, a temperature decrease follows the pressure decrease across the device; if $\mu_{j}$ is negative, a temperature increase results; for $\mu_{j}=0$, a zero temperature change results. Let us express $\mu_{j}$ in terms of $P, l, T$, and $c_{p}$ as we did with the other properties in Sec. 10.4. The differential expression for $d h$ is given in (10.43) as

$$
\begin{equation*}
d h=c_{p} d T+\left[\iota^{\prime}-T\left(\frac{\partial \iota^{\prime}}{\partial T}\right)_{P}\right] d P \tag{10.61}
\end{equation*}
$$

If we hold $h$ constant, as demanded by (10.60), we find

$$
\begin{equation*}
0=c_{p} d T+\left[\imath-T\left(\frac{\partial v}{\partial T}\right)_{p}\right] d P \tag{10.62}
\end{equation*}
$$

or, in terms of partial derivatives,

$$
\begin{equation*}
\mu_{j}=\left(\frac{\partial T}{\partial P}\right)_{h}=\frac{1}{c_{p}}\left[T\left(\frac{\partial \nu}{\partial T}\right)_{P}-\iota\right] \tag{10.63}
\end{equation*}
$$

Since $\mu_{j}$ is quite easy to measure, this relationship provides us with a relatively easy method to evaluate $c_{p}$. For an ideal gas, $h=h(T)$ or $T=T(h)$. Therefore, when $h$ is held constant, $T$ is held constant, and so $\partial T / \partial P=\mu_{j}=0$.

EXAMPLE 10.9 Find the Joule-Thomson coefficient for steam at $400^{\circ} \mathrm{C}$ and 1 MPa using both expressions given in (10.63).

We can use (10.42) and find $c_{p}$ :

$$
c_{p}=T\left(\frac{\partial s}{\partial T}\right)_{P} \cong T\left(\frac{\Delta s}{\Delta T}\right)_{P}=673 \frac{7.619-7.302}{450-350}=2.13 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K}
$$

Then (10.63) gives, using $c_{p}=2130 \mathrm{~J} / \mathrm{kg} \cdot \mathrm{K}$,

$$
\mu_{j}=\frac{1}{c_{p}}\left[T\left(\frac{\partial \iota}{\partial T}\right)_{P}-i\right]=\left(\frac{1}{2130}\right)\left[(673)\left(\frac{0.3304-0.2825}{450-350}\right)-0.3066\right]=7.40 \times 10^{-6} \mathrm{~K} / \mathrm{Pa}
$$

Using the other expression in (10.64) we find (we hold enthalpy constant at $3264 \mathrm{~kJ} / \mathrm{kg}$ )

$$
\mu_{j}=\left(\frac{\partial T}{\partial P}\right)_{h}=\frac{403.7-396.2}{(1.5-0.5) \times 10^{6}}=7.50 \times 10^{-6} \mathrm{~K} / \mathrm{Pa}
$$

Since $\mu_{j}$ is positive, the temperature decreases due to the sudden decrease in pressure across a throttling device.

### 10.7 ENTHALPY, INTERNAL-ENERGY, AND ENTROPY CHANGES OF REAL GASES

Gases at relatively low pressure can usually be treated as an ideal gas so that $P_{c}=R T$. For ideal gases, the relations of the previous sections reduce to the simplified relations of the earlier chapters in this book. In this section we will evaluate the changes in enthalpy, internal energy, and entropy of real (nonideal) gases using the generalized relations of Sec. 10.4.

The general relation for the enthalpy change is found by integrating (10.43):

$$
\begin{equation*}
h_{2}-h_{1}=\int_{T_{1}}^{T_{2}} c_{p} d T+\int_{P_{1}}^{P_{2}}\left[v-T\left(\frac{\partial v}{\partial T}\right)_{P}\right] d P \tag{10.64}
\end{equation*}
$$

The change in a property is independent of the path selected. Rather than going directly from 1 to 2 , let us select the path shown in Fig. 10-3 that takes us to such a low pressure $P^{*}$ that the process from $1^{*}$ to $2^{*}$ involves an ideal gas. Certainly $P^{*}=0$ will work, so let's set $P^{*}=0$. The processes from 1 to $1^{*}$ and from $2^{*}$ to 2 are isothermal, so that

$$
\begin{align*}
& h_{1}^{*}-h_{1}=\int_{P_{1}}^{0}\left[v-T\left(\frac{\partial v}{\partial T}\right)_{P}\right]_{T=T_{1}} d P  \tag{10.65}\\
& h_{2}-h_{2}^{*}=\int_{0}^{P_{2}}\left[v-T\left(\frac{\partial v}{\partial T}\right)_{P}\right]_{T=T_{2}} d P \tag{10.66}
\end{align*}
$$

Fig. 10-3
For the ideal process from $1^{*}$ to $2^{*}$ we have

$$
\begin{equation*}
h_{2}^{*}-h_{1}^{*}=\int_{T_{1}}^{T_{2}} c_{p} d T \tag{10.67}
\end{equation*}
$$

The enthalpy change is then

$$
\begin{equation*}
h_{2}-h_{1}=\left(h_{1}^{*}-h_{1}\right)+\left(h_{2}^{*}-h_{1}^{*}\right)+\left(h_{2}-h_{2}^{*}\right) \tag{10.68}
\end{equation*}
$$

The ideal-gas change ( $h_{2}^{*}-h_{1}^{*}$ ) is found using the $c_{p}(T)$ relationship or the gas tables. For the isothermal changes of the real gas we introduce the equation of state $P v=Z R T$, where $Z$ is the compressibility factor. Using $v=Z R T / P$, the integrals of (10.65) and (10.66) can be put in the form

$$
\begin{equation*}
\frac{h^{*}-h}{T_{c}}=-R T_{R}^{2} \int_{0}^{P_{R}}\left(\frac{\partial Z}{\partial T_{R}}\right)_{P_{R}} \frac{d P_{R}}{P_{R}} \tag{10.69}
\end{equation*}
$$

where the reduced temperature $T_{R}=T / T_{c}$ and the reduced pressure $P_{R}=P / P_{c}$ have been used. The quantity $\left(h^{*}-h\right) / T_{c}$ is called the enthalpy departure and has been determined numerically using a graphical integration of the compressibility chart. The result is presented in Fig. 1-1 using molar units. Obviously, $h^{*}-h=0$ for an ideal gas, since $h=h(T)$ and the process is isothermal.

The internal-energy change is found from the definition of enthalpy [see (10.44)] and is

$$
\begin{equation*}
u_{2}-u_{1}=h_{2}-h_{1}-R\left(Z_{2} T_{2}-Z_{1} T_{1}\right) \tag{10.70}
\end{equation*}
$$

where we have used $P v=Z R T$.
The change in entropy of a real gas can be found using a technique similar to that used for the enthalpy change. For an isothermal process (10.47) provides the entropy change as

$$
\begin{equation*}
s_{2}-s_{1}=-\int_{P_{1}}^{P_{2}}\left(\frac{\partial v}{\partial T}\right)_{P} d P \tag{10.71}
\end{equation*}
$$

We again integrate from the given state along an isothermal path to a low pressure where an ideal gas can be assumed, resulting in

$$
\begin{equation*}
s-s_{0}^{*}=-\int_{P_{\text {low }}}^{P}\left(\frac{\partial v}{\partial T}\right)_{P} d P \tag{10.72}
\end{equation*}
$$

where the asterisk denotes an ideal-gas state. The above equation, integrated along an isotherm from the ideal-gas state to any state that is approximated as an ideal gas, takes the form

$$
\begin{equation*}
s^{*}-s_{0}^{*}=-\int_{P_{\mathrm{low}}}^{P} \frac{R}{P} d P \tag{10.73}
\end{equation*}
$$

Subtracting the above two equations provides, for an isothermal process,

$$
\begin{equation*}
s^{*}-s=-\int_{P_{\mathrm{low}}}^{P}\left[\frac{R}{P}-\left(\frac{\partial v}{\partial T}\right)_{P}\right] d P \tag{10.74}
\end{equation*}
$$

Introducing the nonideal-gas equation of state $P v=Z R T$, we have

$$
\begin{equation*}
s^{*}-s=R \int_{P_{\mathrm{low}}}^{P}\left[(Z-1)+T_{R}\left(\frac{\partial Z}{\partial T_{R}}\right)_{P_{R}}\right] \frac{d P_{R}}{P_{R}} \tag{10.75}
\end{equation*}
$$

which is called the entropy departure. This has also been determined numerically from the compressibility charts and is presented in Appendix J using molar units. We can now find the entropy change between any two states using

$$
\begin{equation*}
s_{2}-s_{1}=-\left(s_{2}^{*}-s_{2}\right)+\left(s_{2}^{*}-s_{1}^{*}\right)+\left(s_{1}^{*}-s_{1}\right) \tag{10.76}
\end{equation*}
$$

In this equation the quantity $s_{2}^{*}-s_{1}^{*}$ represents the entropy change between the two given states, on the assumption that the gas behaves as an ideal gas; it does not represent a change along the $P^{*}=0$ path illustrated in Fig. 10-3.

EXAMPLE 10.10 Calculate the enthalpy change, the internal-energy change, and the entropy change of nitrogen as it undergoes a process from $-50^{\circ} \mathrm{C}, 2 \mathrm{MPa}$, to $40^{\circ} \mathrm{C}, 6 \mathrm{MPa}$. Use (a) the equations for an ideal gas with constant specific heats, ( $b$ ) the ideal-gas tables, and ( $c$ ) the equations of this section.
(a) $\Delta h=c_{p} \Delta T=(1.042)[40-(-50)]=93.8 \mathrm{~kJ} / \mathrm{kg} \quad \Delta u=c_{r} \Delta T=(0.745)[40-(-50)]=67.0 \mathrm{~kJ} / \mathrm{kg}$ $\Delta s=c_{p} \ln \frac{T_{2}}{T_{1}}-R \ln \frac{P_{2}}{P_{1}}=1.042 \ln \frac{313}{223}-0.297 \ln \frac{6}{2}=0.0270 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}$
(b) Interpolating in the ideal-gas table (Table F-2) gives

$$
\begin{aligned}
& \Delta h=h_{2}-h_{1}=(9102-6479) / 28=93.7 \mathrm{~kJ} / \mathrm{kg} \quad \Delta u=u_{2}-u_{1}=(6499-4625) / 28=66.9 \mathrm{~kJ} / \mathrm{kg} \\
& \Delta s=\phi_{2}-\phi_{1}-R \ln \frac{P_{2}}{P_{1}}=(192.9-183.0) / 28-0.297 \ln (6 / 2)=0.0273 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K}
\end{aligned}
$$

(c) Using (10.69) and the enthalpy departure chart in Appendix I we find

$$
\begin{array}{ll}
T_{R 1}=\frac{T_{1}}{T_{c}}=\frac{223}{126.2}=1.77 & P_{R 1}=\frac{P_{1}}{P_{c}}=\frac{2}{3.39}=0.590 \\
T_{R 2}=\frac{T_{2}}{T_{c}}=\frac{313}{126.2}=2.48 & P_{R 2}=\frac{P_{2}}{P_{c}}=\frac{6}{3.39}=1.77
\end{array}
$$

The enthalpy departure chart (Appendix I) provides us with

$$
\begin{array}{ll}
\frac{\bar{h}_{1}^{*}-\bar{h}_{1}}{T_{c}}=1.6 \mathrm{~kJ} / \mathrm{kmol} \cdot \mathrm{~K} & \therefore h_{1}^{*}-h_{1}=\frac{(1.6)(126.2)}{28}=7.21 \mathrm{~kJ} / \mathrm{kg} \\
\frac{\bar{h}_{2}^{*}-\bar{h}_{2}}{T_{c}}=2.5 \mathrm{~kJ} / \mathrm{kmol} \cdot \mathrm{~K} & \therefore h_{2}^{*}-h_{2}=\frac{(2.5)(126.2)}{28}=11.27 \mathrm{~kJ} / \mathrm{kg}
\end{array}
$$

Consequently,

$$
\Delta h=\left(h_{2}-h_{2}^{*}\right)+\left(h_{1}^{*}-h_{1}\right)+\left(h_{2}^{*}-h_{1}^{*}\right)=-11.27+7.21+(1.042)[40-(-50)]=90 \mathrm{~kJ} / \mathrm{kg}
$$

To find the internal energy change we use (10.70). The $Z$ values are found, using the compressibility chart with the above $T_{R}$ and $P_{R}$ values, to be $Z_{1}=0.99$ and $Z_{2}=0.985$. Then

$$
\Delta u=\Delta h-R\left(Z_{2} T_{2}-Z_{1} T_{1}\right)=90-(0.297)[(0.985)(313)-(0.99)(223)]=64 \mathrm{~kJ} / \mathrm{kg}
$$

To find the entropy change we first find $s_{1}^{*}-s_{1}$ and $s_{2}^{*}-s_{2}$ using the entropy departure chart in Appendix J.

$$
\begin{array}{ll}
\bar{s}_{1}^{*}-\bar{s}_{1}=1.0 \mathrm{~kJ} / \mathrm{kmol} \cdot \mathrm{~K} & \therefore s_{1}^{*}-s_{1}=1.0 / 28=0.036 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K} \\
\bar{s}_{2}^{*}-\bar{s}_{2}=1.2 \mathrm{~kJ} / \mathrm{kmol} \cdot \mathrm{~K} & \therefore s_{2}^{*}-s_{2}=1.2 / 28=0.043 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K}
\end{array}
$$

The entropy change is then
$\Delta s=\left(s_{2}-s_{2}^{*}\right)+\left(s_{1}^{*}-s_{1}\right)+\left(s_{2}^{*}-s_{1}^{*}\right)=-0.043+0.036+1.042 \ln \frac{313}{223}-0.297 \ln \frac{6}{2}=0.02 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}$
Note that the real-gas effects in this example were not very pronounced. The temperatures were quite high compared to $T_{c}$ and the pressures were not excessively large. Also, accuracy using the small charts is quite difficult.

## Solved Problems

10.1 Verify (10.15) using the equation of state for an ideal gas.

The equation of state for an ideal gas is $P v=R T$. Let the three variables be $P, v, T$. Relationship (10.15) takes the form

$$
\left(\frac{\partial P}{\partial T}\right)_{C}\left(\frac{\partial T}{\partial \iota^{\prime}}\right)_{P}\left(\frac{\partial L}{\partial P}\right)_{T}=-1
$$

The partial derivatives are

$$
\left(\frac{\partial P}{\partial T}\right)_{t}=\frac{\partial}{\partial T}\left(\frac{R T}{v}\right)_{t}=\frac{R}{v} \quad\left(\frac{\partial T}{\partial v}\right)_{P}=\frac{\partial}{\partial v}\left(\frac{P v}{R}\right)_{P}=\frac{P}{R} \quad\left(\frac{\partial v}{\partial P}\right)_{T}=\frac{\partial}{\partial P}\left(\frac{R T}{P}\right)_{T}=-\frac{R T}{P^{2}}
$$

Form the product and simplify:

$$
\left(\frac{\partial P}{\partial T}\right)_{c}\left(\frac{\partial T}{\partial v}\right)_{P}\left(\frac{\partial v}{\partial P}\right)_{T}=\frac{R}{v} \frac{P}{R}\left(-\frac{R T}{P^{2}}\right)=-\frac{R T}{P_{t}}=-1
$$

The relationship is verified.
10.2 Derive the Maxwell relation (10.23) from (10.22) using (10.15).

The right side of the Maxwell relation (10.23) involves $c, s$, and $P$ so that

$$
\begin{equation*}
\left(\frac{\partial v}{\partial s}\right)_{P}\left(\frac{\partial P}{\partial v}\right)_{s}\left(\frac{\partial s}{\partial P}\right)_{t}=-1 \quad \text { or } \quad\left(\frac{\partial v}{\partial s}\right)_{P}=-\left(\frac{\partial v}{\partial P}\right)_{s}\left(\frac{\partial P}{\partial s}\right)_{t} \tag{1}
\end{equation*}
$$

From calculus,

$$
\left(\frac{\partial T}{\partial v}\right)_{s}\left(\frac{\partial v}{\partial P}\right)_{s}=\left(\frac{\partial T}{\partial P}\right)_{s}
$$

Using (10.22) the above relation is written as

$$
-\left(\frac{\partial P}{\partial s}\right)_{d}\left(\frac{\partial v}{\partial P}\right)_{s}=\left(\frac{\partial T}{\partial P}\right)_{s}
$$

Substituting this into (1) provides

$$
\left(\frac{\partial U}{\partial s}\right)_{P}=\left(\frac{\partial T}{\partial P}\right)_{s}
$$

which is the Maxwell relation (10.23).
10.3 Verify the third Maxwell relation (10.24) using the steam table at $600^{\circ} \mathrm{F}$ and 80 psia .

We approximate the first derivative using central differences if possible:

$$
\begin{aligned}
&\left(\frac{\partial P}{\partial T}\right)_{t:=7.794}=\frac{(100-60)(144)}{857.6-348.2}=11.3 \mathrm{lbf} / \mathrm{ft}^{2}-{ }^{\circ} \mathrm{F} \\
&\left(\frac{\partial s}{\partial t}\right)_{T=600}=\frac{1.7582-1.8165}{6.216-10.425}=0.0139 \mathrm{Btu} / \mathrm{ft}^{3}-{ }^{\circ} \mathrm{R} \quad \text { or } 10.8 \mathrm{lbf} / \mathrm{ft}^{2}-{ }^{\circ} \mathrm{R}
\end{aligned}
$$

The difference in the above is less than 5 percent, which is due primarily to the fact that the entries in the steam table are relatively far apart. A table with more entries would result in less error.
10.4 Verify the Clapeyron equation for Freon 12 at 500 kPa .

The Clapeyron equation is $(\partial P / \partial T)_{t}=h_{f g} / T t_{f g}$. From Table D-2 for Freon 12 we find, at 500 kPa using central differences,

$$
\left(\frac{\partial P}{\partial T}\right)_{c}=\frac{600-400}{22-8.15}=14.44 \mathrm{kPa} /{ }^{\circ} \mathrm{C}
$$

We also observe that at $P=500 \mathrm{kPa}, T=15.6^{\circ} \mathrm{C}, h_{f g}=143.35 \mathrm{~kJ} / \mathrm{kg}$, and $v_{f g}=0.03482-0.0007438=$ $0.03408 \mathrm{~m}^{3} / \mathrm{kg}$.

Checking the above Clapeyron equation, we have

$$
14.44 \stackrel{?}{=} \frac{143.35}{(15.6+273)(0.03408)}=14.57
$$

This is quite close, verifying the Clapeyron equation.
10.5 Find an expression for the change in internal energy if $P=R T /(c-b)-\left(a / L^{2}\right)$ and $c_{1}=A+B T$. Simplify the expression for an ideal gas with constant specific heats.

We integrate ( 10.41 ) as follows:

$$
\begin{aligned}
\Delta u & =\int c_{1} d T+\int\left[T\left(\frac{\partial P}{\partial T}\right)_{r}-P\right] d v^{\prime} \\
& =\int(A+B T) d T+\int\left[T \frac{R}{v-b}-\frac{R T}{v-b}+\frac{a}{v^{2}}\right] d v \\
& =\int_{T_{1}}^{T_{2}}(A+B T) d T+\int_{i_{1}}^{l_{2}} \frac{a}{v^{2}} d v \\
& =A\left(T_{2}-T_{1}\right)+\frac{1}{2} B\left(T_{2}^{2}-T_{1}^{2}\right)-a\left(\frac{1}{v_{2}}-\frac{1}{v_{1}}\right)
\end{aligned}
$$

For an ideal gas $P=R T / t$ so that $a=b=0$, and if $c_{1}=$ const., we set $B=0$. Then the above expression simplifies to $\Delta u=A\left(T_{2}-T_{1}\right)=c_{i}\left(T_{2}-T_{1}\right)$.
10.6 Find an expression for $c_{p}-c_{r}$ if the equation of state is

$$
c=\frac{R T}{P}-\frac{a}{R T}+b
$$

From the equation of state we find $(\partial \nu / \partial T)_{P}=(R / P)+\left(a / R T^{2}\right)$. To find $(\partial P / \partial T)_{t}$ we first write the equation of state as

$$
P=R T\left(c-b+\frac{a}{R T}\right)^{-1}
$$

so that

$$
\left(\frac{\partial P}{\partial T}\right)_{T}=\frac{(u-b) R+2 a / T}{(c-b+a / R T)^{2}}
$$

Using (10.56) the desired expression is

$$
c_{p}-c_{t}=\left(\frac{T R}{P}+\frac{a}{R T}\right) \frac{(c-b) R+2 a / T}{(c-b+a / R T)^{2}}
$$

This reduces to $c_{p}-c_{l^{\prime}}=R$ for an ideal gas; that is, for $a=b=0$.
10.7 The specific heat $c_{1}$ of copper at $200^{\circ} \mathrm{C}$ is desired. If $c_{2}$ is assumed to be equal to $c_{p}$ estimate the error. Use $\beta=5 \times 10^{-5} \mathrm{~K}^{-1}, B=125 \mathrm{GPa}$, and $\rho=8770 \mathrm{~kg} / \mathrm{m}^{3}$.

Equation (10.59) provides the relation

$$
c_{p}-c_{i}=t T \beta^{2} B=\left(\frac{1}{8770}\right)(473)\left(5 \times 10^{-5}\right)^{2}\left(125 \times 10^{9}\right)=16.85 \mathrm{~J} / \mathrm{kg} \cdot \mathrm{~K}
$$

From Table B-4 the specific heat of copper is approximated at $200^{\circ} \mathrm{C}$ to be about $0.40 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}$. Hence,

$$
c_{t}=c_{p}-0.01685=0.4-0.01685=0.383 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K}
$$

Assuming $c_{l}=0.4 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}$,

$$
\% \text { error }=\left(\frac{0.4-0.383}{0.383}\right)(100)=4.4 \%
$$

This error may be significant in certain calculations.
10.8 The Joule-Thomson coefficient is measured to be $0.001^{\circ} \mathrm{R}-\mathrm{ft}^{2} / \mathrm{lbf}$ for steam at $600^{\circ} \mathrm{F}$ and 100 psia. Calculate the value of $c_{p}$.

Equation (10.63) is used to evaluate $c_{p}$. With values from the steam table at $600^{\circ} \mathrm{F}$ and 160 psia we find

$$
\begin{aligned}
c_{p} & =\frac{1}{\mu_{j}}\left[T\left(\frac{\partial v}{\partial T}\right)_{P}-v\right]=\left(\frac{1}{0.001}\right)\left[(1060)\left(\frac{4.243-3.440}{700-500}\right)-3.848\right] \\
& =408 \mathrm{ft}-\mathrm{lbf} / \mathrm{lbm}-{ }^{\circ} \mathrm{R} \text { or } 0.524 \mathrm{Btu} / \mathrm{lbm}-{ }^{\circ} \mathrm{R}
\end{aligned}
$$

10.9 Calculate the change in enthalpy of air which is heated from 300 K and 100 kPa to 700 K and 2000 kPa using the enthalpy departure chart. Compare with Prob. 4.10(c).

The reduced temperatures and pressures are

$$
\begin{aligned}
& T_{R 1}=\frac{T_{1}}{T_{c}}=\frac{300}{133}=2.26 \quad P_{R 1}=\frac{P_{1}}{P_{c}}=\frac{100}{3760}=0.027 \\
& T_{R 2}=\frac{700}{133}=5.26 \quad P_{R 2}=\frac{2000}{3760}=0.532
\end{aligned}
$$

The enthalpy departure chart provides $h_{2}^{*}-h_{2} \cong 0$ and $h_{1}^{*}-h_{1} \cong 0$, so that

$$
h_{2}-h_{1}=h_{2}^{*}-h_{1}^{*}=713.27-300.19=413.1 \mathrm{~kJ} / \mathrm{kg}
$$

where we have used the ideal-gas tables for the ideal-gas enthalpy change $h_{2}^{*}-h_{1}^{*}$. Obviously, the real-gas effects in this problem are negligible and the result is the same as that of Prob. 4.10(c).
10.10 Nitrogen is compressed in a steady-flow device from 1.4 MPa and $20^{\circ} \mathrm{C}$ to 20 MPa and $200^{\circ} \mathrm{C}$. Calculate ( $a$ ) the change in enthalpy, (b) the change in entropy, and (c) the heat transfer if the work input is $200 \mathrm{~kJ} / \mathrm{kg}$.

The reduced temperatures and pressures are

$$
\begin{aligned}
& T_{R 1}=\frac{T_{1}}{T_{c}}=\frac{293}{126.2}=2.32 \quad P_{R 1}=\frac{P_{1}}{P_{c}}=\frac{1.4}{3.39}=0.413 \\
& T_{R 2}=\frac{473}{126.2}=3.75 \quad P_{R 2}=\frac{20}{3.39}=5.90
\end{aligned}
$$

(a) The enthalpy departure chart allows us to find

$$
\begin{aligned}
& h_{1}^{*}-h_{1}=\frac{\bar{h}_{1}^{*}-\bar{h}_{1}}{T_{c}} \frac{T_{c}}{M}=(0.3)\left(\frac{126.2}{28}\right)=1.4 \mathrm{~kJ} / \mathrm{kg} \\
& h_{2}^{*}-h_{2}=\frac{\bar{h}_{2}^{*}-\bar{h}_{2}}{T_{c}} \frac{T_{c}}{M}=(2.5)\left(\frac{126.2}{28}\right)=6.8 \mathrm{~kJ} / \mathrm{kg}
\end{aligned}
$$

The enthalpy change is found to be

$$
\begin{aligned}
h_{2}-h_{1} & =\left(h_{1}^{*}-h_{1}\right)+\left(h_{2}-h_{2}^{*}\right)+\left(h_{2}^{*}-h_{1}^{*}\right)=1.4-6.8+(1.04)(200-20) \\
& =182 \mathrm{~kJ} / \mathrm{kg} .
\end{aligned}
$$

(b) The entropy departure chart provides

$$
\begin{aligned}
& s_{1}^{*}-s_{1}=\frac{\bar{s}_{1}^{*}-\bar{s}_{1}}{M}=\frac{0.1}{28}=0.004 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K} \\
& s_{2}^{*}-s_{2}=\frac{\bar{s}_{2}^{*}-\bar{s}_{2}}{M}=\frac{0.5}{28}=0.02 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K}
\end{aligned}
$$

The entropy change is then
$s_{2}-s_{1}=\left(s_{1}^{*}-s_{1}\right)+\left(s_{2}-s_{2}^{*}\right)+\left(s_{2}^{*}-s_{1}^{*}\right)=0.004-0.02+1.04 \ln \frac{473}{293}-0.297 \ln \frac{20}{1.4}$
$=-0.308 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}$
(c) From the first law, $q=\Delta h+w=182-200=-18 \mathrm{~kJ} / \mathrm{kg}$. The negative sign means that heat is leaving the device.
10.11 Methane is compressed isothermally in a steady-flow compressor from 100 kPa and $20^{\circ} \mathrm{C}$ to 20 MPa . Calculate the minimum power required if the mass flux is $0.02 \mathrm{~kg} / \mathrm{s}$.

The reduced temperatures and pressures are

$$
T_{R 2}=T_{R 1}=\frac{T_{1}}{T_{c}}=\frac{293}{191.1}=1.53 \quad P_{R 1}=\frac{0.1}{4.64}=0.02 \quad P_{R 2}=\frac{20}{4.64}=4.31
$$

Minimum power is required for an isothermal process if the process is reversible, so that the heat transfer is given by $q=T \Delta s$. The entropy change is

$$
\Delta s=\left(s_{1}^{*}-s_{1}\right)^{0}+\left(s_{2}-s_{2}^{*}\right)+\left(s_{2}^{*}-s_{1}^{*}\right)=0-\frac{7}{16}+2.25 \ln 1-0.518 \ln \frac{20}{0.1}=-3.18 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K}
$$

so that $q=T \Delta s=(293)(-3.18)=932 \mathrm{~kJ} / \mathrm{kg}$. The first law, $q-w=\Delta h$, requires that we find $\Delta h$.

We find $\bar{h}_{2}^{*}-\bar{h}_{2}=14 \mathrm{~kJ} / \mathrm{kmol} \cdot \mathrm{K}$, so that

$$
\Delta h=\left(h_{1}^{*}-h_{1}^{*}\right)^{0}+\left(h_{2}-h_{2}^{*}\right)+\left(h_{2}^{*}-h_{1}^{*}\right)^{0}=(-14)\left(\frac{191.1}{16}\right)=-167 \mathrm{~kJ} / \mathrm{kg}
$$

Finally, the required power is

$$
\dot{W}=(q-\Delta h) \dot{m}=[932-(-167)](0.02)=22 \mathrm{~kW}
$$

10.12 Estimate the minimum power needed to compress carbon dioxide in a steady-flow insulated compressor from 200 kPa and $20^{\circ} \mathrm{C}$ to 10 MPa . The inlet flow rate is $0.8 \mathrm{~m}^{3} / \mathrm{min}$.

Minimum power is associated with a reversible process. Insulation results in negligible heat transfer. Consequently, an isentropic process is assumed. First, the reduced pressures and temperature are

$$
P_{R 1}=\frac{P_{1}}{P_{c}}=\frac{0.2}{7.39}=0.027 \quad P_{R 2}=\frac{10}{7.37}=1.37 \quad T_{R 1}=\frac{T_{1}}{T_{c}}=\frac{293}{304.2}=0.963
$$

For the isentropic process $\Delta s=0$ :

$$
\Delta s=0=\left(s_{1}^{*}-s_{1}\right)^{0}+\left(s_{2}-s_{2}^{*}\right)+\left(s_{2}^{*}-s_{1}^{*}\right)=0+\frac{\bar{s}_{2}-\bar{s}_{2}^{*}}{44}+0.842 \ln \frac{T_{2}}{293}-0.189 \ln \frac{10}{0.2}
$$

Since $\bar{s}_{2}-\bar{s}_{2}^{*}$ depends on $T_{2}$, this equation has $T_{2}$ as the only unknown. A trial-and-error procedure provides the solution. First, let $\bar{s}_{2}-\bar{s}_{2}^{*}=0$ and find $T_{2}=705 \mathrm{~K}$. Since $\bar{s}_{2}^{*}-\bar{s}_{2}>0$, we try the following:

$$
\begin{array}{lll}
T_{2}=750 \mathrm{~K}, & T_{R 2}=2.47: & 0 \stackrel{2}{=}-\frac{2}{44}+0.842 \ln \frac{750}{293}-0.189 \ln \frac{10}{0.2}=0.0066 \\
T_{2}=730 \mathrm{~K}, & T_{R 2}=2.03: & 0 \stackrel{\imath}{=}-\frac{2}{44}+0.842 \ln \frac{730}{293}-0.189 \ln \frac{10}{0.2}=-0.016
\end{array}
$$

Interpolating results in $T_{2}=744 \mathrm{~K}$ or $471^{\circ} \mathrm{C}$. The work for this steady-flow process can now be found to be

$$
\begin{aligned}
w & =-\Delta h=h_{T}-h_{1}^{*+0}+h_{2}^{*}-h_{2}+h_{1}^{*}-h_{2}^{*}=0+(2.0)\left(\frac{304.2}{44}\right)+(0.842)(20-471) \\
& =-366 \mathrm{~kJ} / \mathrm{kg}
\end{aligned}
$$

To find $\dot{W}$ we must know $\dot{m}=\left(\rho_{1}\right)(0.8 / 60)$. The density is found using

$$
\rho_{1}=\frac{P_{1}}{Z_{1} R T_{1}}=\frac{200}{(0.99)(0.189)(293)}=3.65 \mathrm{~kg} / \mathrm{m}^{3}
$$

Finally

$$
\dot{W}=\dot{m} w=\left[\frac{(3.65)(0.8)}{60}\right](-366)=-17.8 \mathrm{~kW}
$$

10.13 Calculate the maximum work that can be produced by steam at 30 MPa and $600^{\circ} \mathrm{C}$ if it expands through the high-pressure stage of a turbine to 6 MPa . Use the charts and compare with tabulated values from the steam tables.

Maximum work occurs for an adiabatic reversible process, i.e., for $\Delta s=0$. The reduced temperature and pressures are

$$
T_{R 1}=\frac{T_{1}}{T_{c}}=\frac{873}{647}=1.35 \quad P_{R 1}=\frac{30}{22.1}=1.36 \quad P_{R 2}=\frac{6}{22.1}=0.27
$$

The isentropic process provides us with $T_{2}$ by a trial-and-error procedure:

$$
\Delta s=0=\left(s_{1}^{*}-s_{1}\right)+\left(s_{2}-s_{2}^{*}\right)+\left(s_{2}^{*}-s_{1}^{*}\right)=\frac{4}{18}+s_{2}-s_{2}^{*}+1.872 \ln \frac{T_{2}}{873}-0.462 \ln \frac{6}{30}
$$

If $s_{2}-s_{2}^{*}=0$, we find $T_{2}=521 \mathrm{~K}$ or $248^{\circ} \mathrm{C}$. Since $s_{2}-s_{2}^{*}<0$, we try $T_{2}>521 \mathrm{~K}$ :

$$
\begin{array}{lll}
T_{2}=600 \mathrm{~K}, & T_{R 2}=0.93: & 0 \stackrel{2}{=} \frac{4}{18}-\frac{3}{18}+1.872 \ln \frac{600}{873}-0.462 \ln \frac{6}{30}=0.097 \\
T_{2}=560 \mathrm{~K}, & T_{R 2}=0.87: & 0 \stackrel{2}{=} \frac{4}{18}-\frac{3.5}{18}+1.872 \ln \frac{560}{873}-0.462 \ln \frac{6}{30}=-0.06
\end{array}
$$

Interpolation gives $T_{2}=575 \mathrm{~K}$ or $302^{\circ} \mathrm{C}$. The work produced is then

$$
\begin{aligned}
w & =-\Delta h=\left(h_{1}-h_{1}^{*}\right)+\left(h_{2}^{*}-h_{2}\right)+\left(h_{1}^{*}-h_{2}^{*}\right) \\
& =(-8)\left(\frac{647.4}{18}\right)+(4)\left(\frac{647.4}{18}\right)+\frac{30750-19500}{18}=481 \mathrm{~kJ} / \mathrm{kg}
\end{aligned}
$$

where we have used the ideal-gas Table F-6 to find $h_{1}^{*}-h_{2}^{*}$. A less accurate value would be found using $c_{p} \Delta T$.

To compare with values obtained directly from the steam tables we use

$$
\left.\begin{array}{rl}
s_{2}=s_{1} & =6.2339 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K} \\
P_{2} & =6 \mathrm{MPa}
\end{array}\right\} \quad \therefore h_{2}=2982 \mathrm{~kJ} / \mathrm{kg}
$$

The work is $w=-\Delta h=h_{1}-h_{2}=3444-2982=462 \mathrm{~kJ} / \mathrm{kg}$.

## Supplementary Problems

10.14 Using (10.1), estimate the increase in pressure needed to decrease the volume of 2 kg of air $0.04 \mathrm{~m}^{3}$ if the temperature changes from $30^{\circ} \mathrm{C}$ to $33^{\circ} \mathrm{C}$. The initial volume is $0.8 \mathrm{~m}^{3}$. Ans. 13.7 kPa
10.15 Using (10.1), estimate the temperature change if the pressure changes from 14.7 to 15 psia while the volume changes from 2.2 to $2.24 \mathrm{ft}^{3}$. There is 4 Jbm of air. Ans. $0.851^{\circ} \mathrm{F}$
10.16 Show that the slope of a constant-pressure line on a $T-\iota$ diagram of an ideal gas increases with temperature. Ans. Slope $=T / v$
10.17 Find an expression for the slope of a constant-pressure line on a $T-c^{r}$ diagram, if $\left(P+a / c^{2}\right)(c-b)=$ $R T$. Ans. $\quad\left(P-a / v^{2}+2 a b / v^{3}\right) / R$
10.18 Write two relationships that result from the differential forms of the first law and the relationship $u=u(s, v)$. Verify the two relationships for steam at $300^{\circ} \mathrm{C}$ and 2 MPa .
Ans. $\quad T=(\partial u / \partial s)_{c}, P=-(\partial u / \partial v)_{s}$
10.19 Derive Maxwell relation (10.24) from (10.22) using (10.15).
10.20 Verify (10.25) using the Freon 12 tables at 100 kPa and $0^{\circ} \mathrm{C}$.
$\mathbf{1 0 . 2 1}$ Verify (10.23) using the steam tables at 20 kPa and $400^{\circ} \mathrm{C}$.
10.22 Verify the Clapeyron equation using steam at 40 psia.
10.23 Use the Clapeyron equation to predict the enthalpy of vaporization $h_{f g}$ of steam at $50^{\circ} \mathrm{C},(a)$ assuming that steam is an ideal gas; $(b)$ taking $\varepsilon_{g}$ from the steam table. $(c)$ What is $h_{f g}$ in the steam table? Ans. (a) $2407 \mathrm{~kJ} / \mathrm{kg} \quad$ (b) $2397 \mathrm{~kJ} / \mathrm{kg} \quad$ (c) $2383 \mathrm{~kJ} / \mathrm{kg}$
10.24 Using the Clausius-Clapeyron equation, predict $T_{\text {sat }}$ for $P_{\text {sat }}=0.2$ psia using the values in Table C-2E. Compare this value with that found from interpolation in Table C-1E. Ans. $71^{\circ} \mathrm{F}, 53^{\circ} \mathrm{F}$
10.25 (a) Derive the relationship $c_{p}=T(\partial s / \partial T)_{p}$ and verify the expression for $d h$ given by (10.43). (b) For an ideal gas what is the value of the quantity in brackets in (10.43)? Ans. (b) zero
10.26 Assume an ideal gas with constant $c_{p}$ and $c_{c}$ and derive simplified relationships for $s_{2}-s_{1}$. Refer to (10.47). Ans. $\quad c_{v} \ln T_{2} / T_{1}+R \ln v_{2} / v_{1}, c_{p} \ln T_{2} / T_{1}-R \ln P_{2} / P_{1}$
10.27 Show that $(a) c_{p}=T(\partial P / \partial T)_{s}(\partial v / \partial T)_{P}$ and $(b) c_{v}=-T(\partial P / \partial T)_{R}(\partial u / \partial T)_{s}$.
10.28 (a) Use Problem $10.27(a)$ to estimate the value of $c_{p}$ for steam at 2 MPa and $400^{\circ} \mathrm{C}$ and compare with an estimate using $c_{p}=(\partial h / \partial T)_{P}$ at the same state. (b) Do the same for steam at 4000 psia and $1000^{\circ} \mathrm{F}$. Ans. (a) $2.25 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}$ vs. $2.21 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K} \quad$ (b) $0.871 \mathrm{Btu} / \mathrm{lbm}{ }^{\circ}{ }^{\circ} \mathrm{R}$ vs. $0.860 \mathrm{Btu} / \mathrm{lbm}-{ }^{\circ} \mathrm{R}$
10.29 (a) Use Problem $10.27(b)$ to estimate the value of $c_{t}$ for steam at 2 MPa and $400^{\circ} \mathrm{C}$ and compare with an estimate using $c_{c}=(\partial u / \partial T)_{c}$ at the same state. (b) Do the same for steam at 4000 psia and $1000^{\circ} \mathrm{F}$. Ans. (a) $1.87 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}$ vs. $1.66 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K} \quad$ (b) $0.543 \mathrm{Btu} / \mathrm{lbm} \cdot{ }^{\circ} \mathrm{R}$ vs. $0.500 \mathrm{Btu} / \mathrm{lbm}{ }^{\circ}{ }^{\circ} \mathrm{R}$
10.30 Using $P=R T / v-a / v^{2}$ and assuming an isothermal process, find expressions for (a) $\Delta h,(b) \Delta u$, and
(c) $\Delta s$.
Ans. (a) $P_{2} v_{2}-P_{1} v_{1}+a\left(1 / v_{1}-1 / v_{2}\right)$
(b) $a\left(1 / b_{1}-1 / v_{2}\right)$
(c) $R \ln L_{2} / L_{1}$
10.31 Using $P=R T /(v-b)$ and assuming an isothermal process, find expressions for $(a) \Delta h,(b) \Delta u$, and
(c) $\Delta s$.
Ans. (a) $P_{2} c_{2}-P_{1} v_{1}$
(b) 0
(c) $R \ln \left[\left(c_{2}-b\right) /\left(c_{1}-b\right)\right]$
10.32 Air undergoes a change from $20^{\circ} \mathrm{C}$ and $0.8 \mathrm{~m}^{3} / \mathrm{kg}$ to $200^{\circ} \mathrm{C}$ and $0.03 \mathrm{~m}^{3} / \mathrm{kg}$. Calculate the enthalpy change assuming ( $a$ ) the van der Waals equation of state and constant specific heats, ( $b$ ) the ideal-gas tables, and ( $c$ ) an ideal gas with constant specific heats.
Ans. (a) $182 \mathrm{~kJ} / \mathrm{kg}$
(b) $182 \mathrm{~kJ} / \mathrm{kg}$
(c) $180 \mathrm{~kJ} / \mathrm{kg}$
10.33 Nitrogen undergoes a change from $100^{\circ} \mathrm{F}$ and $5 \mathrm{ft}^{3} / \mathrm{lbm}$ to $600^{\circ} \mathrm{F}$ and $0.8 \mathrm{ft}^{3} / \mathrm{lbm}$. Calculate the enthalpy change assuming ( $a$ ) the van der Waals equation of state and constant specific heats, $(b)$ the ideal-gas tables, and (c) and ideal gas with constant specific heats.
Ans.
(a) $123 \mathrm{Btu} / \mathrm{lbm}$
(b) $126 \mathrm{Btu} / \mathrm{lbm}$
(c) $124 \mathrm{Btu} / \mathrm{lbm}$
10.34 Find an expression for $c_{p}-c_{i}$ if $P=R T / v-a / v^{2}$. Ans. $T R^{2} v /\left(P c^{2}-a\right)$
10.35 Calculate $\beta$ and $B$ for water at 5 MPa and $60^{\circ} \mathrm{C}$. Then estimate the difference $c_{p}-c_{1}$.

Ans. $5.22 \times 10^{-4} \mathrm{~K}^{-1}, 2.31 \times 10^{6} \mathrm{kPa}, 0.212 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}$
10.36 Calculate $\beta$ and $B$ for water at 500 psia and $100^{\circ} \mathrm{F}$. Then estimate the difference $c_{p}-c_{r}$.

Ans. $1.987 \times 10^{-4}{ }^{\circ} \mathrm{R}^{-1}, 48.3 \times 10^{6} \mathrm{psf}, 0.0221 \mathrm{Btu} / \mathrm{lbm}-{ }^{\circ} \mathrm{R}$
10.37 Find an expression for the Joule-Thomson coefficient for a gas if $P=R T / v-a / l^{2}$. What is the inversion temperature (the temperature where $\mu_{j}=0$ )? Ans. $2 a v /\left[c_{p}(R c T-2 a)\right],\left(P v^{2}-a\right) / R v$.
10.38 Estimate the Joule-Thomson coefficient for steam at 6 MPa and $600^{\circ} \mathrm{C}$ using both expressions in (10.63). Approximate the value of $c_{p}$ using $(\partial h / \partial T)_{p} . \quad$ Ans. $3.45^{\circ} \mathrm{C} / \mathrm{MPa}, 3.46^{\circ} \mathrm{C} / \mathrm{MPa}$
10.39 Estimate the temperature change of steam that is throttled from 8 MPa and $600^{\circ} \mathrm{C}$ to 4 MPa .

Ans. $\quad-14^{\circ} \mathrm{C}$
10.40 Estimate the temperature change of Freon 12 that is throttled from 170 psia and $200^{\circ} \mathrm{F}$ to 80 psia . Ans. $\quad-14^{\circ} \mathrm{F}$
10.41 Calculate the change in the enthalpy of air if its state is changed from 200 K and 900 kPa to 700 K and 6 MPa using ( $a$ ) the enthalpy departure chart and ( $b$ ) the ideal-gas tables.
Ans. (a) $518 \mathrm{~kJ} / \mathrm{kg} \quad$ (b) $513 \mathrm{~kJ} / \mathrm{kg}$
10.42 Calculate the change in entropy of nitrogen if its state is changed from $300^{\circ} \mathrm{R}$ and 300 psia to $1000^{\circ} \mathrm{R}$ and 600 psia using ( $a$ ) the entropy departure chart and ( $b$ ) the ideal-gas tables.
Ans. (a) $0.265 \mathrm{Btu} / \mathrm{lbm}-{ }^{\circ} \mathrm{R}$
(b) $0.251 \mathrm{Btu} / \mathrm{lbm}^{\circ}{ }^{\circ} \mathrm{R}$
10.43 Estimate the power needed to compress $2 \mathrm{~kg} / \mathrm{s}$ of methane in a reversible adiabatic process from 400 kPa and $20^{\circ} \mathrm{C}$ to 4 MPa in a steady-flow device ( $a$ ) assuming ideal-gas behavior and ( $b$ ) accounting for real-gas behavior. Ans. (a) 923 kW (b) 923 kW
10.44 An adiabatic reversible turbine changes the state of $10 \mathrm{~kg} / \mathrm{min}$ of carbon dioxide from 10 MPa and 700 K to 400 kPa . Estimate the power produced ( $a$ ) assuming ideal-gas behavior, and ( $b$ ) accounting for real-gas behavior. Ans. (a) $61.2 \mathrm{~kW} \quad$ (b) 59.7 kW
10.45 Air is contained in a rigid tank and the temperature is changed from $20^{\circ} \mathrm{C}$ to $800^{\circ} \mathrm{C}$. If the initial pressure is 1600 kPa , calculate the final pressure and the heat transfer (a) using the enthalpy departure chart and (b) assuming ideal-gas behavior. Ans. (a) $614 \mathrm{~kJ} / \mathrm{kg} \quad$ (b) $612 \mathrm{~kJ} / \mathrm{kg}$
10.46 Air undergoes an isothermal compression in a piston-cylinder arrangement from $100^{\circ} \mathrm{F}$ and 14.7 psia to 1000 psia. Estimate the work required and the heat transfer ( $a$ ) assuming ideal-gas behavior and (b) accounting for real-gas effects.
Ans. (a) $-162 \mathrm{Btu} / \mathrm{lbm},-162 \mathrm{Btu} / \mathrm{lbm}$;
(b) $-164 \mathrm{Btu} / \mathrm{lbm},-168 \mathrm{Btu} / \mathrm{lbm}$
10.47 Nitrogen expands in a turbine from $200^{\circ} \mathrm{C}$ and 20 MPa to $20^{\circ} \mathrm{C}$ and 2 MPa . Estimate the power produced if the mass flux is $3 \mathrm{~kg} / \mathrm{s}$. Ans. 544 kW

## Chapter 11

## Mixtures and Solutions

### 11.1 BASIC DEFINITIONS

Thus far in our thermodynamic analyses we have considered only single-component systems. In this chapter we develop methods for determining thermodynamic properties of a mixture for applying the first law to systems involving mixtures.

We begin by defining two terms which describe and define a mixture. The mole fraction $y$ is defined as

$$
\begin{equation*}
y_{i}=\frac{N_{i}}{N} \tag{11.1}
\end{equation*}
$$

where $N_{i}$ is the number of moles of the $i$ th component and $N$ is the total number of moles. The mass fraction $m f$ is defined as

$$
\begin{equation*}
m f_{i}=\frac{m_{i}}{m} \tag{11.2}
\end{equation*}
$$

where $m_{d}$ is the mass of the $i$ th component and $m$ is the total mass of the mixture. Clearly, the total number of moles and the total mass of a mixture are given, respectively, by

$$
\begin{equation*}
N=N_{1}+N_{2}+N_{3}+\cdots \quad m=m_{1}+m_{2}+m_{3}+\cdots \tag{11.3}
\end{equation*}
$$

Dividing the above equations by $N$ and $m$, respectively, we see that

$$
\begin{equation*}
\Sigma y_{i}=1 \quad \Sigma m f_{i}=1 \tag{11.4}
\end{equation*}
$$

The (mean) molecular weight of a mixture is given by

$$
\begin{equation*}
M=\frac{m}{N}=\frac{\Sigma N_{i} M_{i}}{N}=\Sigma y_{i} M_{i} \tag{11.5}
\end{equation*}
$$

The mixture's gas constant is then

$$
\begin{equation*}
R=\frac{\bar{R}}{M} \tag{11.6}
\end{equation*}
$$

where $\bar{R}$ denotes, as in Chapter 2, the universal molar gas constant.
Analyzing a mixture on the basis of mass (or weight) is gravimetric analysis. Analyzing a mixture on the basis of moles (or volume) is volumetric analysis. The type of analysis must be stated.

EXAMPLE 11.1 Molar analysis of air indicates that it is composed primarily of nitrogen ( $78 \%$ ) and oxygen ( $22 \%$ ). Determine ( $a$ ) the mole fractions, ( $b$ ) the gravimetric analysis, ( $c$ ) its molecular weight, and ( $d$ ) its gas constant. Compare with values from Appendix B.
(a) The mole fractions are given as $y_{1}=0.78$ and $y_{2}=0.22$, where the subscript 1 refers to nitrogen and 2 to oxygen.
(b) If there are 100 mol of the mixture, the mass of each component is

$$
\left.\begin{array}{l}
m_{1}=N_{1} M_{1}=(78)(28)=2184 \mathrm{~kg} \\
m_{2}=N_{2} M_{2}=(22)(32)=704 \mathrm{~kg}
\end{array}\right\} \quad \therefore m=2888 \mathrm{~kg}
$$

Gravimetric analysis yields

$$
m f_{1}=\frac{m_{1}}{m}=\frac{2184}{2888}=0.756 \quad m f_{2}=\frac{m_{2}}{m}=\frac{704}{2888}=0.244
$$

or, by mass, the mixture is $75.6 \% \mathrm{~N}_{2}$ and $24.4 \% \mathrm{O}_{2}$.
(c) The molecular weight of the mixture is $M=m / N=2888 / 100=28.9 \mathrm{~kg} / \mathrm{kmol}$. This compares with 28.97 $\mathrm{kg} / \mathrm{kmol}$ from the appendix, an error of $-0.24 \%$.
(d) The gas constant for air is calculated to be $R=\bar{R} / M=8.314 / 28.9=0.288 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}$. This compares with $0.287 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}$ from the appendix, an error of $0.35 \%$.

By including argon as a component of air, the above calculations could be improved. However, it's obvious that the above analysis is quite acceptable.

### 11.2 IDEAL-GAS LAW FOR MIXTURES

Two models are used to obtain the $P-\tau^{-}-T$ relation for a mixture of ideal gases. The Amagat model treats each component as though it exists separately at the same pressure and temperature of the mixture; the total volume is the sum of the volumes of the components. In this chapter we use the Dalton model, in which each component occupies the same volume and has the same temperature as the mixture; the total pressure is the sum of the component pressures, termed the partial pressures. For the Dalton model

$$
\begin{equation*}
P=P_{1}+P_{2}+P_{3}+\cdots \tag{11.7}
\end{equation*}
$$

For any component of a mixture of ideal gases the ideal-gas law is

$$
\begin{equation*}
P_{i}=\frac{N_{i} \bar{R} T}{V} \tag{11.8}
\end{equation*}
$$

For the mixture as a whole we have

$$
\begin{equation*}
P=\frac{N \bar{R} T}{V} \tag{11.9}
\end{equation*}
$$

so that

$$
\begin{equation*}
\frac{P_{i}}{P}=\frac{N_{i} \bar{R} T / V}{N \bar{R} T / V}=\frac{N_{i}}{N}=y_{i} \tag{11.10}
\end{equation*}
$$

EXAMPLE 11.2 A rigid tank contains 2 kg of $\mathrm{N}_{2}$ and 4 kg of $\mathrm{CO}_{2}$ at a temperature of $25^{\circ} \mathrm{C}$ and 2 MPa . Find the partial pressures of the two gases and the gas constant of the mixture.

To find the partial pressures we need the mole fractions. The moles of $\mathrm{N}_{2}$ and $\mathrm{CO}_{2}$ are, respectively,

$$
\left.\begin{array}{l}
N_{1}=\frac{m_{1}}{M_{1}}=\frac{2}{28}=0.0714 \mathrm{~mol} \\
N_{2}=\frac{m_{2}}{M_{2}}=\frac{4}{44}=0.0909 \mathrm{~mol}
\end{array}\right\} \quad \therefore N=0.1623 \mathrm{~mol}
$$

The mole fractions are

$$
y_{1}=\frac{N_{1}}{N_{1}}=\frac{0.0714}{0.1623}=0.440 \quad y_{2}=\frac{N_{2}}{N}=\frac{0.0909}{0.1623}=0.560
$$

The partial pressures are

$$
P_{1}=y_{1} P=(0.44)(2)=0.88 \mathrm{MPa} \quad P_{2}=y_{2} P=(0.56)(2)=1.12 \mathrm{MPa}
$$

The molecular weight is $M=M_{1} y_{1}+M_{2} y_{2}=(28)(0.44)+(44)(0.56)=36.96 \mathrm{~kg} / \mathrm{kmol}$. The gas constant of the mixture is then

$$
R=\frac{\bar{R}}{M}=\frac{8.314}{36.96}=0.225 \mathrm{~kJ} / \mathrm{kg} \cdot \mathbf{K}
$$

### 11.3 PROPERTIES OF A MIXTURE OF IDEAL GASES

The extensive properties of a mixture, such as $H, U$, and $S$, can be found by simply adding the contributions of each component. For example, the total enthalpy of a mixture is

$$
\begin{equation*}
H=\Sigma H_{i}=H_{1}+H_{2}+H_{3}+\cdots \tag{11.11}
\end{equation*}
$$

In terms of the specific enthalpy $h$,

$$
\begin{equation*}
H=m h=\Sigma m_{i} h_{i} \quad \text { and } \quad H=N \bar{h}=\Sigma N_{i} \bar{h}_{i} \tag{11.12}
\end{equation*}
$$

where the overbar denotes a mole basis. Dividing the above two equations by $m$ and $N$, respectively, we see that

$$
\begin{equation*}
h=\Sigma m f_{i} h_{i} \quad \text { and } \quad \bar{h}=\Sigma y_{i} \bar{h}_{i} \tag{11.13}
\end{equation*}
$$

Since the specific heat $c_{p}$ is related to the change in the enthalpy, we may write

$$
\begin{equation*}
\Delta h=c_{p} \Delta T \quad \Delta h_{i}=c_{p, i} \Delta T \tag{11.14}
\end{equation*}
$$

so that

$$
\begin{equation*}
\Delta h=c_{p} \Delta T=\Sigma m f_{i}\left(c_{p, i} \Delta T\right) \tag{11.15}
\end{equation*}
$$

Dividing both sides by $\Delta T$, there results

$$
\begin{equation*}
c_{p}=\Sigma m f_{i} c_{p, i} \tag{11.16}
\end{equation*}
$$

The molar specific heat is

$$
\begin{equation*}
\bar{c}_{p}=\Sigma y_{i} \bar{c}_{p, i} \tag{11.17}
\end{equation*}
$$

Likewise, using internal energy we would find

$$
\begin{equation*}
c_{t}=\Sigma m f_{i} c_{r, i} \quad \bar{c}_{i}=\Sigma y_{i} \bar{c}_{r, i} \tag{11.18}
\end{equation*}
$$

EXAMPLE 11.3 Gravimetric analysis of a mixture of three gases indicates $20 \% \mathrm{~N}_{2}, 40 \% \mathrm{CO}_{2}$, and $40 \% \mathrm{O}_{2}$. Find the heat transfer needed to increase the temperature of 20 lbm of the mixture from $80^{\circ} \mathrm{F}$ to $300^{\circ} \mathrm{F}$ in a rigid tank.

The heat transfer needed is given by the first law as (the work is zero for a rigid $\operatorname{tank}$ ) $Q=\Delta U=m \Delta u=$ $m c_{r} \Delta T$. We must find $c_{r}$. It is given by (11.18a) as

$$
\begin{aligned}
c_{v} & =m f_{1} c_{l, 1}+m f_{2} c_{v, 2}+m f_{3} c_{v, 3} \\
& =(0.2)(0.177)+(0.4)(0.158)+(0.4)(0.157)=0.161 \mathrm{Btu} / \mathrm{lbm}-{ }^{\circ} \mathrm{R}
\end{aligned}
$$

The heat transfer is then $Q=m c, \Delta T=(20)(0.161)(300-80)=708 \mathrm{Btu}$.
EXAMPLE 11.4 A mixture is composed of $2 \mathrm{~mol} \mathrm{CO}_{2}$ and $4 \mathrm{~mol}_{2}$. It is compressed adiabatically in a cylinder from 100 kPa and $20^{\circ} \mathrm{C}$ to 2 MPa . Assuming constant specific heats, calculate ( $a$ ) the final temperature, (b) the work required, and (c) the change in entropy.
(a) The temperature is found using the isentropic relationship $T_{2}=T_{1}\left(P_{2} / P_{1}\right)^{(k-1) / k}$.

Let's find $k$ for the mixture. The mass is $m=N_{1} M_{1}+N_{2} M_{2}=(2)(44)+(4)(28)=200 \mathrm{~kg}$. The specific heats are

$$
\begin{gathered}
c_{v}=m f_{1} c_{r, 1}+m f_{2} c_{v, 2}=\left(\frac{88}{200}\right)(0.653)+\left(\frac{112}{200}\right)(0.745)=0.705 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K} \\
c_{p}=m f_{1} c_{\rho, 1}+m f_{2} c_{p, 2}=\left(\frac{88}{200}\right)(0.842)+\left(\frac{112}{200}\right)(1.042)=0.954 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K}
\end{gathered}
$$

The ratio of specific heats is $k=c_{p} / c_{r}=0.954 / 0.705=1.353$. Consequently, the final temperature is

$$
T_{2}=T_{1}\left(\frac{P_{2}}{P_{1}}\right)^{(k-11 / k}=(293)\left(\frac{2000}{100}\right)^{0.353 / 1.353}=640 \mathrm{~K} \quad \text { or } 367^{\circ} \mathrm{C}
$$

(b) The work is found using the first law with $Q=0$ :

$$
W=-\Delta U=-m \Delta u=-m c_{1} \Delta T=(-200)(0.705)(367-20)=-48.9 \mathrm{MJ}
$$

(c) The entropy change is

$$
\begin{aligned}
\Delta s & =c_{p} \ln \frac{T_{2}}{T_{1}}-R \ln \frac{P_{2}}{P_{1}} \\
& =0.954 \ln \frac{640}{293}-\frac{8.314}{\left(\frac{2}{6}\right)(44)+\left(\frac{4}{6}\right)(28)} \ln \frac{2000}{100}=-0.00184 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K}
\end{aligned}
$$

Obviously, the entropy change should be zero for this isentropic process. The above small value is a measure of the error in our calculations.

### 11.4 GAS-VAPOR MIXTURES

Air is a mixture of nitrogen, oxygen, and argon plus traces of some other gases. When water vapor is not included, we refer to it as dry air. If water vapor is included, as in atmospheric air, we must be careful to properly account for it. At the relatively low atmospheric temperature we can treat dry air as an ideal gas with constant specific heats. It is also possible to treat the water vapor in the air as an ideal gas, even though the water vapor may be at the saturation state. Consequently, we can consider atmospheric air to be a mixture of two ideal gases. By (11.7), the total pressure is the sum of the partial pressure $P_{a}$ of the dry air and the partial pressure $P_{t}$ of the water vapor (called the capor pressure):

$$
\begin{equation*}
P=P_{a}+P_{i} \tag{11.19}
\end{equation*}
$$

Since we assume that the water vapor is an ideal gas, its enthalpy is dependent on temperature only. Hence we use the enthalpy of the water vapor to be the enthalpy of saturated water vapor at the temperature of the air, expressed as

$$
\begin{equation*}
h_{r}(T)=h_{g}(T) \tag{11.20}
\end{equation*}
$$

In Fig. 11-1 this means that $h_{1}=h_{2}$ where $h_{2}=h_{g}$ from the steam tables at $T=T_{1}$. This is acceptable for situations in which the pressure is relatively low (near atmospheric pressure) and the temperature is below about $60^{\circ} \mathrm{C}\left(140^{\circ} \mathrm{F}\right)$.

Fig. 11-1

The amount of water vapor in the air is related to the relative humidity and the humidity ratio. The relative humidity $\phi$ is defined as the ratio of the mass of the water vapor $m_{v}$ to the maximum amount of water vapor $m_{g}$ the air can hold at the same temperature:

$$
\begin{equation*}
\phi=\frac{m_{\varepsilon}}{m_{g}} \tag{11.21}
\end{equation*}
$$

Using the ideal-gas law we find

$$
\begin{equation*}
\phi=\frac{P_{t} V / R_{t} T}{P_{g} V / R_{t} T}=\frac{P_{t}}{P_{g}} \tag{11.22}
\end{equation*}
$$

where the constant-pressure lines for $P_{t}$ and $P_{g}$ are shown in Fig. 11-1.
The humidity ratio $\omega$ (also referred to as specific humidity) is the ratio of the mass of water vapor to the mass of dry air:

$$
\begin{equation*}
\omega=\frac{m_{i}}{m_{a}} \tag{11.23}
\end{equation*}
$$

Using the ideal-gas law for air and water vapor, this becomes

$$
\begin{align*}
\omega & =\frac{P_{t} V / R_{c} T}{P_{a} V / R_{a} T}=\frac{P_{c} / R_{c}}{P_{a} / R_{a}} \\
& =\frac{P_{c} / 0.4615}{P_{a} / 0.287}=0.622 \frac{P_{r}}{P_{a}} \tag{11.24}
\end{align*}
$$

Combining (11.24) and (11.22), we relate the above two quantities as

$$
\begin{equation*}
\omega=0.622 \frac{\phi P_{g}}{P_{a}} \quad \phi=1.608 \frac{\omega P_{a}}{P_{g}} \tag{11.25}
\end{equation*}
$$

Note that at state 3 in Fig. 11-1 the relative humidity is $1.0(100 \%)$. Also note that for a given mass of water vapor in the air, $\omega$ remains constant but $\phi$ varies depending on the temperature.

The temperature of the air as measured by a conventional thermometer is referred to as the dry-bulb temperature $T$ ( $T_{1}$ in Fig. 11-1). The temperature at which condensation begins if air is cooled at constant pressure is the dew-point temperature $T_{\text {d.p. }}$ ( $T_{3}$ in Fig. 11-1). If the temperature falls below the dew-point temperature, condensation occurs and the amount of water vapor in the air decreases. This may occur on a cool evening; it also may occur on the cool coils of an air conditioner.

EXAMPLE 11.5 The air at $25^{\circ} \mathrm{C}$ and 100 kPa in a $150-\mathrm{m}^{3}$ room has a relative humidity of $60 \%$. Calculate (a) the humidity ratio, $(b)$ the dew point, $(c)$ the mass of water vapor in the air, and ( $d$ ) the mole fraction of the water vapor.
(a) $\mathrm{By}(11.22), P_{r}=P_{g} \phi=(3.169)(0.6)=1.90 \mathrm{kPa}$, where $P_{g}$ is the saturation pressure at $25^{\circ} \mathrm{C}$ found in Table C-1. The partial pressure of the air is then $P_{a}=P-P_{c}=100-1.9=98.1 \mathrm{kPa}$, where we have used the total pressure of the air in the room to be at 100 kPa . The humidity ratio is then

$$
\omega=0.622 \frac{P_{t}}{P_{a}}=(0.622)\left(\frac{1.9}{98.1}\right)=0.01205 \mathrm{~kg} \mathrm{H}_{2} \mathrm{O} / \mathrm{kg} \text { dry air }
$$

(b) The dew point is the temperature $T_{3}$ of Fig. 11-1 associated with the partial pressure $P_{v}$. It is found by interpolation in Table $\mathrm{C}-1$ or Table $\mathrm{C}-2$, whichever appears to be easier: $T_{\text {d.p. }}=16.6^{\circ} \mathrm{C}$.
(c) From the definition of the humidity ratio the mass of water vapor is found to be

$$
m_{t}=\omega m_{a}=\omega \frac{P_{a} V}{R_{a} T}=(0.01205)\left[\frac{(98.1)(150)}{(0.287)(298)}\right]=2.07 \mathrm{~kg}
$$

(d) To find the mole fraction of the water vapor, we first find the total moles:

$$
N_{i}=\frac{m_{i}}{M_{i}}=\frac{2.07}{18}=0.1152 \mathrm{~mol} \quad N_{a}=\frac{m_{a}}{M_{a}}=\frac{(98.1)(150) /(0.287)(298)}{28.97}=5.94 \mathrm{~mol}
$$

The mole fraction of the water vapor is

$$
y_{c}=\frac{0.1152}{5.94+0.1152}=0.0194
$$

This demonstrates that air with $60 \%$ humidity is about $2 \%$ water vapor by volume. We usually ignore this when analyzing air, as in Example 11.1, and consider air to be dry air. Ignoring the water vapor does not lead to significant error in most engineering applications. It must be included, however, when considering problems involving, for example, combustion and air-conditioning.

EXAMPLE 11.6 The air in Example 11.5 is cooled below the dew point to $10^{\circ} \mathrm{C}$. (a) Estimate the amount of water vapor that will condense. (b) Reheat the air back to $25^{\circ} \mathrm{C}$ and calculate the relative humidity.
(a) At $10^{\circ} \mathrm{C}$ the air is saturated, with $\phi=100 \%$. In Fig. 11-1 we are at a state on the saturation line that lies below state 3 . At $10^{\circ} \mathrm{C}$ we find from Table $\mathrm{C}-1$ that $P_{c}=1.228 \mathrm{kPa}$, so that

$$
P_{u}=P-P_{r}=100-1.228=98.77 \mathrm{kPa}
$$

The humidity ratio is then $\omega=(0.622)\left(P_{t} / P_{a}\right)=(0.622)(1.228 / 98.77)=0.00773 \mathrm{~kg} \mathrm{H}_{2} \mathrm{O} / \mathrm{kg}$ dry air. The difference in the humidity ratio just calculated and the humidity ratio of Example 11.5 is $\Delta \omega=0.01205$ $0.00773=0.00432 \mathrm{~kg} \mathrm{H}_{2} \mathrm{O} / \mathrm{kg}$ dry air. The mass of water vapor removed (condensed) is found to be

$$
\Delta m_{c}=\Delta \omega m_{a}=(0.00432)\left[\frac{(98.1)(150)}{(0.287)(298)}\right]=0.743 \mathrm{~kg} \mathrm{H}_{2} \mathrm{O}
$$

where we have used the initial mass of dry air.
(b) As we reheat the air back to $25^{\circ} \mathrm{C}$, the $\omega$ remains constant at 0.00773 . Using ( $/ 1.25$ ), the relative humidity is then reduced to

$$
\phi=1.608 \frac{\omega P_{a}}{P_{g}}=1.608 \frac{(0.00773)(98.77)}{3.169}=0.387 \text { or } 38.7 \%
$$

where $P_{g}$ is used as the saturation pressure at $25^{\circ} \mathrm{C}$ from Table $\mathrm{C}-1$.

### 11.5 ADIABATIC SATURATION AND WET-BULB TEMPERATURES

It is quite difficult to measure the relative humidity and the humidity ratio directly, at least with any degree of accuracy. This section presents two indirect methods for determining these quantities accurately.

Consider a relatively long insulated channel, shown in Fig. 11-2; air with an unknown relative humidity enters, moisture is added to the air by the pool of water, and saturated air exits. This process involves no heat transfer because the channel is insulated and hence it is called the adiabatic saturation process. The exit temperature is the adiabatic saturation temperature. Let us find an expression for the humidity ratio. Consider that the liquid water added is at temperature $T_{2}$. An energy balance on this control volume, neglecting kinetic and potential energy changes, is done

Fig. 11-2
considering the dry air and the water vapor components. With $\dot{Q}=\dot{W}=0$ we have

$$
\begin{equation*}
\dot{m}_{r 1} h_{r 1}+\dot{m}_{a 1} h_{a 1}+\dot{m}_{f} h_{f 2}=\dot{m}_{a 2} h_{a 2}+\dot{m}_{r 2} h_{r 2} \tag{11.26}
\end{equation*}
$$

But, from conservation of mass for both the dry air and the water vapor,

$$
\begin{equation*}
\dot{m}_{a 1}=\dot{m}_{a 2}=\dot{m}_{a} \quad \dot{m}_{i 11}+\dot{m}_{f}=\dot{m}_{t 2} \tag{11.27}
\end{equation*}
$$

Using the definition of $\omega$ in (11.23), the above equations allow us to write

$$
\begin{equation*}
\dot{m}_{a} \omega_{1}+\dot{m}_{f}=\omega_{2} \dot{m}_{a} \tag{11.28}
\end{equation*}
$$

Substituting this into (11.26) for $\dot{m}_{f}$, there results, using $h_{c} \cong h_{g}$,

$$
\begin{equation*}
\dot{m}_{a} \omega_{1} h_{g 1}+\dot{m}_{a} h_{a 1}+\left(\omega_{2}-\omega_{1}\right) \dot{m}_{a} h_{f 2}=\dot{m}_{a} h_{a 2}+\omega_{2} \dot{m}_{a} h_{g 2} \tag{11.29}
\end{equation*}
$$

At state 2 we know that $\phi_{2}=1.0$ and, using (11.25),

$$
\begin{equation*}
\omega_{2}=0.622 \frac{P_{g 2}}{P-P_{g 2}} \tag{11.30}
\end{equation*}
$$

Thus, (11.29) becomes

$$
\begin{equation*}
\omega_{1}=\frac{\omega_{2} h_{f g 2}+c_{p}\left(T_{2}-T_{1}\right)}{h_{g 1}-h_{f 2}} \tag{11.31}
\end{equation*}
$$

where $h_{a 2}-h_{a 1}=c_{p}\left(T_{2}-T_{1}\right)$ for the dry air and $h_{f g 2}=h_{g 2}-h_{f 2}$. Consequently, if we measure the temperatures $T_{2}$ and $T_{1}$ and the total pressure $P$ we can find $\omega_{2}$ from (11.30) with the remaining quantities in (11.31) given in Appendix C.

Because $T_{2}$ is significantly less than $T_{1}$, the apparatus sketched in Fig. 11-2 can be used to cool an airstream. This is done in relatively dry climates so that $T_{2}$ is reduced but usually not to the saturation temperature. Such a device is often referred to as a "swamp cooler." A fan blowing air through a series of wicks that stand in water is quite effective at cooling low-humidity air.

Using the device of Fig. 11-2 to obtain the adiabatic saturation temperature is a rather involved process. A much simpler approach is to wrap the bulb of a thermometer with a cotton wick saturated with water, and then either to blow air over the wick or to swing the thermometer through the air until the temperature reaches a steady-state value. This wet-bulb temperature $T_{w . b}$ and the adiabatic saturation temperature are essentially the same for water if the pressure is approximately atmospheric.

EXAMPLE 11.7 The dry-bulb and wet-bulb temperatures of a 14.7 -psia airstream are $100^{\circ} \mathrm{F}$ and $80^{\circ} \mathrm{F}$, respectively. Determine ( $a$ ) the humidity ratio, $(b)$ the relative humidity, and ( $c$ ) the specific enthalpy of the air.
(a) We use (11.31) to find $\omega_{1}$. But first $\omega_{2}$ is found using (11.30):

$$
\omega_{2}=0.622 \frac{P_{g 2}}{P-P_{g 2}}=(0.622)\left(\frac{0.5073}{14.7-0.5073}\right)=0.0222
$$

where $P_{g_{2}}$ is the saturation pressure at $80^{\circ} \mathrm{F}$. Now (11.30) gives

$$
\omega_{1}=\frac{\omega_{2} h_{f g 2}+c_{p}\left(T_{2}-T_{1}\right)}{h_{g 1}-h_{f 2}}=\frac{(0.0222)(1048)+(0.24)(80-100)}{1105-48.09}=0.01747 \mathrm{lbm} \mathrm{H} \mathrm{H}_{2} \mathrm{O} / \mathrm{lbm} \text { dry air }
$$

(b) The partial pressure of the water vapor is found using (11.24):

$$
\omega_{1}=0.622 \frac{P_{r 1}}{P_{a 1}} \quad 0.01747=0.622 \frac{P_{r 1}}{14.7-P_{r 1}} \quad \therefore P_{r 1}=0.402 \mathrm{psia}
$$

The relative humidity is obtained from (11.22): $\phi=P_{t 1} / P_{g 1}=0.402 / 0.9503=0.423$ or $42.3 \%$.
(c) The specific enthalpy is found by assuming a zero value for air at $T=0^{\circ} \mathrm{F}$. The enthalpy for the mixture is $H=H_{a}+H_{t}=m_{a} h_{a}+m_{r} h_{t}$. Dividing by $m_{a}$, we find that

$$
h=h_{a}+\omega h_{r}=c_{p} T+\omega h_{g}=(0.24)(100)+(0.01747)(1105)=43.3 \mathrm{Btu} / \mathrm{lbm} \text { dry air }
$$

where we have used $h_{i}=h_{g}$ (see Fig. 11-2). The enthalpy is always expressed per mass unit of dry air.

### 11.6 THE PSYCHROMETRIC CHART

A convenient way of relating the various properties associated with a water vapor-air mixture is to plot these quantities on a psychrometric chart such as Fig. 11-3 or (for standard atmospheric pressure) Fig. G-1 in the Appendix. Any two of the properties establishes a state from which the other properties are determined. As an example, consider a state $A$ that is located by specifying the dry-bulb temperature and the relative humidity. The wet-bulb temperature would be read at 1 , the dew-point temperature at 2, the enthalpy at 3, and the humidity ratio at 4. Referring to Fig. G-1, a dry-bulb temperature of $30^{\circ} \mathrm{C}$ and a relative humidity of $80 \%$ would provide the following: $T_{\text {d.p. }}=26^{\circ} \mathrm{C}$, $T_{\text {w.b. }}=27^{\circ} \mathrm{C}, h=85 \mathrm{~kJ} / \mathrm{kg}$ dry air, and $\omega=0.0215 \mathrm{~kg} \mathrm{H}_{2} \mathrm{O} / \mathrm{kg}$ dry air. The chart provides us with a quick, relatively accurate method for finding the quantities of interest. If the pressure is significantly different from standard atmospheric pressure, the equations presented in the preceding sections must be used.

Fig. 11-3

EXAMPLE 11.8 Using Fig. G-1E, rework Example $11.7\left(T_{\text {d.b. }}=100^{\circ} \mathrm{F}, T_{w . b}=80^{\circ} \mathrm{F}\right)$ to find $\omega, \phi$, and $h$. Using the chart, the intersection of $T_{\text {d.b. }}=100^{\circ} \mathrm{F}$ and $T_{\text {w.b. }}=80^{\circ} \mathrm{F}$ gives

$$
\omega=0.0175 \mathrm{lbm} \mathrm{H} \mathrm{H}_{2} \mathrm{O} / \mathrm{lbm} \text { dry air } \quad \phi=42 \% \quad h=44 \mathrm{Btu} / \mathrm{lbm} \text { dry air }
$$

These values are less accurate than those calculated in Example 11.7, but certainly are acceptable.

### 11.7 AIR-CONDITIONING PROCESSES

Generally, people feel most comfortable when the air is in the "comfort zone": the temperature is between $22^{\circ} \mathrm{C}\left(72{ }^{\circ} \mathrm{F}\right)$ and $27^{\circ} \mathrm{C}\left(80^{\circ} \mathrm{F}\right)$ and the relative humidity is between $40 \%$ and $60 \%$. In Fig. 11-4, the area enclosed by the dotted lines represents the comfort zone. There are several situations in which air must be conditioned to put it in the comfort zone:

The air is too cold or too hot. Heat is simply added or extracted. This is represented by $A-C$ and $B-C$ in Fig. 11-4.
The air is too cold and the humidity is too low. The air can first be heated, and then moisture added, as in $D-E-C$.
The temperature is acceptable but the humidity is too high. The air is first cooled from $F$ to $G$. Moisture is removed from $G$ to $H$. Heat is added from $H$ to $I$.

Fig. 11-4

The air is too hot and the humidity is low. Moisture is added, and the process represented by $J-K$ results.
An airstream from the outside is mixed with an airstream from the inside to provide natural cooling or fresh air. Process $I-M$ represents the warmer inside air mixed with the outside air represented by $L-M$. State $M$ represents the mixed air.
Each of these situations will be considered in the following examples. The first law will be used to predict the heating or cooling needed or to establish the final state.

EXAMPLE 11.9 Outside air at $5^{\circ} \mathrm{C}$ and $70 \%$ relative humidity is heated to $25^{\circ} \mathrm{C}$. Calculate the rate of heat transfer needed if the incoming volume flow rate is $50 \mathrm{~m}^{3} / \mathrm{min}$. Also, find the final relative humidity. Assume $P=100 \mathrm{kPa}$.

The density of dry air is found using the partial pressure $P_{a 1}$ in the ideal-gas law:

$$
\begin{gathered}
P_{a 1}=P-P_{c 1}=P-\phi P_{g 1}=100-(0.7)(0.872)=99.4 \mathrm{kPa} \\
\therefore \rho_{a 1}=\frac{P_{a 1}}{R_{a} T_{1}}=\frac{99.4}{(0.287)(278)}=1.246 \mathrm{~kg} / \mathrm{m}^{3}
\end{gathered}
$$

The mass flux of dry air is then $\dot{m}_{a}=(50 / 60)(1.246)=1.038 \mathrm{~kg} / \mathrm{s}$. Using the psychrometric chart at state 1 ( $T_{1}=5^{\circ} \mathrm{C}, \phi_{1}=70 \%$ ), we find $h_{1}=14 \mathrm{~kJ} / \mathrm{kg}$ air. Since $\omega$ remains constant (no moisture is added or removed), we follow curve $A-C$ in Fig. 11-4; at state 2 we find that $h_{2}=35 \mathrm{~kJ} / \mathrm{kg}$ air. Hence,

$$
\dot{Q}=\dot{m}_{a}\left(h_{2}-h_{1}\right)=1.038(35-14)=11.4 \mathrm{~kJ} / \mathrm{s}
$$

At state 2 we also note from the chart that $\phi_{2}=19 \%$.

EXAMPLE 11.10 Outside air at $5^{\circ} \mathrm{C}$ and $40 \%$ relative humidity is heated to $25^{\circ} \mathrm{C}$ and the final relative humidity is raised to $40 \%$ while the temperature remains constant by introducing steam at 400 kPa into the
airstream. ( $a$ ) Find the needed rate of heat transfer if the incoming volume flow rate of air is $60 \mathrm{~m}^{3} / \mathrm{min}$. (b) Calculate the rate of steam supplied. (c) Calculate the state of the steam introduced.
(a) The process we must follow is first simple heating and then humidification; the latter is sketched as $D-E-C$ in Fig. 11-4, except the $E-C$ leg is vertical at constant temperature. The partial pressure of dry air is

$$
P_{a 1}=P-P_{t, 1}=P-\phi P_{g 1}=100-(0.4)(0.872)=99.7 \mathrm{kPa}
$$

where we have assumed standard atmospheric pressure. The dry air density is

$$
\rho_{a 1}=\frac{P_{a 1}}{R_{a} T_{1}}=\frac{99.7}{(0.287)(278)}=1.25 \mathrm{~kg} / \mathrm{m}^{3}
$$

so that the mass flux of dry air is $\dot{m}_{a}=(60 / 60)(125)=1.25 \mathrm{~kg} / \mathrm{s}$. The rate of heat addition is found using $h_{1}$ and $h_{2}$ from the psychrometric chart:

$$
\dot{Q}=\dot{m}_{a}\left(h_{2}-h_{1}\right)=(1.25)(31-10)=26.2 \mathrm{~kJ} / \mathrm{s}
$$

(b) We assume that all the heating is done in the $D-E$ process and that humidification takes place in a process in which the steam is mixed with the air flow. Assuming a constant temperature in the mixing process, conservation of mass demands that

$$
\dot{m}_{s}=\left(\omega_{3}-\omega_{2}\right) \dot{m}_{a}=(0.008-0.0021)(1.25)=0.0074 \mathrm{~kg} / \mathrm{s}
$$

where the air enters the humidifier at state 2 and leaves at state 3 .
(c) An energy balance around the humidifier provides us with $h_{5} \dot{m}_{s}=\left(h_{3}-h_{2}\right) \dot{m}_{a}$. Hence,

$$
h_{s}=\frac{\dot{m}_{a}}{\dot{m}_{s}}\left(h_{3}-h_{2}\right)=\left(\frac{1.25}{0.0074}\right)(45-31)=2365 \mathrm{~kJ} / \mathrm{kg}
$$

This is less that $h_{g}$ at 400 kPa . Consequently, the temperature is $143.6^{\circ} \mathrm{C}$ and the quality is

$$
x_{s}=\frac{2365-604.7}{2133.8}=0.82
$$

Only two significant figures are used because of the inaccuracy of the enthalpy values.
EXAMPLE 11.11 Outside air at $80^{\circ} \mathrm{F}$ and $90 \%$ relative humidity is conditioned so that it enters a building at $75^{\circ} \mathrm{F}$ and $40 \%$ relative humidity. Estimate ( $a$ ) the amount of moisture removed, ( $b$ ) the heat removed, and (c) the necessary added heat.
(a) The overall process is sketched as $F-G-H-I$ in Fig. 11-4. Heat is removed during the $F-H$ process, moisture is removed during the $G-H$ process, and heat is added during the $H-I$ process. Using the psychrometric chart, we find the moisture removed to be

$$
\Delta \omega=\omega_{3}-\omega_{2}=0.0075-0.0177=-0.010 \mathrm{lbm} \mathrm{H}_{2} \mathrm{O} / \mathrm{lbm} \text { dry air }
$$

where states 2 and 3 are at $G$ and $H$, respectively.
(b) The heat that must be removed to cause the air to follow the $F-G-H$ process is $q=h_{3}-h_{1}=20-39.5=$ $-18.5 \mathrm{Btu} / \mathrm{lbm}$ dry air.
(c) The heat that must be added to change the state of the air from the saturated state at $H$ to the desired state at $I$ is

$$
q=h_{4}-h_{3}=26.5-20=6.5 \mathrm{Btu} / \mathrm{lbm} \text { dry air }
$$

EXAMPLE 11.12 Hot , dry air at $40^{\circ} \mathrm{C}$ and $10 \%$ relative humidity passes through an evaporative cooler. Water is added as the air passes through a series of wicks and the mixture exits at $27^{\circ} \mathrm{C}$. Find ( $a$ ) the outlet relative humidity, $(b)$ the amount of water added, and ( $c$ ) the lowest temperature that could be realized.
(a) The heat transfer is negligible in an evaporative cooler, so that $h_{2} \cong h_{1}$. A constant enthalpy line is shown in Fig. 11-4 and is represented by $J-K$. From the psychrometric chart we find, at $27^{\circ} \mathrm{C}, \phi_{2}=45 \%$.
(b) The added water is found to be $\omega_{2}-\omega_{1}=0.010-0.0046=0.0054 \mathrm{~kg} \mathrm{H}_{2} \mathrm{O} \mathrm{kg}$ dry air.
(c) The lowest possible temperature occurs when $\phi=100 \%: T_{\min }=18.5^{\circ} \mathrm{C}$.

EXAMPLE 11.13 Outside cool air at $15^{\circ} \mathrm{C}$ and $40 \%$ relative humidity (airstream 1) is mixed with inside air taken near the ceiling at $32^{\circ} \mathrm{C}$ and $70 \%$ relative humidity (airstream 2). Determine the relative humidity and temperature of the resultant airstream 3 if the outside flow rate is $40 \mathrm{~m}^{3} / \mathrm{min}$ and the inside flow rate is $20 \mathrm{~m}^{3} / \mathrm{min}$.

An energy and mass balance of the mixing of airstream 1 with airstream 2 to produce airstream 3 would reveal the following facts relative to the psychrometric chart:

State 3 lies on a straight line connecting state 1 and state 2.
The ratio of the distance 2-3 to the distance 3-1 is equal to $\dot{m}_{a 1} / \dot{m}_{a 2}$.
State 1 and state 2 can easily be located on the psychrometric chart. We must determine $\dot{m}_{a 1}$ and $\dot{m}_{a_{2}}$ :

$$
\begin{array}{cc}
P_{a 1}=P-P_{t \cdot 1}=100-1.7=98.3 \mathrm{kPa} & P_{a 2}=P-P_{t \cdot 2}=100-4.8=95.2 \mathrm{kPa} \\
\therefore \rho_{a 1}=\frac{98.3}{(0.287)(288)}=1.19 \mathrm{~kg} / \mathrm{m}^{3} & \rho_{a 2}=\frac{95.2}{(0.287)(305)}=1.09 \mathrm{~kg} / \mathrm{m}^{3} \\
\therefore \dot{m}_{a 1}=(40)(1.19)=47.6 \mathrm{~kg} / \mathrm{min} & \dot{m}_{a 2}=(20)(1.09)=21.8 \mathrm{~kg} / \mathrm{min}
\end{array}
$$

State 3 is located by the ratio $d_{2-3} / d_{3-1}=\dot{m}_{a 1} / \dot{m}_{a 2}=47.6 / 21.8=2.18$, where $d_{2-3}$ is the distance from state 2 to state 3. State 3 is positioned on the psychrometric chart, and we find $\phi_{3}=63 \%$ and $T_{3}=20.2^{\circ} \mathrm{C}$.

EXAMPLE 11.14 Water is used to remove the heat from the condenser of a power plant. 10000 kg per minute of $40-^{\circ} \mathrm{C}$ water enters a cooling tower, as shown in Fig. $11-5$. Water leaves at $25^{\circ} \mathrm{C}$. Air enters at $20^{\circ} \mathrm{C}$ and leaves at $32^{\circ} \mathrm{C}$. Estimate ( $a$ ) the volume flow rate of air into the cooling tower, and ( $b$ ) the mass flux of water that leaves the cooling tower from the bottom.

Fig. 11-5
(a) An energy balance for the cooling tower provides $\dot{m}_{a 1} h_{1}+\dot{m}_{w 3} h_{3}=\dot{m}_{a 2} h_{2}+\dot{m}_{w-4} h_{4}$, where $\dot{m}_{a 1}=\dot{m}_{a 2}=$ $\dot{m}_{a}$ is the mass flux of dry air. From the psychrometric chart we find

$$
\begin{aligned}
& h_{1}=37 \mathrm{~kJ} / \mathrm{kg} \text { dry air } \quad h_{2}=110 \mathrm{~kJ} / \mathrm{kg} \text { dry air } \quad \omega_{1}=0.0073 \mathrm{~kg} \mathrm{H} \\
& 2
\end{aligned}
$$

From the steam tables we use $h_{f}$ at the given temperature and find $h_{3}=167.5 \mathrm{~kJ} / \mathrm{kg}$ and $h_{4}=104.9$ $\mathrm{kJ} / \mathrm{kg}$. A mass balance on the water results in $\dot{m}_{w 4}=\dot{m}_{w 3}-\left(\omega_{2}-\omega_{1}\right) \dot{m}_{a}$. Substituting this into the energy balance, with $\dot{m}_{a 1}=\dot{m}_{a 2}=\dot{m}_{a}$,

$$
\dot{m}_{a}=\frac{\dot{m}_{w 3}\left(h_{4}-h_{3}\right)}{h_{1}-h_{2}+\left(\omega_{2}-\omega_{1}\right) h_{4}}=\frac{(10000)(104.9-167.5)}{37-110+(0.0302-0.0073)(104.9)}=8870 \mathrm{~kg} / \mathrm{min}
$$

From the psychrometric chart we find that $v_{1}=0.84 \mathrm{~m}^{3} / \mathrm{kg}$ dry air. This allows us to find the volume flow rate:
Volume flow rate $=\dot{m}_{a} v_{1}=(8870)(0.84)=7450 \mathrm{~m}^{3} / \mathrm{min}$
This air flow rate requires fans, although there is some "chimney effect" since the hotter air wants to rise.
(b) $\dot{m}_{4}=\dot{m}_{w 3}-\left(\omega_{2}-\omega_{1}\right) \dot{m}_{a}=10000-(0.0302-0.0073)(8870)=9800 \mathrm{~kg} / \mathrm{min}$

If the exiting water is returned to the condenser, it must be augmented by $200 \mathrm{~kg} / \mathrm{min}$ so that $10000 \mathrm{~kg} / \mathrm{min}$ is furnished. The added water is called makeup water.

## Solved Problems

11.1 Gravimetric analysis of a mixture indicates $2 \mathrm{~kg} \mathrm{~N}_{2}, 4 \mathrm{~kg} \mathrm{O}_{2}$, and 6 kg CO 2 . Determine (a) the mass fraction of each component, ( $b$ ) the mole fraction of each component, ( $c$ ) the molecular weight of the mixture, and ( $d$ ) its gas constant.
(a) The total mass of the mixture is $m=2+4+6=12 \mathrm{~kg}$. The respective mass fractions are

$$
m f_{1}=\frac{2}{12}=0.1667 \quad m f_{2}=\frac{4}{12}=0.3333 \quad m f_{3}=\frac{6}{12}=0.5
$$

(b) To find the mole fractions we first determine the number of moles of each component:

$$
N_{1}=\frac{2}{28}=0.0714 \mathrm{kmol} \quad N_{2}=\frac{4}{32}=0.125 \mathrm{kmol} \quad N_{3}=\frac{6}{44}=0.1364 \mathrm{kmol}
$$

The total number of moles is $N=0.0714+0.125+0.1364=0.3328 \mathrm{~mol}$. The respective mole fractions are

$$
y_{1}=\frac{0.0714}{0.3328}=0.215 \quad y_{2}=\frac{0.125}{0.3328}=0.376 \quad y_{3}=\frac{0.1364}{0.3328}=0.410
$$

(c) The molecular weight of the mixture is $M=m / N=12 / 0.3328=36.1 \mathrm{~kg} / \mathrm{kmol}$. Alternatively, we could write

$$
M=\sum y_{i} M_{i}=(0.215)(28)+(0.376)(32)+(0.410)(44)=36.1 \mathrm{~kg} / \mathrm{kmol}
$$

(d) The gas constant is $R=\frac{\bar{R}}{M}=\frac{8.314}{36.1}=0.230 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}$
11.2 The partial pressure of each component of a mixture of $\mathrm{N}_{2}$ and $\mathrm{O}_{2}$ is 10 psia. If the temperature is $80^{\circ} \mathrm{F}$ find the specific volume of the mixture.

The mole fractions are equal since the partial pressures are equal [see (11.10)]: $y_{1}=0.5$ and $y_{2}=0.5$. The molecular weight is then

$$
M=\sum y_{i} M_{i}=(0.5)(28)+(0.5)(32)=40 \mathrm{lbm} / \mathrm{lbmol}
$$

and the gas constant is $R=\bar{R} / M=1545 / 40=38.6 \mathrm{ft}-\mathrm{lbf} / \mathrm{lbm}{ }^{\circ}{ }^{\circ} \mathrm{R}$. Hence,

$$
v=\frac{R T}{P}=\frac{(38.6)(540)}{(20)(144)}=7.24 \mathrm{ft}^{3} / \mathrm{lbm}
$$

 and 20 kPa . Heat is added until the temperature increases to $400^{\circ} \mathrm{C}$ while the pressure remains constant. Calculate $(a)$ the heat transfer, $(b)$ the work done, and $(c)$ the change in entropy.

To find the quantities of interest we first calculate the specific heats of the mixture, using Table B-2:

$$
\begin{gathered}
\left.\begin{array}{c}
m_{1}=(2)(16)=32 \mathrm{~kg} \\
m_{2}=(1)(14)=14 \mathrm{~kg} \\
m_{3}=(1)(44)=44 \mathrm{~kg}
\end{array}\right\} \quad \therefore m=90 \mathrm{~kg} \\
m f_{1}=\frac{32}{90}=0.356 \quad m f_{2}=\frac{14}{90}=0.1556 \quad m f_{3}=\frac{44}{90}=0.489 \\
\therefore c_{p}=\sum m f_{i} c_{p, i}=(0.356)(2.254)+(0.1556)(1.042)+(0.489)(0.842)=1.376 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K} \\
c_{i}=\sum m f_{i} c_{i, i}=(0.356)(1.735)+(0.1556)(0.745)+(0.489)(0.653)=1.053 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{~K}
\end{gathered}
$$

(a) For a constant-pressure process, $Q=\Delta H=m c_{p} \Delta T=(90)(1.376)(400-20)=47060 \mathrm{~kJ}$.

$$
\begin{equation*}
W=Q-\Delta U=Q-m c_{v} \Delta T=47060-(90)(1.053)(400-20)=11050 \mathrm{~kJ} \tag{b}
\end{equation*}
$$

(c) $\quad \Delta S=m\left(c_{p} \ln T_{2} / T_{1}-R \ln 1\right)=(90)(1.376 \ln 673 / 293)=103.0 \mathrm{~kJ} / \mathrm{K}$
11.4 An insulated, rigid tank contains $2 \mathrm{~mol} \mathrm{~N}_{2}$ at $20^{\circ} \mathrm{C}$ and 200 kPa separated by a membrane from $4 \mathrm{~mol} \mathrm{CO}+2$ at $100^{\circ} \mathrm{C}$ and 100 kPa . The membrane ruptures and the mixture reaches equilibrium. Calculate the final temperature and pressure.

The first law, with $Q=W=0$, requires $0=\Delta U=N_{1} \bar{c}_{\iota, 1}(T-20)+N_{2} \bar{c}_{i, 2}(T-100)$. The specific heat $\bar{c}_{v, i}=M_{i} c_{v, i}$. Using values from Table B-2, we have

$$
0=(2)(28)(0.745)(T-20)+(4)(44)(0.653)(T-100)
$$

This equation can be solved to yield the equilibrium temperature as $T=78.7^{\circ} \mathrm{C}$. The initial volumes occupied by the gases are

$$
V_{1}=\frac{N_{1} \bar{R} T_{1}}{P_{1}}=\frac{(2)(8.314)(293)}{200}=24.36 \mathrm{~m}^{3} \quad V_{2}=\frac{N_{2} \bar{R} T_{2}}{P_{2}}=\frac{(4)(8.314)(373)}{100}=124 \mathrm{~m}^{3}
$$

The total volume remains fixed at $124.0+24.4=148.4 \mathrm{~m}^{3}$. The pressure is then

$$
P=\frac{N \bar{R} T}{V}=\frac{(6)(8.314)(273+78.7)}{148.4}=118.2 \mathrm{kPa}
$$

11.5 A mixture of $40 \% \mathrm{~N}_{2}$ and $60 \% \mathrm{O}_{2}$ by weight is compressed from $70^{\circ} \mathrm{F}$ and 14.7 psia to 60 psia. Estimate the horsepower required by an 80 percent-efficient compressor and the entropy change, if the mass flux is $10 \mathrm{lbm} / \mathrm{min}$.

The efficiency of a compressor is based on an isentropic process. Let us find $k$ and $c_{p}$ :

$$
\begin{aligned}
c_{p} & =m f_{1} c_{p, 1}+m f_{2} c_{p, 2}=(0.4)(0.248)+(0.6)(0.219)=0.231 \mathrm{Btu} / \mathrm{lbm}-{ }^{\circ} \mathrm{R} \\
c_{v} & =m f_{1} c_{v, 1}+m f_{2} c_{v, 2}=(0.4)(0.177)+(0.6)(0.157)=0.165 \mathrm{Btu} / \mathrm{lbm}-{ }^{\circ} \mathrm{R} \\
k & =\frac{c_{p}}{c_{v}}=\frac{0.231}{0.165}=1.4
\end{aligned}
$$

The isentropic relation provides

$$
T_{2}=T_{1}\left(\frac{P_{2}}{P_{1}}\right)^{(k-1) / k}=(530)\left(\frac{60}{14.7}\right)^{(1.4-1) / 1.4}=792^{\circ} \mathrm{R}
$$

For an ideal compressor, $\left.\dot{W}_{\text {comp }}=\dot{m} \Delta h=\dot{m} c_{p} \Delta T=\left(\frac{10}{60}\right)(0.231) \times 778\right)(792-530)=7850 \mathrm{ft}-\mathrm{lbf} / \mathrm{sec}$, where the factor $778 \mathrm{ft}-\mathrm{lbf} / \mathrm{Btu}$ provides us with the desired units. If the compressor is 80 percent efficient, the actual power is $\dot{W}_{\text {comp }}=7850 / 0.8=9810 \mathrm{ft}-\mathrm{lbf} / \mathrm{sec}$ or 17.8 hp .

To find the entropy change we need the actual outlet temperature. Using the definition of compressor efficiency,

$$
\eta_{\mathrm{comp}}=\frac{w_{s}}{w_{a}}=\frac{c_{p}(\Delta T)_{s}}{c_{p}(\Delta T)_{a}}
$$

we find $0.8=(792-530) /\left(T_{2}-530\right)$ and $T_{2}=857.5^{\circ} \mathrm{R}$. The change in entropy is then

$$
\Delta s=c_{p} \ln \frac{T_{2}}{T_{2}}-R \ln \frac{P_{2}}{P_{1}}=0.231 \ln \frac{857.5}{530}-0.066 \ln \frac{60}{14.7}=0.0183 \mathrm{Btu} / \mathrm{lbm}-{ }^{\circ} \mathrm{R}
$$

where we have used $R=c_{p}-c_{t}=0.231-0.165=0.066 \mathrm{Btu} / \mathrm{lbm}{ }^{\circ} \mathrm{R}$.
11.6 Outside air at $30^{\circ} \mathrm{C}$ and 100 kPa is observed to have a dew point of $20^{\circ} \mathrm{C}$. Find the relative humidity, the partial pressure of the dry air, and the humidity ratio using equations only.

At $30^{\circ} \mathrm{C}$ we find the saturation pressure from Table $\mathrm{C}-1$ (see Fig. 11-1) to be $P_{g}=4.246 \mathrm{kPa}$. At $20^{\circ} \mathrm{C}$ the partial pressure of the water vapor is $P_{l}=2.338 \mathrm{kPa}$. Consequently, the relative humidity is

$$
\phi=\frac{P_{r}}{P_{g}}=\frac{2.338}{4.246}=0.551 \quad \text { or } 55.1 \%
$$

The partial pressure of the dry air is $P_{a}=P-P_{r}=100-2.338=97.66 \mathrm{kPa}$. The humidity ratio is found to be

$$
\omega=0.622 \frac{P_{i}}{P_{a}}=(0.622)\left(\frac{2.338}{97.66}\right)=0.01489 \mathrm{~kg} \mathrm{H}_{2} \mathrm{O} / \mathrm{kg} \text { dry air }
$$

11.7 Outside air at $25^{\circ} \mathrm{C}$ has a relative humidity of $60 \%$. What would be the expected wet-bulb temperature?

We assume an atmospheric pressure of 100 kPa . The saturation pressure at $25^{\circ} \mathrm{C}$ is $P_{g}=3.169$ kPa , so that

$$
P_{t}=\phi P_{g}=(0.6)(3.169)=1.901 \mathrm{kPa}
$$

and

$$
P_{a}=P-P_{r}=100-1.901=98.1 \mathrm{kPa}
$$

The humidity ratio of the outside air is

$$
\omega_{1}=0.622 \frac{P_{r}}{P_{a}}=(0.622)\left(\frac{1.901}{98.1}\right)=0.01206 \mathrm{~kg} \mathrm{H}_{2} \mathrm{O} / \mathrm{kg} \text { dry air }
$$

Using $\omega_{2}$ from (11.30) we can write (11.31) as

$$
\left(h_{g 1}-h_{f 2}\right) \omega_{1}=0.622 \frac{P_{g 2}}{P-P_{g 2}} h_{f g 2}+c_{p}\left(T_{2}-T_{1}\right)
$$

Substituting in the known values, we must solve

$$
\left(2547.2-h_{f 2}\right)(0.01206)=0.622 \frac{P_{g^{2}}}{100-P_{g 2}} h_{f g^{2}}+(1.00)\left(T_{2}-25\right)
$$

This is solved by trial and error:

$$
T_{2}=20^{\circ} \mathrm{C}: \quad 29.7 \stackrel{ }{=} 32.2 \quad T_{2}=15^{\circ} \mathrm{C}: \quad 30.0 \stackrel{?}{=} 16.6
$$

Interpolation yields $T_{2}=19.3^{\circ} \mathrm{C}$.
11.8 Rework Prob. 11.7 using the psychrometric chart.

The wet-bulb or adiabatic saturation temperature is found by first locating the intersection of a vertical line for which $T=25^{\circ} \mathrm{C}$ and the curved line for which $\phi_{.}=60 \%$ humidity. Follow the line for which $T_{\text {w.b. }}=$ const. that slopes upward to the left and read $T_{w . b}=19.4^{\circ} \mathrm{C}$.
11.9 Air at $90^{\circ} \mathrm{F}$ and $20 \%$ relative humidity is cooled to $75^{\circ} \mathrm{F}$. Assuming standard atmospheric pressure, calculate the required rate of energy transfer, if the inlet flow rate is $1500 \mathrm{ft}^{3} / \mathrm{min}$, and find the final humidity, using $(a)$ the psychrometric chart and ( $b$ ) the equations.
(a) The partial pressure is $P_{a 1}=P-P_{c 1}=P-\phi P_{g 1}=14.7-(0.2)(0.6988)=14.56$ psia; hence,

$$
\rho_{a 1}=\frac{P_{a 1}}{R_{a} T_{1}}=\frac{(14.56)(144)}{(53.3)(550)}=0.0715 \mathrm{lbm} / \mathrm{ft}^{3}
$$

and $\dot{m}_{a}=(1500 / 60)(0.0715)=1.788 \mathrm{lbm} / \mathrm{sec}$. The psychrometric chart at state 1 provides $h_{1}=28.5 \mathrm{Btu} / \mathrm{lbm}$ dry air. With $\omega=$ const., state 2 is located by following an $A-C$ curve in Fig. 11-4; we find $h_{2}=24.5 \mathrm{Btu} / \mathrm{lbm}$ dry air. This gives

$$
\dot{Q}_{a}=\dot{m}\left(h_{2}-h_{1}\right)=(1.788)(24.5-28.5)=-7.2 \mathrm{Btu} / \mathrm{sec}
$$

The relative humidity is found on the chart at state 2 to be $\phi_{2}=32.5 \%$.
(b) The equations provide more accurate results than can be obtained by using the psychrometric chart. The value for $\dot{m}_{a}$ from part ( $a$ ) has been calculated so we'll simply use that number. The rate of heat transfer is

$$
\dot{Q}=\dot{m}_{a}\left(h_{a 2}-h_{a 1}\right)+\dot{m}_{v}\left(h_{t 2}-h_{i 1}\right)=\dot{m}_{a} c_{p}\left(T_{2}-T_{1}\right)+\dot{m}_{i}\left(h_{t 2}-h_{t 11}\right)
$$

We find $\dot{m}_{e}$ as follows:

$$
\dot{m}_{v}=\omega \dot{m}_{a}=0.622 \frac{\phi P_{g}}{P_{a}} \dot{m}_{a}=(0.622)(0.2)\left(\frac{0.6988}{14.56}\right)(1.788)=0.01067 \mathrm{lbm} / \mathrm{sec}
$$

Thus $\dot{Q}=(1.788)(0.24)(75-90)+(0.01067)(1094.2-1100.7)=-6.51 \mathrm{Btu} / \mathrm{sec}$.
To find the relative humidity using ( 11.22 ) we must find $P_{c \cdot 2}$ and $P_{g 2}$. The final temperature is $75^{\circ} \mathrm{F}$; Table C-1E gives, by interpolation, $P_{s 2}=0.435 \mathrm{psia}$. Since the mass of vapor and the mass of dry air remain constant, the partial pressure of vapor and dry air remain constant. Hence,

$$
P_{c 2}=P_{c 1}=\phi P_{g 1}=(0.2)(0.6988)=0.1398 \mathrm{psia}
$$

The final relative humidity is $\phi_{2}=P_{t \cdot 2} / P_{g_{2}}=0.1398 / 0.435=0.321$ or $32.1 \%$. The values found in part ( $b$ ) are more accurate than those of part ( $a$ ), especially for $\dot{Q}$, since it is difficult to read $h_{1}$ and $h_{2}$ accurately.
11.10 Air at $90^{\circ} \mathrm{F}$ and $90 \%$ relative humidity is cooled to $75^{\circ} \mathrm{F}$. Calculate the required rate of energy transfer if this inlet flow rate is $1500 \mathrm{ft}^{3} / \mathrm{min}$. Also, find the final humidity. Compare with the results of Prob. 11.9. Use the psychrometric chart.

The first step is to find the mass flux of dry air. It is found as follows:

$$
P_{a 1}=P-P_{v 1}=P-\phi P_{\mathrm{g} 1}=14.7-(0.9)(0.6988)=14.07 \mathrm{psia}
$$

$\therefore \rho_{a 1}=\frac{P_{a 1}}{R_{a} T_{1}}=\frac{(14.07)(144)}{(53.3)(550)}=0.0691 \mathrm{lbm} / \mathrm{ft}^{3} \quad$ and $\quad \dot{m}_{a}=\left(\frac{1500}{60}\right)(0.0691)=1.728 \mathrm{lbm} / \mathrm{sec}$
State 1 is located on the psychrometric chart by $T_{\text {d.b. }}=90^{\circ} \mathrm{F}, \phi=90 \%$. Hence, by extrapolation, $h_{1}=52 \mathrm{Btu} / \mathrm{lbm}$ dry air. To reduce the temperature to $75^{\circ} \mathrm{F}$, it is necessary to remove moisture, following curve $F-G-H$ in Fig. 11-4. State 2 ends on the saturation line, and $h_{2}=38.6 \mathrm{Btu} / \mathrm{lbm}$ dry air. This gives

$$
\dot{Q}=\dot{m}\left(h_{2}-h_{1}\right)=(1.728)(38.6-52)=-23.2 \mathrm{Btu} / \mathrm{sec}
$$

The relative humidity is $\phi_{2}=100 \%$.
11.11 A rigid $2-\mathrm{m}^{3}$ tank contains air at $160^{\circ} \mathrm{C}$ and 400 kPa and a relative humidity of $20 \%$. Heat is removed until the final temperature is $20^{\circ} \mathrm{C}$. Determine ( $a$ ) the temperature at which condensation begins, $(b)$ the mass of water condensed during the process, and ( $c$ ) the heat transfer.
(a) The pressure in this problem is not atmospheric, so the psychrometric chart is not applicable. The initial partial pressure of the vapor is $P_{v 1}=\phi P_{g 1}=(0.2)(617.8)=123.6 \mathrm{kPa}$. The specific volume
of the water vapor is

$$
v_{t \cdot 1}=\frac{R_{t} T_{1}}{P_{v 1}}=\frac{(0.462)(433)}{123.6}=1.62 \mathrm{~m}^{3} / \mathrm{kg}
$$

At this specific volume (the volume remains constant), the temperature at which condensation begins is $T_{\text {cond }}=92.5^{\circ} \mathrm{C}$.
(b) The partial pressure of the dry air is $P_{a 1}=P-P_{c 1}=400-123.6=276.4 \mathrm{kPa}$. The mass of dry air is

$$
m_{a}=\frac{P_{a 1} V_{1}}{R_{a} T_{1}}=\frac{(276.4)(2)}{(0.287)(433)}=4.45 \mathrm{~kg}
$$

The initial humidity ratio is

$$
\omega_{1}=0.622 \frac{P_{c 1}}{P_{a 1}}=(0.622)\left(\frac{123.6}{276.4}\right)=0.278 \mathrm{~kg} \mathrm{H}_{2} \mathrm{O} / \mathrm{kg} \text { dry air }
$$

The final relative humidity is $\phi_{2}=1.0$, so that $P_{c 2}=2.338 \mathrm{kPa}$. The final partial pressure of the dry air results from $P_{a 1} / T_{1}=P_{a 2} / T_{2}$, so that $P_{a 2}=\left(P_{a 1} \times T_{2} / T_{1}\right)=(276.4)(293 / 433)=187 \mathrm{kPa}$. The final humidity ratio becomes

$$
\omega_{2}=0.622 \frac{P_{t 2}}{P_{a 2}}=(0.622)\left(\frac{2.338}{187}\right)=0.00778 \mathrm{~kg} \mathrm{H}_{2} \mathrm{O} / \mathrm{kg} \text { dry air }
$$

The moisture removed is $m_{\text {cond }}=m_{a}\left(\omega_{1}-\omega_{2}\right)=(4.45)(0.278-0.00778)=1.20 \mathrm{~kg}$.
(c) The heat transfer results from the first law:

$$
\begin{aligned}
Q & =m_{a}\left(u_{a 2}-u_{a 1}\right)+m_{i \cdot 2} u_{v 2}-m_{i \cdot 1} u_{i \cdot 1}+\Delta m_{w}\left(h_{f g}\right)_{\mathrm{avg}} \\
& =m_{a}\left[c_{v}\left(T_{2}-T_{1}\right)+\omega_{2} u_{i \cdot 2}-\omega_{1} u_{i \cdot 1}+\left(\omega_{2}-\omega_{1}\right)\left(h_{f g}\right)_{\mathrm{avg}}\right]
\end{aligned}
$$

Treating the vapor as an ideal gas, that is, $u_{c}=u_{g}$ at the given temperatures, we have

$$
\begin{aligned}
Q=(4.45)[ & (0.717)(20-160)+(0.00778)(2402.9) \\
& -(0.278)(2568.4)+(0.00778-0.278)(2365)]=-6290 \mathrm{~kJ}
\end{aligned}
$$

11.12 Hot, dry air at $40^{\circ} \mathrm{C}, 1 \mathrm{~atm}$, and $20 \%$ humidity passes through an evaporative cooler until the humidity is $40 \%$; it is then cooled to $25^{\circ} \mathrm{C}$. For an inlet airflow of $50 \mathrm{~m}^{3} / \mathrm{min},(a)$ how much water is added per hour and ( $b$ ) what is the rate of cooling?
(a) The psychrometric chart is used with $h_{1}=h_{2}$, providing us with

$$
\omega_{1}=0.0092 \mathrm{~kg} \mathrm{H}_{2} \mathrm{O} / \mathrm{kg} \text { dry air } \quad \omega_{2}=0.0122 \mathrm{~kg} \mathrm{H}_{2} \mathrm{O} / \mathrm{kg} \text { dry air }
$$

We find the mass flux $\dot{m}_{a}$ of dry air as follows:

$$
\begin{gathered}
P_{a 1}=P-P_{t 1}=P-\phi P_{g 1}=100-(0.2)(7.383)=98.52 \mathrm{kPa} \\
\therefore \rho_{a 1}=\frac{P_{a 1}}{R_{a} T_{1}}=\frac{98.52}{(0.287)(313)}=1.097 \mathrm{~kg} / \mathrm{m}^{3}
\end{gathered}
$$

and

$$
\therefore \dot{m}_{a}=\left(\rho_{a 1}\right)(50)=(1.097)(50)=54.8 \mathrm{~kg} / \mathrm{min}
$$

The water addition rate is

$$
\left(\dot{m}_{w}\right)_{\text {added }}=\dot{m}_{a}\left(\omega_{2}-\omega_{1}\right)=(54.8)(0.0122-0.0092)=0.1644 \mathrm{~kg} / \mathrm{min}=9.86 \mathrm{~kg} / \mathrm{h}
$$

(b) No heat is transferred during the process from 1 to 2 . From 2 to 3 the humidity ratio remains constant and the psychrometric chart yields

$$
h_{2}=64 \mathrm{~kJ} / \mathrm{kg} \text { dry air } \quad h_{3}=56 \mathrm{~kJ} / \mathrm{kg} \text { dry air }
$$

The rate of heat transfer is $\dot{Q}=\dot{m}_{a}\left(h_{3}-h_{2}\right)=(54.8)(56-64)=-440 \mathrm{~kJ} / \mathrm{min}$.
11.13 Outside air at $10^{\circ} \mathrm{C}$ and $30 \%$ relative humidity is available to mix with inside air at $30^{\circ} \mathrm{C}$ and $60 \%$ humidity. The inside flow rate is $50 \mathrm{~m}^{3} / \mathrm{min}$. Use the equations to determine what the outside flow rate should be to provide a mixed stream at $22^{\circ} \mathrm{C}$.

Mass balances and an energy balance provide

$$
\begin{array}{ll}
\text { Dry air: } & \dot{m}_{a 1}+\dot{m}_{a 2}=\dot{m}_{a 3} \\
\text { Vapor: } & \dot{m}_{a 1} \omega_{1}+\dot{m}_{a 2} \omega_{2}=\dot{m}_{a 3} \omega_{3} \\
\text { Energy: } & \dot{m}_{a 1} h_{1}+\dot{m}_{a 2} h_{2}=\dot{m}_{a 3} h_{3}
\end{array}
$$

Using the given quantities we find, assuming a pressure of 100 kPa :

$$
\begin{gathered}
P_{a 1}=P-P_{r 1}=P-\phi_{1} P_{g 1}=100-(0.3)(1.228)=99.6 \mathrm{kPa} \\
P_{a 2}=P-\phi_{2} P_{g 2}=100-(0.6)(4.246)=97.5 \mathrm{kPa} \\
\rho_{a 1}=\frac{P_{a 1}}{R_{a} T_{1}}=\frac{99.6}{(0.287)(283)}=1.226 \mathrm{~kg} / \mathrm{m}^{3} \quad \rho_{a 2}=\frac{P_{a 2}}{R_{a} T_{2}}=\frac{97.5}{(0.287)(303)}=1.121 \mathrm{~kg} / \mathrm{m}^{3} \\
\omega_{1}=\frac{0.622 P_{r 1}}{P_{a 1}}=\frac{(0.622)(0.3)(1.228)}{99.6}=0.00230 \mathrm{~kg} \mathrm{H}_{2} \mathrm{O} / \mathrm{kg} \mathrm{dry} \text { air } \\
\omega_{2}=\frac{(0.622)(0.6)(4.246)}{97.5}=0.01625 \mathrm{~kg} \mathrm{H}_{2} \mathrm{O} / \mathrm{kg} \text { dry air } \\
h_{1}=c_{p} T_{1}+\omega_{1} h_{g 1}=(1.00)(10)+(0.0023)(2519.7)=15.8 \mathrm{~kJ} / \mathrm{kg} \text { dry air } \\
h_{2}=c_{p} T_{2}+\omega_{2} h_{82}=(1.00)(30)+(0.01625)(2556.2)=71.5 \mathrm{~kJ} / \mathrm{kg} \text { dry air } \\
h_{3}=c_{p} T_{3}+\omega_{3} h_{83}=(1.00)(22)+\left(\omega_{3}\right)(2542)=22+3542 \omega_{3}
\end{gathered}
$$

Substituting the appropriate values in the energy equation and choosing the outside flow rate as $V_{1}$ gives

$$
\left(1.226 \dot{V}_{1}\right)(15.8)+(1.121)(50)(71.5)=\left[1.226 \dot{V}_{1}+(1.121)(50)\right]\left(22+2542 \omega_{3}\right)
$$

The vapor mass balance is $\left(1.226 \dot{V}_{1}\right)(0.0023)+(1.121)(50)(0.01625)=\left[1.226 \dot{V}_{1}+(1.121)(50)\right] \omega_{3}$. Solving for $\omega_{3}$ in terms of $\dot{V}_{1}$ from the above equation and substituting into the energy equation, we find $\dot{V}_{1}=31.1 \mathrm{~m}^{3} / \mathrm{min}$.

## Supplementary Problems

11.14 For the following mixtures calculate the mass fraction of each component and the gas constant of the mixture. (a) $2 \mathrm{kmol} \mathrm{CO}_{2}, 3 \mathrm{kmol} \mathrm{N}_{2}, 4 \mathrm{kmol}_{2}$; (b) $2 \mathrm{lbmol} \mathrm{N}_{2}, 3 \mathrm{lbmol} \mathrm{CO}, 4 \mathrm{lbmol} \mathrm{O}_{2}$; (c) 3 kmol $\mathrm{N}_{2}, 2 \mathrm{kmol} \mathrm{O}_{2}, 5 \mathrm{kmol} \mathrm{H}_{2} ;(d) 3 \mathrm{kmol}_{\mathrm{CH}_{4}} ; 2 \mathrm{kmol}$ air, $1 \mathrm{kmol} \mathrm{CO}_{2}$; and (e) $21 \mathrm{lbmol} \mathrm{O}_{2}, 78 \mathrm{lbmol} \mathrm{N}_{2}$, 1 lbmol Ar.
Ans. (a) $0.293,0.28,0.427,0.249 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}$;
(b) $0.209,0.313,0.478,51.9 \mathrm{ft}-\mathrm{lbf} / \mathrm{lbm}-{ }^{\circ} \mathrm{R}$;
(c) $0.532,0.405,0.063,0.526 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}$;
(d) $0.32,0.386,0.293,0.333 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}$;
(e) $0.232,0.754,0.014,53.4 \mathrm{ft}-\mathrm{lbf} / \mathrm{lbm} \cdot{ }^{\circ} \mathrm{R}$
11.15 For the following mixtures calculate the mole fraction of each component and, the gas constant of the mixture. (a) $2 \mathrm{~kg} \mathrm{CO}_{2}, 3 \mathrm{~kg} \mathrm{~N}_{2}, 4 \mathrm{~kg} \mathrm{O}_{2}$; (b) $2 \mathrm{lbm} \mathrm{N}_{2}, 3 \mathrm{lbm} \mathrm{CO}, 4 \mathrm{lbm} \mathrm{O}_{2}$; (c) $3 \mathrm{~kg} \mathrm{~N}_{2}, 2 \mathrm{~kg} \mathrm{O}_{2}, 5 \mathrm{~kg}$ $\mathrm{H}_{2}$; (d) $3 \mathrm{~kg} \mathrm{CH}_{4}, 2 \mathrm{~kg}$ air, $1 \mathrm{~kg} \mathrm{CO}_{2}$; and (e) $21 \mathrm{lbm} \mathrm{O}_{2}, 78 \mathrm{lbm} \mathrm{N}_{2}, 1 \mathrm{lbm} \mathrm{Ar}$.

11.16 A mixture of gases consists of $21 \% \mathrm{~N}_{2}, 32 \% \mathrm{O}_{2}, 16 \% \mathrm{CO}_{2}$, and $31 \% \mathrm{H}_{2}$, by volume. Determine: (a) the mass fraction of each component, (b) the mixture's molecular weight, and ( $c$ ) its gas constant.
Ans. (a) 0.247, 0.431, 0.296, 0.026
(b) 23.78
(c) $0.350 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}$
11.17 Gravimetric analysis of a mixture of gases indicates $21 \% \mathrm{O}_{2}, 30 \% \mathrm{CO}_{2}$, and $49 \% \mathrm{~N}_{2}$. Calculate (a) its volumetric analysis and (b) its gas constant. Ans. (a) $0.212,0.221,0.567 \quad$ (b) $0.257 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}$
11.18 Volumetric analysis of a mixture of gases shows $60 \% \mathrm{~N}_{2}, 20 \% \mathrm{O}_{2}$, and $20 \% \mathrm{CO}_{2}$. (a) How many kilograms would be contained in $10 \mathrm{~m}^{3}$ at 200 kPa and $40^{\circ} \mathrm{C}$ ? ( $b$ ) How many pounds would be contained in $300 \mathrm{ft}^{3}$ at 39 psia and $100^{\circ} \mathrm{F}$ ? Ans. (a) 24.59 kg (b) 47.93 lbm
11.19 A mixture of gases contains $2 \mathrm{kmol}_{2}, 3 \mathrm{kmol} \mathrm{CO}_{2}$, and $4 \mathrm{kmol} \mathrm{N}_{2}$. If 100 kg of the mixture is contained in a $10-\mathrm{m}^{3}$ tank at $50{ }^{\circ} \mathrm{C}$, estimate ( $a$ ) the pressure in the tank and (b) the partial pressure of the $\mathrm{N}_{2}$. Ans. (a) $785 \mathrm{kPa} \quad$ (b) 349 kPa
11.20 Gravimetric analysis of a mixture of gases indicates $60 \% \mathrm{~N}_{2}, 20 \% \mathrm{O}_{2}$, and $20 \% \mathrm{CO}_{2}$. (a) What volume is needed to contain 100 kg of the mixture at $25^{\circ} \mathrm{C}$ and 200 kPa ? (b) What volume is needed to contain 200 lbm of the mixture at $80^{\circ} \mathrm{F}$ and 30 psia ? Ans. (a) $39.9 \mathrm{~m}^{3} \quad$ (b) $206 \mathrm{ft}^{3}$
11.21 Volumetric analysis of a mixture of gases contained in a $10-\mathrm{m}^{3}$ tank at 400 kPa indicates $60 \% \mathrm{H}_{2}, 25 \%$ $\mathrm{N}_{2}$, and $15 \% \mathrm{CO}_{2}$. Determine the temperature of the mixture if its total mass is 20 kg .
Ans. $83.0^{\circ} \mathrm{C}$
11.22 The partial pressures of a mixture of gases are $20 \mathrm{kPa}\left(\mathrm{N}_{2}\right), 60 \mathrm{kPa}\left(\mathrm{O}_{2}\right)$, and $80 \mathrm{kPa}\left(\mathrm{CO}_{2}\right)$. If 20 kg of the mixture is contained in a tank at $60^{\circ} \mathrm{C}$ and 300 kPa , what is the volume of the tank?
Ans. $\quad 4.92$ m $^{3}$
11.23 A mixture of oxygen and hydrogen has the same molecular weight as does air. (a) What is its volumetric analysis? (b) What is its gravimetric analysis?
Ans. (a) $89.9 \%, 10.1 \%$ (b) $0.934,0.0656$
11.24 A rigid tank contains 10 kg of a mixture of $20 \% \mathrm{CO}_{2}$ and $80 \% \mathrm{~N}_{2}$ by volume. The initial pressure and temperature are 200 kPa and $60^{\circ} \mathrm{C}$. Calculate the heat transfer needed to increase the pressure to 600 kPa using ( $a$ ) constant specific heats and (b) the ideal-gas tables.
Ans. (a) $4790 \mathrm{~kJ} \quad$ (b) 5490 kJ
11.25 Twenty lb of a mixture of gases is contained in a $30-\mathrm{ft}^{3}$ rigid tank at 30 psia and $70^{\circ} \mathrm{F}$. Volumetric analysis indicates $20 \% \mathrm{CO}_{2}, 30 \% \mathrm{O}_{2}$, and $50 \% \mathrm{~N}_{2}$. Calculate the final temperature if 400 Btu of heat is added. Assume constant specific heats. Ans. $190^{\circ} \mathrm{F}$
11.26 An insulated cylinder contains a mixture of gases initially at 100 kPa and $25^{\circ} \mathrm{C}$ with a volumetric analysis of $40 \% \mathrm{~N}_{2}$ and $60 \% \mathrm{CO}_{2}$. Calculate the work needed to compress the mixture to 400 kPa assuming a reversible process. Use constant specific heats. Ans. $82.3 \mathrm{~kJ} / \mathrm{kg}$
11.27 A mixture of gases is contained in a cylinder at an initial state of $0.2 \mathrm{~m}^{3}, 200 \mathrm{kPa}$, and $40^{\circ} \mathrm{C}$. Gravimetric analysis is $20 \% \mathrm{CO}_{2}$ and $80 \%$ air. Calculate ( $a$ ) the heat transfer needed to maintain the temperature at $40^{\circ} \mathrm{C}$ while the pressure is reduced to 100 kPa and (b) the entropy change. Assume constant specific heats. Ans. (a) $27.7 \mathrm{~kJ} \quad$ (b) $88.6 \mathrm{~J} / \mathrm{K}$
11.28 A mixture of gases with a volumetric analysis of $30 \% \mathrm{H}_{2}, 50 \% \mathrm{~N}_{2}$, and $20 \% \mathrm{O}_{2}$ undergoes a constant-pressure process in a cylinder at an initial state of $30 \mathrm{psia}, 100^{\circ} \mathrm{F}$, and $0.4 \mathrm{ft}^{3}$. If the volume increases to $1.2 \mathrm{ft}^{3}$ determine ( $a$ ) the heat transfer and ( $b$ ) the entropy change. Assume constant specific heats. Ans. (a) 15.5 Btu (b) $0.0152 \mathrm{Btu} /{ }^{\circ} \mathrm{R}$
11.29 A tank containing 3 kg of $\mathrm{CO}_{2}$ at 200 kPa and $140^{\circ} \mathrm{C}$ is connected to a second tank containing 2 kg of $\mathrm{N}_{2}$ at 400 kPa and $60^{\circ} \mathrm{C}$. A valve is opened and the two tanks are allowed to equalize in pressure. If the final temperature is $50^{\circ} \mathrm{C}$, find $(a)$ the heat transfer, $(b)$ the final pressure, and ( $c$ ) the entropy change. Ans. (a) $191 \mathrm{~kJ} \quad$ (b) $225 \mathrm{kPa} \quad$ (c) $-0.410 \mathrm{~kJ} / \mathrm{K}$
11.30 A stream of nitrogen at 150 kPa and $50^{\circ} \mathrm{C}$ mixes with a stream of oxygen at 150 kPa and $20^{\circ} \mathrm{C}$. The mass flux of nitrogen is $2 \mathrm{~kg} / \mathrm{min}$ and that of oxygen is $4 \mathrm{~kg} / \mathrm{min}$. The mixing occurs in a steady-flow insulated chamber. Calculate the temperature of the exiting stream. Ans. $30.8^{\circ} \mathrm{C}$
11.31 A mixture of gases with a volumetric analysis of $20 \% \mathrm{CO}_{2}, 30 \% \mathrm{~N}_{2}$, and $50 \% \mathrm{O}_{2}$ is cooled from $1000^{\circ} \mathrm{R}$ in a steady-flow heat exchanger. Estimate the heat transfer using ( $a$ ) constant specific heats and (b) the ideal-gas tables.

Ans. (a) $-111 \mathrm{Btu} / \mathrm{lbm}$
(b) $-116 \mathrm{Btu} / \mathrm{lbm}$
11.32 A mixture of gases with a gravimetric analysis of $20 \% \mathrm{CO}_{2}, 30 \% \mathrm{~N}_{2}$, and $50 \% \mathrm{O}_{2}$ is cooled from $400{ }^{\circ} \mathrm{C}$ to $50^{\circ} \mathrm{C}$ by transferring 1 MW of heat from the steady-flow heat exchanger. Find the mass flux, assuming constant specific heats. Ans. $3.03 \mathrm{~kg} / \mathrm{s}$
11.33 A mixture of $40 \% \mathrm{O}_{2}$ and $60 \% \mathrm{CO}_{2}$ by volume enters a nozzle at $40 \mathrm{~m} / \mathrm{s}, 200^{\circ} \mathrm{C}$, and 200 kPa . It passes through an adiabatic nozzle and exits at $20^{\circ} \mathrm{C}$. Find the exit velocity and pressure. Assume constant specific heats. Ans. $567 \mathrm{~m} / \mathrm{s}, 178 \mathrm{kPa}$
11.34 If the inlet diameter of the nozzle of Prob. 11.33 is 20 cm , find the exit diameter. Ans. 4.4 cm
11.35 A mixture of $40 \% \mathrm{~N}_{2}$ and $60 \% \mathrm{CO}_{2}$ by volume enters a nozzle at negligible velocity and 80 psia and $1000^{\circ} \mathrm{F}$. If the mixture exits at 20 psia , what is the maximum possible exit velocity? Assume constant specific heats. Ans. $373 \mathrm{ft} / \mathrm{sec}$
11.36 A mixture of $40 \% \mathrm{~N}_{2}$ and $60 \% \mathrm{CO}_{2}$ by volume enters a supersonic diffuser at $1000 \mathrm{~m} / \mathrm{s}$ and $20^{\circ} \mathrm{C}$ and exits at $400 \mathrm{~m} / \mathrm{s}$. Find the exit temperature. Assume constant specific heats. Ans. $484^{\circ} \mathrm{C}$
11.37 A mixture of $60 \%$ air and $40 \% \mathrm{CO}_{2}$ by volume at 600 kPa and $400^{\circ} \mathrm{C}$ expands through a turbine to 100 kPa . Estimate the maximum power output if the mass flux is $4 \mathrm{~kg} / \mathrm{min}$. Assume constant specific heats. Ans. 22.2 kW
11.38 If the turbinc of Prob. 11.37 is 85 percent efficient, estimate the exit temperature. Ans. $189^{\circ} \mathrm{C}$
11.39 A compressor increases the pressure of a mixture of gases from 100 to 400 kPa . If the mixture enters at $25^{\circ} \mathrm{C}$, find the minimum power requirement if the mass flux is $0.2 \mathrm{~kg} / \mathrm{s}$. Assume constant specific heats for the following gravimetric analyses of the mixture: (a) $10 \% \mathrm{H}_{2}$ and $90 \% \mathrm{O}_{2}$; (b) $90 \% \mathrm{H}_{2}$ and $10 \%$ $\mathrm{O}_{2}$; and (c) $20 \% \mathrm{~N}_{2}, 30 \% \mathrm{CO}_{2}$, and $50 \% \mathrm{O}_{2}$. Ans. (a) 65.6 kW (b) 380 kW (c) 24.6 kW
11.40 Atmospheric air at $30^{\circ} \mathrm{C}$ and 100 kPa has a relative humidity of $40 \%$. Determine (a) the humidity ratio, (b) the dew-point temperature, and (c) the specific volume of the dry air.
Ans. (a) $0.01074 \mathrm{~kg} \mathrm{H} 2 \mathrm{O} / \mathrm{kg}$ dry air
(b) $14.9^{\circ} \mathrm{C}$
(c) $0.885 \mathrm{~m}^{3} / \mathrm{kg}$
11.41 Atmospheric air at $90^{\circ} \mathrm{F}$ and 14.2 psia has a humidity ratio of 0.02 . Calculate ( $a$ ) the relative humidity, ( $b$ ) the dew-point temperature, ( $c$ ) the specific volume of the dry air, and ( $d$ ) the enthalpy ( $h=0$ at $0^{\circ} \mathrm{F}$ ) per unit mass of dry air.
Ans. (a) $63.3 \%$
(b) $75.5^{\circ} \mathrm{F}$
(c) $14.8 \mathrm{ft}^{3} / \mathrm{lbm}$
(d) 43.6 Btu/lbm dry air
11.42 The air in a $12 \times 15 \times 3 \mathrm{~m}$ room is at $25^{\circ} \mathrm{C}$ and 100 kPa , with a $50 \%$ relative humidity. Estimate ( $a$ ) the humidity ratio, (b) the mass of dry air, ( $c$ ) the mass of water vapor in the room, and (d) the enthalpy in the room ( $h=0$ at $0^{\circ} \mathrm{C}$ ).
Ans.
(a) $0.01001 \mathrm{~kg} \mathrm{H}_{2} \mathrm{O} / \mathrm{kg}$ dry air
(b) 621 kg
(c) 6.22 kg
(d) 31.4 MJ
11.43 A tank contains 0.4 kg of dry air and 0.1 kg of saturated water vapor at $30^{\circ} \mathrm{C}$. Calculate ( $a$ ) the volume of the tank and (b) the pressure in the tank.

Ans. (a) $3.29 \mathrm{~m}^{3}$
(b) 14.82 kPa
11.44 The partial pressure of water vapor is 1 psia in atmospheric air at 14.5 psia and $110^{\circ} \mathrm{F}$. Find (a) the relative humidity, $(b)$ the humidity ratio, $(c)$ the dew-point temperature, $(d)$ the specific volume of the dry air, and ( $e$ ) the enthalpy per unit mass of dry air.
Ans.
(a) $78.4 \%$
(b) 0.0461
(c) $101.7^{\circ} \mathrm{F}$
(d) $15.4 \mathrm{ft}^{3} / \mathrm{lbm}$
(e) $77.5 \mathrm{Btu} / \mathrm{lbm}$ dry air
11.45 A person wearing glasses comes from outside, where the temperature is $10^{\circ} \mathrm{C}$, into a room with $40 \%$ relative humidity. At what room temperature will the glasses start to fog up? Ans. $24.2^{\circ} \mathrm{C}$
11.46 The outer surface temperature of a glass of cola, in a room at $28^{\circ} \mathrm{C}$, is $5^{\circ} \mathrm{C}$. At what relative humidity will water begin to collect on the outside of the glass? Ans. $22.9 \%$
11.47 A cold-water pipe at $50^{\circ} \mathrm{F}$ runs through a basement where the temperature is $70^{\circ} \mathrm{F}$. At what relative humidity will water begin to condense on the pipe?

Ans. 49\%
11.48 On a cold winter day the temperature on the inside of a thermopane window is $10^{\circ} \mathrm{C}$. If the inside temperature is $27^{\circ} \mathrm{C}$, what relative humidity is needed to just cause condensation on the window?
Ans. $34.1 \%$
11.49 Atmospheric air has a dry-bulb temperature of $30^{\circ} \mathrm{C}$ and a wet-bulb temperature of $20^{\circ} \mathrm{C}$. Calculate (a) the humidity ratio, $(b)$ the relative humidity, and (c) the enthalpy per kg of dry air ( $h=0$ at $0^{\circ} \mathrm{C}$ ).
Ans.
(a) 0.01074
(b) $40.2 \%$
(c) $57.5 \mathrm{~kJ} / \mathrm{kg}$ dry air
11.50 Use the psychrometric chart (Appendix G) to provide the missing values in Table 11-1.
Ans. (a) $17.9^{\circ} \mathrm{C}, 82 \%, 16.9^{\circ} \mathrm{C}, 50.5 \mathrm{~kJ} / \mathrm{kg}$;
(b) $25 \%, 0.0035,-1^{\circ} \mathrm{C}, 29 \mathrm{~kJ} / \mathrm{kg}$;
(c) $61^{\circ} \mathrm{F}, 0.0095,55.7^{\circ} \mathrm{F}, 27 \mathrm{Btu} / \mathrm{lbm}$;
(d) $66^{\circ} \mathrm{F}, 0.0097,56^{\circ} \mathrm{F}, 26.5 \mathrm{Btu} / \mathrm{lbm}$;
(e) $47.5^{\circ} \mathrm{C}, 17 \%, 0.0107,76 \mathrm{~kJ} / \mathrm{kg}$;
(f) $73.5^{\circ} \mathrm{F}, 85 \% 68.5^{\circ} \mathrm{F}, 34 \mathrm{Btu} / \mathrm{lbm}$

Table 11-1

|  | Dry-Bulb <br> Temperature | Wet-Bulb <br> Temperature | Relative <br> Humidity | Humidity <br> Ratio | Dew-Point <br> Temperature | Specific <br> Enthalpy |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $(a)$ | $20^{\circ} \mathrm{C}$ |  |  | 0.012 |  |  |
| $(b)$ | $20^{\circ} \mathrm{C}$ | $10^{\circ} \mathrm{C}$ |  |  |  |  |
| $(c)$ | $70^{\circ} \mathrm{F}$ |  | $60 \%$ |  |  |  |
| $(d)$ |  | $60^{\circ} \mathrm{F}$ | $70 \%$ |  | $15^{\circ} \mathrm{C}$ |  |
| $(e)$ |  | $25^{\circ} \mathrm{C}$ |  | 0.015 |  |  |
| $(f)$ |  | $70^{\circ} \mathrm{F}$ |  |  |  |  |

11.51 Atmospheric air at $10^{\circ} \mathrm{C}$ and $60 \%$ relative humidity is heated to $27^{\circ} \mathrm{C}$. Use the psychrometric chart to estimate the final humidity and the rate of heat transfer needed if the mass flux of dry air is $50 \mathrm{~kg} / \mathrm{min}$. Ans. $20 \%, 14 \mathrm{~kW}$
11.52 Heat is removed from a room without condensing out any of the water vapor. Use the psychrometric chart to calculate the final relative humidity if the air is initially at $35^{\circ} \mathrm{C}$ and $50 \%$ relative humidity and the temperature is reduced to $25^{\circ} \mathrm{C}$. Ans. $88 \%$
11.53 Outside air at $40^{\circ} \mathrm{F}$ and $40 \%$ relative humidity enters through the cracks in a house and is heated to $75^{\circ} \mathrm{F}$. Estimate the final relative humidity of the air if no other sources of water vapor are available.
Ans. $12 \%$
11.54 Atmospheric air at $10^{\circ} \mathrm{C}$ and $40 \%$ relative humidity is heated to $25^{\circ} \mathrm{C}$ in the heating section of an air-conditioning device and then steam is introduced to increase the relative humidity to $50 \%$ while the temperature increases to $26^{\circ} \mathrm{C}$. Calculate the mass flux of water vapor added and the rate of heat transfer needed in the heating section if the volume flow rate of inlet air is $50 \mathrm{~m}^{3} / \mathrm{min}$.
Ans. $0.458 \mathrm{~kg} / \mathrm{min}, 19.33 \mathrm{~kW}$
11.55 Atmospheric air at $40^{\circ} \mathrm{F}$ and $50 \%$ relative humidity enters the heating section of an air-conditioning device at a volume flow rate of $100 \mathrm{ft}^{3} / \mathrm{min}$. Water vapor is added to the heated air to increase the relative humidity to $55 \%$. Estimate the rate of heat transfer needed in the heating section and the mass flux of water vapor added if the temperature after the heating section is $72^{\circ} \mathrm{F}$ and the temperature at the exit is $74^{\circ} \mathrm{F}$. Ans. $609 \mathrm{Btu} / \mathrm{min}, 0.514 \mathrm{lbm} / \mathrm{min}$
11.56 Outside air in a dry climate enters an air conditioner at $40^{\circ} \mathrm{C}$ and $10 \%$ relative humidity and is cooled to $22^{\circ} \mathrm{C}$. (a) Calculate the heat removed. (b) Calculate the total energy required to condition outside (humid) air at $30^{\circ} \mathrm{C}$ and $90 \%$ relative humidity to $22^{\circ} \mathrm{C}$ and $10 \%$ relative humidity. (Hint: Sum the energy removed and the energy added.) Ans. (a) $19 \mathrm{~kJ} / \mathrm{kg}$ dry air, (b) $98 \mathrm{~kJ} / \mathrm{kg}$ dry air
11.57 One hundred $\mathrm{m}^{3} / \mathrm{min}$ of outside air at $36^{\circ} \mathrm{C}$ and $80 \%$ relative humidity is conditioned for an office building by cooling and heating. Estimate both the rate of cooling and the rate of heating required if the final state of the air is $25^{\circ} \mathrm{C}$ and $40 \%$ relative humidity. Ans. $152 \mathrm{~kW}, 26.8 \mathrm{~kW}$
11.58 Room air at $29^{\circ} \mathrm{C}$ and $70 \%$ relative humidity is cooled by passing it over coils through which chilled water at $5^{\circ} \mathrm{C}$ flows. The mass flux of the chilled water is $0.5 \mathrm{~kg} / \mathrm{s}$ and it experiences a $10^{\circ} \mathrm{C}$ temperature rise. If the room air exits the conditioner at $18^{\circ} \mathrm{C}$ and $100 \%$ relative humidity, estimate ( $a$ ) the mass flux of the room air and (b) the heat transfer rate. Ans. (a) $0.91 \mathrm{~kg} / \mathrm{s} \quad$ (b) 20.9 kW
11.59 Atmospheric air at $100^{\circ} \mathrm{F}$ and $15 \%$ relative humidity enters an evaporative cooler at $900 \mathrm{ft}^{3} / \mathrm{min}$ and leaves with a relative humidity of $60 \%$. Estimate ( $a$ ) the exit temperature and ( $b$ ) the mass flux at which water must be supplied to the cooler. Ans. (a) $76^{\circ} \mathrm{F} \quad$ (b) $0.354 \mathrm{lbm} / \mathrm{min}$
11.60 Outside air at $40^{\circ} \mathrm{C}$ and $20 \%$ relative humidity is to be cooled by using an evaporative cooler. If the flow rate of the air is $40 \mathrm{~m}^{3} / \mathrm{min}$, estimate ( $a$ ) the minimum possible temperature of the exit stream and (b) the maximum mass flux needed for the water supply. Ans. (a) $21.7^{\circ} \mathrm{C} \quad$ (b) $0.329 \mathrm{~kg} / \mathrm{min}$
11.61 Thirty $\mathrm{m}^{3} / \mathrm{min}$ of outside air at $0^{\circ} \mathrm{C}$ and $40 \%$ relative humidity is first heated and then passed through an evaporative cooler so that the final state is $25^{\circ} \mathrm{C}$ and $50 \%$ relative humidity. Determine the temperature of the air when it enters the cooler, the heat transfer rate needed during the heating process, and the mass flux of water required by the cooler. Ans. $45^{\circ} \mathrm{C}, 30 \mathrm{~kW}, 0.314 \mathrm{~kg} / \mathrm{min}$
11.62 Outside air at $10^{\circ} \mathrm{C}$ and $60 \%$ relative humidity mixes with $50 \mathrm{~m}^{3} / \mathrm{min}$ of inside air at $28^{\circ} \mathrm{C}$ and $40 \%$ relative humidity. If the outside flow rate is $30 \mathrm{~m}^{3} / \mathrm{min}$, estimate the relative humidity, the temperature, and the mass flux of the exiting stream. Ans. $49 \%, 20.7^{\circ} \mathrm{C}, 94.2 \mathrm{~kg} / \mathrm{min}$
11.63 Inside air at $80^{\circ} \mathrm{F}$ and $80 \%$ relative humidity is mixed with $900 \mathrm{ft}^{3} / \mathrm{min}$ of outside air at $40^{\circ} \mathrm{F}$ and $20 \%$ relative humidity. If the relative humidity of the exiting stream is $60 \%$, estimate ( $a$ ) the flow rate of the inside air, $(b)$ the temperature of the exiting stream, and $(c)$ the heat transfer rate from the outside air to the inside air. Ans. (a) $180 \mathrm{ft}^{3} / \mathrm{min} \quad$ (b) $47.8^{\circ} \mathrm{F} \quad$ (c) $240 \mathrm{Btu} / \mathrm{min}$
11.64 Cooling water leaves the condenser of a power plant at $38^{\circ} \mathrm{C}$ with a mass flux of $40 \mathrm{~kg} / \mathrm{s}$. It is cooled to $24^{\circ} \mathrm{C}$ in a cooling tower that receives atmospheric air at $25^{\circ} \mathrm{C}$ and $60 \%$ relative humidity. Saturated air exits the tower at $32^{\circ} \mathrm{C}$. Estimate ( $a$ ) the required volume flow rate of entering air and (b) the mass flux of the makeup water. Ans. (a) $37 \mathrm{~m}^{3} / \mathrm{s} \quad$ (b) $0.8 \mathrm{~kg} / \mathrm{s}$
11.65 A cooling tower cools $40 \mathrm{lbm} / \mathrm{sec}$ of water from $80^{\circ} \mathrm{F}$ to $60^{\circ} \mathrm{F}$ by moving $800 \mathrm{ft}^{3} / \mathrm{sec}$ of atmospheric air with dry-bulb and wet-bulb temperatures of $75^{\circ} \mathrm{F}$ and $55^{\circ} \mathrm{F}$, respectively, through the tower. Saturated air exits the tower. Find ( $a$ ) the temperature of the exiting air stream and ( $b$ ) the mass flux of the makeup water. Ans. (a) $73^{\circ} \mathrm{F} \quad$ (b) $0.78 \mathrm{lbm} / \mathrm{sec}$
11.66 A cooling tower cools water from $35^{\circ} \mathrm{C}$ to $27^{\circ} \mathrm{C}$. The tower receives $200 \mathrm{~m}^{3} / \mathrm{s}$ of atmospheric air at $30^{\circ} \mathrm{C}$ and $40^{\circ} \%$ relative humidity. The air exits the tower at $33^{\circ} \mathrm{C}$ and $95 \%$ relative humidity. Estimate ( $a$ ) the mass flux of water that is cooled and ( $b$ ) the mass flux of makeup water.
Ans. (a) $530 \mathrm{~kg} / \mathrm{s}$
(b) $5.9 \mathrm{~kg} / \mathrm{s}$

## Chapter 12

## Combustion

### 12.1 COMBUSTION EQUATIONS

Let us begin our review of this particular variety of chemical-reaction equations by considering the combustion of propane in a pure oxygen environment. The chemical reaction is represented by

$$
\begin{equation*}
\mathrm{C}_{3} \mathrm{H}_{8}+5 \mathrm{O}_{2} \rightarrow 3 \mathrm{CO}_{2}+4 \mathrm{H}_{2} \mathrm{O} \tag{12.1}
\end{equation*}
$$

Note that the number of moles of the elements on the left-hand side may not equal the number of moles on the right-hand side. However, the number of atoms of an element must remain the same before, after, and during a chemical reaction; this demands that the mass of each element be conserved during combustion.

In writing the equation we have demonstrated some knowledge of the products of the reaction. Unless otherwise stated we will assume complete combustion: the products of the combustion of a hydrocarbon fuel will be $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{CO}_{2}$. Incomplete combustion results in products that contain $\mathrm{H}_{2}$, $\mathrm{CO}, \mathrm{C}$, and/or OH .

For a simple chemical reaction, such as (12.1), we can immediately write down a balanced chemical equation. For more complex reactions the following systematic method proves useful:

1. Set the number of moles of fuel equal to 1 .
2. Balance $\mathrm{CO}_{2}$ with number of C from the fuel.
3. Balance $\mathrm{H}_{2} \mathrm{O}$ with H from the fuel.
4. Balance $\mathrm{O}_{2}$ from $\mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$.

For the combustion of propane we assumed that the process occurred in a pure oxygen environment. Actually, such a combustion process would normally occur in air. For our purposes we assume that air consists of $21 \% \mathrm{O}_{2}$ and $79 \% \mathrm{~N}_{2}$ by volume so that for each mole of $\mathrm{O}_{2}$ in a reaction we will have

$$
\begin{equation*}
\frac{79}{21}=3.76 \frac{\mathrm{~mol} \mathrm{~N}_{2}}{\mathrm{~mol} \mathrm{O}_{2}} \tag{12.2}
\end{equation*}
$$

Thus, on the (simplistic) assumption that $\mathrm{N}_{2}$ will not undergo any chemical reaction, (12.I) is replaced by

$$
\begin{equation*}
\mathrm{C}_{3} \mathrm{H}_{8}+5\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \rightarrow 3 \mathrm{CO}_{2}+4 \mathrm{H}_{2} \mathrm{O}+18.8 \mathrm{~N}_{2} \tag{12.3}
\end{equation*}
$$

The minimum amount of air that supplies sufficient $\mathrm{O}_{2}$ for the complete combustion of the fuel is called theoretical air or stoichiometric air. When complete combustion is achieved with theoretical air, the products contain no $\mathrm{O}_{2}$, as in the reaction of (12.3). In practice, it is found that if complete combustion is to occur, air must be supplied in an amount greater than theoretical air. This is due to the chemical kinetics and molecular activity of the reactants and products. Thus we often speak in terms of percent theoretical air or percent excess air, where

$$
\begin{equation*}
\% \text { theoretical air }=100 \%+\% \text { excess air } \tag{12.4}
\end{equation*}
$$

Slightly insufficient air results in CO being formed; some hydrocarbons may result from larger deficiencies.

The parameter that relates the amount of air used in a combustion process is the air-fuel ratio ( $A F$ ), which is the ratio of the mass of air to the mass of fuel. The reciprocal is the fuel-air ratio (FA). Thus

$$
\begin{equation*}
A F=\frac{m_{\text {air }}}{m_{\text {fuel }}} \quad F A=\frac{m_{\text {fuel }}}{m_{\text {air }}} \tag{12.5}
\end{equation*}
$$

Again, considering propane combustion with theoretical air as in (12.3), the air-fuel ratio is

$$
\begin{equation*}
A F=\frac{m_{\text {air }}}{m_{\text {fuel }}}=\frac{(5)(4.76)(29)}{(1)(44)}=15.69 \frac{\mathrm{~kg} \text { air }}{\mathrm{kg} \text { fuel }} \tag{12.6}
\end{equation*}
$$

where we have used the molecular weight of air as $29 \mathrm{~kg} / \mathrm{kmol}$ and that of propane as $44 \mathrm{~kg} / \mathrm{kmol}$. If, for the combustion of propane, $A F>15.69$, a lean mixture occurs; if $A F<15.69$, a rich mixture results.

The combustion of hydrocarbon fuels involves $\mathrm{H}_{2} \mathrm{O}$ in the products of combustion. The calculation of the dew point of the products is often of interest; it is the saturation temperature at the partial pressure of the water vapor. If the temperature drops below the dew point, the water vapor begins to condense. The condensate usually contains corrosive elements, and thus it is often important to ensure that the temperature of the products does not fall below the dew point.

EXAMPLE 12.1 Butane is burned with dry air at air-fuel ratio of 20 . Calculate ( $a$ ) the percent excess air, (b) the volume percentage of $\mathrm{CO}_{2}$ in the products, and (c) the dew-point temperature of the products.

The reaction equation for theoretical air is

$$
\mathrm{C}_{4} \mathrm{H}_{10}+6.5\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \rightarrow 4 \mathrm{CO}_{2}+5 \mathrm{H}_{2} \mathrm{O}+24.44 \mathrm{~N}_{2}
$$

(a) The air-fuel ratio for theoretical air is

$$
A F_{\mathrm{th}}=\frac{m_{\text {air }}}{m_{\text {fuel }}}=\frac{(6.5)(4.76)(29)}{(1)(58)}=15.47 \frac{\mathrm{~kg} \text { air }}{\mathrm{kg} \text { fuel }}
$$

This represents $100 \%$ theoretical air. The actual air-fuel ratio is 20 . The excess air is then

$$
\% \text { excess air }=\left(\frac{A F_{\mathrm{act}}-A F_{\mathrm{th}}}{A F_{\mathrm{th}}}\right)(100 \%)=\left(\frac{20-15.47}{15.47}\right)(100 \%)=29.28 \%
$$

(b) The reaction equation with $129.28 \%$ theoretical air is

$$
\mathrm{C}_{4} \mathrm{H}_{10}+(6.5)(1.2928)\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \rightarrow 4 \mathrm{CO}_{2}+5 \mathrm{H}_{2} \mathrm{O}+1.903 \mathrm{O}_{2}+31.6 \mathrm{~N}_{2}
$$

The volume percentage is obtained using the total moles in the products of combustion. For $\mathrm{CO}_{2}$ we have

$$
\% \mathrm{CO}_{2}=\left(\frac{4}{42.5}\right)(100 \%)=9.41 \%
$$

(c) To find the dew-point temperature of the products we need the partial pressure of the water vapor. It is found using the mole fraction to be

$$
P_{r}=y_{\mathrm{H}_{2} \mathrm{O}} P_{\mathrm{atm}}=\left(\frac{5}{42.5}\right)(100)=11.76 \mathrm{kPa}
$$

where we have assumed an atmospheric pressure of 100 kPa . Using Table C-2 we find the dew-point temperature to be $T_{\text {d.p. }}=49^{\circ} \mathrm{C}$.

EXAMPLE 12.2 Butane is burned with $90 \%$ theoretical air. Calculate the volume percentage of CO in the products and the air-fuel ratio. Assume no hydrocarbons in the products.

For incomplete combustion we add CO to the products of combustion. Using the reaction equation from Example 12.1,

$$
\mathrm{C}_{4} \mathrm{H}_{10}+(0.9)(6.5)\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \rightarrow a \mathrm{CO}_{2}+5 \mathrm{H}_{2} \mathrm{O}+22 \mathrm{~N}_{2}+b \mathrm{CO}
$$

With atomic balances on the carbon and oxygen we find:

$$
\left.\begin{array}{rlrl}
\mathrm{C}: & & 4 & =a+b \\
\mathrm{O}: & 11.7 & =2 a+5+b
\end{array}\right\} \quad \therefore a=2.7, b=1.3
$$

The volume percentage of CO is then

$$
\% \mathrm{CO}=\left(\frac{1.3}{31}\right)(100 \%)=4.19 \%
$$

The air-fuel ratio is

$$
A F=\frac{m_{\text {air }}}{m_{\text {fuel }}}=\frac{(0.9)(6.5)(4.76)(29)}{(1)(58)}=13.92 \frac{\mathrm{lbm} \text { air }}{\mathrm{lbm} \text { fuel }}
$$

EXAMPLE 12.3 Butane is burned with dry air, and volumetric analysis of the products on a dry basis (the water vapor is not measured) gives $11.0 \% \mathrm{CO}_{2}, 1.0 \% \mathrm{CO}, 3.5 \% \mathrm{O}_{2}$, and $84.5 \% \mathrm{~N}_{2}$. Determine the percent theoretical air.

The problem is solved assuming that there is 100 moles of dry products. The chemical equation is

$$
a \mathrm{C}_{4} \mathrm{H}_{10}+b\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \rightarrow \mathrm{CO}_{2}+1 \mathrm{CO}+3.5 \mathrm{O}_{2}+84.5 \mathrm{~N}_{2}+c \mathrm{H}_{2} \mathrm{O}
$$

We perform the following balances:

$$
\begin{array}{rlrl}
\mathrm{C} & & 4 a & =11+1 \quad \therefore a=3 \\
\mathrm{H}: & & 10 a & =2 c \quad \therefore c=15 \\
\mathrm{O}: & 2 b & =22+1+7+c \quad \therefore b=22.5
\end{array}
$$

A balance on the nitrogen allows a check: $3.76 b=84.5$, or $b=22.47$. This is quite close, so the above values are acceptable. Dividing through the chemical equation by the value of $a$ so that we have 1 mol fuel,

$$
\mathrm{C}_{4} \mathrm{H}_{10}+7.5\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \rightarrow 3.67 \mathrm{CO}_{2}+0.33 \mathrm{CO}+1.17 \mathrm{O}_{2}+28.17 \mathrm{~N}_{2}+5 \mathrm{H}_{2} \mathrm{O}
$$

Comparing this with the combustion equation of Example 12.1 using theoretical air, we find

$$
\% \text { theoretical air }=\left(\frac{7.5}{6.5}\right)(100 \%)=107.7 \%
$$

EXAMPLE 12.4 Volumetric analysis of the products of combustion of an unknown hydrocarbon, measured on a dry basis, gives $10.4 \% \mathrm{CO}_{2}, 1.2 \% \mathrm{CO}, 2.8 \% \mathrm{O}_{2}$, and $85.6 \% \mathrm{~N}_{2}$. Determine the composition of the hydrocarbon and the percent theoretical air.

The chemical equation for 100 mol dry products is

$$
\mathrm{C}_{a} \mathrm{H}_{b}+c\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \rightarrow 10.4 \mathrm{CO}_{2}+1.2 \mathrm{CO}+2.8 \mathrm{O}_{2}+85.6 \mathrm{~N}_{2}+d \mathrm{H}_{2} \mathrm{O}
$$

Balancing each element,

$$
\begin{aligned}
\mathrm{C}: & a & =10.4+1.2 & \therefore a=11.6 \\
\mathrm{~N}: & 3.76 c & =85.6 \quad \therefore c=22.8 & \\
\mathrm{O}: & 2 c & =20.8+1.2+5.6+d & \therefore d=18.9 \\
\mathrm{H}: & b & =2 d \quad \therefore b=37.9 &
\end{aligned}
$$

The chemical formula for the fuel is $\mathrm{C}_{11.6} \mathrm{H}_{37.9}$. This could represent a mixture of hydrocarbons, but it is not any species listed in Appendix B, since the ratio of hydrogen atoms to carbon atoms is $3.27 \simeq 13 / 4$.

To find the percent theoretical air we must have the chemical equation using $100 \%$ theoretical air:

$$
\mathrm{C}_{11.6} \mathrm{H}_{37.9}+21.08\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \rightarrow 11.6 \mathrm{CO}_{2}+18.95 \mathrm{H}_{2} \mathrm{O}+79.26 \mathrm{~N}_{2}
$$

Using the number of moles of air from the actual chemical cquation, we find

$$
\% \text { theoretical air }=\left(\frac{22.8}{21.08}\right)(100 \%)=108 \%
$$

### 12.2 ENTHALPY OF FORMATION, ENTHALPY OF COMBUSTION, AND THE FIRST LAW

When a chemical reaction occurs, there may be considerable change in the chemical composition of a system. The problem this creates is that for a control volume the mixture that exits is different from the mixture that enters. Since various tables use different zeros for the enthalpy, it is necessary to establish a standard reference state, which we shall choose as $25^{\circ} \mathrm{C}\left(77^{\circ} \mathrm{F}\right)$ and 1 atm and which shall be denoted by the superscript "o," for example, $h^{\circ}$.

Consider the combustion of $\mathrm{H}_{2}$ with $\mathrm{O}_{2}$, resulting in $\mathrm{H}_{2} \mathrm{O}$ :

$$
\begin{equation*}
\mathrm{H}_{2}+\frac{1}{2} \mathrm{O}_{2} \rightarrow \mathrm{H}_{2} \mathrm{O}(l) \tag{12.7}
\end{equation*}
$$

If $\mathrm{H}_{2}$ and $\mathrm{O}_{2}$ enter a combustion chamber at $25^{\circ} \mathrm{C}\left(77^{\circ} \mathrm{F}\right)$ and 1 atm and $\mathrm{H}_{2} \mathrm{O}(l)$ leaves the chamber at $25^{\circ} \mathrm{C}\left(77^{\circ} \mathrm{F}\right)$ and 1 atm , then measured heat transfer will be -285830 kJ for each kmol of $\mathrm{H}_{2} \mathrm{O}(\mathrm{l})$
formed. [The symbol ( $l$ ) after a chemical compound implies the liquid phase and ( $g$ ) implies the gaseous. If no symbol is given, a gas is implied.] The negative sign on the heat transfer means energy has left the control volume, as shown schematically in Fig. 12-1.

Fig. 12-1

The first law applied to a combustion process in a control volume is

$$
\begin{equation*}
Q=H_{P}-H_{R} \tag{12.8}
\end{equation*}
$$

where $H_{P}$ is the enthalpy of the products of combustion that leave the combustion chamber and $H_{R}$ is the enthalpy of the reactants that enter. If the reactants are stable elements, as in our example in Fig. $12-1$, and the process is at constant temperature and constant pressure, then the enthalpy change is called the enthalpy of formation, denoted by $h_{f}^{\circ}$. The enthalpies of formation of numerous compounds are listed in Table B-6. Note that some compounds have a positive $h_{f}^{\circ}$, indicating that they require energy to form (an endothermic reaction); others have a negative $h_{f}^{\circ}$, indicating that they give off energy when they are formed (an exothermic reaction).

The enthalpy of formation is the enthalpy change when a compound is formed. The enthalpy change when a compound undergoes complete combustion at constant temperature and pressure is called the enthalpy of combustion. For example, the enthalpy of formation of $\mathrm{H}_{2}$ is zero, yet when $1 \mathrm{~mol} \mathrm{H}_{2}$ undergoes complete combustion to $\mathrm{H}_{2} \mathrm{O}(\mathrm{l})$, it gives off 285830 kJ heat; the enthalpy of combustion of $\mathrm{H}_{2}$ is $285830 \mathrm{~kJ} / \mathrm{kmol}$. Values are listed for several compounds in Table B-7. If the products contain liquid water, the enthalpy of combustion is the higher heating value (HHV); if the products contain water vapor, the enthalpy of combustion is the lower heating lalue. The difference between the higher heating value and the lower heating value is the heat of vaporization $\bar{h}_{f g}$ at standard conditions.

For any reaction the first law, represented by ( 12.8 ), can be applied to a control volume. If the reactants and products consist of several components, the first law is, neglecting kinetic and potential energy changes,

$$
\begin{equation*}
Q-W_{s}=\sum_{\text {prod }} N_{i}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{i}-\sum_{\text {react }} N_{i}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{i} \tag{12.9}
\end{equation*}
$$

where $N_{i}$ represents the number of moles of substance $i$. The work is often zero, but not in, for example, a combustion turbine.

If combustion occurs in a rigid chamber, for example, a bomb calorimeter, the first law is

$$
\begin{equation*}
Q=U_{P}-U_{R}=\sum_{\text {prod }} N_{i}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}-P_{i}\right)_{i}-\sum_{\text {react }} N_{i}\left(\bar{h}_{j}^{\circ}+\bar{h}-\bar{h}^{\circ}-P_{l}\right)_{i} \tag{12.10}
\end{equation*}
$$

where we have used enthalpy since the $h_{f}^{\circ}$ values are tabulated. Since the volume of any liquid or solid
is negligible compared to the volume of the gases, we write (12.11) as

$$
\begin{equation*}
Q=\sum_{\text {prod }} N_{i}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}-\bar{R} T\right)_{i}-\sum_{\text {react }} N_{i}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}-\bar{R} T\right)_{i} \tag{12.11}
\end{equation*}
$$

If $N_{\text {prod }}=N_{\text {react }}$, then $Q$ for the rigid volume is equal to $Q$ for the control volume for the isothermal process.

In the above relations we employ one of the following methods to find ( $\bar{h}-\bar{h}^{\circ}$ ):
For a solid or liquid

$$
\text { Use } \bar{c}_{p} \Delta T
$$

For gases
Method 1: Assume an ideal gas with constant specific heat so that $\bar{h}-\bar{h}^{\circ}=\bar{c}_{p} \Delta T$.
Method 2: Assume an ideal gas and use tabulated values for $\bar{h}$.
Method 3: Assume nonideal-gas behavior and use the generalized charts.
Method 4: Use tables for vapors, such as the superheated steam tables.
Which method to use (especially for gases) is left to the judgment of the engineer. In our examples we'll usually use method 2 for gases since temperature changes for combustion processes are often quite large and method 1 introduces substantial error.

EXAMPLE 12.5 Calculate the enthalpy of combustion of gaseous propane and of liquid propane assuming the reactants and products to be at $25^{\circ} \mathrm{C}$ and 1 atm . Assume liquid water in the products exiting the steady-flow combustion chamber.

Assuming theoretical air (the use of excess air would not influence the result since the process is isothermal), the chemical equation is

$$
\mathrm{C}_{3} \mathrm{H}_{\mathrm{B}}+5\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \rightarrow 3 \mathrm{CO}_{2}+4 \mathrm{H}_{2} \mathrm{O}(l)+18.8 \mathrm{~N}_{2}
$$

where, for the HHV, a liquid is assumed for $\mathrm{H}_{2} \mathrm{O}$. The first law becomes, for the isothermal process $h=h^{\circ}$,

$$
\begin{aligned}
Q & =H_{P}-H_{R}=\sum_{\text {prod }} N_{i}\left(\bar{h}_{f}^{\circ}\right)_{i}-\sum_{\text {react }} N_{i}\left(\bar{h}_{f}^{\circ}\right)_{i} \\
& =(3)(-393520)+(4)(-285830)-(-103850)=-2220000 \mathrm{~kJ} / \mathrm{kmol} \text { fuel }
\end{aligned}
$$

This is the enthalpy of combustion; it is stated with the negative sign. The sign is dropped for the HHV; for gaseous propane it is 2220 MJ for each kmol of fuel.

For liquid propane we find

$$
Q=(3)(-393520)+(4)(-285830)-(-103850-15060)=-2205000 \mathrm{~kJ} / \mathrm{kmol} \text { fucl }
$$

This is slightly less than the HHV for gaseous propane, because some energy is needed to vaporize the liquid fuel.
EXAMPLE 12.6 Calculate the heat transfer required if propane and air enter a steady-flow combustion chamber at $25^{\circ} \mathrm{C}$ and 1 atm and the products leave at 600 K and 1 atm . Use theorctical air.

The combustion equation is written using $\mathrm{H}_{2} \mathrm{O}$ in the vapor form due to the high exit temperature:

$$
\mathrm{C}_{3} \mathrm{H}_{8}+5\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \rightarrow 3 \mathrm{CO}_{2}+4 \mathrm{H}_{2} \mathrm{O}(\mathrm{~g})+18.8 \mathrm{~N}_{2}
$$

The first law takes the form [see (12.9)]

$$
\begin{aligned}
Q= & \sum_{\text {prod }} N_{l}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\mathrm{o}}\right)_{i}-\sum_{\text {react }} N_{i}\left(\bar{h}_{f}^{\mathrm{o}}+\bar{h}-\bar{h}^{\mathrm{o}}\right)_{i} \\
= & (3)(-393520+22280-9360)+(4)(-241810+20400-9900) \\
& +(18.8)(17560-8670)-(-103850)=-1796000 \mathrm{~kJ} / \mathrm{kmol} \text { fuel }
\end{aligned}
$$

where we have used method 2 listed for gases. This heat transfer is less than the enthalpy of combustion of propane, as it should be, since some energy is needed to heat the products to 600 K .

EXAMPLE 12.7 Liquid octane at $25^{\circ} \mathrm{C}$ fuels a jet engine. Air at 600 K enters the insulated combustion chamber and the products leave at 1000 K . The pressure is assumed constant at 1 atm . Estimate the exit velocity using theoretical air.

The equation is $\mathrm{C}_{8} \mathrm{H}_{18}(l)+12.5\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \rightarrow 8 \mathrm{CO}_{2}+9 \mathrm{H}_{2} \mathrm{O}+47 \mathrm{~N}_{2}$. The first law, with $Q=W_{s}=0$ and including the kinetic energy change (neglect $V_{\text {inlet }}$ ), is

$$
\mathrm{O}=H_{P}-H_{R}++\frac{V^{2}}{2} M_{P} \quad \text { or } \quad V^{2}=\frac{2}{M_{P}}\left(H_{R}-H_{P}\right)
$$

where $M_{P}$ is the mass of the products per kmol fuel. For the products,

$$
\begin{aligned}
H_{P} & =(8)(-393520+42770-9360)+(9)(-241810+35880-9900)+(47)(30130-8670) \\
& =-3814700 \mathrm{~kJ} / \mathrm{kmol} \text { fuel }
\end{aligned}
$$

For the reactants, $H_{R}=(-249910)+(12.5)(17930-8680)+(47)(17560-8670)=283540 \mathrm{~kJ} / \mathrm{kmol}$.
The mass of the products is $M_{P}=(8)(44)+(9)(18)+(47)(28)=1830 \mathrm{~kg} / \mathrm{kmol}$ fuel and so

$$
V^{2}=\frac{2}{1830}\left[(0.28354+3.8147) 10^{9}\right] \quad \therefore V=2120 \mathrm{~m} / \mathrm{s}
$$

EXAMPLE 12.8 Liquid octane is burned with $300 \%$ excess air. The octane and air enter the steady-flow combustion chamber at $25^{\circ} \mathrm{C}$ and 1 atm and the products exit at 1000 K and 1 atm . Estimate the heat transfer.

The reaction with theoretical air is $\mathrm{C}_{8} \mathrm{H}_{18}+12.5\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \rightarrow 8 \mathrm{CO}_{2}+9 \mathrm{H}_{2} \mathrm{O}+47 \mathrm{~N}_{2}$. For $300 \%$ excess air ( $400 \%$ theoretical air) the reaction is

$$
\mathrm{C}_{8} \mathrm{H}_{18}(l)+50\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \rightarrow 8 \mathrm{CO}_{2}+9 \mathrm{H}_{2} \mathrm{O}+37.5 \mathrm{O}_{2}+188 \mathrm{~N}_{2}
$$

The first law applied to the combustion chamber is

$$
\begin{aligned}
Q=H_{P}-H_{R}= & (8)(-393520+42770-9360)+(9)(-241810+35880-9900) \\
& +(37.5)(31390-8680)+(188)(30130-8670)-(-249910)=312500 \mathrm{~kJ} / \mathrm{kmol} \text { fuel }
\end{aligned}
$$

In this situation heat must be added to obtain the desired exit temperature.

EXAMPLE 12.9 A constant-volume bomb calorimeter is surrounded by water at $77^{\circ} \mathrm{F}$. Liquid propane is burned with pure oxygen in the calorimeter, and the heat transfer is determined to be $-874,000 \mathrm{Btu} / \mathrm{lbmol}$. Calculate the enthalpy of formation and compare with that given in Table B-6E.

The complete combustion of propane follows $\mathrm{C}_{3} \mathrm{H}_{8}+5 \mathrm{O}_{2} \rightarrow 3 \mathrm{CO}_{2}+4 \mathrm{H}_{2} \mathrm{O}(\mathrm{g})$. The surrounding water sustains a constant-temperature process, so that (12.11) becomes

$$
\begin{gathered}
Q=\sum_{\text {prod }} N_{i}\left(\bar{h}_{f}^{\mathrm{o}}\right)_{i}-\sum_{\text {react }} N_{i}\left(\bar{h}_{f}^{\mathrm{o}}\right)_{i}+\left(N_{R}-N_{P}\right) \bar{R} T=-874,000 \\
-874,000=(3)(-169,300)+(4)(-104,040)-\left(\bar{h}_{f}^{\mathrm{o}}\right)_{C_{3} \mathbf{H}_{*}}+(6-7)(1.987)(537) \\
\therefore\left(\bar{h}_{f}^{\mathrm{o}}\right)_{\mathrm{C}_{3} \mathrm{H}_{*}}=-51,130 \mathrm{Btu} / \mathrm{lbmol}
\end{gathered}
$$

This compares with $\bar{h}_{f}^{\circ}$ from the Table B-6E of $(-44,680-6480)=-51,160 \mathrm{Btu} / \mathrm{lbmol}$.

### 12.3 ADIABATIC FLAME TEMPERATURE

If we consider a combustion process that takes place adiabatically, with no work or changes in kinetic and potential energy, then the temperature of the products is referred to as the adiabatic flame temperature. We find that the maximum adiabatic flame temperature that can be achieved occurs at theoretical air. This fact allows us to control the adiabatic flame temperature by the amount of excess air involved in the process: The greater the amount of excess air the lower the adiabatic flame temperature. If the blades in a turbine can withstand a certain maximum temperature, we can determine the excess air needed so that the maximum allowable blade temperature is not exceeded, We will find that an iterative (trial-and-error) procedure is needed to find the adiabatic flame temperature. A quick approximation to the adiabatic flame temperature is found by assuming the products to be completely $\mathrm{N}_{2}$. An example will illustrate.

The adiabatic flame temperature is calculated assuming complete combustion, no heat transfer from the combustion chamber, and no dissociation of the products into other chemical species. Each of these effects tends to reduce the adiabatic flame temperature. Consequently, the adiabatic flame temperature that we will calculate represents the maximum possible flame temperature for the specified percentage of theoretical air.

If a significant amount of heat transfer does occur, we can account for it by including the following term in the energy equation:

$$
\begin{equation*}
\dot{Q}=U A\left(T_{P}-T_{E}\right) \tag{12.12}
\end{equation*}
$$

where $U=$ overall heat-transfer coefficient (specified),
$T_{E}=$ temperature of environment
$T_{p}=$ temperature of products,
$A=$ surface area of combustion chamber.
[Note that the units on $U$ are $\mathrm{kW} / \mathrm{m}^{2} \cdot \mathrm{~K}$ or $\mathrm{Btu} / \mathrm{sec}-\mathrm{ft}^{2}{ }^{\circ}{ }^{\circ} \mathrm{R}$.]
EXAMPLE 12.10 Propane is burned with $250 \%$ theoretical air; both are at $25^{\circ} \mathrm{C}$ and 1 atm . Predict the adiabatic flame temperature in the steady-flow combustion chamber.

The combustion with theoretical air is $\mathrm{C}_{3} \mathrm{H}_{8}+5\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \rightarrow 3 \mathrm{CO}_{2}+4 \mathrm{H}_{2} \mathrm{O}+18.8 \mathrm{~N}_{2}$. For $250 \%$ theoretical air we have

$$
\mathrm{C}_{3} \mathrm{H}_{8}+12.5\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \rightarrow 3 \mathrm{CO}_{2}+4 \mathrm{H}_{2} \mathrm{O}+7.5 \mathrm{O}_{2}+47 \mathrm{~N}_{2}
$$

Since $Q=0$ for an adiabatic process we demand that $H_{R}=H_{P}$. The enthalpy of the reactants, at $25^{\circ} \mathrm{C}$, is $H_{R}=-103850 \mathrm{~kJ} / \mathrm{kmol}$ fucl.

The temperature of the products is the unknown; and we cannot obtain the enthalpies of the components of the products from the tables without knowing the temperatures. This requires a trial-and-error solution. To obtain an initial guess, we assume the products to be composed entirely of nitrogen:

$$
H_{R}=H_{P}=-103850=(3)(-393520)+(4)(-241820)+(61.5)\left(\bar{h}_{P}-8670\right)
$$

where we have noted that the products contain 61.5 mol of gas. This gives $\vec{h}_{P}=43400 \mathrm{~kJ} / \mathrm{kmol}$, which suggests a temperature of about 1380 K (take $T_{p}$ a little less than that predicted by the all-nitrogen assumption). Using this temperature we check using the actual products:

$$
\begin{aligned}
-103850 \stackrel{?}{=} & (3)(-393520+64120-9360)+(4)(-241820+52430-9900) \\
& +(7.5)(44920-8680)+(47)(42920-8670)=68110
\end{aligned}
$$

The temperature is obviously too high. We select a lower value, $T_{P}=1300 \mathrm{~K}$. There results:

$$
\begin{aligned}
-103850 \stackrel{?}{=} & (3)(-393520+59520-9360)+(4)(-241820+48810-9900) \\
& +(7.5)(44030-8680)+(47)(40170-8670)=-96100
\end{aligned}
$$

We use the above two results for 1380 K and 1300 K and, assuming a linear relationship, predict that $T_{P}$ is

$$
T_{P}=1300-\left[\frac{103850-96100}{68110-(-96100)}\right](1380-1300)=1296 \mathrm{~K}
$$

EXAMPLE 12.11 Propane is burned with theoretical air; both are at $25^{\circ} \mathrm{C}$ and 1 atm in a steady-flow combustion chamber. Predict the adiabatic flame temperature.

The combustion with theoretical air is $\mathrm{C}_{3} \mathrm{H}_{8}+5\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \rightarrow 3 \mathrm{CO}_{2}+4 \mathrm{H}_{2} \mathrm{O}+18.8 \mathrm{~N}_{2}$. For the adiabatic process the first law takes the form $H_{R}=H_{P}$. Hence, assuming the products to be composed entirely of nitrogen,

$$
-103850=(3)(-393520)+(4)(-241820)+(25.8)\left(\bar{h}_{P}-8670\right)
$$

where the products contain 25.8 mol gas. This gives $\bar{h}_{P}=87900 \mathrm{~kJ} / \mathrm{kmol}$, which suggests a temperature of about 2600 K . With this temperature we find, using the actual products:

$$
\begin{aligned}
-103850 & \stackrel{?}{( } 3)(-393520+137400-9360)+(4)(-241820+114300-9900)+(18.8)(86600-8670) \\
& =119000
\end{aligned}
$$

At 2400 K there results:

$$
\begin{aligned}
-103850 & \stackrel{?}{=}(3)(-393520+125200-9360)+(4)(-241820+103500-9900)+(18.8)(79320-8670) \\
& =-97700
\end{aligned}
$$

A straight line extrapolation gives $T_{P}=2394 \mathrm{~K}$.
EXAMPLE 12.12 The overall heat-transfer coefficient of a steady-flow combustion chamber with a $2-\mathrm{m}^{2}$ surface area is determined to be $0.5 \mathrm{~kW} / \mathrm{m}^{2} \cdot \mathrm{~K}$. Propane is burned with theoretical air, both at $25^{\circ} \mathrm{C}$ and 1 atm . Predict the temperature of the products of combustion if the propane mass flow rate is $0.2 \mathrm{~kg} / \mathrm{s}$.

The molar influx is $\dot{m}_{\text {fuel }}=0.2 / 44=0.004545 \mathrm{kmol} / \mathrm{s}$, where the molecular weight of propane, $44 \mathrm{~kg} / \mathrm{kmol}$, is used. Referring to the chemical reaction given in Example 12.11, the mole fluxes of the products are given by:

$$
\begin{array}{rlr}
\dot{M}_{\mathrm{CO}_{2}} & =(3)(0.004545)=0.01364 \mathrm{kmol} / \mathrm{s} & \dot{M}_{\mathrm{H}_{2} \mathrm{O}}=(4)(0.004545)=0.02273 \mathrm{kmol} / \mathrm{s} \\
\dot{M}_{\mathrm{N}_{2}} & =(18.8)(0.004545)=0.1068 \mathrm{kmol} / \mathrm{s} &
\end{array}
$$

We can write the energy equation (the first law) as

$$
\dot{Q}+\dot{H}_{R}=\dot{H}_{P}
$$

Using (12.12), the energy equation becomes

$$
\begin{aligned}
& -(0.5)(2)\left(T_{P}-298\right)+(0.004545)(-103850) \\
& \quad=(0.01364)\left(-393520+\bar{h}_{\mathrm{CO}_{2}}-9360\right)+(0.02273)\left(-241820+\bar{h}_{\mathrm{H}_{2} \mathrm{O}}-9900\right)+(0.1068)\left(\bar{h}_{\mathrm{N}_{2}}-8670\right)
\end{aligned}
$$

For a first guess at $T_{P}$ let us assume a somewhat lower temperature than that of Example 12.11, since energy is leaving the combustion chamber. The guesses follow:

$$
\begin{array}{ll}
T_{P}=1600 \mathrm{~K}: & -1774 \stackrel{?}{=}-4446-4295+4475=-4266 \\
T_{P}=2000 \mathrm{~K}: & -2174 \stackrel{?}{=}-4120-3844+5996=-1968 \\
T_{P}=1900 \mathrm{~K}: & -2074 \stackrel{?}{=}-4202-3960+5612=-2550
\end{array}
$$

Interpolation between the last two entries gives $T_{P}=1970 \mathrm{~K}$. Checking,

$$
T_{P}=1970 \mathrm{~K}: \quad-2144 \stackrel{?}{=}-4145-3879+5881=-2143
$$

Hence, $T_{P}=1970 \mathrm{~K}$. If we desire the temperature of the products to be less than this, we can increase the overall heat-transfer coefficient or add excess air.

## Solved Problems

12.1 Ethane $\left(\mathrm{C}_{2} \mathrm{H}_{6}\right)$ is burned with dry air which contains $5 \mathrm{~mol} \mathrm{O} \mathrm{O}_{2}$ for each mole of fuel. Calculate ( $a$ ) the percent of excess air, ( $b$ ) the air-fuel ratio, and ( $c$ ) the dew-point temperature.

The stoichiometric equation is $\mathrm{C}_{2} \mathrm{H}_{6}+3.5\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \rightarrow 2 \mathrm{CO}_{2}+3 \mathrm{H}_{2} \mathrm{O}+6.58 \mathrm{~N}_{2}$. The required combustion equation is

$$
\mathrm{C}_{2} \mathrm{H}_{6}+5\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \rightarrow 2 \mathrm{CO}_{2}+3 \mathrm{H}_{2} \mathrm{O}+1.5 \mathrm{O}_{2}+18.8 \mathrm{~N}_{2}
$$

(a) There is excess air since the actual reaction uses $5 \mathrm{~mol} \mathrm{O}_{2}$ rather than 3.5 mol . The percent of excess air is

$$
\% \text { excess air }=\left(\frac{5-3.5}{3.5}\right)(100 \%)=42.9 \%
$$

(b) The air-fuel ratio is a mass ratio. Mass is found by multiplying the number of moles by the molecular weight:

$$
A F=\frac{(5)(4.76)(29)}{(1)(3 \theta)}=23.0 \mathrm{~kg} \mathrm{air} / \mathrm{kg} \text { fuel }
$$

(c) The dew-point temperature is found using the partial pressure of the water vapor in the combustion products. Assuming atmospheric pressure of 100 kPa , we find

$$
P_{t}=y_{\mathrm{H}_{2} \mathrm{O}} P_{\mathrm{atm}}=\left(\frac{3}{25.3}\right)(100)=1.86 \mathrm{kPa}
$$

Using the Table C-2, we interpolate and find $T_{\text {d.p. }}=49^{\circ} \mathrm{C}$.
12.2 A fuel mixture of $60 \%$ methane, $30 \%$ ethane, and $10 \%$ propane by volume is burned with stoichiometric air. Calculate the volume flow rate of air required if the fuel mass is $12 \mathrm{lbm} / \mathrm{h}$ assuming the air to be at $70^{\circ} \mathrm{F}$ and 14.7 psia .

The reaction equation, assuming 1 mol fuel, is

$$
0.6 \mathrm{CH}_{4}+0.3 \mathrm{C}_{2} \mathrm{H}_{6}+0.1 \mathrm{C}_{3} \mathrm{H}_{8}+a\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \rightarrow b \mathrm{CO}_{2}+c \mathrm{H}_{2} \mathrm{O}+d \mathrm{~N}_{2}
$$

We find $a, b, c$, and $d$ by balancing the various elements as follows:

$$
\begin{array}{lrl}
\mathrm{C}: & 0.6+0.6+0.3=b & \therefore b=1.5 \\
\mathrm{H}: & 2.4+1.8+0.8=2 c & \therefore c=2.5 \\
\mathrm{O}: & 2 a=2 b+c & \therefore a=2.75 \\
\mathrm{~N}: & (2)(3.76 a)=2 d & \therefore d=10.34
\end{array}
$$

The air-fuel ratio is

$$
A F=\frac{(2.75)(4.76)(29)}{(0.6)(16)+(0.3)(30)+(0.1)(44)}=\frac{379.6}{23}=16.5 \frac{\mathrm{lbm} \text { air }}{\mathrm{lbm} \text { fuel }}
$$

and $\dot{m}_{\text {air }}=(A F) \dot{m}_{\text {fuel }}=(16.5)(12)=198 \mathrm{lbm} / \mathrm{h}$. To find the volume flow rate we need the air density. It is

$$
\rho_{\mathrm{air}}=\frac{P}{R T}=\frac{(14.7)(144)}{(53.3)(530)}=0.0749 \mathrm{lbm} / \mathrm{ft}^{3}
$$

whence

$$
A V=\frac{\dot{m}}{\rho_{\text {air }}}=\frac{198 / 60}{0.0749}=44.1 \mathrm{ft}^{3} / \mathrm{min}
$$

(The volume flow rate is usually given in $\mathrm{ft}^{3} / \mathrm{min}(\mathrm{cfm})$ )
12.3 Butane $\left(\mathrm{C}_{4} \mathrm{H}_{10}\right)$ is burned with $20^{\circ} \mathrm{C}$ air at $70 \%$ relative humidity. The air-fuel ratio is 20 . Calculate the dew-point temperature of the products. Compare with Example 12.1.

The reaction equation using dry air (the water vapor in the air does not react, but simply tags along, it will be included later) is

$$
\mathrm{C}_{4} \mathrm{H}_{10}+a\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \rightarrow 4 \mathrm{CO}_{2}+5 \mathrm{H}_{2} \mathrm{O}+b \mathrm{O}_{2}+c \mathrm{~N}_{2}
$$

The air-fuel ratio of 20 allows us to calculate the constant $a$, using $M_{\text {fuel }}=58 \mathrm{~kg} / \mathrm{kmol}$, as follows:

$$
A F=\frac{m_{\mathrm{dry} \mathrm{air}}}{m_{\text {fuel }}}=\frac{(a)(4.76)(29)}{(1)(58)}=20 \quad \therefore a=8.403
$$

We also find that $b=1.903$ and $c=31.6$. The partial pressure of the moisture in the $20^{\circ} \mathrm{C}$ air is

$$
P_{c}=\phi P_{g}=(0.7)(2.338)=1.637 \mathrm{kPa}
$$

The ratio of the partial pressure to the total pressure ( 100 kPa ) equals the mole ratio, so that

$$
N_{i}=N \frac{P_{i}}{P}=\left[(8.403)(4.76)+N_{i}\right]\left(\frac{1.637}{100}\right) \quad \text { or } \quad N_{i}=0.666 \mathrm{kmol} / \mathrm{kmol} \text { fuel }
$$

We simply add $N_{c}$ to each side of the reaction equation:

$$
\mathrm{C}_{4} \mathrm{H}_{10}+8.403\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right)+0.666 \mathrm{H}_{2} \mathrm{O} \rightarrow 4 \mathrm{CO}_{2}+5.666 \mathrm{H}_{2} \mathrm{O}+1.903 \mathrm{O}_{2}+31.6 \mathrm{~N}_{2}
$$

The partial pressure of water vapor in the products is $P_{c}=P y_{\mathbf{H}_{2} \mathrm{O}}=(100)(5.666 / 43.17)=13.1 \mathrm{kPa}$. From Table $\mathrm{C}-2$ we find the dew-point temperature to be $T_{\text {d.p. }}=51^{\circ} \mathrm{C}$, which compares with $49^{\circ} \mathrm{C}$ using dry air as in Example 12.1. Obviously the moisture in the combustion air does not significantly influence the products. Consequently, we usually neglect the moisture.
12.4 Methane is burned with dry air, and volumetric analysis of the products on a dry basis gives $10 \% \mathrm{CO}_{2}, 1 \% \mathrm{CO}, 1.8 \% \mathrm{O}_{2}$, and $87.2 \% \mathrm{~N}_{2}$. Calculate ( $a$ ) the air-fuel ratio, ( $b$ ) the percent excess air, and $(c)$ the percentage of water vapor that condenses if the products are cooled to $30^{\circ} \mathrm{C}$.

Assume 100 mol dry products. The reaction equation is

$$
a \mathrm{CH}_{4}+b\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \rightarrow 10 \mathrm{CO}_{2}+\mathrm{CO}+1.8 \mathrm{O}_{2}+87.2 \mathrm{~N}_{2}+c \mathrm{H}_{2} \mathrm{O}
$$

A balance on the atomic masses provides the following:

$$
\begin{array}{rlrlrl}
\mathrm{C}: & & a & =10+1 \quad & \therefore a=11 & \\
\mathrm{H}: & 4 a & =2 c \quad \therefore c=22 & & \\
\mathrm{O}: & & 2 b & =20+1+3.6+c \quad \therefore b=23.3
\end{array}
$$

Dividing the reaction equation by $a$ so that we have 1 mol fuel:

$$
\mathrm{CH}_{4}+2.12\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \rightarrow 0.909 \mathrm{CO}_{2}+0.091 \mathrm{CO}+0.164 \mathrm{O}_{2}+7.93 \mathrm{~N}_{2}+2 \mathrm{H}_{2} \mathrm{O}
$$

(a) The air-fuel ratio is calculated from the reaction equation to be

$$
A F=\frac{m_{\text {air }}}{m_{\text {fuel }}}=\frac{(2.12)(4.76)(29)}{(1)(16)}=18.29 \mathrm{~kg} \text { air } / \mathrm{kg} \text { fuel }
$$

(b) The stoichiometric reaction is $\mathrm{CH}_{4}+2\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \rightarrow \mathrm{CO}_{2}+2 \mathrm{H}_{2} \mathrm{O}+7.52 \mathrm{~N}_{2}$. This gives the excess air as

$$
\% \text { excess air }=\left(\frac{2.12-2}{2}\right)(100 \%)=6 \%
$$

(c) There are 2 mol water vapor in the combustion products before condensation. If $N_{w}$ represents moles of water vapor that condense when the products reach $30^{\circ} \mathrm{C}$, then $2-N_{w}$ is the number of water vapor moles and $11.09-N_{w}$ is the total number of moles in the combustion products at $30^{\circ} \mathrm{C}$. We find $N_{w}$ as follows:

$$
\frac{N_{c}}{N}=\frac{P_{c}}{P} \quad \frac{2-N_{w}}{11.09-N_{w}}=\frac{4.246}{100} \quad \therefore N_{w}=1.597 \mathrm{~mol} \mathrm{H}_{2} \mathrm{O}
$$

The percentage of water vapor that condenses out is

$$
\% \text { condensate }=\left(\frac{1.597}{2}\right)(100)=79.8 \%
$$

12.5 An unknown hydrocarbon fuel combusts with dry air; the resulting products have the following dry volumetric analysis: $12 \% \mathrm{CO}_{2}, 1.5 \% \mathrm{CO}, 3 \% \mathrm{O}_{2}$, and $83.5 \% \mathrm{~N}_{2}$. Calculate the percent excess air.

The reaction equation for 100 mol dry products is

$$
\mathrm{C}_{a} \mathrm{H}_{b}+c\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \rightarrow 12 \mathrm{CO}_{2}+1.5 \mathrm{CO}+3 \mathrm{O}_{2}+83.5 \mathrm{~N}_{2}+d \mathrm{H}_{2} \mathrm{O}
$$

A balance on each element provides the following:

$$
\begin{aligned}
& \text { C: } \quad a=12+1.5 \quad \therefore a=13.5 \\
& \mathrm{~N}: \quad 3.76 c=83.5 \quad \therefore c=22.2 \\
& \text { O: } \quad 2 c=24+1.5+6+d \quad \therefore d=12.9 \\
& \text { H: } \quad b=2 d \quad \therefore b=25.8
\end{aligned}
$$

The fuel mixture is represented by $\mathrm{C}_{13.5} \mathrm{H}_{25.8}$. For theoretical air with this fuel, we have

$$
\mathrm{C}_{13.5} \mathrm{H}_{25.8}+19.95\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \rightarrow 13.5 \mathrm{CO}_{2}+12.9 \mathrm{H}_{2} \mathrm{O}+75.0 \mathrm{~N}_{2}
$$

Comparing this with the actual equation above, we find

$$
\% \text { excess air }=\left(\frac{22.2-19.95}{19.95}\right)(100 \%)=11.3 \%
$$

12.6 Carbon reacts with oxygen to form carbon dioxide in a steady-flow chamber. Calculate the energy involved and state the type of reaction. Assume the reactants and products are at $25^{\circ} \mathrm{C}$ and 1 atm .

The reaction equation is $\mathrm{C}+\mathrm{O}_{2} \rightarrow \mathrm{CO}_{2}$. The first law and Table B-6 give

$$
\begin{aligned}
Q & =H_{P}-H_{R}=\sum_{\text {prod }} N_{i}\left(\bar{h}_{f}^{\circ}\right)_{i}-\sum_{\text {react }} N_{i}\left(\bar{h}_{f}^{\circ}\right)_{i} \\
& =(1)(-393520)-0-0=-393520 \mathrm{~kJ} / \mathrm{kmol}
\end{aligned}
$$

The reaction is exothermic (negative $Q$ ).
12.7 Methane enters a steady-flow combustion chamber at $77^{\circ} \mathrm{F}$ and 1 atm with $80 \%$ excess air which is at $800^{\circ} \mathrm{R}$ and 1 atm . Calculate the heat transfer if the products leave at $1600^{\circ} \mathrm{R}$ and 1 atm.

The reaction equation with $180 \%$ theoretical air and with the water in vapor form is

$$
\mathrm{CH}_{4}+3.6\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \rightarrow \mathrm{CO}_{2}+2 \mathrm{H}_{2} \mathrm{O}(g)+1.6 \mathrm{O}_{2}+13.54 \mathrm{~N}_{2}
$$

The first law, with zero work, provides the heat transfer:

$$
\begin{aligned}
Q= & \sum_{\text {prod }} N_{i}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{i}-\sum_{\text {react }} N_{i}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{i} \\
= & (1)(-169,300+15,829-4030)+(2)(-104,040+13,494-4258)+(1.6)(11,832-3725) \\
& +(13.54)(11,410-3730)-(-32,210)-(3.6)(5602-3725)-(13.54)(5564-3730) \\
= & -229,500 \mathrm{Btu} / \text { lbmol fuel }
\end{aligned}
$$

12.8 Ethane at $25^{\circ} \mathrm{C}$ is burned in a steady-flow combustion chamber with $20 \%$ excess air at $127^{\circ} \mathrm{C}$, but only $95 \%$ of the carbon is converted to $\mathrm{CO}_{2}$. If the products leave at 1200 K , calculate the heat transfer. The pressure remains constant at 1 atm.

The stoichiometric reaction equation is

$$
\mathrm{C}_{2} \mathrm{H}_{6}+3.5\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \rightarrow 2 \mathrm{CO}_{2}+3 \mathrm{H}_{2} \mathrm{O}+11.28 \mathrm{~N}_{2}
$$

With $120 \%$ theoretical air and the product CO , the reaction equation becomes

$$
\mathrm{C}_{2} \mathrm{H}_{6}+4.2\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \rightarrow 1.9 \mathrm{CO}_{2}+0.1 \mathrm{CO}+3 \mathrm{H}_{2} \mathrm{O}+0.75 \mathrm{O}_{2}+11.28 \mathrm{~N}_{2}
$$

The first law with zero work is $Q=H_{P}-H_{R}$. The enthalpy of the products is [see (12.9)]

$$
\begin{aligned}
H_{P}= & (1.9)(-393520+53850-9360)+(0.1)(-110530+37100-8670) \\
& +(3)(-241820+44380-9900)+(0.75)(38450-8680)+(11.28)(36780-8670) \\
= & -1049000 \mathrm{~kJ} / \mathrm{kmol} \text { fuel }
\end{aligned}
$$

The enthalpy of the reactants is

$$
H_{R}=-84680+(4.2)(11710-8680)+(15.79)(11640-8670)=-25060 \mathrm{~kJ} / \mathrm{kmol} \text { fuel }
$$

Then $Q=-1049000-(-25060)=-1024000 \mathrm{~kJ} / \mathrm{kmol}$ fuel.
12.9 A rigid volume contains 0.2 lbm of propane gas and 0.8 lbm of oxygen at $77^{\circ} \mathrm{F}$ and 30 psia. The propane burns completely, and the final temperature, after a period of time, is observed to be $1600^{\circ} \mathrm{R}$. Calculate $(a)$ the final pressure and $(b)$ the heat transfer.

The moles of propane and oxygen are $N_{\text {propane }}=0.2 / 44=0.004545 \mathrm{lbmol}$ and $N_{\text {oxygen }}=0.8 / 32$ $=0.025 \mathrm{lbmol}$. For each mole of propane there is $0.025 / 0.004545=5.5 \mathrm{~mol} \mathrm{O}_{2}$. The reaction equation for complete combustion is then

$$
\mathrm{C}_{3} \mathrm{H}_{8}+5.5 \mathrm{O}_{2} \rightarrow 3 \mathrm{CO}_{2}+4 \mathrm{H}_{2} \mathrm{O}(g)+0.5 \mathrm{O}_{2}
$$

(a) We use the ideal-gas law to predict the final pressure. Since the volume remains constant, we have

$$
V=\frac{N_{1} \bar{R} T_{1}}{P_{1}}=\frac{N_{2} \bar{R} T_{2}}{P_{2}} \quad \frac{(6.5)(537)}{30}=\frac{(7.5)(1600)}{P_{2}} \quad \therefore P_{2}=103.1 \mathrm{psia}
$$

(b) By (12.11), with $\bar{R}=1.986 \mathrm{Btu} / \mathrm{lbmol}-{ }^{\circ} \mathrm{R}$, we have for each mole of propane:

$$
\begin{aligned}
Q= & \sum_{\text {prod }} N_{i}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}-\bar{R} T\right)_{i}-\sum_{\text {react }} N_{i}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}-\bar{R} T\right)_{i} \\
= & (3)[-169,300+15,830-4030-(1.986)(1600)] \\
& +(4)[-104,040+13,490-4260-(1.986)(1600)] \\
& +(0.5)[11,830-3720-(1.986)(1600)] \\
& -(1)[-44,680-(1.986)(537)]-(5.5)[(-1.986)(537)] \\
= & -819,900 \text { Btu/lbmol fuel }
\end{aligned}
$$

Thus $Q=(-819,900)(0.004545)=3730 \mathrm{Btu}$.
12.10 Propane is burned in a steady-flow combustion chamber with $80 \%$ theoretical air, both at $25^{\circ} \mathrm{C}$ and 1 atm . Estimate the adiabatic flame temperature and compare with that of Examples 12.10 and 12.11.

Using the stoichiometric reaction equation of Example 12.11 and assuming production of CO , the combustion with $80 \%$ theoretical air follows

$$
\mathrm{C}_{3} \mathrm{H}_{8}+4\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \rightarrow \mathrm{CO}_{2}+4 \mathrm{H}_{2} \mathrm{O}+2 \mathrm{CO}+15.04 \mathrm{~N}_{2}
$$

(A mass balance of the elements is required to obtain this equation.)
For an adiabatic process, the first law takes the form $H_{R}=H_{P}$, where $H_{R}$ for propane is -103850 $\mathrm{kJ} / \mathrm{kmol}$. Assuming the temperature close to but less than that of Example 12.11 , we try $T_{P}=2200 \mathrm{~K}$ :

$$
\begin{aligned}
-103850 \stackrel{?}{=} & (-393520+112940-9360)+(4)(-241820+92940-9900) \\
& +(2)(-110530+72690-8670)+(15.04)(72040-8670)=-65000
\end{aligned}
$$

At 2100 K :

$$
\begin{aligned}
-103850 \stackrel{?}{=} & (-393520+106860-9360)+(4)(-241820+87740-9900) \\
& +(2)(-110530+69040-8670)+(15.04)(68420-8670)=-153200
\end{aligned}
$$

A straight-line interpolation provides the adiabatic flame temperature $T_{P}=2156 \mathrm{~K}$. Note that this temperature is less than that of the stoichiometric reaction of Example 12.11, as was the temperature for Example 12.10 where excess air was used. The stoichiometric reaction provides the maximum adiabatic flame temperature.
12.11 An insulated, rigid $0.7-\mathrm{m}^{3}$ tank contains 0.05 kg of ethane and $100 \%$ theoretical air at $25^{\circ} \mathrm{C}$. The fuel is ignited and complete combustion occurs. Estimate (a) the final temperature and (b) the final pressure.

With $100 \%$ theoretical air, $\mathrm{C}_{2} \mathrm{H}_{6}+3.5\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \rightarrow 2 \mathrm{CO}_{2}+3 \mathrm{H}_{2} \mathrm{O}+13.16 \mathrm{~N}_{2}$.
(a) The first law, with $Q=W=0$, is written for this constant-volume process using (12.11):

$$
\sum_{\text {react }} N_{i}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}-\bar{R} T\right)_{i}=\sum_{\text {prod }} N_{i}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}-\bar{R} T\right)_{i}
$$

The reactants are at $25^{\circ} \mathrm{C}$ (the initial pressure is unimportant if not extremely large) and the products are at $T_{P}$; therefore,

$$
\begin{aligned}
\text { L.H.S. }= & (1)[-84680-(8.314)(298)]+(3.5)[(-8.314)(298)]+(13.16)[(-8.314)(298)] \\
\text { R.H.S. }= & (2)\left[-393520+\bar{h}_{\mathrm{CO}_{2}}-9360-8.314 T_{P}\right] \\
& +(3)\left[\left(-241820+\bar{h}_{\mathrm{H}_{2} \mathrm{O}}-9900-8.314 T_{P}\right)+(13.16)\left(\bar{h}_{\mathrm{N}_{2}}-8670-8.314 T_{P}\right)\right]
\end{aligned}
$$

or

$$
1579000=2 \bar{h}_{\mathrm{CO}_{2}}+3 \bar{h}_{\mathrm{H}_{2} \mathrm{O}}+13.16 \bar{h}_{\mathrm{N}_{2}}-151 T_{P}
$$

We solve for $T_{P}$ by trial and error:

$$
\begin{aligned}
& T_{P}=2600 \mathrm{~K}: \quad 1579000 \stackrel{?}{=}(2)(137400)+(3)(114300)+(13.16)(86850)-(151)(2600) \\
& =1365000 \\
& T_{P}=2800 \mathrm{~K}: \quad 1579000 \stackrel{?}{=}(2)(149810)+(3)(125200)+(13.16)(94010)-(151)(2800) \\
& =1490000 \\
& T_{P}=3000 \mathrm{~K}: \quad 1579000 \stackrel{?}{=}(2)(162230)+(3)(136260)+(13.16)(101410)-(151)(3000) \\
& =1615000
\end{aligned}
$$

Interpolation provides a temperature between 2800 K and $3000 \mathrm{~K}: \quad T_{P}=2942 \mathrm{~K}$.
(b) We have $N_{\text {fuel }}=0.05 / 30=0.001667 \mathrm{kmol}$; therefore, $N_{\text {prod }}=(18.16)(0.001667)=0.03027 \mathrm{kmol}$. The pressure in the products is then

$$
P_{\text {prod }}=\frac{N_{\text {prod }} \bar{R} T_{\text {prod }}}{V}=\frac{(0.03027)(8.314)(2942)}{0.7}=1058 \mathrm{kPa}
$$

## Supplementary Problems

12.12 The following fuels combine with stoichiometric air: (a) $\mathrm{C}_{2} \mathrm{H}_{4}$, (b) $\mathrm{C}_{3} \mathrm{H}_{6}$, (c) $\mathrm{C}_{4} \mathrm{H}_{10}$, (d) $\mathrm{C}_{5} \mathrm{H}_{12}$, (e) $\mathrm{C}_{8} \mathrm{H}_{18}$, and (d) $\mathrm{CH}_{3} \mathrm{OH}$. Provide the correct values for $x, y, z$ in the reaction equation

$$
\mathrm{C}_{a} \mathrm{H}_{b}+w\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \rightarrow x \mathrm{CO}_{2}+y \mathrm{H}_{2} \mathrm{O}+z \mathrm{~N}_{2}
$$

Ans. (a) 2, 2, 11.28
(b) 3, 3, 16.92
(c) $4,5,24.44$
(d) $5,6,30.08$
(e) $8,9,47$
(f) 1, 2, 5.64
12.13 Methane $\left(\mathrm{CH}_{4}\right)$ is burned with stoichiometric air and the products are cooled to $20^{\circ} \mathrm{C}$ assuming complete combustion at 100 kPa . Calculate ( $a$ ) the air-fuel ratio, ( $b$ ) the percentage of $\mathrm{CO}_{2}$ by weight of the products, ( $c$ ) the dew-point temperature of the products, and ( $d$ ) the percentage of water vapor $\begin{array}{lllll}\text { condensed. Ans. (a) } 17.23 & \text { (b) } 15.14 \% & \text { (c) } 59^{\circ} \mathrm{C} & \text { (d) } 89.8 \%\end{array}$
12.14 Repeat Prob. 12.13 for ethane ( $\mathrm{C}_{2} \mathrm{H}_{6}$ ).
Ans. (a) 16.09
(b) $17.24 \%$
(c) $55.9^{\circ} \mathrm{C}$
(d) $87.9 \%$
12.15 Repeat Prob. 12.13 for propane $\left(\mathrm{C}_{3} \mathrm{H}_{8}\right)$.
Ans. (a) 15.67
(b) $18.07 \%$
(c) $53.1^{\circ} \mathrm{C}$
(d) $87.0 \%$
12.16 Repeat Prob. 12.13 for butane $\left(\mathrm{C}_{4} \mathrm{H}_{10}\right)$.
Ans. (a) 15.45
(b) $18.52 \%$
(c) $53.9^{\circ} \mathrm{C}$
(d) $86.4 \%$
12.17 Repeat Prob. 12.13 for octane ( $\mathrm{C}_{4} \mathrm{H}_{18}$ ).
Ans. (a) 16.80
(b) $15.92 \%$
(c) $57.9^{\circ} \mathrm{C}$
(d) $89.2 \%$
12.18 Ethane $\left(\mathrm{C}_{2} \mathrm{H}_{6}\right)$ undergoes complete combustion at 95 kPa with $180 \%$ theoretical air. Find (a) the air-fuel ratio, ( $b$ ) the percentage of $\mathrm{CO}_{2}$ by volume in the products, and ( $c$ ) and dew-point temperature. Ans. (a) 28.96 (b) $6.35 \% \quad$ (c) $43.8^{\circ} \mathrm{C}$
12.19 Repeat Prob. 12.18 for propane $\left(\mathrm{C}_{3} \mathrm{H}_{8}\right)$.

Ans. (a) 28.21
(b) $6.69 \%$
(c) $42.5^{\circ} \mathrm{C}$
12.20 Repeat Prob. 12.18 for butane $\left(\mathrm{C}_{4} \mathrm{H}_{10}\right)$.

Ans. (a) 27.82
(b) $6.87 \%$
(c) $41.8^{\circ} \mathrm{C}$

Repeat Prob. 12.18 for octane ( $\mathrm{C}_{5} \mathrm{H}_{18}$ ).
Ans. (a) 30.23
(b) $10.48 \%$
(c) $45.7^{\circ} \mathrm{C}$
12.22 Calculate the mass flux of fuel required if the inlet air flow rate is $20 \mathrm{~m}^{3} / \mathrm{min}$ at $20^{\circ} \mathrm{C}$ and 100 kPa using stoichiometric air with (a) methane $\left(\mathrm{CH}_{4}\right)$, (b) ethane ( $\mathrm{C}_{2} \mathrm{H}_{6}$ ), (c) propane ( $\mathrm{C}_{3} \mathrm{H}_{8}$ ), (d) butane $\left(\mathrm{C}_{4} \mathrm{H}_{10}\right)$, and (e) octane ( $\mathrm{C}_{5} \mathrm{H}_{18}$ ).
Ans. (a) $1.38 \mathrm{~kg} / \mathrm{min}$
(b) $1.478 \mathrm{~kg} / \mathrm{min}$
(c) $1.518 \mathrm{~kg} / \mathrm{min}$
(d) $1.539 \mathrm{~kg} / \mathrm{min}$
(e) $1.415 \mathrm{~kg} / \mathrm{min}$
12.23 Propane $\left(\mathrm{C}_{3} \mathrm{H}_{8}\right)$ undergoes complete combustion at 90 kPa and $20^{\circ} \mathrm{C}$ with $130 \%$ theoretical air. Calculate the air-fuel ratio and the dew-point temperature if the relative humidity of the combustion air is (a) $90 \%$, (b) $80 \%$, (c) $60 \%$, and (d) $40 \%$.
Ans. (a) $20.67,50.5^{\circ} \mathrm{C}$
(b) $20.64,50.2^{\circ} \mathrm{C}$
(c) $20.57,49.5^{\circ} \mathrm{C}$
(d) $20.50,48.9^{\circ} \mathrm{C}$
12.24 An air-fuel ratio of 25 is used in an engine that burns octane $\left(\mathrm{C}_{8} \mathrm{H}_{18}\right)$. Find the percentage of excess air required and the percentage of $\mathrm{CO}_{2}$ by volume in the products. Ans. $165.4 \%, 7.78 \%$
12.25 Butane $\left(\mathrm{C}_{4} \mathrm{H}_{10}\right)$ is burned with $50 \%$ excess air. If $5 \%$ of the carbon in the fuel is converted to CO , calculate the air-fuel ratio and the dew-point of the products. Combustion takes place at 100 kPa .
Ans. $23.18,46.2^{\circ} \mathrm{C}$
12.26 A fuel which is $60 \%$ ethane and $40 \%$ octane by volume undergoes complete combustion with $200 \%$ theoretical air. Find ( $a$ ) the air-fuel ratio, $(b)$ the percent by volume of $N_{2}$ in the products, and (c) the dew-point temperature of the products if the pressure is 98 kPa .
$\begin{array}{llll}\text { Ans. (a) } 30.8 & \text { (b) } 76.0 \% & \text { (c) } 40.3^{\circ} \mathrm{C}\end{array}$
12.27 One lbm of butane, 2 lbm of methane, and 2 lbm of octane undergo complete combustion with 20 lbm of air. Calculate ( $a$ ) the air-fuel ratio, ( $b$ ) the percent excess air, and ( $c$ ) the dew-point temperature of the products if the combustion process occurs at 14.7 psia .
Ans. (a) 19.04
(b) $118.7 \%$
(c) $127^{\circ} \mathrm{F}$
12.28 Each minute 1 kg of methane, 2 kg of butane, and 2 kg of octane undergo complete combustion with stoichiometric $20^{\circ} \mathrm{C}$ air. Calculate the flow rate of air required if the process takes place at 100 kPa . Ans. $\quad 65.92 \mathrm{~m}^{3} / \mathrm{min}$
12.29 A volumetric analysis of the products of butane $\left(\mathrm{C}_{4} \mathrm{H}_{10}\right)$ on a dry basis yields $7.6 \% \mathrm{CO}_{2}, 8.2 \% \mathrm{O}_{2}$, $82.8 \% \mathrm{~N}_{2}$, and $1.4 \% \mathrm{CO}$. What percent excess air was used? Ans. $159 \%$
12.30 A volumetric analysis of the products of combustion of octane $\left(\mathrm{C}_{8} \mathrm{H}_{18}\right)$ on a dry basis yields $9.1 \% \mathrm{CO}_{2}$, $7.0 \% \mathrm{O}_{2}, 83.0 \% \mathrm{~N}_{2}$, and $0.9 \% \mathrm{CO}$. Calculate the air-fuel ratio. Ans. 21.46
12.31 Three moles of a mixture of hydrocarbon fuels, denoted by $\mathrm{C}_{x} \mathrm{H}_{y}$, is burned and a volumetric analysis on a dry basis of the products yields $10 \% \mathrm{CO}_{2}, 8 \% \mathrm{O}_{2}, 1.2 \% \mathrm{CO}$, and $80.8 \% \mathrm{~N}_{2}$. Estimate the values for $x$ and $y$ and the percent theoretical air utilized. Ans. 3.73, 3.85, 152.6\%
12.32 Producer gas, created from coal, has a volumetric analysis of $3 \% \mathrm{CH}_{4}, 14 \% \mathrm{H}_{2}, 50.9 \% \mathrm{~N}_{2}, 0.6 \% \mathrm{O}_{2}$, $27 \% \mathrm{CO}$, and $4.5 \% \mathrm{CO}_{2}$. Complete combustion occurs with $150 \%$ theoretical air at 100 kPa . What percentage of the water vapor will condense out if the temperature of the products is $20^{\circ} \mathrm{C}$ ?
Ans. 76.8\%
12.33 Using the enthalpy of formation data from Table B-6 calculate the enthalpy of combustion for a steady-flow process, assuming liquid water in the products. Inlet and outlet temperatures are $25^{\circ} \mathrm{C}$ and the pressure is 100 kPa . (Compare with the value listed in Table B-7.) The fuel is ( $a$ ) methane, (b) acetylene, (c) propane gas, and (d) liquid pentane.
Ans. (a) $-890300 \mathrm{~kJ} / \mathrm{kmol}$
(b) - $1299600 \mathrm{~kJ} / \mathrm{kmol}$
(c) $-2220000 \mathrm{~kJ} / \mathrm{kmol}$ (d) $-3505000 \mathrm{~kJ} / \mathrm{kmol}$
12.34 Propane gas $\left(\mathrm{C}_{3} \mathrm{H}_{8}\right)$ undergoes complete combustion with stoichiometric air; both are at $77^{\circ} \mathrm{F}$ and 1 atm. Calculate the heat transfer if the products from a steady-flow combustor are at (a) $77^{\circ} \mathrm{F},(b)$ $1540^{\circ} \mathrm{F}$, and (c) $2540^{\circ} \mathrm{F}$.
Ans. (a) $-955,100 \mathrm{Btu} / \mathrm{lbmol} \quad(b)-572,500 \mathrm{Btu} / \mathrm{lbmol} \quad(c)-13,090 \mathrm{Btu} / \mathrm{lbmol}$
12.35 Liquid propane $\left(\mathrm{C}_{3} \mathrm{H}_{8}\right)$ undergoes complete combustion with air; both are at $25^{\circ} \mathrm{C}$ and 1 atm . Calculate the heat transfer if the products from a steady-flow combustor are at 1000 K and the percent theoretical air is (a) $100 \%$, (b) $150 \%$, (c) $200 \%$.
Ans. (a) $-1436000 \mathrm{~kJ} / \mathrm{kmol}$
(b) $-1178000 \mathrm{~kJ} / \mathrm{kmol}$
(c) $-919400 \mathrm{~kJ} / \mathrm{kmol}$
12.36 Ethane gas $\left(\mathrm{C}_{2} \mathrm{H}_{6}\right)$ at $25^{\circ} \mathrm{C}$ is burned with $150 \%$ theoretical air at 500 K and 1 atm. Find the heat transfer from a steady-flow combustor if the products are at 1000 K and (a) complete combustion occurs; (b) $95 \%$ of the carbon is converted to $\mathrm{CO}_{2}$ and $5 \%$ to CO .
Ans. (a) $-968400 \mathrm{~kJ} / \mathrm{kmol}$ (b) $-929100 \mathrm{~kJ} / \mathrm{kmol}$
12.37 Complete combustion occurs between butane gas $\left(\mathrm{C}_{4} \mathrm{H}_{10}\right)$ and air; both are at $25^{\circ} \mathrm{C}$ and 1 atm . If the steady-flow combustion chamber is insulated, what percent theoretical air is needed to maintain the products at (a) 1000 K and (b) 1500 K ? Ans. (a) $411 \%$ (b) $220 \%$
12.38 Complete combustion occurs between ethylene gas $\left(\mathrm{C}_{2} \mathrm{H}_{4}\right)$ and air; both are at $77^{\circ} \mathrm{F}$ and 1 atm . If $150,000 \mathrm{Btu}$ of heat is removed per lbmol of fuel from the steady-flow combustor, estimate the percent theoretical air required to maintain the products at $1500^{\circ} \mathrm{R}$. Ans. $820 \%$
12.39 Butane gas $\left(\mathrm{C}_{4} \mathrm{H}_{10}\right)$ at $25^{\circ} \mathrm{C}$ is burned in a steady-flow combustion chamber with $150 \%$ theoretical air at 500 K and 1 atm . If $90 \%$ of the carbon is converted to $\mathrm{CO}_{2}$ and $10 \%$ to CO , estimate the heat transfer if the products are at 1200 K . Ans. $-1298700 \mathrm{~kJ} / \mathrm{kmol}$
12.40 Butane gas $\left(\mathrm{C}_{4} \mathrm{H}_{10}\right)$ undergoes complete combustion with $40 \%$ excess air; both are at $25^{\circ} \mathrm{C}$ and 100 kPa . Calculate the heat transfer from the steady-flow combustor if the products are at 1000 K and the humidity of the combustion air is (a) $90 \%$, (b) $70 \%$, and (c) $50 \%$.
Ans. (a) $-1854800 \mathrm{~kJ} / \mathrm{kmol} \quad$ (b) $-1790000 \mathrm{~kJ} / \mathrm{kmol} \quad$ (c) $-1726100 \mathrm{~kJ} / \mathrm{kmol}$
12.41 A rigid tank contains a mixture of 0.2 kg of ethane gas $\left(\mathrm{C}_{2} \mathrm{H}_{6}\right)$ and 1.2 kg of $\mathrm{O}_{2}$ at $25^{\circ} \mathrm{C}$ and 100 kPa . The mixture is ignited and complete combustion occurs. If the final temperature is 1000 K , find the heat transfer and the final pressure. Ans. $-12780 \mathrm{~kJ}, 437 \mathrm{kPa}$
12.42 A mixture of 1 lbmol methane gas $\left(\mathrm{CH}_{4}\right)$ and stoichiometric air at $77^{\circ} \mathrm{F}$ and 20 psia is contained in a rigid tank. If complete combustion occurs, calculate the heat transfer and the final pressure if the final temperature is $1540^{\circ} \mathrm{F}$. Ans. $-220,600 \mathrm{Btu}, 74.5$ psia
12.43 A mixture of octane gas $\left(\mathrm{C}_{8} \mathrm{H}_{18}\right)$ and $20 \%$ excess air at $25^{\circ} \mathrm{C}$ and 200 kPa is contained in a 50 -liter cylinder. Ignition occurs and the pressure remains constant until the temperature reaches 800 K . Assuming complete combustion, estimate the heat transfer during the expansion process.
Ans. -219 kJ
12.44 A mixture of butane gas $\left(\mathrm{C}_{4} \mathrm{H}_{10}\right)$ and stoichiometric air is contained in a rigid tank at $25^{\circ} \mathrm{C}$ and 100 kPa . If $95 \%$ of the carbon is burned to $\mathrm{CO}_{2}$ and the remainder to CO , calculate the heat transfer from the tank and the volume percent of the water that condenses out if the final temperature is $25^{\circ} \mathrm{C}$.
Ans. $\quad-2600400 \mathrm{~kJ} / \mathrm{kmol}$ fuel, $81.3 \%$
12.45 Butane gas $\left(\mathrm{C}_{4} \mathrm{H}_{10}\right)$ mixes with air, both at $25^{\circ} \mathrm{C}$ and 1 atm, and undergoes complete combustion in a steady-flow insulated combustion chamber. Calculate the adiabatic flame temperature for (a) $100 \%$ theoretical air, (b) $150 \%$ theoretical air, and (c) $100 \%$ excess air.
$\begin{array}{lll}\text { Ans. (a) } 2520 \mathrm{~K} & \text { (b) } 1830 \mathrm{~K} & \text { (c) } 1510 \mathrm{~K}\end{array}$
12.46 Ethane $\left(\mathrm{C}_{2} \mathrm{H}_{6}\right)$ at $25^{\circ} \mathrm{C}$ undergoes complete combustion with air at 400 K and 1 atm in a steady-flow insulated combustor. Determine the exit temperature for $50 \%$ excess air. Ans. 1895 K
12.47 Hydrogen gas and air, both of 400 K and 1 atm , undergo complete combustion in a steady-flow insulated combustor. Estimate the exit temperature for $200 \%$ theoretical air. Ans. 1732 K
12.48 Liquid methyl alcohol $\left(\mathrm{CH}_{3} \mathrm{OH}\right)$ at $25^{\circ} \mathrm{C}$ reacts with $150 \%$ theoretical air. Find the exit temperature, assuming complete combustion, from a steady-flow insulated combustor if the air enters at (a) $25^{\circ} \mathrm{C}$, (b) 400 K , and (c) 600 K . Assume atmospheric pressure.
$\begin{array}{lll}\text { Ans. (a) } 2110 \mathrm{~K} & \text { (b) } 2180 \mathrm{~K} & \text { (c) } 2320 \mathrm{~K}\end{array}$
12.49 Ethene $\left(\mathrm{C}_{2} \mathrm{H}_{4}\right)$ at $77^{\circ} \mathrm{F}$ undergoes complete combustion with stoichiometric air at $77^{\circ} \mathrm{F}$ and $70 \%$ humidity in an insulated steady-flow combustion chamber. Estimate the exit temperature assuming a pressure of 14.5 psia. Ans. $4740^{\circ} \mathrm{R}$
12.50 Ethane $\left(\mathrm{C}_{2} \mathrm{H}_{6}\right)$ at $25^{\circ} \mathrm{C}$ combusts with $90 \%$ theoretical air at 400 K and 1 atm in an insulated steady-flow combustor. Determine the exit temperature. Ans. 2410 K
12.51 A mixture of liquid propane $\left(\mathrm{C}_{3} \mathrm{H}_{8}\right)$ and stoichiometric air at $25^{\circ} \mathrm{C}$ and 100 kPa undergoes complete combustion in a rigid container. Determine the maximum temperature and pressure (the explosion pressure) immediately after combustion. Ans. $3080 \mathrm{~K}, 1075 \mathrm{kPa}$

## SAMPLE Screens From The Companion Interactive Outline

As described on the back cover, this book has a companion Interactive Schaum's Outline using Mathcad $_{(B)}$ which is designed to help you learn the subject matter more quickly and effectively. The Interactive Outline uses the LIVE-MATH environment of Mathcad technical calculation software to give you on-screen access to approximately 100 representative solved problems from this book, along with summaries of key theoretical points and electronic cross-referencing and hyperlinking. The following pages reproduce a representative sample of screens from the Interactive Outline and will help you understand the powerful capabilities of this electronic learning tool. Compare these screens with the associated solved problems from this book (the corresponding page numbers are listed at the start of each problem) to see how one complements the other.

In the Interactive Schaum's Outline, you'll find all related text, diagrams, and equations for a particular solved problem together on your computer screen. As you can see on the following pages, all the math appears in familiar notation, including units. The format differences you may notice between the printed Schaum's Outline and the Interactive Outline are designed to encourage your interaction with the material or show you alternate ways to solve challenging problems.

As you view the following pages, keep in mind that every number, formula, and graph shown is completely interactive when viewed on the computer screen. You can change the starting parameters of a problem and watch as new output graphs are calculated before your eyes; you can change any equation and immediately see the effect of the numerical calculations on the solution. Every equation, graph, and number you see is available for experimentation. Each adapted solved problem becomes a worksheet you can modify to solve dozens of related problems. The companion Interactive Outline thus will help you to learn and retain the material taught in this book more effectively and can also serve as a working problem-solving tool.

The Mathcad icon shown on the right is printed throughout this Schaum's Outline, indicating which problems are included in the Interactive Outline.

For more information about system requirements and the availability of titles in Schaum's Interactive Outline Series, please see the back cover.

## Summation of Extensive Properties

(Schaum's Thermodynamics for Engineers Solved Problem 1.7, p. 13)

## Statement

System
Parameters
Radius of sphere: $\quad \mathrm{r}_{\mathrm{s}}=150 \mathrm{~mm}$
Mass of sphere: $\quad \mathrm{m}_{\mathrm{s}}=10 \cdot \mathrm{~kg}$

Acceleration of sphere:

$$
\mathrm{a}_{\mathrm{s}}=10 \cdot \frac{\mathrm{~m}}{\sec ^{2}}
$$

Density of water:

$$
\rho_{\text {water }}:=1000 \cdot \frac{\mathrm{~kg}}{\mathrm{~m}^{3}}
$$

Volume of sphere:

$$
\mathrm{V}_{\mathrm{s}}=\frac{4}{3} \cdot \pi \cdot \mathrm{r}^{3}
$$

Solution
When a body is accelerated under water, some of the water is also accelerated, making the body appear to have a larger mass than it actually has. For a sphere at rest, this added mass is equal to the mass of one-half of the displaced water.

First, compute the mass added by the water:

$$
\mathrm{m}_{\text {added }}=-\frac{\mathrm{v}_{\mathrm{s}} \cdot \rho_{\text {water }}}{2} \quad \mathrm{~m}_{\text {added }}=7.069 \cdot \mathrm{~kg}
$$

Because extensive properties can be summed, the two masses can simply be added. This makes the apparent mass of the sphere

$$
\mathrm{m}_{\mathrm{app}}=\mathrm{m}_{\text {added }}+\mathrm{m}_{\mathrm{s}} \quad \mathrm{~m}_{\mathrm{app}}=17.069 \cdot \mathrm{~kg}
$$

Using Newton's second law of motion, the force necessary to accelerate the sphere is then

$$
\mathrm{F}=\mathrm{m}_{\mathrm{app}} \cdot \mathrm{a}_{\mathrm{s}} \quad \mathrm{~F}=170.686 \cdot \text { newton }
$$

## Computation of Quality of Steam

(Schaum's Thermodynamics for Engineers Solved Problem 2.1, p. 27)

## Statement

For a specific volume $\mathbf{v}$ and absolute pressure $\mathbf{P}_{\mathbf{a}}$, find the quality $\mathbf{x}$ of steam.

System Parameters

Specific volume: $\quad v=0.2 \cdot \frac{\mathrm{~m}^{3}}{\mathrm{~kg}}$
Absolute pressure: $\quad \mathrm{P}_{\mathrm{a}}=40 \cdot \mathrm{kPa}$
Units: $\quad \mathrm{kPa} \equiv 10^{3} \cdot \mathrm{~Pa} \quad \mathrm{MPa} \equiv 10^{6} \cdot \mathrm{~Pa}$

Solution
The quality is derived from

$$
v=v_{f}+x \cdot\left(v_{g}-v_{f}\right)
$$

making it necessary to determine $\mathbf{v}_{\mathbf{f}}$ and $\mathbf{v}_{\mathbf{g}}$. To do this, an interpolation is performed on the data in Table B-2. For your convenience, each step of the interpolation is explained here.

First, read in the vector containing the data for the known quantity (in this case, the pressure):

$$
\mathrm{P}_{\text {sat }}=\operatorname{READPRN}\left(\mathrm{tb} 2 \_\mathrm{pm}\right) \cdot \mathrm{MPa}
$$

Next read in the vector(s) with the data corresponding to the properties for which you wish to solve:

$$
v_{\mathrm{f}}=\operatorname{READPRN}\left(\mathrm{tb} 2 \_\mathrm{vf}\right) \cdot \frac{\mathrm{m}^{3}}{\mathrm{~kg}} \quad \quad \mathrm{v}_{\mathrm{g}}=\operatorname{READPRN}\left(\mathrm{tb} 2 \_\mathrm{vg}\right) \cdot \frac{\mathrm{m}^{3}}{\mathrm{~kg}}
$$

Perform a spline on the x and y data. This computes the second derivative at each point:

$$
\mathrm{vfs}=\operatorname{cspline}\left(\mathrm{P}_{\mathrm{sat}}, \mathrm{v}_{\mathrm{f}}\right) \quad \mathrm{vgs}=\operatorname{cspline}\left(\mathrm{P}_{\mathrm{sat}}, v_{\mathrm{g}}\right)
$$

Define the built-in interpolation routine as a function of the known variable:

$$
v f(P):=\operatorname{interp}\left(v f s, P_{s a t}, v_{f}, P\right) \quad v g(P):=\operatorname{interp}\left(v g s, P_{s a t},{ }^{v} g, P\right)
$$

Solve for the unknowns:

$$
{ }^{v_{\mathrm{f}}}=\mathrm{vf}\left(\mathrm{P}_{\mathrm{a}}\right) \quad v_{\mathrm{g}}=\mathrm{vg}\left(\mathrm{P}_{\mathrm{a}}\right)
$$

With this done, rearranging the definition of $v$ gives the quality as

$$
x:=\frac{v-v_{f}}{v_{g}-v_{f}} \quad x=0.04984
$$

To see how the quality varies with pressure, a plot can be created as follows:

$$
\begin{aligned}
& P_{\text {range }}=1 \cdot \mathrm{kPa}, 100 \cdot \mathrm{kPa} . .10 \cdot \mathrm{MPa} \\
& x(\mathrm{vf}, \mathrm{vg}, \mathrm{P}):=\frac{\mathrm{v}-\mathrm{vf}(\mathrm{P})}{\mathrm{vg}(\mathrm{P})-\mathrm{vf}(\mathrm{P})}
\end{aligned}
$$

Notice the interesting result that the quality goes above 1. Obviously, this isn't possible, so what does it mean? The point at which $\mathbf{x}$ becomes greater than 1 corresponds to the limiting factor of your value for $v$; that is, once $\mathbf{v}_{\mathbf{g}}=\mathbf{v}$, you have $100 \%$ steam.

Editor's Note: The two data files used in this example, tb2_vf and tb2_vg, are supplied with the Electronic Book companion. The data is taken from the steam tables in the appendixes of this Schaum's Outline. Differences in interpolation and numerical accuracy will affect how closely this answer matches that in the original solved problem on page 27.

## The First Law Applied to an Adiabatic Process

(Schaum's Thermodynamics for Engineers Solved Problem 4.15, p. 79)

## Statement

The air in the cylinder of an air compressor is compressed from $\mathbf{P}_{\mathbf{1}}$ to $\mathbf{P}_{\mathbf{2}}$. Estimate the final temperature and the work required if the air is initially at temperature $\mathbf{T}$.

## System Parameters

Initial pressure:
$P_{1}=100 \cdot 10^{3} \cdot \mathrm{~Pa}$

Final pressure:
$P_{2}:=10 \cdot 10^{6} \cdot \mathrm{~Pa}$

Initial temperature:
$\mathrm{T}_{1}=373 \cdot \mathrm{~K}$

Units:
$\mathrm{kJ} \equiv 10^{3} \cdot$ joule

Constants
Constant-volume specific heat: $\quad c_{\mathrm{v}}=0.717 \cdot \frac{\mathrm{~kJ}}{\mathrm{~kg} \cdot \mathrm{~K}}$

Specific heat ratio:
$k=1.4$

Solution
Since the process occurs quite fast, an adiabatic ( $\mathbf{q}=\mathbf{0}$ ) quasiequilibrium process (Chapter 1) is assumed. The first law for a quasiequilibrium process takes the form

$$
d u+P \cdot d v=0
$$

After a little investigation and substitution, this takes the form

$$
c_{v} \cdot d T+\frac{R \cdot T}{v} \cdot d v=0
$$

for the adiabatic process of an ideal gas with constant specific heats.
Rearranging gives

$$
\frac{c^{v} v}{R} \cdot \frac{d T}{T}=\frac{d v}{v}
$$

Assuming constant $\mathbf{c}_{\mathbf{v}}$, integrate $\mathbf{d v} / \mathbf{v}$ between states 1 and 2 to yield

$$
\frac{c_{v}}{\mathrm{R}} \cdot \ln \left(\frac{\mathrm{~T}_{2}}{\mathrm{~T}_{1}}\right)=\ln \left(\frac{\mathrm{v}_{2}}{\mathrm{v}_{1}}\right)
$$

Recalling that $\mathbf{c}_{\mathbf{v}}=\mathbf{R} /(\mathbf{k}-1)$, this can be put in the form

$$
\frac{T_{2}}{T_{1}}=\left(\frac{v_{2}}{v_{1}}\right)^{\frac{R}{c_{v}}}=\left(\frac{v_{1}}{v_{2}}\right)^{k-1}
$$

Using the ideal-gas equation (Chapter 2), this can be written as

$$
\frac{T_{2}}{T_{1}}=\left(\frac{P_{2}}{P_{1}}\right)^{\frac{k-1}{k}} \quad \text { or } \quad \frac{P_{2}}{P_{1}}=\left(\frac{v_{1}}{v_{2}}\right)^{k}
$$

which gives the final temperature as

$$
T_{2}=T_{1} \cdot\left(\frac{P_{2}}{P_{1}}\right)^{\frac{k-1}{k}} \quad T_{2}=1390 \cdot K
$$

The work is found from the first law, $\mathbf{q}-\mathbf{w}=\mathbf{e}$. The total energy of this system, $\mathbf{e}$, is composed of the internal energy $\mathbf{u}$ (kinetic and potential energies equal zero). Because energy is a property, it is only necessary to determine $\mathbf{u}_{\mathbf{2}}-\mathbf{u}_{\mathbf{1}}$ (Chapter 3).

$$
\mathrm{u}_{2}-\mathrm{u}_{1}=\int_{\mathrm{T}_{1}}^{\mathrm{T}_{2}} \mathrm{c}_{\mathrm{v}} \mathrm{dT} \quad \Delta \mathrm{u}:=\mathrm{c}_{\mathrm{v}} \cdot\left(\mathrm{~T}_{2}-\mathrm{T}_{1}\right)
$$

With $\mathrm{q}=0$, the work is equal to

$$
w:=-\Delta u \quad w=-729.47 \cdot \frac{\mathrm{~kJ}}{\mathrm{~kg}}
$$

Editor's Note: The boldface, underlined text in the paragraph above indicates a hyperlinked piece of text. If you were working on a computer, double-clicking on the bold text with the mouse would take you to the file indicated by the text.

## The Efficiency of a Steam Turbine

(Schaum's Thermodynamics for Engineers Solved Problem 6.19, p. 130)

## Statement

## System

 ParametersA steam turbine produces power $\mathbf{W}^{\prime}$ from a mass flux $\mathbf{m}^{\prime}$. The steam enters at temperature $\mathbf{T}_{1}$ and pressure $\mathbf{P}_{\mathbf{1}}$ and exits at pressure $\mathbf{P}_{\mathbf{2}}$. Calculate the efficiency of the turbine.

Steam inlet temperature:

Steam inlet pressure:

Steam outlet pressure:

Turbine power output:

Steam mass flux:

Units:
$\mathrm{MPa} \equiv 10^{6} \cdot \mathrm{~Pa}$
$k J \equiv 10^{3} \cdot$ joule
$\mathrm{R}=\frac{\mathrm{K}}{1.8}$

Solution

The efficiency is determined by the ratio of the actual work (Chapter 3) output $\mathbf{w}_{\mathbf{a}}$ to the ideal work output $\mathbf{w}_{\mathbf{s}}$. The ideal work output corresponds to an isentropic (constant-entropy) process and is defined as

$$
w_{s}=-\left(h_{2}-h_{1}\right)
$$

where $h$ is the enthalpy (Chapter 4a) of the system. To find $\mathbf{h}_{\mathbf{1}}$ and $\mathbf{h}_{\mathbf{2}}$, the following steps are required.

Knowing $P_{1}$ and $\mathbf{T}_{\mathbf{1}}, h_{1}$ can be found from interpolation of the data in Table B-3:

$$
\mathrm{h}_{\mathrm{l}}=\mathrm{hi}\left(\mathrm{Ti}_{1}, \mathrm{Pi}_{1}\right) \quad \mathrm{h}_{1}=1.512 \cdot 10^{3} \cdot \frac{\mathrm{BTU}}{\mathrm{lb}}
$$

With $h_{1}$ determined, you can now compute $h_{2}$ from

$$
\mathrm{h}_{2}=\mathrm{h}_{\mathrm{f} 2}-\mathrm{x}_{2} \cdot\left(\mathrm{~h}_{\mathrm{g} 2}-\mathrm{h}_{\mathrm{f} 2}\right)
$$

To determine $x_{2}$ (the quality (Chapter 2) of the steam), it is necessary to know $\mathbf{s}_{\mathbf{2}}$. Again, from Table B-3, you get

$$
\mathrm{s}_{1}=\operatorname{si}\left(\mathrm{Ti}_{1}, \mathrm{Pi}_{1}\right) \quad \mathrm{s}_{1}=1.682 \cdot \frac{\mathrm{BTU}}{\mathrm{lb} \cdot \mathrm{R}}
$$

Since the process is isentropic ( $\Delta \mathrm{s}=0$ ),

$$
s_{2}=s_{1}
$$

The quality of the outlet steam, $\mathbf{x}_{2}$, can then calculated from

$$
\mathrm{s}_{2}=\mathrm{s}_{\mathrm{f} 2}+\mathrm{x}_{2} \cdot\left(\mathrm{~s}_{\mathrm{g} 2}-\mathrm{s}_{\mathrm{f} 2}\right)
$$

Interpolation of the data in Table $\mathbf{B - 2}$ provides $\mathbf{S}_{\mathbf{f} 2}$ and $\mathbf{s}_{\mathbf{g} 2}$ :

$$
\begin{aligned}
& P_{\text {sat }}=\operatorname{READPRN}(\mathrm{tb2} 2 \mathrm{pm}) \cdot \mathrm{MPa} \\
& s_{f}=\operatorname{READPRN}\left(t b 2_{-} s f\right) \cdot \frac{B T U}{l b \cdot R} \quad s_{g}=: \operatorname{READPRN}\left(t b 2_{-} s g\right) \frac{B T U}{l b \cdot R} \\
& \mathrm{sfs}=\operatorname{cspline}\left(\mathrm{P}_{\text {sat }}, \mathrm{s}_{\mathrm{f}}\right) \\
& \operatorname{sf}(P)=\operatorname{interp}\left(\operatorname{sfs}, P_{s a t},{ }^{s} f, P\right) \quad s g(P)=\operatorname{interp}\left(\operatorname{sgs}, P_{s a t}, s_{g}, P\right) \\
& s_{\mathrm{f} 2}=\mathrm{sf}\left(\mathrm{P}_{2}\right) \quad \mathrm{s}_{\mathrm{g} 2}=\mathrm{sg}\left(\mathrm{P}_{2}\right)
\end{aligned}
$$

For a description of how the interpolation of one variable works, see the previous example, Computation of Quality of Steam.

This gives the quality of the outlet steam as

$$
x_{2}=\frac{s_{2}-s_{f 2}}{s_{\mathrm{g} 2}-s_{\mathrm{f} 2}} \quad \mathrm{x}_{2}=0.13
$$

The outlet specific enthalpy depends on variables found in Table B-2:

$$
\begin{array}{ll}
\mathrm{h}_{\mathrm{f}}: \square \mathrm{READPRN}\left(\mathrm{tb} 2_{-} \mathrm{hf}\right) \cdot \frac{\mathrm{BTU}}{\mathrm{lb}} & \mathrm{~h}_{\mathrm{g}}:=\operatorname{READPRN}\left(\mathrm{tb} 2_{-} \mathrm{hg}\right) \cdot \frac{\mathrm{BTU}}{\mathrm{lb}} \\
\mathrm{hfs}:=\operatorname{cspline}\left(\mathrm{P}_{\text {sat }}, \mathrm{h}_{\mathrm{f}}\right) & \mathrm{hgs} \text { acspline }\left(\mathrm{P}_{\text {sat }}, \mathrm{h}_{\mathrm{g}}\right) \\
\mathrm{hf}(\mathrm{P}):=\operatorname{interp}\left(\mathrm{hfs}, \mathrm{P}_{\text {sat }}, \mathrm{h}_{\mathrm{f}}, \mathrm{P}\right) & \mathrm{hg}(\mathrm{P})=\operatorname{interp}\left(\mathrm{hgs}, \mathrm{P}_{\text {sat }}, \mathrm{h}_{\mathrm{g}}, \mathrm{P}\right) \\
\mathrm{h}_{\mathrm{f} 2}:=\mathrm{hf}\left(\mathrm{P}_{2}\right) & \mathrm{h}_{\mathrm{g} 2}=\mathrm{hg}\left(\mathrm{P}_{2}\right)
\end{array}
$$

which allows us to finally compute the outlet specific enthalpy from

$$
\mathrm{h}_{2}:=\mathrm{h}_{\mathrm{f} 2}+\mathrm{x}_{2} \cdot\left(\mathrm{~h}_{\mathrm{g} 2}-\mathrm{h}_{\mathrm{f} 2}\right) \quad \mathrm{h}_{2}=527.715 \cdot \frac{\mathrm{BTU}}{\mathrm{lb}}
$$

The work output $\mathbf{w}_{\mathbf{s}}$ associated with the isentropic process can now be calculated as

$$
w_{\mathbf{s}}:=-\left(\mathrm{h}_{2}-\mathrm{h}_{1}\right) \quad \mathrm{w}_{\mathbf{s}}=984.005 \cdot \frac{\mathrm{BTU}}{\mathrm{lb}}
$$

The actual work output $\mathbf{w}_{\mathbf{a}}$ is evaluated from the power and the mass flux to be

$$
\mathrm{w}_{\mathrm{a}}=\frac{\mathrm{w}^{\prime}}{\mathrm{m}^{\prime}} \quad \mathrm{w}_{\mathrm{a}}=381.665 \cdot \frac{\mathrm{BTU}}{\mathrm{lb}}
$$

giving the efficiency as

$$
\eta:=\frac{w_{a}}{w_{s}} \quad \eta=71.351 \% \%
$$

Editor's Note: The four data files used in this example, tb2_sf, tb2_sg, tb2_hf and tb2_hg, are supplied with the Electronic Book companion. The data are taken from the steam tables in the appendixes of this Schaum's Outline. Differences in interpolation and numerical accuracy will affect how closely this answer matches that in the original solved problem on page 130 .

## Otto Cycle

(Schaum's Thermodynamics for Engineers Solved Problem 9.8, p. 215)

Statement
A six-cylinder engine with a compression ratio $\mathbf{r}$ and a total volume $\mathbf{V}_{\mathbf{2}}$ at top dead center (TDC), which is the minimum volume, intakes atmospheric air at temperature $\mathbf{T}_{1}$. Assuming an Otto cycle, calculate the heat supplied per cycle, the thermal efficiency, and the power output for $\mathbf{C}$ cycles per minute.

## System <br> Parameters

Inlet air pressure: $\quad P_{1}:=100 \cdot \mathrm{kPa}$

Inlet air temperature:

Maximum temperature:

Compression ratio:

Volume at TDC:

Cycles per second:
$\mathrm{V}_{2}:=600 \cdot \mathrm{~mL}$

Units: $\quad \mathrm{kPa} \equiv 10^{3} \cdot \mathrm{~Pa}$

Constants
Specific-heat ratio for air:
$\mathrm{k}=1.4$

Constant-volume specific heat for air:

To determine the heat supplied per cycle, it is necessary to know the temperature at state 2. It is given by

$$
\begin{aligned}
& \mathrm{T}_{2}=\mathrm{T}_{1} \cdot\left(\frac{\mathrm{v}_{1}}{\mathrm{~V}_{2}}\right)^{\mathrm{k}-1} \\
& \mathrm{~T}_{2}=\mathrm{T}_{1} \cdot \mathrm{r}^{\mathrm{k}-1}
\end{aligned}
$$

The heat per unit mass $\left(\mathbf{Q}_{\mathbf{i n}} / \mathrm{m}_{\mathbf{a}}\right)$ (simulating combustion) is supplied between state 2 and state 3 and is given by

$$
\mathrm{q}_{\text {in }}=\mathrm{c}_{\mathrm{v}} \cdot\left(\mathrm{~T}_{3}-\mathrm{T}_{2}\right) \quad \mathrm{q}_{\text {in }}=788.602 \cdot \frac{\mathrm{~kJ}}{\mathrm{~kg}}
$$

The mass of air in the six cylinders is found from the ideal-gas equation of state (Chapter 2).

$$
\begin{aligned}
& \mathrm{m}_{\mathrm{a}}=\frac{\mathrm{P}_{1} \cdot \mathrm{~V}_{1}}{\mathrm{R} \cdot \mathrm{~T}_{1}} \\
& \mathrm{~m}_{\mathrm{a}}=\frac{P_{1} \cdot\left(\mathrm{~V}_{2} \cdot r\right)}{\mathrm{c}_{\mathrm{v}} \cdot(\mathrm{k}-1) \cdot \mathrm{T}_{1}} \quad \quad \mathrm{~m}_{\mathrm{a}}=0.006 \cdot \mathrm{~kg}
\end{aligned}
$$

The heat supplied per cycle is then

$$
Q_{\text {in }}=m_{a} \cdot q_{\text {in }} \quad Q_{\text {in }}=4.505 \cdot \mathrm{~kJ}
$$

and the thermal efficiency is given by

$$
\eta=1-r^{1-k} \quad \eta=56.472 \cdot \%
$$

The power output is hence

$$
w_{\text {out }}=\eta \cdot Q_{\text {in }} \quad w_{\text {out }}=2.544 \cdot \mathrm{~kJ}
$$

For an idealized cycle, 1 cycle occurs each revolution. This gives

$$
\mathrm{W}_{\text {out }}=\mathrm{W}_{\text {out }} \mathrm{C}^{2} \quad \mathrm{~W}_{\text {out }}=169.589 \cdot \mathrm{~kW}
$$

Plots of $\eta$ vs $\mathbf{r}$ and $\mathbf{Q}_{\mathrm{in}}$ vs $\mathbf{r}$ are provided to demonstrate how the efficiency is affected by the compression ratio. Calculate a vector of values for each of these quantities, with index $i$.

$$
\begin{aligned}
& i=1 . .60 \\
& \eta_{i}=1-\left(r_{i}\right)^{1-k} \\
& T_{2}=T_{1} \cdot\left(r_{i}\right)^{k-1} \\
& m_{a_{i}}:=\frac{P_{1} \cdot\left(V_{2} \cdot r_{i}\right)}{c_{v} \cdot(k-1) \cdot T_{1}} \\
& Q_{i n_{i}}=m a_{i} \cdot q_{i n_{i}}
\end{aligned}
$$

You can see that with a large compression ratio, the efficiency is high. However, design dictates that the efficiency remain in the $20 \%-30 \%$ range because of such practical issues as size of engine, cost, etc. This can be seen in the plot of $Q_{i n}$, where a theoretical cut-off is shown around $r_{i}=40$.

## Differential Change in Specific Volume

(Schaum's Thermodynamics for Engineers Solved Example 10.1, p. 231)

## Statement

Estimate the change in the specific volume of air, assuming an ideal gas, using the differential form for $\mathbf{d v}$, if the temperature and pressure change from $\mathbf{T}_{\mathbf{i}}$ and $\mathbf{P}_{\mathbf{i}}$ to $\mathbf{T}_{\mathbf{f}}$ and $\mathbf{P}_{\mathbf{f}}$. Compare with the change calculated directly from the ideal-gas law.
System
Parameter Parameters

Initial temperature: $\quad \mathrm{T}_{\mathrm{i}}=298 \cdot \mathrm{~K}$

Final temperature
$T_{f}=302 \cdot \mathrm{~K}$

Initial pressure:

Final pressure:

Units
$\mathrm{MPa} \equiv 10^{6} \cdot \mathrm{~Pa}$
$\mathrm{kJ} \equiv 10^{3}$.joule

Constants
Gas constant for air:

$$
\mathrm{R}:=0.287 \cdot \frac{\mathrm{~kJ}}{\mathrm{~kg} \cdot \mathrm{~K}}
$$

Solution Using the Ideal gas law (Chapter 2), that is,

$$
\mathrm{v}=\frac{\mathrm{R} \cdot \mathrm{~T}}{\mathrm{P}}
$$

the change in the specific volume of air is

$$
d v=\left(\frac{\delta v}{\delta T}\right) \cdot d T+\left(\frac{\delta v}{\delta P}\right) \cdot d P=\frac{R}{P} \cdot d T-\frac{R \cdot T}{P^{2}} \cdot d P
$$

Here, $\mathbf{P}$ and $\mathbf{T}$ are to be the average values of the pressures and temperature, that is,

$$
\begin{array}{ll}
\mathrm{P}=0.5 \cdot\left(\mathrm{P}_{\mathrm{i}}+\mathrm{P}_{\mathrm{f}}\right) & \mathrm{P}=0.121 \cdot \mathrm{MPa} \\
\mathrm{~T}=0.5 \cdot\left(\mathrm{~T}_{\mathrm{i}}+\mathrm{T}_{\mathrm{f}}\right) & \mathrm{T}=300 \cdot \mathrm{~K}
\end{array}
$$

Thus,

$$
\begin{aligned}
& d v=\frac{R}{P} \cdot\left(T_{f}-\mathbf{T}_{i}\right)-\frac{R \cdot T}{P^{2}} \cdot\left(\mathbf{P}_{f^{-}} \mathbf{P}_{i}\right) \\
& d v=0.021 \cdot \frac{\mathrm{~m}^{3}}{\mathrm{~kg}}
\end{aligned}
$$

The ideal-gas law provides directly

$$
\Delta v:=R \cdot\left(\frac{T_{f}}{P_{f}}-\frac{T_{i}}{P_{i}}\right) \quad \Delta v=0.021 \cdot \frac{\mathrm{~m}^{3}}{\mathrm{~kg}}
$$

Obviously, the change in state is sufficiently small that the differential change $\mathbf{d v}$ approximates the actual change $\Delta \mathbf{v}$.

To see over what ranges $d \mathbf{v}$ will approximate $\Delta \mathbf{v}$, you can define the appropriate values and plot them as follows.

$$
\begin{aligned}
& \mathrm{i}:=0 . .99 \quad \mathrm{kPa日} 10^{3} \cdot \mathrm{~Pa} \\
& \mathrm{~T}_{\mathrm{i}_{\mathrm{i}}}:=(\mathrm{i} \cdot 10) \cdot \mathrm{K} \quad \mathrm{P}_{\mathrm{i}_{\mathrm{i}}}:=(\mathrm{i}+1) \cdot 50 \cdot \mathrm{kPa} \\
& T_{f_{i}} \text { ㅁ(i•30).K } \\
& \mathrm{P}_{\mathrm{f}_{\mathrm{i}}}:=(\mathrm{i}+1) \cdot 100 \cdot \mathrm{kPa} \\
& T_{i}=\frac{T_{f_{i}}+T_{i_{i}}}{2} \\
& P_{i}=\frac{P_{f_{i}}+P_{i_{i}}}{2} \\
& \Delta T_{i}:=T_{f_{i}}-T_{i_{i}} \\
& \Delta \mathrm{P}_{\mathrm{i}}:=\mathrm{P}_{\mathrm{f}_{\mathrm{i}}}-\mathrm{P}_{\mathrm{i}_{\mathrm{i}}} \\
& d v_{i}:=\frac{R}{P_{i}} \cdot\left(\Delta T_{i}\right)-\frac{R \cdot T_{i}}{\left(P_{i}\right)^{2}} \cdot\left(\Delta P_{i}\right) \quad \Delta v_{i}:=R \cdot\left(\frac{T_{f_{i}}}{P_{f_{i}}}-\frac{T_{i_{i}}}{P_{i_{i}}}\right)
\end{aligned}
$$

So, as you can see, with a wide range of $\Delta P$ and $\Delta T, \Delta v$ and $d v$ will generally remain close in value.

# A Companion Schaum＇s Interactive Outline in Thermodynamics For Engineers using Mathcad ${ }^{\text { }}$ ， the leading technical calculation software． 

## For a description of this powerful electronic tool for learning course content and solving numerical problems，please see the following boxed excerpt from the Interactive Outline package．

#### Abstract

Schaum＇s Interactive Outlines ．．．useful and practical Electronic Books providing students，educators，and profes－ sionals with the course content of the world renowned Schaum＇s Outiine Series together with the interactivity and ease of use of Mathcad，the leading technical calculation soft－ ware． MathSoft and McGraw－Hill have joined forces to offer you electronic access to the Schaum＇s Outtine of Thermodynamics for Engineers．Designed for students and educators，but also of interest to professional scientists and engineers，this resource uses the Mathcad Engine to present and solve approximately 100 problems from the Schaum＇s Outline，In addition to providing a wealth of solved problems，the Interactive Outline gives helpful summaries of key theoretical points，hyperlinked cross－references，and an electronic search feature，making it easy to find related topics． The big advantage of the Interactive Outline is its use of LIVE MATH．Every number，formula，and graph is interactive．You can change the starting parameters of a problem and watch as graphs are calculated before your eyes；you can change any equation and immediately see the effect on the solution．You can experiment with every equation，graph，and number．Each solved problem becomes a worksheet you can modify to solve dozens of related problerns． The student will find this an excellent resource for exploring and understanding the laws of thermodynamics as applied to engineering，and for gaining insight into the relationships between basic thermodynamic properties．The engineering educator will find a comprehensive selection of laboratory and homework exercises in Mathcad，with room for creativity and expansion．The engineering professional will find this Electronic Book to be an invaluable quick reference guide for theory and applications． Topics covered include work and heat，the first and second laws of thermodynamics，power and refrigeration vapor cycies，mixtures and solutions，and thermodynamic relations and combustion，as well as a thorough treatment of entropy and enthalpy and their relation to the laws of thermodynam－ ics． Everything you need is on the diskettes contained in this pack－ age ．．．including the Mathcad Enginet Sample Topics from the Table of Contents －Properties of Ideal and Real Gases －The First and Second Laws of Thermodynamics －Entropy and Enthalpy －Reversible Work，Irreversibility，and Availability

－Power and Refrigeration Vapor Cycles：
－Rankine Cycle
－Supercritical Rankine Cycle
－Reheat Cycle
－Vapor Refrigeration Cycle
－Regenerative Cycle－Absorption Refrigeration Cycle
－Power and Refrigeration Gas Cycles：
－Alr－Standard Cycle－Duat Cycle
－Carnot Cycle
－Brayton Cycle
－Regenerative
－Diesel Cycle
Gas－Turbine Cycle－Gas Refrigeration Cycle
－Otto Cycle
－Combustion
Also included are numerous interpolated tables listing ther－ modynamic constants and other properties of a variety of materials，including：
－Thermodynamic Properties of Water
－Thermodynamic Properties of Freon－12
－Thermodynamic Properties of Ammonia
－Ideal－Gas Tables

## System Requirements

－80386／80486 PC or compatibles，with Microsoft Windows 3.1 or higher，and $3^{1 / 2^{\prime \prime}}$ disk drive．

## Ace your thermodynamics course with this powerful study guide! It can help pump up your problem-solving skills, improve your comprehension, and reduce the time you need to spend studying!

Students love Schaum's Outlines! Each and every year, students purchase hundreds of thousands of the best study guides available anywhere. Students know that Schaum's delivers the goods-in faster learning curves, better test scores, and higher grades!

If you don't have a lot of time but want to excel in class, this book helps you:

- Brush up before tests
- Find answers fast
- Study quickly and more effectively
- Get the big picture without spending hours poring over lengthy textbooks

Schaum's Outlines give you the information teachers expect you to know in a handy and succinct format-without overwheiming you with unnecessary details. You get a complete overview of the subject-and no distracting minutiae. Plus, you get plenty of practice exercises to test your skill. Compatible with any classroom text, Schaum's lets you study at your own pace and reminds you of all the important facts you need to rememberfast! And Schaum's is so complete if's the perfect tool for preparing for graduate or professional exams!

If you want top grades and excellent understanding of thermodynamics, this powerful study tool is the best tutor you can havel inside, you will find:

- 222 detailed problems, including step-by-step solutions
- Hundreds of additional practice problems, with answers supplied
- Clear explanations of both theory and practical applications of thermodynamics
- Easy-to-grasp coverage of all relevant topics, with accompanying sample problems and solutions

Chapters include: Concepts, Definitions, and Basic Principles - Properties of Pure Substances - Work and Heat - The First Law of Thermodynamics * The Second Law of Thermodynamics - Entropy - Reversible Work, Irreversibility, and Availability - Power and Refrigeration Vapor Cycles Power and Refrigeration Gas Cycles - Thermodynamic Relations - Mixtures and Solutions * Combustion - Appendixes: Conversion of Units • Material Properties - Thermodynamic Properties of Water (Steam Tables) Thermodynamic Properties of Freon 12 - Thermodynamic Properties of Ammonia • Ideal-Gas Tables - Psychrometric Charts • Compressibility Chart - Enthalpy Departure Charts • Entropy Departure Charts * Sample Screens from the Companion Schaum's Electronic Tutor

A companion Schaum's Electronic Tutor is also available!
