## Chapter 15

## CHEMICAL REACTIONS

## Fuels and Combustion

15-1C Gasoline is $\mathrm{C}_{8} \mathrm{H}_{18}$, diesel fuel is $\mathrm{C}_{12} \mathrm{H}_{26}$, and natural gas is $\mathrm{CH}_{4}$.

15-2C Nitrogen, in general, does not react with other chemical species during a combustion process but its presence affects the outcome of the process because nitrogen absorbs a large proportion of the heat released during the chemical process.

15-3C Moisture, in general, does not react chemically with any of the species present in the combustion chamber, but it absorbs some of the energy released during combustion, and it raises the dew point temperature of the combustion gases.

15-4C The dew-point temperature of the product gases is the temperature at which the water vapor in the product gases starts to condense as the gases are cooled at constant pressure. It is the saturation temperature corresponding to the vapor pressure of the product gases.

15-5C The number of atoms are preserved during a chemical reaction, but the total mole numbers are not.

15-6C Air-fuel ratio is the ratio of the mass of air to the mass of fuel during a combustion process. Fuelair ratio is the inverse of the air-fuel ratio.

15-7C No. Because the molar mass of the fuel and the molar mass of the air, in general, are different.

15-8 Sulfur is burned with oxygen to form sulfur dioxide. The minimum mass of oxygen required and the mass of sulfur dioxide in the products are to be determined when 1 kg of sulfur is burned.
Properties The molar masses of sulfur and oxygen are $32.06 \mathrm{~kg} / \mathrm{kmol}$ and $32.00 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).
Analysis The chemical reaction is given by

$$
\mathrm{S}+\mathrm{O}_{2} \longrightarrow \mathrm{SO}_{2}
$$

Hence, 1 kmol of oxygen is required to burn 1 kmol of sulfur which

$$
\mathrm{S}+\mathrm{O}_{2} \longrightarrow \mathrm{SO}_{2}
$$

produces 1 kmol of sulfur dioxide whose molecular weight is

$$
M_{\mathrm{SO} 2}=M_{\mathrm{S}}+M_{\mathrm{O} 2}=32.06+32.00=64.06 \mathrm{~kg} / \mathrm{kmol}
$$

Then,

$$
\frac{m_{\mathrm{O} 2}}{m_{\mathrm{S}}}=\frac{N_{\mathrm{O} 2} M_{\mathrm{O} 2}}{N_{\mathrm{S}} M_{\mathrm{S}}}=\frac{(1 \mathrm{kmol})(32 \mathrm{~kg} / \mathrm{kmol})}{(1 \mathrm{kmol})(32.06 \mathrm{~kg} / \mathrm{kmol})}=\mathbf{0 . 9 9 8} \mathrm{kg} \mathrm{O}_{\mathbf{2}} / \mathbf{k g ~ S}
$$

and

$$
\frac{m_{\mathrm{SO} 2}}{m_{\mathrm{S}}}=\frac{N_{\mathrm{SO} 2} M_{\mathrm{SO} 2}}{N_{\mathrm{S}} M_{\mathrm{S}}}=\frac{(1 \mathrm{kmol})(64.06 \mathrm{~kg} / \mathrm{kmol})}{(1 \mathrm{kmol})(32.06 \mathrm{~kg} / \mathrm{kmol})}=1.998 \mathrm{~kg} \mathrm{SO}_{2} / \mathrm{kg} \mathrm{~S}
$$

15-9E Methane is burned with diatomic oxygen. The mass of water vapor in the products is to be determined when 1 lbm of methane is burned.

Properties The molar masses of $\mathrm{CH}_{4}, \mathrm{O}_{2}, \mathrm{CO}_{2}$, and $\mathrm{H}_{2} \mathrm{O}$ are $16,32,44$, and $18 \mathrm{lbm} / \mathrm{lbmol}$, respectively (Table A-1E).

Analysis The chemical reaction is given by

$$
\mathrm{CH}_{4}+2 \mathrm{O}_{2} \longrightarrow \mathrm{CO}_{2}+2 \mathrm{H}_{2} \mathrm{O}
$$

$$
\begin{aligned}
& \mathrm{CH}_{4}+2 \mathrm{O}_{2} \\
& \rightarrow \mathrm{CO}_{2}+2 \mathrm{H}_{2} \mathrm{O}
\end{aligned}
$$

Hence, for each lbmol of methane burned, 2 lbmol of water vapor are formed. Then,

$$
\frac{m_{\mathrm{H} 2 \mathrm{O}}}{m_{\mathrm{CH} 4}}=\frac{N_{\mathrm{H} 2 \mathrm{O}} M_{\mathrm{H} 2 \mathrm{O}}}{N_{\mathrm{CH} 4} M_{\mathrm{CH} 4}}=\frac{(2 \mathrm{lbmol})(18 \mathrm{lbm} / \mathrm{lbmol})}{(1 \mathrm{lbmol})(16 \mathrm{lbm} / \mathrm{lbmol})}=\mathbf{2 . 2 5} \mathrm{lbm} \mathrm{H}_{2} \mathrm{O} / \mathrm{lbm} \mathrm{CH}_{4}
$$

## Theoretical and Actual Combustion Processes

15-10C The causes of incomplete combustion are insufficient time, insufficient oxygen, insufficient mixing, and dissociation.

15-11C CO. Because oxygen is more strongly attracted to hydrogen than it is to carbon, and hydrogen is usually burned to completion even when there is a deficiency of oxygen.

15-12C It represent the amount of air that contains the exact amount of oxygen needed for complete combustion.

15-13C No. The theoretical combustion is also complete, but the products of theoretical combustion does not contain any uncombined oxygen.

15-14C Case (b).

15-15 Propane is burned with theoretical amount of air. The mass fraction of carbon dioxide and the mole and mass fractions of the water vapor in the products are to be determined.
Properties The molar masses of $\mathrm{C}_{3} \mathrm{H}_{8}, \mathrm{O}_{2}, \mathrm{~N}_{2}, \mathrm{CO}_{2}$, and $\mathrm{H}_{2} \mathrm{O}$ are $44,32,28,44$, and $18 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).
Analysis (a) The reaction in terms of undetermined coefficients is

$$
\mathrm{C}_{3} \mathrm{H}_{8}+x\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow y \mathrm{CO}_{2}+z \mathrm{H}_{2} \mathrm{O}+p \mathrm{~N}_{2}
$$

Balancing the carbon in this reaction gives

$$
y=3
$$

and the hydrogen balance gives

The oxygen balance produces

$$
2 x=2 y+z \longrightarrow x=y+z / 2=3+4 / 2=5
$$

A balance of the nitrogen in this reaction gives

$$
2 \times 3.76 x=2 p \longrightarrow p=3.76 x=3.76 \times 5=18.8
$$

In balanced form, the reaction is

$$
\mathrm{C}_{3} \mathrm{H}_{8}+5 \mathrm{O}_{2}+18.8 \mathrm{~N}_{2} \longrightarrow 3 \mathrm{CO}_{2}+4 \mathrm{H}_{2} \mathrm{O}+18.8 \mathrm{~N}_{2}
$$

The mass fraction of carbon dioxide is determined from

$$
\begin{aligned}
\mathrm{mf}_{\mathrm{CO} 2} & =\frac{m_{\mathrm{CO} 2}}{m_{\text {products }}}=\frac{N_{\mathrm{CO} 2} M_{\mathrm{CO} 2}}{N_{\mathrm{CO} 2} M_{\mathrm{CO} 2}+N_{\mathrm{H} 2 \mathrm{O}} M_{\mathrm{H} 2 \mathrm{O}}+N_{\mathrm{N} 2} M_{\mathrm{N} 2}} \\
& =\frac{(3 \mathrm{kmol})(44 \mathrm{~kg} / \mathrm{kmol})}{(3 \mathrm{kmol})(44 \mathrm{~kg} / \mathrm{kmol})+(4 \mathrm{kmol})(18 \mathrm{~kg} / \mathrm{kmol})+(18.8 \mathrm{kmol})(28 \mathrm{~kg} / \mathrm{kmol})} \\
& =\frac{132 \mathrm{~kg}}{730.4 \mathrm{~kg}}=\mathbf{0 . 1 8 1}
\end{aligned}
$$

(b) The mole and mass fractions of water vapor are

$$
\begin{aligned}
y_{\mathrm{H} 2 \mathrm{O}} & =\frac{N_{\mathrm{H} 2 \mathrm{O}}}{N_{\text {products }}}=\frac{N_{\mathrm{H} 2 \mathrm{O}}}{N_{\mathrm{CO} 2}+N_{\mathrm{H} 2 \mathrm{O}}+N_{\mathrm{N} 2}}=\frac{4 \mathrm{kmol}}{3 \mathrm{kmol}+4 \mathrm{kmol}+18.8 \mathrm{kmol}}=\frac{4 \mathrm{kmol}}{25.8 \mathrm{kmol}}=\mathbf{0 . 1 5 5} \\
\mathrm{mf}_{\mathrm{H} 2 \mathrm{O}} & =\frac{m_{\mathrm{H} 2 \mathrm{O}}}{m_{\text {products }}}=\frac{N_{\mathrm{H} 2 \mathrm{O}} M_{\mathrm{H} 2 \mathrm{O}}}{N_{\mathrm{CO} 2} M_{\mathrm{CO} 2}+N_{\mathrm{H} 2 \mathrm{O}} M_{\mathrm{H} 2 \mathrm{O}}+N_{\mathrm{N} 2} M_{\mathrm{N} 2}} \\
& =\frac{(4 \mathrm{kmol})(18 \mathrm{~kg} / \mathrm{kmol})}{(3 \mathrm{kmol})(44 \mathrm{~kg} / \mathrm{kmol})+(4 \mathrm{kmol})(18 \mathrm{~kg} / \mathrm{kmol})+(18.8 \mathrm{kmol})(28 \mathrm{~kg} / \mathrm{kmol})} \\
& =\frac{72 \mathrm{~kg}}{730.4 \mathrm{~kg}}=\mathbf{0 . 0 9 8 6}
\end{aligned}
$$

15-16 Methane is burned with air. The mass flow rates at the two inlets are to be determined.
Properties The molar masses of $\mathrm{CH}_{4}, \mathrm{O}_{2}, \mathrm{~N}_{2}, \mathrm{CO}_{2}$, and $\mathrm{H}_{2} \mathrm{O}$ are $16,32,28,44$, and $18 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).
Analysis The stoichiometric combustion equation of $\mathrm{CH}_{4}$ is

$$
\mathrm{CH}_{4}+a_{\mathrm{th}}\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow \mathrm{CO}_{2}+2 \mathrm{H}_{2} \mathrm{O}+3.76 a_{\mathrm{th}} \mathrm{~N}_{2}
$$

$\mathrm{O}_{2}$ balance: $\quad a_{\mathrm{th}}=1+1 \longrightarrow a_{\mathrm{th}}=2$

Substituting, $\mathrm{CH}_{4}+2\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow \mathrm{CO}_{2}+2 \mathrm{H}_{2} \mathrm{O}+7.52 \mathrm{~N}_{2}$
The masses of the reactants are

$$
\begin{aligned}
m_{\mathrm{CH} 4} & =N_{\mathrm{CH} 4} M_{\mathrm{CH} 4}=(1 \mathrm{kmol})(16 \mathrm{~kg} / \mathrm{kmol})=16 \mathrm{~kg} \\
m_{\mathrm{O} 2} & =N_{\mathrm{O} 2} M_{\mathrm{O} 2}=(2 \mathrm{kmol})(32 \mathrm{~kg} / \mathrm{kmol})=64 \mathrm{~kg} \\
m_{\mathrm{N} 2} & =N_{\mathrm{N} 2} M_{\mathrm{N} 2}=(2 \times 3.76 \mathrm{kmol})(28 \mathrm{~kg} / \mathrm{kmol})=211 \mathrm{~kg}
\end{aligned}
$$

The total mass is

$$
m_{\text {total }}=m_{\mathrm{CH} 4}+m_{\mathrm{O} 2}+N_{\mathrm{N} 2}=16+64+211=291 \mathrm{~kg}
$$

Then the mass fractions are

$$
\begin{aligned}
& \mathrm{mf}_{\mathrm{CH} 4}=\frac{m_{\mathrm{CH} 4}}{m_{\text {total }}}=\frac{16 \mathrm{~kg}}{291 \mathrm{~kg}}=0.05498 \\
& \mathrm{mf}_{\mathrm{O} 2}=\frac{m_{\mathrm{O} 2}}{m_{\text {total }}}=\frac{64 \mathrm{~kg}}{291 \mathrm{~kg}}=0.2199 \\
& \mathrm{mf}_{\mathrm{N} 2}=\frac{m_{\mathrm{N} 2}}{m_{\text {total }}}=\frac{211 \mathrm{~kg}}{291 \mathrm{~kg}}=0.7251
\end{aligned}
$$

For a mixture flow of $0.01 \mathrm{~kg} / \mathrm{s}$, the mass flow rates of the reactants are

$$
\begin{aligned}
\dot{m}_{\mathrm{CH} 4} & =\mathrm{mf}_{\mathrm{CH} 4} \dot{m}=(0.05498)(0.01 \mathrm{~kg} / \mathrm{s})=\mathbf{0 . 0 0 0 5 4 9 8} \mathbf{~ k g} / \mathbf{s} \\
\dot{m}_{\mathrm{air}} & =\dot{m}-\dot{m}_{\mathrm{CH} 4}=0.01-0.0005498=\mathbf{0 . 0 0 9 4 5 0} \mathbf{~ k g} / \mathbf{s}
\end{aligned}
$$

15-17 n-Octane is burned with stoichiometric amount of oxygen. The mass fractions of each of the products and the mass of water in the products per unit mass of fuel burned are to be determined.
Assumptions 1 Combustion is complete. 2 The combustion products contain $\mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O} .3$ Combustion gases are ideal gases.
Properties The molar masses of $\mathrm{C}, \mathrm{H}_{2}$, and $\mathrm{O}_{2}$ are $12 \mathrm{~kg} / \mathrm{kmol}, 2 \mathrm{~kg} / \mathrm{kmol}$, and $32 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).

Analysis The combustion equation in this case is

$$
\mathrm{C}_{8} \mathrm{H}_{18}+12.5 \mathrm{O}_{2} \longrightarrow 8 \mathrm{CO}_{2}+9 \mathrm{H}_{2} \mathrm{O}
$$

The mass of each product and the total mass are

$$
\begin{aligned}
& m_{\mathrm{CO} 2}=N_{\mathrm{CO} 2} M_{\mathrm{CO} 2}=(8 \mathrm{kmol})(44 \mathrm{~kg} / \mathrm{kmol})=352 \mathrm{~kg} \\
& m_{\mathrm{H} 2 \mathrm{O}}=N_{\mathrm{H} 2 \mathrm{O}} M_{\mathrm{H} 2 \mathrm{O}}=(9 \mathrm{kmol})(18 \mathrm{~kg} / \mathrm{kmol})=162 \mathrm{~kg} \\
& m_{\text {total }}=m_{\mathrm{CO} 2}+m_{\mathrm{H} 2 \mathrm{O}}=352+162=514 \mathrm{~kg}
\end{aligned}
$$

Then the mass fractions are

$$
\begin{aligned}
& \mathrm{mf}_{\mathrm{CO} 2}=\frac{m_{\mathrm{CO} 2}}{m_{\text {total }}}=\frac{352 \mathrm{~kg}}{514 \mathrm{~kg}}=\mathbf{0 . 6 8 4 8} \\
& \mathrm{mf}_{\mathrm{H} 2 \mathrm{O}}=\frac{m_{\mathrm{H} 2 \mathrm{O}}}{m_{\text {total }}}=\frac{162 \mathrm{~kg}}{514 \mathrm{~kg}}=\mathbf{0 . 3 1 5 2}
\end{aligned}
$$

The mass of water in the products per unit mass of fuel burned is determined from

$$
\frac{m_{\mathrm{H} 2 \mathrm{O}}}{m_{\mathrm{C} 8 \mathrm{H} 18}}=\frac{(9 \times 18) \mathrm{kg}}{(1 \times 114) \mathrm{kg}}=1.42 \mathbf{k g ~ H}_{2} \mathrm{O} / \mathrm{kg} \mathrm{C}_{8} \mathbf{H}_{18}
$$

15-18 Acetylene is burned with 10 percent excess oxygen. The mass fractions of each of the products and the mass of oxygen used per unit mass of fuel burned are to be determined.
Assumptions 1 Combustion is complete. 2 The combustion products contain $\mathrm{CO}_{2}, \mathrm{H}_{2} \mathrm{O}$, and $\mathrm{O}_{2}$. 3
Combustion gases are ideal gases.
Properties The molar masses of $\mathrm{C}, \mathrm{H}_{2}$, and $\mathrm{O}_{2}$ are $12 \mathrm{~kg} / \mathrm{kmol}, 2 \mathrm{~kg} / \mathrm{kmol}$, and $32 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).

Analysis The stoichiometric combustion equation is

$$
\mathrm{C}_{2} \mathrm{H}_{2}+2.5 \mathrm{O}_{2} \longrightarrow 2 \mathrm{CO}_{2}+\mathrm{H}_{2} \mathrm{O}
$$

The combustion equation with $10 \%$ excess oxygen is

$$
\mathrm{C}_{2} \mathrm{H}_{2}+2.75 \mathrm{O}_{2} \longrightarrow 2 \mathrm{CO}_{2}+\mathrm{H}_{2} \mathrm{O}+0.25 \mathrm{O}_{2}
$$

The mass of each product and the total mass are

$$
\begin{aligned}
m_{\mathrm{CO} 2} & =N_{\mathrm{CO} 2} M_{\mathrm{CO} 2}=(2 \mathrm{kmol})(44 \mathrm{~kg} / \mathrm{kmol})=88 \mathrm{~kg} \\
m_{\mathrm{H} 2 \mathrm{O}} & =N_{\mathrm{H} 2 \mathrm{O}} M_{\mathrm{H} 2 \mathrm{O}}=(1 \mathrm{kmol})(18 \mathrm{~kg} / \mathrm{kmol})=18 \mathrm{~kg} \\
m_{\mathrm{O} 2} & =N_{\mathrm{O} 2} M_{\mathrm{O} 2}=(0.25 \mathrm{kmol})(32 \mathrm{~kg} / \mathrm{kmol})=8 \mathrm{~kg} \\
m_{\mathrm{total}} & =m_{\mathrm{CO} 2}+m_{\mathrm{H} 2 \mathrm{O}}+m_{\mathrm{O} 2}=88+18+8=114 \mathrm{~kg}
\end{aligned}
$$

Then the mass fractions are

$$
\begin{aligned}
\mathrm{mf}_{\mathrm{CO} 2} & =\frac{m_{\mathrm{CO} 2}}{m_{\text {total }}}=\frac{88 \mathrm{~kg}}{114 \mathrm{~kg}}=\mathbf{0 . 7 7 1 9} \\
\mathrm{mf}_{\mathrm{H} 2 \mathrm{O}} & =\frac{m_{\mathrm{H} 2 \mathrm{O}}}{m_{\text {total }}}=\frac{18 \mathrm{~kg}}{114 \mathrm{~kg}}=\mathbf{0 . 1 5 7 9} \\
\mathrm{mf}_{\mathrm{O} 2} & =\frac{m_{\mathrm{O} 2}}{m_{\text {total }}}=\frac{8 \mathrm{~kg}}{114 \mathrm{~kg}}=\mathbf{0 . 0 7 0 2}
\end{aligned}
$$

The mass of oxygen per unit mass of fuel burned is determined from

$$
\frac{m_{\mathrm{O} 2}}{m_{\mathrm{C} 2 \mathrm{H} 2}}=\frac{(2.75 \times 32) \mathrm{kg}}{(1 \times 26) \mathrm{kg}}=\mathbf{3 . 3 8 5} \mathbf{k g ~ O}_{2} / \mathbf{k g ~ C}_{2} \mathrm{H}_{2}
$$

15-19 Coal whose mass percentages are specified is burned with 50 percent excess air. The fuel-air ratio is to be determined.

Assumptions 1 Combustion is complete. 2 The combustion products contain $\mathrm{CO}_{2}, \mathrm{H}_{2} \mathrm{O}, \mathrm{SO}_{2}, \mathrm{~N}_{2}$, and $\mathrm{O}_{2}$. 3 Combustion gases are ideal gases.
Properties The molar masses of $\mathrm{C}, \mathrm{H}_{2}, \mathrm{O}_{2}, \mathrm{~S}$, and air are $12,2,32,32$, and $29 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).

Analysis The mass fractions of the constituent of the coal when the ash is substituted are

$$
\begin{aligned}
\mathrm{mf}_{\mathrm{C}} & =\frac{m_{\mathrm{C}}}{m_{\text {total }}}=\frac{79.61 \mathrm{~kg}}{(100-8.62) \mathrm{kg}}=\frac{79.61 \mathrm{~kg}}{91.38 \mathrm{~kg}}=0.8712 \\
\mathrm{mf}_{\mathrm{H} 2} & =\frac{m_{\mathrm{H} 2}}{m_{\text {total }}}=\frac{4.66 \mathrm{~kg}}{91.38 \mathrm{~kg}}=0.05100 \\
\mathrm{mf}_{\mathrm{O} 2} & =\frac{m_{\mathrm{O} 2}}{m_{\text {total }}}=\frac{4.76 \mathrm{~kg}}{91.38 \mathrm{~kg}}=0.05209 \\
\mathrm{mf}_{\mathrm{N} 2} & =\frac{m_{\mathrm{N} 2}}{m_{\text {total }}}=\frac{1.83 \mathrm{~kg}}{91.38 \mathrm{~kg}}=0.02003 \\
\mathrm{mf}_{\mathrm{S}} & =\frac{m_{\mathrm{S}}}{m_{\text {total }}}=\frac{0.52 \mathrm{~kg}}{91.38 \mathrm{~kg}}=0.00569
\end{aligned}
$$

We now consider 100 kg of this mixture. Then the mole numbers of each component are

$$
\begin{aligned}
N_{\mathrm{C}} & =\frac{m_{\mathrm{C}}}{M_{\mathrm{C}}}=\frac{87.12 \mathrm{~kg}}{12 \mathrm{~kg} / \mathrm{kmol}}=7.26 \mathrm{kmol} \\
N_{\mathrm{H} 2} & =\frac{m_{\mathrm{H} 2}}{M_{\mathrm{H} 2}}=\frac{5.10 \mathrm{~kg}}{2 \mathrm{~kg} / \mathrm{kmol}}=2.55 \mathrm{kmol} \\
N_{\mathrm{O} 2} & =\frac{m_{\mathrm{O} 2}}{M_{\mathrm{O} 2}}=\frac{5.209 \mathrm{~kg}}{32 \mathrm{~kg} / \mathrm{kmol}}=0.1628 \mathrm{kmol} \\
N_{\mathrm{N} 2} & =\frac{m_{\mathrm{N} 2}}{M_{\mathrm{N} 2}}=\frac{2.003 \mathrm{~kg}}{28 \mathrm{~kg} / \mathrm{kmol}}=0.07154 \mathrm{kmol} \\
N_{\mathrm{S}} & =\frac{m_{\mathrm{S}}}{M_{\mathrm{S}}}=\frac{0.569 \mathrm{~kg}}{32 \mathrm{~kg} / \mathrm{kmol}}=0.01778 \mathrm{kmol}
\end{aligned}
$$

The mole number of the mixture and the mole fractions are

$$
\begin{aligned}
& N_{m}=7.26+2.55+0.1628+0.07154+0.01778=10.06 \mathrm{kmol} \\
& y_{\mathrm{C}}=\frac{N_{\mathrm{C}}}{N_{m}}=\frac{7.26 \mathrm{kmol}}{10.06 \mathrm{kmol}}=0.7215 \\
& y_{\mathrm{H} 2}=\frac{N_{\mathrm{H} 2}}{N_{m}}=\frac{2.55 \mathrm{kmol}}{10.06 \mathrm{kmol}}=0.2535 \\
& y_{\mathrm{O} 2}=\frac{N_{\mathrm{O} 2}}{N_{m}}=\frac{0.1628 \mathrm{kmol}}{10.06 \mathrm{kmol}}=0.01618 \\
& y_{\mathrm{N} 2}=\frac{N_{\mathrm{N} 2}}{N_{m}}=\frac{0.07154 \mathrm{kmol}}{10.06 \mathrm{kmol}}=0.00711 \\
& y_{\mathrm{S}}=\frac{N_{\mathrm{S}}}{N_{m}}=\frac{0.01778 \mathrm{kmol}}{10.06 \mathrm{kmol}}=0.00177
\end{aligned}
$$

Then, the combustion equation in this case may be written as

$$
\begin{aligned}
& 0.7215 \mathrm{C}+0.2535 \mathrm{H}_{2}+0.01618 \mathrm{O}_{2}+ 0.00711 \mathrm{~N}_{2}+0.00177 \mathrm{~S}+1.5 a_{\mathrm{th}}\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \\
& \longrightarrow x \mathrm{CO}_{2}+y \mathrm{H}_{2} \mathrm{O}+z \mathrm{SO}_{2}+k \mathrm{~N}_{2}+0.5 a_{t h} \mathrm{O}_{2}
\end{aligned}
$$

According to the species balances,
C balance: $x=0.7215$
$\mathrm{H}_{2}$ balance: $y=0.2535$
S balance: $z=0.00177$
$\mathrm{O}_{2}$ balance:
$0.01618+1.5 a_{\mathrm{th}}=x+0.5 y+z+0.5 a_{\mathrm{th}}$
$1.5 a_{\mathrm{th}}-0.5 a_{\mathrm{th}}=0.7215+0.5(0.2535)+0.00177-0.01617 \longrightarrow a_{\mathrm{th}}=0.8339$
$\mathrm{N}_{2}$ balance: $0.00711+1.5 \times 3.76 a_{\mathrm{th}}=k \longrightarrow k=0.00711+1.5 \times 3.76 \times 0.8339=4.710$
Substituting,

$$
\begin{aligned}
0.7215 \mathrm{C}+0.2535 \mathrm{H}_{2} & +0.01617 \mathrm{O}_{2}+0.00711 \mathrm{~N}_{2}+0.00177 \mathrm{~S}+1.2509\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \\
& \longrightarrow 0.7215 \mathrm{CO}_{2}+0.2535 \mathrm{H}_{2} \mathrm{O}+0.0018 \mathrm{SO}_{2}+4.71 \mathrm{~N}_{2}+0.4170 \mathrm{O}_{2}
\end{aligned}
$$

The fuel-air mass ratio is then

$$
\begin{aligned}
\mathrm{FA} & =\frac{m_{\text {fuel }}}{m_{\text {air }}}=\frac{(0.7215 \times 12+0.2535 \times 2+0.01617 \times 32+0.00711 \times 28+0.00177 \times 32) \mathrm{kg}}{(1.2509 \times 4.76 \times 29) \mathrm{kg}} \\
& =\frac{9.938 \mathrm{~kg}}{172.5 \mathrm{~kg}}=\mathbf{0 . 0 5 7 6} \mathbf{~ k g} \text { fuel } / \mathrm{kg} \text { air }
\end{aligned}
$$

15-20 Propane is burned with 75 percent excess air during a combustion process. The AF ratio is to be determined.

Assumptions 1 Combustion is complete. 2 The combustion products contain $\mathrm{CO}_{2}, \mathrm{H}_{2} \mathrm{O}, \mathrm{O}_{2}$, and $\mathrm{N}_{2}$ only.
Properties The molar masses of C, $\mathrm{H}_{2}$, and air are $12 \mathrm{~kg} / \mathrm{kmol}, 2 \mathrm{~kg} / \mathrm{kmol}$, and $29 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).
Analysis The combustion equation in this case can be written as

$$
\mathrm{C}_{3} \mathrm{H}_{8}+1.75 a_{\mathrm{th}}\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow 3 \mathrm{CO}_{2}+4 \mathrm{H}_{2} \mathrm{O}+0.75 a_{\mathrm{th}} \mathrm{O}_{2}+(1.75 \times 3.76) a_{\mathrm{th}} \mathrm{~N}_{2}
$$

where $a_{\mathrm{th}}$ is the stoichiometric coefficient for air. We have automatically accounted for the 75\% excess air by using the factor $1.75 a_{\mathrm{th}}$ instead of $a_{\mathrm{th}}$ for air. The stoichiometric amount of oxygen $\left(a_{\mathrm{th}} \mathrm{O}_{2}\right)$ will be used to oxidize the fuel, and the remaining excess amount $\left(0.75 a_{\mathrm{th}} \mathrm{O}_{2}\right)$ will appear in the products as free oxygen.
 The coefficient $a_{\mathrm{th}}$ is determined from the $\mathrm{O}_{2}$ balance,

O2 balance: $\quad 1.75 a_{\mathrm{th}}=3+2+0.75 a_{\mathrm{th}} \longrightarrow a_{\mathrm{th}}=5$
Substituting,

$$
\mathrm{C}_{3} \mathrm{H}_{8}+8.75\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow 3 \mathrm{CO}_{2}+4 \mathrm{H}_{2} \mathrm{O}+3.75 \mathrm{O}_{2}+32.9 \mathrm{~N}_{2}
$$

The air-fuel ratio is determined by taking the ratio of the mass of the air to the mass of the fuel,

$$
\mathrm{AF}=\frac{m_{\text {air }}}{m_{\text {fuel }}}=\frac{(8.75 \times 4.76 \mathrm{kmol})(29 \mathrm{~kg} / \mathrm{kmol})}{(3 \mathrm{kmol})(12 \mathrm{~kg} / \mathrm{kmol})+(4 \mathrm{kmol})(2 \mathrm{~kg} / \mathrm{kmol})}=\mathbf{2 7 . 5} \mathbf{~ k g ~ a i r} / \mathbf{k g} \text { fuel }
$$

15-21 Acetylene is burned with the stoichiometric amount of air during a combustion process. The AF ratio is to be determined on a mass and on a mole basis.

Assumptions 1 Combustion is complete. 2 The combustion products contain $\mathrm{CO}_{2}, \mathrm{H}_{2} \mathrm{O}$, and $\mathrm{N}_{2}$ only.
Properties The molar masses of $\mathrm{C}, \mathrm{H}_{2}$, and air are $12 \mathrm{~kg} / \mathrm{kmol}, 2 \mathrm{~kg} / \mathrm{kmol}$, and $29 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).
Analysis This is a theoretical combustion process since $\mathrm{C}_{2} \mathrm{H}_{2}$ is burned completely with stoichiometric amount of air. The stoichiometric combustion equation of $\mathrm{C}_{2} \mathrm{H}_{2}$ is

$$
\mathrm{C}_{2} \mathrm{H}_{2}+a_{\mathrm{th}}\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow 2 \mathrm{CO}_{2}+\mathrm{H}_{2} \mathrm{O}+3.76 a_{\mathrm{th}} \mathrm{~N}_{2}
$$

$\mathrm{O}_{2}$ balance: $\quad a_{\mathrm{th}}=2+0.5 \longrightarrow a_{\mathrm{th}}=2.5$
Substituting,

$$
\mathrm{C}_{2} \mathrm{H}_{2}+2.5\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow 2 \mathrm{CO}_{2}+\mathrm{H}_{2} \mathrm{O}+9.4 \mathrm{~N}_{2}
$$

The air-fuel ratio is determined by taking the ratio of the mass of the air to the mass of the fuel,

$$
\mathrm{AF}=\frac{m_{\text {air }}}{m_{\text {fuel }}}=\frac{(2.5 \times 4.76 \mathrm{kmol})(29 \mathrm{~kg} / \mathrm{kmol})}{(2 \mathrm{kmol})(12 \mathrm{~kg} / \mathrm{kmol})+(1 \mathrm{kmol})(2 \mathrm{~kg} / \mathrm{kmol})}=\mathbf{1 3 . 3} \mathbf{~ k g ~ a i r} / \mathbf{k g} \text { fuel }
$$

On a mole basis, the air-fuel ratio is expressed as the ratio of the mole numbers of the air to the mole numbers of the fuel,

$$
\mathrm{AF}_{\text {mole basis }}=\frac{N_{\text {air }}}{N_{\text {fuel }}}=\frac{(2.5 \times 4.76) \mathrm{kmol}}{1 \mathrm{kmol} \text { fuel }}=\mathbf{1 1 . 9} \mathbf{~ k m o l ~ a i r} / \mathbf{k m o l} \text { fuel }
$$

15-22E Ethylene is burned with 200 percent theoretical air during a combustion process. The AF ratio and the dew-point temperature of the products are to be determined.
Assumptions 1 Combustion is complete. 2 The combustion products contain $\mathrm{CO}_{2}, \mathrm{H}_{2} \mathrm{O}, \mathrm{O}_{2}$, and $\mathrm{N}_{2}$ only. 3 Combustion gases are ideal gases.
Properties The molar masses of $\mathrm{C}, \mathrm{H}_{2}$, and air are 12 $\mathrm{lbm} / \mathrm{lbmol}, 2 \mathrm{lbm} / \mathrm{lbmol}$, and $29 \mathrm{lbm} / \mathrm{lbmol}$, respectively (Table A-1E).

Analysis (a) The combustion equation in this case can be written as

$$
\mathrm{C}_{2} \mathrm{H}_{4}+2 a_{\mathrm{th}}\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow 2 \mathrm{CO}_{2}+2 \mathrm{H}_{2} \mathrm{O}+a_{\mathrm{th}} \mathrm{O}_{2}+(2 \times 3.76) a_{\mathrm{th}} \mathrm{~N}_{2}
$$

where $a_{\mathrm{th}}$ is the stoichiometric coefficient for air.
It is determined from
$\mathrm{O}_{2}$ balance: $\quad 2 a_{\mathrm{th}}=2+1+a_{\mathrm{th}} \longrightarrow \quad a_{\mathrm{th}}=3$
Substituting,

$$
\mathrm{C}_{2} \mathrm{H}_{4}+6\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow 2 \mathrm{CO}_{2}+2 \mathrm{H}_{2} \mathrm{O}+3 \mathrm{O}_{2}+22.56 \mathrm{~N}_{2}
$$

The air-fuel ratio is determined by taking the ratio of the mass of the air to the mass of the fuel,

$$
\mathrm{AF}=\frac{m_{\text {air }}}{m_{\text {fuel }}}=\frac{(6 \times 4.76 \mathrm{lbmol})(29 \mathrm{lbm} / \mathrm{lbmol})}{(2 \mathrm{lbmol})(12 \mathrm{lbm} / \mathrm{lbmol})+(2 \mathrm{lbmol})(2 \mathrm{lbm} / \mathrm{lbmol})}=\mathbf{2 9 . 6} \mathbf{~ l b m} \text { air } / \mathbf{l b m} \text { fuel }
$$

(b) The dew-point temperature of a gas-vapor mixture is the saturation temperature of the water vapor in the product gases corresponding to its partial pressure. That is,

$$
P_{v}=\left(\frac{N_{v}}{N_{\text {prod }}}\right) P_{\text {prod }}=\left(\frac{2 \mathrm{lbmol}}{29.56 \mathrm{lbmol}}\right)(14.5 \mathrm{psia})=0.981 \mathrm{psia}
$$

Thus,

$$
T_{\mathrm{dp}}=T_{\text {sat @0.981 psia }}=\mathbf{1 0 1}^{\circ} \mathrm{F}
$$

15-23 Propylene is burned with 50 percent excess air during a combustion process. The AF ratio and the temperature at which the water vapor in the products will start condensing are to be determined.
Assumptions 1 Combustion is complete. 2 The combustion products contain $\mathrm{CO}_{2}, \mathrm{H}_{2} \mathrm{O}, \mathrm{O}_{2}$, and $\mathrm{N}_{2}$ only. 3 Combustion gases are ideal gases.
Properties The molar masses of $\mathrm{C}, \mathrm{H}_{2}$, and air are $12 \mathrm{~kg} / \mathrm{kmol}$, $2 \mathrm{~kg} / \mathrm{kmol}$, and $29 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).

Analysis (a) The combustion equation in this case can be
 written as

$$
\mathrm{C}_{3} \mathrm{H}_{6}+1.5 a_{\mathrm{th}}\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow 3 \mathrm{CO}_{2}+3 \mathrm{H}_{2} \mathrm{O}+0.5 a_{\mathrm{th}} \mathrm{O}_{2}+(1.5 \times 3.76) a_{\mathrm{th}} \mathrm{~N}_{2}
$$

where $a_{\mathrm{th}}$ is the stoichiometric coefficient for air. It is determined from
$\mathrm{O}_{2}$ balance: $\quad 1.5 a_{\mathrm{th}}=3+1.5+0.5 a_{\mathrm{th}} \longrightarrow \quad a_{\mathrm{th}}=4.5$
Substituting,

$$
\mathrm{C}_{3} \mathrm{H}_{6}+6.75\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow 3 \mathrm{CO}_{2}+3 \mathrm{H}_{2} \mathrm{O}+2.25 \mathrm{O}_{2}+25.38 \mathrm{~N}_{2}
$$

The air-fuel ratio is determined by taking the ratio of the mass of the air to the mass of the fuel,

$$
\mathrm{AF}=\frac{m_{\text {air }}}{m_{\text {fuel }}}=\frac{(6.75 \times 4.76 \mathrm{kmol})(29 \mathrm{~kg} / \mathrm{kmol})}{(3 \mathrm{kmol})(12 \mathrm{~kg} / \mathrm{kmol})+(3 \mathrm{kmol})(2 \mathrm{~kg} / \mathrm{kmol})}=\mathbf{2 2 . 2} \mathbf{~ k g ~ a i r} / \mathbf{k g} \text { fuel }
$$

(b) The dew-point temperature of a gas-vapor mixture is the saturation temperature of the water vapor in the product gases corresponding to its partial pressure. That is,

$$
P_{v}=\left(\frac{N_{v}}{N_{\text {prod }}}\right) P_{\text {prod }}=\left(\frac{3 \mathrm{kmol}}{33.63 \mathrm{kmol}}\right)(105 \mathrm{kPa})=9.367 \mathrm{kPa}
$$

Thus,

$$
T_{\mathrm{dp}}=T_{\mathrm{sat} @ 9.367 \mathrm{kPa}}=\mathbf{4 4 . 5}{ }^{\circ} \mathbf{C}
$$

15-24 Butane $\mathrm{C}_{4} \mathrm{H}_{10}$ is burned with 200 percent theoretical air. The kmol of water that needs to be sprayed into the combustion chamber per kmol of fuel is to be determined.
Assumptions 1 Combustion is complete. 2 The combustion products contain $\mathrm{CO}_{2}, \mathrm{H}_{2} \mathrm{O}, \mathrm{O}_{2}$, and $\mathrm{N}_{2}$ only.
Properties The molar masses of $\mathrm{C}, \mathrm{H}_{2}, \mathrm{O}_{2}$ and air are $12 \mathrm{~kg} / \mathrm{kmol}, 2 \mathrm{~kg} / \mathrm{kmol}, 32 \mathrm{~kg} / \mathrm{kmol}$, and $29 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).
Analysis The reaction equation for $200 \%$ theoretical air without the additional water is

$$
\mathrm{C}_{4} \mathrm{H}_{10}+2 a_{\mathrm{th}}\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow B \mathrm{CO}_{2}+D \mathrm{H}_{2} \mathrm{O}+E \mathrm{O}_{2}+F \mathrm{~N}_{2}
$$

where $a_{\mathrm{th}}$ is the stoichiometric coefficient for air. We have automatically accounted for the $100 \%$ excess air by using the factor $2 a_{\mathrm{th}}$ instead of $a_{t h}$ for air. The coefficient $a_{\mathrm{th}}$ and other coefficients are to be determined from the mass balances

Carbon balance: $\quad B=4$
Hydrogen balance: $\quad 2 D=10 \longrightarrow D=5$
Oxygen balance:

$$
2 \times 2 a_{\mathrm{th}}=2 B+D+2 E
$$

$$
a_{\mathrm{th}}=E
$$

Nitrogen balance: $\quad 2 a_{\text {th }} \times 3.76=F$
Solving the above equations, we find the coefficients ( $E=6.5, F=48.88$, and $a_{\mathrm{th}}=6.5$ ) and write the balanced reaction equation as

$$
\mathrm{C}_{4} \mathrm{H}_{10}+13\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow 4 \mathrm{CO}_{2}+5 \mathrm{H}_{2} \mathrm{O}+6.5 \mathrm{O}_{2}+48.88 \mathrm{~N}_{2}
$$

With the additional water sprayed into the combustion chamber, the balanced reaction equation is

$$
\mathrm{C}_{4} \mathrm{H}_{10}+13\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right]+N_{v} \mathrm{H}_{2} \mathrm{O} \longrightarrow 4 \mathrm{CO}_{2}+\left(5+N_{v}\right) \mathrm{H}_{2} \mathrm{O}+6.5 \mathrm{O}_{2}+48.88 \mathrm{~N}_{2}
$$

The partial pressure of water in the saturated product mixture at the dew point is

$$
P_{v, \text { prod }}=P_{\text {sat@ } @ 0^{\circ} \mathrm{C}}=19.95 \mathrm{kPa}
$$

The vapor mole fraction is

$$
y_{v}=\frac{P_{v, \text { prod }}}{P_{\text {prod }}}=\frac{19.95 \mathrm{kPa}}{100 \mathrm{kPa}}=0.1995
$$

The amount of water that needs to be sprayed into the combustion chamber can be determined from

$$
y_{v}=\frac{N_{\text {water }}}{N_{\text {total, product }}} \longrightarrow 0.1995=\frac{5+N_{v}}{4+5+N_{v}+6.5+48.88} \longrightarrow N_{v}=9.796 \mathbf{~ k m o l}
$$

15-25 A fuel mixture of $20 \%$ by mass methane, $\mathrm{CH}_{4}$, and $80 \%$ by mass ethanol, $\mathrm{C}_{2} \mathrm{H}_{6} \mathrm{O}$, is burned completely with theoretical air. The required flow rate of air is to be determined.
Assumptions 1 Combustion is complete. 2 The combustion products contain $\mathrm{CO}_{2}, \mathrm{H}_{2} \mathrm{O}$, and $\mathrm{N}_{2}$ only.
Properties The molar masses of $\mathrm{C}, \mathrm{H}_{2}, \mathrm{O}_{2}$ and air are $12 \mathrm{~kg} / \mathrm{kmol}, 2 \mathrm{~kg} / \mathrm{kmol}, 32 \mathrm{~kg} / \mathrm{kmol}$, and $29 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).
Analysis The combustion equation in this case can be written as

$$
x \mathrm{CH}_{4}+y \mathrm{C}_{2} \mathrm{H}_{6} \mathrm{O}+a_{\mathrm{th}}\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow B \mathrm{CO}_{2}+D \mathrm{H}_{2} \mathrm{O}+F \mathrm{~N}_{2}
$$

where $a_{\mathrm{th}}$ is the stoichiometric coefficient for air. The coefficient $a_{\mathrm{th}}$ and other coefficients are to be determined from the mass balances

| Carbon balance: | $x+2 y=B$ |
| :--- | :--- |
| Hydrogen balance: | $4 x+6 y=2 D$ |
| Oxygen balance: | $2 a_{\mathrm{th}}+y=2 B+D$ |
| Nitrogen balance: | $3.76 a_{\mathrm{th}}=F$ |

Solving the above equations, we find the coefficients as

$$
\begin{array}{rlrl}
x & =0.4182 & B & =1.582 \\
y & =0.5818 & D & =2.582 \\
a_{\mathrm{th}} & =2.582 & & F=9.708
\end{array}
$$

Then, we write the balanced reaction equation as

$$
0.4182 \mathrm{CH}_{4}+0.5818 \mathrm{C}_{2} \mathrm{H}_{6} \mathrm{O}+2.582\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow 1.582 \mathrm{CO}_{2}+2.582 \mathrm{H}_{2} \mathrm{O}+9.708 \mathrm{~N}_{2}
$$

The air-fuel ratio is determined by taking the ratio of the mass of the air to the mass of the fuel,

$$
\begin{aligned}
\mathrm{AF} & =\frac{m_{\text {air }}}{m_{\text {fuel }}} \\
& =\frac{(2.582 \times 4.76 \mathrm{kmol})(29 \mathrm{~kg} / \mathrm{kmol})}{(0.4182 \mathrm{kmol})(12+4 \times 1) \mathrm{kg} / \mathrm{kmol}+(0.5818 \mathrm{kmol})(2 \times 12+6 \times 1+16) \mathrm{kg} / \mathrm{kmol}} \\
& =10.64 \mathrm{~kg} \text { air } / \mathrm{kg} \text { fuel }
\end{aligned}
$$

Then, the required flow rate of air becomes

$$
\dot{m}_{\text {air }}=\mathrm{AF} \dot{m}_{\text {fuel }}=(10.64)(31 \mathrm{~kg} / \mathrm{s})=\mathbf{3 3 0} \mathbf{~ k g} / \mathrm{s}
$$

15-26 Octane is burned with 250 percent theoretical air during a combustion process. The AF ratio and the dew-pint temperature of the products are to be determined.
Assumptions 1 Combustion is complete. 2 The combustion products contain $\mathrm{CO}_{2}, \mathrm{H}_{2} \mathrm{O}, \mathrm{O}_{2}$, and $\mathrm{N}_{2}$ only. 3 Combustion gases are ideal gases.
Properties The molar masses of $\mathrm{C}, \mathrm{H}_{2}$, and air are $12 \mathrm{~kg} / \mathrm{kmol}, 2 \mathrm{~kg} / \mathrm{kmol}$, and $29 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).

Analysis (a) The combustion equation in this case can be written as

$$
\mathrm{C}_{8} \mathrm{H}_{18}+2.5 a_{\mathrm{th}}\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow 8 \mathrm{CO}_{2}+9 \mathrm{H}_{2} \mathrm{O}+1.5 a_{\mathrm{th}} \mathrm{O}_{2}+(2.5 \times 3.76) a_{\mathrm{th}} \mathrm{~N}_{2}
$$

where $a_{\mathrm{th}}$ is the stoichiometric coefficient for air.
It is determined from
$\mathrm{O}_{2}$ balance: $\quad 2.5 a_{\mathrm{th}}=8+4.5+1.5 a_{\mathrm{th}} \longrightarrow a_{\mathrm{th}}=12.5$
Substituting,

$$
\mathrm{C}_{8} \mathrm{H}_{18}+31.25\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \rightarrow 8 \mathrm{CO}_{2}+9 \mathrm{H}_{2} \mathrm{O}+18.75 \mathrm{O}_{2}+117.5 \mathrm{~N}_{2}
$$

Thus,

$$
\mathrm{AF}=\frac{m_{\text {air }}}{m_{\text {fuel }}}=\frac{(31.25 \times 4.76 \mathrm{kmol})(29 \mathrm{~kg} / \mathrm{kmol})}{(8 \mathrm{kmol})(12 \mathrm{~kg} / \mathrm{kmol})+(9 \mathrm{kmol})(2 \mathrm{~kg} / \mathrm{kmol})}=37.8 \mathbf{~ k g} \text { air } / \mathbf{k g} \text { fuel }
$$

(b) The dew-point temperature of a gas-vapor mixture is the saturation temperature of the water vapor in the product gases corresponding to its partial pressure. That is,

$$
P_{v}=\left(\frac{N_{v}}{N_{\text {prod }}}\right) P_{\text {prod }}=\left(\frac{9 \mathrm{kmol}}{153.25 \mathrm{kmol}}\right)(101.325 \mathrm{kPa})=5.951 \mathrm{kPa}
$$

Thus,

$$
T_{\mathrm{dp}}=T_{\mathrm{sat} @ 5.951 \mathrm{kPa}}=\mathbf{3 6 . 0 ^ { \circ }} \mathbf{C}
$$

15-27 Gasoline is burned steadily with air in a jet engine. The AF ratio is given. The percentage of excess air used is to be determined.

Assumptions 1 Combustion is complete. 2 The combustion products contain $\mathrm{CO}_{2}, \mathrm{H}_{2} \mathrm{O}$, and $\mathrm{N}_{2}$ only.
Properties The molar masses of $\mathrm{C}, \mathrm{H}_{2}$, and air are $12 \mathrm{~kg} / \mathrm{kmol}, 2 \mathrm{~kg} / \mathrm{kmol}$, and $29 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).
Analysis The theoretical combustion equation in this case can be written as

$$
\mathrm{C}_{8} \mathrm{H}_{18}+a_{\mathrm{th}}\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow 8 \mathrm{CO}_{2}+9 \mathrm{H}_{2} \mathrm{O}+3.76 a_{\mathrm{th}} \mathrm{~N}_{2}
$$

where $a_{\mathrm{th}}$ is the stoichiometric coefficient for air. It is determined from

Gasoline

$\mathrm{O}_{2}$ balance: $\quad a_{\mathrm{th}}=8+4.5 \longrightarrow \quad a_{\mathrm{th}}=12.5$
The air-fuel ratio for the theoretical reaction is determined by taking the ratio of the mass of the air to the mass of the fuel for,

$$
\mathrm{AF}_{\text {th }}=\frac{m_{\text {air,th }}}{m_{\text {fuel }}}=\frac{(12.5 \times 4.76 \mathrm{kmol})(29 \mathrm{~kg} / \mathrm{kmol})}{(8 \mathrm{kmol})(12 \mathrm{~kg} / \mathrm{kmol})+(9 \mathrm{kmol})(2 \mathrm{~kg} / \mathrm{kmol})}=15.14 \mathrm{~kg} \text { air } / \mathrm{kg} \text { fuel }
$$

Then the percent theoretical air used can be determined from

$$
\text { Percent theoretical air }=\frac{\mathrm{AF}_{\mathrm{act}}}{\mathrm{AF}_{\mathrm{th}}}=\frac{18 \mathrm{~kg} \text { air } / \mathrm{kg} \text { fuel }}{15.14 \mathrm{~kg} \text { air } / \mathrm{kg} \text { fuel }}=\mathbf{1 1 9 \%}
$$

15-28 n-butane is burned with stoichiometric amount of air. The mass fraction of each product, the mass of $\mathrm{CO}_{2}$ and air per unit mass of fuel burned are to be determined.

Assumptions 1 Combustion is complete. 2 The combustion products contain $\mathrm{CO}_{2}, \mathrm{H}_{2} \mathrm{O}, \mathrm{O}_{2}$, and $\mathrm{N}_{2}$ only.
Properties The molar masses of $\mathrm{C}, \mathrm{H}_{2}, \mathrm{O}_{2}$ and air are $12 \mathrm{~kg} / \mathrm{kmol}, 2 \mathrm{~kg} / \mathrm{kmol}, 32 \mathrm{~kg} / \mathrm{kmol}$, and $29 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).
Analysis The reaction equation for $100 \%$ theoretical air is

$$
\mathrm{C}_{4} \mathrm{H}_{10}+a_{\mathrm{th}}\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow B \mathrm{CO}_{2}+D \mathrm{H}_{2} \mathrm{O}+E \mathrm{~N}_{2}
$$

where $a_{\mathrm{th}}$ is the stoichiometric coefficient for air. The coefficient $a_{\mathrm{th}}$ and other coefficients are to be determined from the mass balances

Carbon balance:

$$
B=4
$$

Hydrogen balance: $\quad 2 D=10 \longrightarrow D=5$
Oxygen balance: $\quad 2 a_{\mathrm{th}}=2 B+D \longrightarrow a_{\mathrm{th}}=0.5(2 \times 4+5)=6.5$
Nitrogen balance: $\quad a_{\mathrm{th}} \times 3.76=E \longrightarrow E=6.5 \times 3.76=24.44$
Substituting, the balanced reaction equation is

$$
\mathrm{C}_{4} \mathrm{H}_{10}+6.5\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow 4 \mathrm{CO}_{2}+5 \mathrm{H}_{2} \mathrm{O}+24.44 \mathrm{~N}_{2}
$$

The mass of each product and the total mass are

$$
\begin{aligned}
m_{\mathrm{CO} 2} & =N_{\mathrm{CO} 2} M_{\mathrm{CO} 2}=(4 \mathrm{kmol})(44 \mathrm{~kg} / \mathrm{kmol})=176 \mathrm{~kg} \\
m_{\mathrm{H} 2 \mathrm{O}} & =N_{\mathrm{H} 2 \mathrm{O}} M_{\mathrm{H} 2 \mathrm{O}}=(5 \mathrm{kmol})(18 \mathrm{~kg} / \mathrm{kmol})=90 \mathrm{~kg} \\
m_{\mathrm{N} 2} & =N_{\mathrm{N} 2} M_{\mathrm{N} 2}=(24.44 \mathrm{kmol})(28 \mathrm{~kg} / \mathrm{kmol})=684 \mathrm{~kg} \\
m_{\mathrm{total}} & =m_{\mathrm{CO} 2}+m_{\mathrm{H} 2 \mathrm{O}}=176+90+684=950 \mathrm{~kg}
\end{aligned}
$$

Then the mass fractions are

$$
\begin{aligned}
\mathrm{mf}_{\mathrm{CO} 2} & =\frac{m_{\mathrm{CO} 2}}{m_{\text {total }}}=\frac{176 \mathrm{~kg}}{950 \mathrm{~kg}}=\mathbf{0 . 1 8 5 3} \\
\mathrm{mf}_{\mathrm{H} 2 \mathrm{O}} & =\frac{m_{\mathrm{H} 2 \mathrm{O}}}{m_{\text {total }}}=\frac{90 \mathrm{~kg}}{950 \mathrm{~kg}}=\mathbf{0 . 0 9 4 7} \\
\mathrm{mf}_{\mathrm{O} 2} & =\frac{m_{\mathrm{O} 2}}{m_{\text {total }}}=\frac{684 \mathrm{~kg}}{950 \mathrm{~kg}}=\mathbf{0 . 7 2 0}
\end{aligned}
$$

The mass of carbon dioxide per unit mass of fuel burned is

$$
\frac{m_{\mathrm{CO} 2}}{m_{\mathrm{C} 4 \mathrm{H} 10}}=\frac{(4 \times 44) \mathrm{kg}}{(1 \times 58) \mathrm{kg}}=\mathbf{3 . 0 3 4} \mathrm{kg} \mathrm{CO}_{2} / \mathrm{kg} \mathrm{C}_{4} \mathrm{H}_{10}
$$

The mass of air required per unit mass of fuel burned is

$$
\frac{m_{\mathrm{air}}}{m_{\mathrm{C} 4 \mathrm{H} 10}}=\frac{(6.5 \times 4.76 \times 29) \mathrm{kg}}{(1 \times 58) \mathrm{kg}}=\mathbf{1 5 . 4 7} \mathbf{~ k g ~ a i r} / \mathrm{kg} \mathrm{C}_{4} \mathrm{H}_{10}
$$

15-29 Coal whose mass percentages are specified is burned with stoichiometric amount of air. The mole fractions of the products, the apparent molecular weight of the product gas, and the air-fuel ratio are to be determined.
Assumptions 1 Combustion is complete. 2 The combustion products contain $\mathrm{CO}_{2}, \mathrm{H}_{2} \mathrm{O}, \mathrm{SO}_{2}$, and $\mathrm{N}_{2} .3$ Combustion gases are ideal gases.
Properties The molar masses of $\mathrm{C}, \mathrm{H}_{2}, \mathrm{O}_{2}, \mathrm{~S}$, and air are $12,2,32,32$, and $29 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).

Analysis The mass fractions of the constituent of the coal when the ash is substituted are

$$
\begin{aligned}
& \mathrm{mf}_{\mathrm{C}}=\frac{m_{\mathrm{C}}}{m_{\text {total }}}=\frac{84.36 \mathrm{~kg}}{(100-7.83) \mathrm{kg}}=\frac{84.36 \mathrm{~kg}}{92.17 \mathrm{~kg}}=0.9153 \\
& \mathrm{mf}_{\mathrm{H} 2}=\frac{m_{\mathrm{H} 2}}{m_{\text {total }}}=\frac{1.89 \mathrm{~kg}}{92.17 \mathrm{~kg}}=0.02051 \\
& \mathrm{mf}_{\mathrm{O} 2}=\frac{m_{\mathrm{O} 2}}{m_{\text {total }}}=\frac{4.40 \mathrm{~kg}}{92.17 \mathrm{~kg}}=0.04774 \\
& \mathrm{mf}_{\mathrm{N} 2}=\frac{m_{\mathrm{N} 2}}{m_{\text {total }}}=\frac{0.63 \mathrm{~kg}}{92.17 \mathrm{~kg}}=0.006835 \\
& \mathrm{mf}_{\mathrm{S}}=\frac{m_{\mathrm{S}}}{m_{\text {total }}}=\frac{0.89 \mathrm{~kg}}{92.17 \mathrm{~kg}}=0.009656
\end{aligned}
$$

(by mass)

We now consider 100 kg of this mixture. Then the mole numbers of each component are

$$
\begin{aligned}
N_{\mathrm{C}} & =\frac{m_{\mathrm{C}}}{M_{\mathrm{C}}}=\frac{91.53 \mathrm{~kg}}{12 \mathrm{~kg} / \mathrm{kmol}}=7.628 \mathrm{kmol} \\
N_{\mathrm{H} 2} & =\frac{m_{\mathrm{H} 2}}{M_{\mathrm{H} 2}}=\frac{2.051 \mathrm{~kg}}{2 \mathrm{~kg} / \mathrm{kmol}}=1.026 \mathrm{kmol} \\
N_{\mathrm{O} 2} & =\frac{m_{\mathrm{O} 2}}{M_{\mathrm{O} 2}}=\frac{4.774 \mathrm{~kg}}{32 \mathrm{~kg} / \mathrm{kmol}}=0.1492 \mathrm{kmol} \\
N_{\mathrm{N} 2} & =\frac{m_{\mathrm{N} 2}}{M_{\mathrm{N} 2}}=\frac{0.6835 \mathrm{~kg}}{28 \mathrm{~kg} / \mathrm{kmol}}=0.02441 \mathrm{kmol} \\
N_{\mathrm{S}} & =\frac{m_{\mathrm{S}}}{M_{\mathrm{S}}}=\frac{0.9656 \mathrm{~kg}}{32 \mathrm{~kg} / \mathrm{kmol}}=0.03018 \mathrm{kmol}
\end{aligned}
$$

The mole number of the mixture and the mole fractions are

$$
\begin{aligned}
& N_{m}=7.628+1.026+0.1492+0.02441+0.03018=8.858 \mathrm{kmol} \\
& y_{\mathrm{C}}=\frac{N_{\mathrm{C}}}{N_{m}}=\frac{7.628 \mathrm{kmol}}{8.858 \mathrm{kmol}}=0.8611 \\
& y_{\mathrm{H} 2}=\frac{N_{\mathrm{H} 2}}{N_{m}}=\frac{1.026 \mathrm{kmol}}{8.858 \mathrm{kmol}}=0.1158 \\
& y_{\mathrm{O} 2}=\frac{N_{\mathrm{O} 2}}{N_{m}}=\frac{0.1492 \mathrm{kmol}}{8.858 \mathrm{kmol}}=0.01684 \\
& y_{\mathrm{N} 2}=\frac{N_{\mathrm{N} 2}}{N_{m}}=\frac{0.02441 \mathrm{kmol}}{8.858 \mathrm{kmol}}=0.002756 \\
& y_{\mathrm{S}}=\frac{N_{\mathrm{S}}}{N_{m}}=\frac{0.03018 \mathrm{kmol}}{8.858 \mathrm{kmol}}=0.003407
\end{aligned}
$$

Then, the combustion equation in this case may be written as

$$
\begin{aligned}
0.8611 \mathrm{C}+0.1158 \mathrm{H}_{2}+0.01684 \mathrm{O}_{2}+ & 0.002756 \mathrm{~N}_{2}+0.003407 \mathrm{~S}+a_{\mathrm{th}}\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \\
& x \mathrm{CO}_{2}+y \mathrm{H}_{2} \mathrm{O}+\mathrm{zSO}_{2}+k \mathrm{~N}_{2}
\end{aligned}
$$

According to the species balances,
C balance: $x=0.8611$
$\mathrm{H}_{2}$ balance: $y=0.1158$
S balance: $z=0.003407$
$\mathrm{O}_{2}$ balance:

$$
\begin{aligned}
& 0.01684+a_{\mathrm{th}}=x+0.5 y+z \\
& a_{\mathrm{th}}=0.8611+0.5(0.1158)+0.003407-0.01684=0.9056 \\
& \mathrm{~N}_{2} \text { balance }: \quad k=0.002756+3.76 a_{\mathrm{th}}=0.002756+3.76 \times 0.9056=3.408
\end{aligned}
$$

Substituting,

$$
\begin{aligned}
0.8611 \mathrm{C}+0.1158 \mathrm{H}_{2}+0.01684 \mathrm{O}_{2} & +0.002756 \mathrm{~N}_{2}+0.003407 \mathrm{~S}+0.9056\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \\
& \longrightarrow 0.8611 \mathrm{CO}_{2}+0.1158 \mathrm{H}_{2} \mathrm{O}+0.00341 \mathrm{SO}_{2}+3.408 \mathrm{~N}_{2}
\end{aligned}
$$

The mole fractions of the products are

$$
\begin{aligned}
& N_{m}=0.8611+0.1158+0.00341+3.408=4.388 \mathrm{kmol} \\
& y_{\mathrm{CO} 2}=\frac{N_{\mathrm{CO} 2}}{N_{m}}=\frac{0.8611 \mathrm{kmol}}{4.388 \mathrm{kmol}}=\mathbf{0 . 1 9 6 2} \\
& y_{\mathrm{H} 2 \mathrm{O}}=\frac{N_{\mathrm{H} 2 \mathrm{O}}}{N_{m}}=\frac{0.1158 \mathrm{kmol}}{4.388 \mathrm{kmol}}=\mathbf{0 . 0 2 6 3 9} \\
& y_{\mathrm{SO} 2}=\frac{N_{\mathrm{SO} 2}}{N_{m}}=\frac{0.00341 \mathrm{kmol}}{4.388 \mathrm{kmol}}=\mathbf{0 . 0 0 0 7 8} \\
& y_{\mathrm{N} 2}=\frac{N_{\mathrm{N} 2}}{N_{m}}=\frac{3.408 \mathrm{kmol}}{4.388 \mathrm{kmol}}=\mathbf{0 . 7 7 6 7}
\end{aligned}
$$

The apparent molecular weight of the product gas is

$$
M_{m}=\frac{m_{m}}{N_{m}}=\frac{(0.8611 \times 44+0.1158 \times 18+0.00341 \times 64+3.408 \times 28) \mathrm{kg}}{4.388 \mathrm{kmol}}=\mathbf{3 0 . 9 1} \mathbf{k g} / \mathbf{k m o l}
$$

The air-fuel mass ratio is then

$$
\begin{aligned}
\mathrm{AF} & =\frac{m_{\text {air }}}{m_{\text {fuel }}}=\frac{(0.9056 \times 4.76 \times 29) \mathrm{kg}}{(0.8611 \times 12+0.1158 \times 2+0.01684 \times 32+0.002756 \times 28+0.003408 \times 32) \mathrm{kg}} \\
& =\frac{125.0 \mathrm{~kg}}{11.29 \mathrm{~kg}}=\mathbf{1 1 . 0 7} \mathbf{~ k g} \text { air } / \mathrm{kg} \text { fuel }
\end{aligned}
$$

15-30 Methyl alcohol is burned with stoichiometric amount of air. The mole fraction of each product, the apparent molar mass of the product gas, and the mass of water in the products per unit mass of fuel burned are to be determined.

Assumptions 1 Combustion is complete. 2 The combustion products contain $\mathrm{CO}_{2}, \mathrm{H}_{2} \mathrm{O}$, and $\mathrm{N}_{2}$ only.
Properties The molar masses of C, $\mathrm{H}_{2}, \mathrm{O}_{2}$ and air are $12 \mathrm{~kg} / \mathrm{kmol}, 2 \mathrm{~kg} / \mathrm{kmol}, 32 \mathrm{~kg} / \mathrm{kmol}$, and $29 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).
Analysis The balanced reaction equation for stoichiometric air is

$$
\mathrm{CH}_{3} \mathrm{OH}+1.5\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow \mathrm{CO}_{2}+2 \mathrm{H}_{2} \mathrm{O}+5.64 \mathrm{~N}_{2}
$$

The mole fractions of the products are

$$
\begin{aligned}
& N_{m}=1+2+5.64=8.64 \mathrm{kmol} \\
& y_{\mathrm{CO} 2}=\frac{N_{\mathrm{CO} 2}}{N_{m}}=\frac{1 \mathrm{kmol}}{8.64 \mathrm{kmol}}=\mathbf{0 . 1 1 5 7} \\
& y_{\mathrm{H} 2 \mathrm{O}}=\frac{N_{\mathrm{H} 2 \mathrm{O}}}{N_{m}}=\frac{2 \mathrm{kmol}}{8.64 \mathrm{kmol}}=\mathbf{0 . 2 3 1 5} \\
& y_{\mathrm{N} 2}=\frac{N_{\mathrm{N} 2}}{N_{m}}=\frac{5.64 \mathrm{kmol}}{8.64 \mathrm{kmol}}=\mathbf{0 . 6 5 2 8}
\end{aligned}
$$

The apparent molecular weight of the product gas is

$$
M_{m}=\frac{m_{m}}{N_{m}}=\frac{(1 \times 44+2 \times 18+5.64 \times 28) \mathrm{kg}}{8.64 \mathrm{kmol}}=\mathbf{2 7 . 5 4} \mathbf{~ k g} / \mathbf{k m o l}
$$

The mass of water in the products per unit mass of fuel burned is

$$
\frac{m_{\mathrm{H} 2 \mathrm{O}}}{m_{\mathrm{CH} 3 \mathrm{OH}}}=\frac{(2 \times 18) \mathrm{kg}}{(1 \times 32) \mathrm{kg}}=\mathbf{1 . 1 2 5 \mathbf { k g ~ H } _ { 2 } \mathrm { O } / \mathrm { kg } \mathrm { CH } _ { 3 } \mathrm { OH }}
$$

15-31 Coal whose mass percentages are specified is burned with stoichiometric amount of air. The combustion is incomplete. The mass fractions of the products, the apparent molecular weight of the product gas, and the air-fuel ratio are to be determined.
Assumptions 1 Combustion is complete. 2 The combustion products contain $\mathrm{CO}_{2}, \mathrm{CO}, \mathrm{H}_{2} \mathrm{O}, \mathrm{SO}_{2}$, and $\mathrm{N}_{2}$. 3 Combustion gases are ideal gases.
Properties The molar masses of $\mathrm{C}, \mathrm{H}_{2}, \mathrm{O}_{2}, \mathrm{~S}$, and air are $12,2,32,32$, and $29 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).

Analysis The mass fractions of the constituent of the coal when the ash is substituted are

$$
\begin{aligned}
& \mathrm{mf}_{\mathrm{C}}=\frac{m_{\mathrm{C}}}{m_{\text {total }}}=\frac{61.40 \mathrm{~kg}}{(100-5.00) \mathrm{kg}}=\frac{61.40 \mathrm{~kg}}{95.00 \mathrm{~kg}}=0.6463 \\
& \mathrm{mf}_{\mathrm{H} 2}=\frac{m_{\mathrm{H} 2}}{m_{\text {total }}}=\frac{5.79 \mathrm{~kg}}{95.00 \mathrm{~kg}}=0.06095 \\
& \mathrm{mf}_{\mathrm{O} 2}=\frac{m_{\mathrm{O} 2}}{m_{\text {total }}}=\frac{25.31 \mathrm{~kg}}{95.00 \mathrm{~kg}}=0.2664 \\
& \mathrm{mf}_{\mathrm{N} 2}=\frac{m_{\mathrm{N} 2}}{m_{\text {total }}}=\frac{1.09 \mathrm{~kg}}{95.00 \mathrm{~kg}}=0.01147 \\
& \mathrm{mf}_{\mathrm{S}}=\frac{m_{\mathrm{S}}}{m_{\text {total }}}=\frac{1.41 \mathrm{~kg}}{95.00 \mathrm{~kg}}=0.01484
\end{aligned}
$$

$61.40 \% \mathrm{C}$
$5.79 \% \mathrm{H}_{2}$
$25.31 \% \mathrm{O}_{2}$
$1.09 \% \mathrm{~N}_{2}$
$1.41 \% \mathrm{~S}$
$5.00 \%$ ash
(by mass)

We now consider 100 kg of this mixture. Then the mole numbers of each component are

$$
\begin{aligned}
N_{\mathrm{C}} & =\frac{m_{\mathrm{C}}}{M_{\mathrm{C}}}=\frac{64.63 \mathrm{~kg}}{12 \mathrm{~kg} / \mathrm{kmol}}=5.386 \mathrm{kmol} \\
N_{\mathrm{H} 2} & =\frac{m_{\mathrm{H} 2}}{M_{\mathrm{H} 2}}=\frac{6.095 \mathrm{~kg}}{2 \mathrm{~kg} / \mathrm{kmol}}=3.048 \mathrm{kmol} \\
N_{\mathrm{O} 2} & =\frac{m_{\mathrm{O} 2}}{M_{\mathrm{O} 2}}=\frac{26.64 \mathrm{~kg}}{32 \mathrm{~kg} / \mathrm{kmol}}=0.8325 \mathrm{kmol} \\
N_{\mathrm{N} 2} & =\frac{m_{\mathrm{N} 2}}{M_{\mathrm{N} 2}}=\frac{1.147 \mathrm{~kg}}{28 \mathrm{~kg} / \mathrm{kmol}}=0.04096 \mathrm{kmol} \\
N_{\mathrm{S}} & =\frac{m_{\mathrm{S}}}{M_{\mathrm{S}}}=\frac{1.484 \mathrm{~kg}}{32 \mathrm{~kg} / \mathrm{kmol}}=0.04638 \mathrm{kmol}
\end{aligned}
$$

The mole number of the mixture and the mole fractions are

$$
\begin{aligned}
& N_{m}=5.386+3.048+0.8325+0.04096+0.04638=9.354 \mathrm{kmol} \\
& y_{\mathrm{C}}=\frac{N_{\mathrm{C}}}{N_{m}}=\frac{5.386 \mathrm{kmol}}{9.354 \mathrm{kmol}}=0.5758 \\
& y_{\mathrm{H} 2}=\frac{N_{\mathrm{H} 2}}{N_{m}}=\frac{3.048 \mathrm{kmol}}{9.354 \mathrm{kmol}}=0.3258 \\
& y_{\mathrm{O} 2}=\frac{N_{\mathrm{O} 2}}{N_{m}}=\frac{0.8325 \mathrm{kmol}}{9.354 \mathrm{kmol}}=0.0890 \\
& y_{\mathrm{N} 2}=\frac{N_{\mathrm{N} 2}}{N_{m}}=\frac{0.04096 \mathrm{kmol}}{9.354 \mathrm{kmol}}=0.00438 \\
& y_{\mathrm{S}}=\frac{N_{\mathrm{S}}}{N_{m}}=\frac{0.04638 \mathrm{kmol}}{9.354 \mathrm{kmol}}=0.00496
\end{aligned}
$$

Then, the combustion equation in this case may be written as

$$
\begin{aligned}
& 0.5758 \mathrm{C}+0.3258 \mathrm{H}_{2}+0.0890 \mathrm{O}_{2}+0.00438 \mathrm{~N}_{2}+0.00496 \mathrm{~S}+a_{\mathrm{th}}\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \\
& \longrightarrow x\left(0.95 \mathrm{CO}_{2}+0.05 \mathrm{CO}\right)+y \mathrm{H}_{2} \mathrm{O}+z \mathrm{SO}_{2}+k \mathrm{~N}_{2}
\end{aligned}
$$

According to the species balances,
C balance: $x=0.5758$
$\mathrm{H}_{2}$ balance: $y=0.3258$
S balance: $z=0.00496$
$\mathrm{O}_{2}$ balance:

$$
\begin{aligned}
& 0.0890+a_{\text {th }}=0.95 x+0.5 \times 0.05 x+0.5 y+z \\
& a_{\text {th }}=0.95 \times 0.5758+0.5 \times 0.05 \times 0.5758+0.5 \times 0.3258+0.00496-0.0890=0.6403 \\
& \mathrm{~N}_{2} \text { balance }: k=0.00438+3.76 a_{\text {th }}=0.00438+3.76 \times 0.6403=2.412
\end{aligned}
$$

Substituting,

$$
\begin{aligned}
0.5758 \mathrm{C}+0.3258 \mathrm{H}_{2}+0.0890 \mathrm{O}_{2} & +0.00438 \mathrm{~N}_{2}+0.00496 \mathrm{~S}+0.7293\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \\
\longrightarrow & 0.5470 \mathrm{CO}_{2}+0.0288 \mathrm{CO}+0.3258 \mathrm{H}_{2} \mathrm{O}+0.00496 \mathrm{SO}_{2}+2.412 \mathrm{~N}_{2}
\end{aligned}
$$

The mass fractions of the products are

$$
\begin{aligned}
& m_{\text {total }}=0.5470 \times 44+0.0288 \times 28+0.3258 \times 18+0.00496 \times 64+2.412 \times 28=98.6 \mathrm{~kg} \\
& \mathrm{mf}_{\mathrm{CO} 2}=\frac{m_{\mathrm{CO} 2}}{m_{\text {total }}}=\frac{(0.5470 \times 44) \mathrm{kg}}{98.6 \mathrm{~kg}}=\mathbf{0 . 2 4 4 1} \\
& \mathrm{mf}_{\mathrm{CO}}=\frac{m_{\mathrm{CO}}}{m_{\text {total }}}=\frac{(0.0288 \times 28) \mathrm{kg}}{98.6 \mathrm{~kg}}=\mathbf{0 . 0 0 8 2} \\
& \mathrm{mf}_{\mathrm{H} 2 \mathrm{O}}=\frac{m_{\mathrm{H} 2 \mathrm{O}}}{m_{\text {total }}}=\frac{(0.3258 \times 18) \mathrm{kg}}{98.6 \mathrm{~kg}}=\mathbf{0 . 0 5 9 5} \\
& \mathrm{mf}_{\mathrm{SO} 2}=\frac{m_{\text {SO2 }}}{m_{\text {total }}}=\frac{(0.00496 \times 64) \mathrm{kg}}{98.6 \mathrm{~kg}}=\mathbf{0 . 0 0 3 2} \\
& \mathrm{mf}_{\mathrm{N} 2}=\frac{m_{\mathrm{N} 2}}{m_{\text {total }}}=\frac{(2.412 \times 28) \mathrm{kg}}{98.6 \mathrm{~kg}}=\mathbf{0 . 6 8 4 9}
\end{aligned}
$$

The total mole number of the products is

$$
N_{m}=0.5470+0.0288+0.3258+0.00496+2.712=3.319 \mathrm{kmol}
$$

The apparent molecular weight of the product gas is

$$
M_{m}=\frac{m_{m}}{N_{m}}=\frac{98.6 \mathrm{~kg}}{3.319 \mathrm{kmol}}=29.71 \mathrm{~kg} / \mathrm{kmol}
$$

The air-fuel mass ratio is then

$$
\begin{aligned}
\mathrm{AF} & =\frac{m_{\text {air }}}{m_{\text {fuel }}}=\frac{(0.6403 \times 4.76 \times 29) \mathrm{kg}}{(0.5758 \times 12+0.3258 \times 2+0.0890 \times 32+0.00438 \times 28+0.00496 \times 32) \mathrm{kg}} \\
& =\frac{88.39 \mathrm{~kg}}{10.69 \mathrm{~kg}} \\
& =\mathbf{8 . 2 7} \mathbf{~ k g} \text { air } / \mathbf{k g} \text { fuel }
\end{aligned}
$$

15-32 Propane is burned with 30 percent excess air. The mole fractions of each of the products, the mass of water in the products per unit mass of the fuel, and the air-fuel ratio are to be determined.

Assumptions 1 Combustion is complete. 2 The combustion products contain $\mathrm{CO}_{2}, \mathrm{H}_{2} \mathrm{O}, \mathrm{O}_{2}$, and $\mathrm{N}_{2}$ only.
Properties The molar masses of $\mathrm{C}, \mathrm{H}_{2}, \mathrm{O}_{2}$, and air are $12 \mathrm{~kg} / \mathrm{kmol}, 2 \mathrm{~kg} / \mathrm{kmol}, 32 \mathrm{~kg} / \mathrm{kmol}$, and $29 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).
Analysis The combustion equation in this case can be written as

$$
\mathrm{C}_{3} \mathrm{H}_{8}+1.3 a_{\mathrm{th}}\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow 3 \mathrm{CO}_{2}+4 \mathrm{H}_{2} \mathrm{O}+0.3 a_{\mathrm{th}} \mathrm{O}_{2}+(1.3 \times 3.76) a_{\mathrm{th}} \mathrm{~N}_{2}
$$

where $a_{\mathrm{th}}$ is the stoichiometric coefficient for air. We have automatically accounted for the $30 \%$ excess air by using the factor $1.3 a_{\mathrm{th}}$ instead of $a_{\mathrm{th}}$ for air. The stoichiometric amount of oxygen $\left(a_{\mathrm{th}} \mathrm{O}_{2}\right)$ will be used to oxidize the fuel, and the remaining excess amount $\left(0.3 a_{\mathrm{th}} \mathrm{O}_{2}\right)$ will appear in the products as free oxygen. The coefficient $a_{\mathrm{th}}$ is determined from the $\mathrm{O}_{2}$ balance,
$\mathrm{O}_{2}$ balance: $\quad 1.3 a_{\mathrm{th}}=3+2+0.3 a_{\mathrm{th}} \longrightarrow a_{\mathrm{th}}=5$
Substituting, $\quad \mathrm{C}_{3} \mathrm{H}_{8}+6.5\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow 3 \mathrm{CO}_{2}+4 \mathrm{H}_{2} \mathrm{O}+1.5 \mathrm{O}_{2}+24.44 \mathrm{~N}_{2}$
The mole fractions of the products are

$$
\begin{aligned}
& N_{m}=3+4+1.5+24.44=32.94 \mathrm{kmol} \\
& y_{\mathrm{CO} 2}=\frac{N_{\mathrm{CO} 2}}{N_{m}}=\frac{3 \mathrm{kmol}}{32.94 \mathrm{kmol}}=\mathbf{0 . 0 9 1 1} \\
& y_{\mathrm{H} 2 \mathrm{O}}=\frac{N_{\mathrm{H} 2 \mathrm{O}}}{N_{m}}=\frac{4 \mathrm{kmol}}{32.94 \mathrm{kmol}}=\mathbf{0 . 1 2 1 4} \\
& y_{\mathrm{O} 2}=\frac{N_{\mathrm{O} 2}}{N_{m}}=\frac{1.5 \mathrm{kmol}}{32.94 \mathrm{kmol}}=\mathbf{0 . 0 4 5 5} \\
& y_{\mathrm{N} 2}=\frac{N_{\mathrm{N} 2}}{N_{m}}=\frac{24.44 \mathrm{kmol}}{32.94 \mathrm{kmol}}=\mathbf{0 . 7 4 2 0}
\end{aligned}
$$

The mass of water in the products per unit mass of fuel burned is

$$
\frac{m_{\mathrm{H} 2 \mathrm{O}}}{m_{\mathrm{C} 3 \mathrm{H} 8}}=\frac{(4 \times 18) \mathrm{kg}}{(1 \times 44) \mathrm{kg}}=1.636 \mathrm{~kg} \mathrm{H}_{2} \mathrm{O} / \mathrm{kg} \mathrm{C}_{3} \mathrm{H}_{8}
$$

The air-fuel ratio is determined by taking the ratio of the mass of the air to the mass of the fuel,

$$
\mathrm{AF}=\frac{m_{\text {air }}}{m_{\text {fuel }}}=\frac{(6.5 \times 4.76 \mathrm{kmol})(29 \mathrm{~kg} / \mathrm{kmol})}{(3 \mathrm{kmol})(12 \mathrm{~kg} / \mathrm{kmol})+(4 \mathrm{kmol})(2 \mathrm{~kg} / \mathrm{kmol})}=\mathbf{2 0 . 3 9} \mathbf{~ k g} \text { air } / \mathbf{k g} \text { fuel }
$$

15-33 The volumetric fractions of the constituents of a certain natural gas are given. The AF ratio is to be determined if this gas is burned with the stoichiometric amount of dry air.
Assumptions 1 Combustion is complete. 2 The combustion products contain $\mathrm{CO}_{2}, \mathrm{H}_{2} \mathrm{O}$, and $\mathrm{N}_{2}$ only.
Properties The molar masses of $\mathrm{C}, \mathrm{H}_{2}, \mathrm{~N}_{2}, \mathrm{O}_{2}$, and air are $12 \mathrm{~kg} / \mathrm{kmol}, 2 \mathrm{~kg} / \mathrm{kmol}, 28 \mathrm{~kg} / \mathrm{kmol}, 32 \mathrm{~kg} / \mathrm{kmol}$, and $29 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).
Analysis Considering 1 kmol of fuel, the combustion equation can be written as

$$
\left(0.65 \mathrm{CH}_{4}+0.08 \mathrm{H}_{2}+0.18 \mathrm{~N}_{2}+0.03 \mathrm{O}_{2}+0.06 \mathrm{CO}_{2}\right)+a_{\mathrm{th}}\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow x \mathrm{CO}_{2}+y \mathrm{H}_{2} \mathrm{O}+z \mathrm{~N}_{2}
$$

The unknown coefficients in the above equation are determined from mass balances,

$$
\begin{aligned}
& \mathrm{C}: 0.65+0.06=x \quad \longrightarrow x=0.71 \\
& \mathrm{H}: 0.65 \times 4+0.08 \times 2=2 y \quad \longrightarrow y=1.38 \\
& \mathrm{O}_{2}: 0.03+0.06+a_{\mathrm{th}}=x+y / 2 \longrightarrow a_{\mathrm{th}}=1.31 \\
& \mathrm{~N}_{2}: 0.18+3.76 a_{\mathrm{th}}=z \quad \mathrm{z}=5.106
\end{aligned}
$$

Thus,

$$
\begin{aligned}
&\left(0.65 \mathrm{CH}_{4}+0.08 \mathrm{H}_{2}+0.18 \mathrm{~N}_{2}+0.03 \mathrm{O}_{2}+0.06 \mathrm{CO}_{2}\right)+1.31\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \\
& \\
& 0.71 \mathrm{CO}_{2}+1.38 \mathrm{H}_{2} \mathrm{O}+5.106 \mathrm{~N}_{2}
\end{aligned}
$$

The air-fuel ratio for the this reaction is determined by taking the ratio of the mass of the air to the mass of the fuel,

$$
\begin{aligned}
m_{\text {air }} & =(1.31 \times 4.76 \mathrm{kmol})(29 \mathrm{~kg} / \mathrm{kmol})=180.8 \mathrm{~kg} \\
m_{\text {fuel }} & =(0.65 \times 16+0.08 \times 2+0.18 \times 28+0.03 \times 32+0.06 \times 44) \mathrm{kg}=19.2 \mathrm{~kg}
\end{aligned}
$$

and

$$
\mathrm{AF}_{\mathrm{th}}=\frac{m_{\text {air,th }}}{m_{\text {fuel }}}=\frac{180.8 \mathrm{~kg}}{19.2 \mathrm{~kg}}=\mathbf{9 . 4 2} \mathbf{~ k g ~ a i r} / \mathbf{k g} \text { fuel }
$$

15-34 The composition of a certain natural gas is given. The gas is burned with stoichiometric amount of moist air. The AF ratio is to be determined.
Assumptions 1 Combustion is complete. 2 The combustion products contain $\mathrm{CO}_{2}, \mathrm{H}_{2} \mathrm{O}$, and $\mathrm{N}_{2}$ only.
Properties The molar masses of $\mathrm{C}, \mathrm{H}_{2}, \mathrm{~N}_{2}, \mathrm{O}_{2}$, and air are $12 \mathrm{~kg} / \mathrm{kmol}, 2 \mathrm{~kg} / \mathrm{kmol}, 28 \mathrm{~kg} / \mathrm{kmol}, 32 \mathrm{~kg} / \mathrm{kmol}$, and $29 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).
Analysis The fuel is burned completely with the stoichiometric amount of air, and thus the products will contain only $\mathrm{H}_{2} \mathrm{O}, \mathrm{CO}_{2}$ and $\mathrm{N}_{2}$, but no free $\mathrm{O}_{2}$. The moisture in the air does not react with anything; it simply shows up as additional $\mathrm{H}_{2} \mathrm{O}$ in the products. Therefore, we can simply balance the combustion equation using dry air, and then add the moisture to both sides of the equation. Considering 1 kmol of fuel, the combustion equation can be written as

$$
\left(0.65 \mathrm{CH}_{4}+0.08 \mathrm{H}_{2}+0.18 \mathrm{~N}_{2}+0.03 \mathrm{O}_{2}+0.06 \mathrm{CO}_{2}\right)+a_{\mathrm{th}}\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow x \mathrm{CO}_{2}+y \mathrm{H}_{2} \mathrm{O}+z \mathrm{~N}_{2}
$$

The unknown coefficients in the above equation are determined from mass balances,

$$
\begin{aligned}
& \mathrm{C}: 0.65+0.06=x \quad \longrightarrow x=0.71 \\
& \mathrm{H}: 0.65 \times 4+0.08 \times 2=2 y \quad \longrightarrow y=1.38 \\
& \mathrm{O}_{2}: 0.03+0.06+a_{\mathrm{th}}=x+y / 2 \longrightarrow a_{\mathrm{th}}=1.31 \\
& \mathrm{~N}_{2}: 0.18+3.76 a_{\mathrm{th}}=z \quad \longrightarrow z=5.106
\end{aligned}
$$

Thus,

$$
\begin{aligned}
\left(0.65 \mathrm{CH}_{4}+0.08 \mathrm{H}_{2}+0.18 \mathrm{~N}_{2}+0.03 \mathrm{O}_{2}+0.06 \mathrm{CO}_{2}\right)+1.31\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \\
\longrightarrow 0.71 \mathrm{CO}_{2}+1.38 \mathrm{H}_{2} \mathrm{O}+5.106 \mathrm{~N}_{2}
\end{aligned}
$$

Next we determine the amount of moisture that accompanies $4.76 a_{\mathrm{th}}=(4.76)(1.31)=6.24 \mathrm{kmol}$ of dry air. The partial pressure of the moisture in the air is

$$
P_{v, \text { in }}=\phi_{\text {air }} P_{\text {sat } @ 25^{\circ} \mathrm{C}}=(0.85)(3.1698 \mathrm{kPa})=2.694 \mathrm{kPa}
$$

Assuming ideal gas behavior, the number of moles of the moisture in the air ( $\mathrm{N}_{\mathrm{v}, \text { in }}$ ) is determined to be

$$
N_{v, \text { in }}=\left(\frac{P_{v, \text { in }}}{P_{\text {total }}}\right) N_{\text {total }}=\left(\frac{2.694 \mathrm{kPa}}{101.325 \mathrm{kPa}}\right)\left(6.24+N_{v, \text { in }}\right) \longrightarrow N_{v, \text { air }}=0.17 \mathrm{kmol}
$$

The balanced combustion equation is obtained by substituting the coefficients determined earlier and adding 0.17 kmol of $\mathrm{H}_{2} \mathrm{O}$ to both sides of the equation,

$$
\begin{aligned}
\left(0.65 \mathrm{CH}_{4}+0.08 \mathrm{H}_{2}+0.18 \mathrm{~N}_{2}+0.03 \mathrm{O}_{2}+0.06 \mathrm{CO}_{2}\right)+1.31\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right)+0.17 \mathrm{H}_{2} \mathrm{O} \\
\longrightarrow 0.71 \mathrm{CO}_{2}+1.55 \mathrm{H}_{2} \mathrm{O}+5.106 \mathrm{~N}_{2}
\end{aligned}
$$

The air-fuel ratio for the this reaction is determined by taking the ratio of the mass of the air to the mass of the fuel,

$$
\begin{aligned}
m_{\text {air }} & =(1.31 \times 4.76 \mathrm{kmol})(29 \mathrm{~kg} / \mathrm{kmol})+(0.17 \mathrm{kmol} \times 18 \mathrm{~kg} / \mathrm{kmol})=183.9 \mathrm{~kg} \\
m_{\text {fuel }} & =(0.65 \times 16+0.08 \times 2+0.18 \times 28+0.03 \times 32+0.06 \times 44) \mathrm{kg}=19.2 \mathrm{~kg}
\end{aligned}
$$

and

$$
\mathrm{AF}_{\mathrm{th}}=\frac{m_{\text {air, th }}}{m_{\text {fuel }}}=\frac{183.9 \mathrm{~kg}}{19.2 \mathrm{~kg}}=\mathbf{9 . 5 8} \mathbf{~ k g ~ a i r} / \mathbf{k g} \text { fuel }
$$

15-35 The composition of a gaseous fuel is given. It is burned with 130 percent theoretical air. The AF ratio and the fraction of water vapor that would condense if the product gases were cooled are to be determined.

Assumptions 1 Combustion is complete. 2 The combustion products contain $\mathrm{CO}_{2}, \mathrm{H}_{2} \mathrm{O}, \mathrm{O}_{2}$, and $\mathrm{N}_{2}$ only.
Properties The molar masses of $\mathrm{C}, \mathrm{H}_{2}, \mathrm{~N}_{2}$, and air are $12 \mathrm{~kg} / \mathrm{kmol}, 2 \mathrm{~kg} / \mathrm{kmol}, 28 \mathrm{~kg} / \mathrm{kmol}$, and $29 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).
Analysis (a) The fuel is burned completely with excess air, and thus the products will contain $\mathrm{H}_{2} \mathrm{O}, \mathrm{CO}_{2}$, $\mathrm{N}_{2}$, and some free $\mathrm{O}_{2}$. Considering 1 kmol of fuel, the combustion equation can be written as

$$
\left(0.60 \mathrm{CH}_{4}+0.30 \mathrm{H}_{2}+0.10 \mathrm{~N}_{2}\right)+1.3 a_{\mathrm{th}}\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow x \mathrm{CO}_{2}+y \mathrm{H}_{2} \mathrm{O}+0.3 a_{\mathrm{th}} \mathrm{O}_{2}+z \mathrm{~N}_{2}
$$

The unknown coefficients in the above equation are determined from mass balances,

$$
\begin{aligned}
& \mathrm{C}: 0.60=x \quad \longrightarrow x=0.60 \\
& \mathrm{H}: 0.60 \times 4+0.30 \times 2=2 y \quad \longrightarrow y=1.50 \\
& \mathrm{O}_{2}: 1.3 a_{\mathrm{th}}=x+y / 2+0.3 a_{\mathrm{th}} \quad \longrightarrow a_{\mathrm{th}}=1.35 \\
& \mathrm{~N}_{2}: 0.10+3.76 \times 1.3 a_{\mathrm{th}}=z \quad \longrightarrow z=6.70
\end{aligned}
$$

Thus,

$$
\left(0.60 \mathrm{CH}_{4}+0.30 \mathrm{H}_{2}+0.10 \mathrm{~N}_{2}\right)+1.755\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 0.6 \mathrm{CO}_{2}+1.5 \mathrm{H}_{2} \mathrm{O}+0.405 \mathrm{O}_{2}+6.7 \mathrm{~N}_{2}
$$

The air-fuel ratio for the this reaction is determined by taking the ratio of the mass of the air to the mass of the fuel,

$$
\begin{aligned}
m_{\text {air }} & =(1.755 \times 4.76 \mathrm{kmol})(29 \mathrm{~kg} / \mathrm{kmol})=242.3 \mathrm{~kg} \\
m_{\text {fuel }} & =(0.6 \times 16+0.3 \times 2+0.1 \times 28) \mathrm{kg}=13.0 \mathrm{~kg}
\end{aligned}
$$

and

$$
\mathrm{AF}=\frac{m_{\text {air }}}{m_{\text {fuel }}}=\frac{242.3 \mathrm{~kg}}{13.0 \mathrm{~kg}}=\mathbf{1 8 . 6} \mathbf{~ k g ~ a i r} / \mathbf{k g} \text { fuel }
$$

(b) For each kmol of fuel burned, $0.6+1.5+0.405+6.7=9.205 \mathrm{kmol}$ of products are formed, including 1.5 kmol of $\mathrm{H}_{2} \mathrm{O}$. Assuming that the dew-point temperature of the products is above $20^{\circ} \mathrm{C}$, some of the water vapor will condense as the products are cooled to $20^{\circ} \mathrm{C}$. If $N_{w} \mathrm{kmol}$ of $\mathrm{H}_{2} \mathrm{O}$ condenses, there will be $1.5-N_{w} \mathrm{kmol}$ of water vapor left in the products. The mole number of the products in the gas phase will also decrease to $9.205-N_{w}$ as a result. Treating the product gases (including the remaining water vapor) as ideal gases, $N_{w}$ is determined by equating the mole fraction of the water vapor to its pressure fraction,

$$
\frac{N_{v}}{N_{\text {prod,gas }}}=\frac{P_{v}}{P_{\text {prod }}} \longrightarrow \frac{1.5-N_{w}}{9.205-N_{w}}=\frac{2.3392 \mathrm{kPa}}{101.325 \mathrm{kPa}} \longrightarrow N_{w}=1.32 \mathrm{kmol}
$$

since $P_{v}=P_{\text {sat @ } 20^{\circ} \mathrm{C}}=2.3392 \mathrm{kPa}$. Thus the fraction of water vapor that condenses is $1.32 / 1.5=0.88$ or 88\%.

15-36 EES Problem 15-35 is reconsidered. The effects of varying the percentages of $\mathrm{CH} 4, \mathrm{H} 2$ and N 2 making up the fuel and the product gas temperature are to be studied.

Analysis The problem is solved using EES, and the solution is given below.

Let's modify this problem to include the fuels butane, ethane, methane, and propane in pull down menu. Adiabatic Combustion of fuel CnHm entering at $\mathrm{T}_{\mathrm{I}}$ fuel with Stoichiometric Air at T_air:
Reaction: $a C x H y+b H 2+c N 2+\left(a^{*} y / 4+a^{*} x+b / 2\right)($ Theo_air/100) (O2 + 3.76 N2)

 educators for course preparation. If you are a student using this Manual, you are using it without permission.

15-37 Carbon is burned with dry air. The volumetric analysis of the products is given. The AF ratio and the percentage of theoretical air used are to be determined.
Assumptions 1 Combustion is complete. 2 The combustion products contain $\mathrm{CO}_{2}, \mathrm{CO}, \mathrm{O}_{2}$, and $\mathrm{N}_{2}$ only.
Properties The molar masses of $\mathrm{C}, \mathrm{H}_{2}$, and air are $12 \mathrm{~kg} / \mathrm{kmol}, 2 \mathrm{~kg} / \mathrm{kmol}$, and $29 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).
Analysis Considering 100 kmol of dry products, the combustion equation can be written as

$$
\mathrm{xC}+\mathrm{a}\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow 10.06 \mathrm{CO}_{2}+0.42 \mathrm{CO}+10.69 \mathrm{O}_{2}+78.83 \mathrm{~N}_{2}
$$

The unknown coefficients $x$ and $a$ are determined from mass balances,

$$
\begin{array}{ll}
\mathrm{N}_{2}: 3.76 a=78.83 & \longrightarrow a=20.965 \\
\mathrm{C}: x=10.06+0.42 & \longrightarrow x=10.48
\end{array}
$$

(CheckO $2: a=10.06+0.21+10.69 \longrightarrow 20.96=20.96$ )

Thus,

$$
10.48 \mathrm{C}+20.96\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow 10.06 \mathrm{CO}_{2}+0.42 \mathrm{CO}+10.69 \mathrm{O}_{2}+78.83 \mathrm{~N}_{2}
$$

The combustion equation for 1 kmol of fuel is obtained by dividing the above equation by 10.48 ,

$$
\mathrm{C}+2.0\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow 0.96 \mathrm{CO}_{2}+0.04 \mathrm{CO}+1.02 \mathrm{O}_{2}+7.52 \mathrm{~N}_{2}
$$

(a) The air-fuel ratio is determined by taking the ratio of the mass of the air to the mass of the fuel,

$$
\mathrm{AF}=\frac{m_{\text {air }}}{m_{\text {fuel }}}=\frac{(2.0 \times 4.76 \mathrm{kmol})(29 \mathrm{~kg} / \mathrm{kmol})}{(1 \mathrm{kmol})(12 \mathrm{~kg} / \mathrm{kmol})}=\mathbf{2 3 . 0} \mathbf{~ k g ~ a i r} / \mathbf{k g} \text { fuel }
$$

(b) To find the percent theoretical air used, we need to know the theoretical amount of air, which is determined from the theoretical combustion equation of the fuel,

$$
\mathrm{C}+1\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow \mathrm{CO}_{2}+3.76 \mathrm{~N}_{2}
$$

Then,

$$
\text { Percent theoretical air }=\frac{m_{\text {air,act }}}{m_{\mathrm{air}, \mathrm{th}}}=\frac{N_{\text {air,act }}}{N_{\mathrm{air}, \mathrm{th}}}=\frac{(2.0)(4.76) \mathrm{kmol}}{(1.0)(4.76) \mathrm{kmol}}=\mathbf{2 0 0 \%}
$$

15-38 Methane is burned with dry air. The volumetric analysis of the products is given. The AF ratio and the percentage of theoretical air used are to be determined.
Assumptions 1 Combustion is complete. 2 The combustion products contain $\mathrm{CO}_{2}, \mathrm{CO}, \mathrm{H}_{2} \mathrm{O}, \mathrm{O}_{2}$, and $\mathrm{N}_{2}$ only.
Properties The molar masses of $\mathrm{C}, \mathrm{H}_{2}$, and air are $12 \mathrm{~kg} / \mathrm{kmol}, 2 \mathrm{~kg} / \mathrm{kmol}$, and $29 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).

Analysis Considering 100 kmol of dry products, the combustion equation can be written as

$$
x \mathrm{CH}_{4}+a\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow 5.20 \mathrm{CO}_{2}+0.33 \mathrm{CO}+11.24 \mathrm{O}_{2}+83.23 \mathrm{~N}_{2}+b \mathrm{H}_{2} \mathrm{O}
$$

The unknown coefficients $x, a$, and $b$ are determined from mass balances,

$$
\begin{array}{ll}
\mathrm{N}_{2}: 3.76 a=83.23 & \longrightarrow a=22.14 \\
\mathrm{C}: x=5.20+0.33 & \longrightarrow x=5.53 \\
\mathrm{H}: 4 x=2 b \quad \longrightarrow b=11.06
\end{array}
$$

(Check $\mathrm{O}_{2}: a=5.20+0.165+11.24+b / 2 \longrightarrow 22.14=22.14$ )
Thus,

$$
5.53 \mathrm{CH}_{4}+22.14\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow 5.20 \mathrm{CO}_{2}+0.33 \mathrm{CO}+11.24 \mathrm{O}_{2}+83.23 \mathrm{~N}_{2}+11.06 \mathrm{H}_{2} \mathrm{O}
$$

The combustion equation for 1 kmol of fuel is obtained by dividing the above equation by 5.53 ,

$$
\mathrm{CH}_{4}+4.0\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow 0.94 \mathrm{CO}_{2}+0.06 \mathrm{CO}+2.03 \mathrm{O}_{2}+15.05 \mathrm{~N}_{2}+2 \mathrm{H}_{2} \mathrm{O}
$$

(a) The air-fuel ratio is determined from its definition,

$$
\mathrm{AF}=\frac{m_{\text {air }}}{m_{\text {fuel }}}=\frac{(4.0 \times 4.76 \mathrm{kmol})(29 \mathrm{~kg} / \mathrm{kmol})}{(1 \mathrm{kmol})(12 \mathrm{~kg} / \mathrm{kmol})+(2 \mathrm{kmol})(2 \mathrm{~kg} / \mathrm{kmol})}=34.5 \mathbf{~ k g} \text { air } / \mathbf{k g} \text { fuel }
$$

(b) To find the percent theoretical air used, we need to know the theoretical amount of air, which is determined from the theoretical combustion equation of the fuel,

$$
\begin{aligned}
& \mathrm{CH}_{4}+a_{\mathrm{th}}\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow \mathrm{CO}_{2}+2 \mathrm{H}_{2} \mathrm{O}+3.76 a_{\mathrm{th}} \mathrm{~N}_{2} \\
& \mathrm{O}_{2}:
\end{aligned} \quad a_{\mathrm{th}}=1+1 \longrightarrow a_{\mathrm{th}}=2.0 \mathrm{l}
$$

Then,

$$
\text { Percent theoretical air }=\frac{m_{\text {air,act }}}{m_{\mathrm{air}, \mathrm{th}}}=\frac{N_{\mathrm{air}, \mathrm{act}}}{N_{\mathrm{air}, \mathrm{th}}}=\frac{(4.0)(4.76) \mathrm{kmol}}{(2.0)(4.76) \mathrm{kmol}}=\mathbf{2 0 0 \%}
$$

15-39 Methyl alcohol is burned with $50 \%$ excess air. The combustion is incomplete. The mole fraction of carbon monoxide and the apparent molar mass of the products are to be determined.
Assumptions 1 Combustion is complete. 2 The combustion products contain $\mathrm{CO}_{2}, \mathrm{CO}, \mathrm{H}_{2} \mathrm{O}, \mathrm{O}_{2}$, and $\mathrm{N}_{2}$ only.
Properties The molar masses of $\mathrm{C}, \mathrm{H}_{2}, \mathrm{O}_{2}, \mathrm{~N}_{2}$ and air are $12 \mathrm{~kg} / \mathrm{kmol}, 2 \mathrm{~kg} / \mathrm{kmol}, 32 \mathrm{~kg} / \mathrm{kmol}, 28 \mathrm{~kg} / \mathrm{kmol}$, and $29 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).

Analysis The balanced reaction equation for
 stoichiometric air is

$$
\mathrm{CH}_{3} \mathrm{OH}+1.5\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow \mathrm{CO}_{2}+2 \mathrm{H}_{2} \mathrm{O}+5.64 \mathrm{~N}_{2}
$$

The reaction with $50 \%$ excess air and incomplete combustion can be written as

$$
\mathrm{CH}_{3} \mathrm{OH}+1.5 \times 1.5\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow 0.90 \mathrm{CO}_{2}+0.10 \mathrm{CO}+2 \mathrm{H}_{2} \mathrm{O}+x \mathrm{O}_{2}+1.5 \times 1.5 \times 3.76 \mathrm{~N}_{2}
$$

The coefficient for CO is determined from a mass balance,
$\mathrm{O}_{2}$ balance: $\quad 0.5+1.5 \times 1.5=0.9+0.05+1+x \longrightarrow x=0.8$
Substituting,

$$
\mathrm{CH}_{3} \mathrm{OH}+2.25\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow 0.90 \mathrm{CO}_{2}+0.10 \mathrm{CO}+2 \mathrm{H}_{2} \mathrm{O}+0.8 \mathrm{O}_{2}+8.46 \mathrm{~N}_{2}
$$

The total moles of the products is

$$
N_{m}=0.9+0.10+2+0.8+8.46=12.26 \mathrm{kmol}
$$

The mole fraction of carbon monoxide in the products is

$$
y_{\mathrm{CO}}=\frac{N_{\mathrm{CO}}}{N_{m}}=\frac{0.8 \mathrm{kmol}}{12.26 \mathrm{kmol}}=\mathbf{0 . 0 6 5 3}
$$

The apparent molecular weight of the product gas is

$$
M_{m}=\frac{m_{m}}{N_{m}}=\frac{(0.9 \times 44+0.10 \times 28+2 \times 18+0.8 \times 32+8.46 \times 28) \mathrm{kg}}{12.26 \mathrm{kmol}}=\mathbf{2 7 . 8 0} \mathbf{~ k g} / \mathbf{k m o l}
$$

$\mathbf{1 5 - 4 0}$ n-Octane is burned with $100 \%$ excess air. The combustion is incomplete. The mole fractions of products and the dew-point temperature of the water vapor in the products are to be determined.
Assumptions 1 Combustion is complete. 2 The combustion products contain $\mathrm{CO}_{2}, \mathrm{CO}, \mathrm{H}_{2} \mathrm{O}, \mathrm{O}_{2}$, and $\mathrm{N}_{2}$ only.
Properties The molar masses of $\mathrm{C}, \mathrm{H}_{2}, \mathrm{O}_{2}, \mathrm{~N}_{2}$ and air are $12 \mathrm{~kg} / \mathrm{kmol}, 2 \mathrm{~kg} / \mathrm{kmol}, 32 \mathrm{~kg} / \mathrm{kmol}, 28 \mathrm{~kg} / \mathrm{kmol}$, and $29 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).

Analysis The combustion reaction for stoichiometric air is

$$
\mathrm{C}_{8} \mathrm{H}_{18}+12.5\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow 8 \mathrm{CO}_{2}+9 \mathrm{H}_{2} \mathrm{O}+(12.5 \times 3.76) \mathrm{N}_{2}
$$

The combustion equation with $100 \%$ excess air and incomplete combustion is

$$
\mathrm{C}_{8} \mathrm{H}_{18}+2 \times 12.5\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow(0.85 \times 8) \mathrm{CO}_{2}+(0.15 \times 8) \mathrm{CO}+9 \mathrm{H}_{2} \mathrm{O}+x \mathrm{O}_{2}+(2 \times 12.5 \times 3.76) \mathrm{N}_{2}
$$

The coefficient for CO is determined from a mass balance,
$\mathrm{O}_{2}$ balance: $\quad 25=0.85 \times 8+0.5 \times 0.15 \times 8+0.5 \times 9+x \longrightarrow x=13.1$
Substituting,

$$
\mathrm{C}_{8} \mathrm{H}_{18}+25\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow 6.8 \mathrm{CO}_{2}+1.2 \mathrm{CO}+9 \mathrm{H}_{2} \mathrm{O}+13.1 \mathrm{O}_{2}+94 \mathrm{~N}_{2}
$$

The mole fractions of the products are

$$
\begin{aligned}
& N_{\text {prod }}=6.8+1.2+9+13.1+94=124.1 \mathrm{kmol} \\
& y_{\mathrm{CO} 2}=\frac{N_{\mathrm{CO} 2}}{N_{\text {prod }}}=\frac{6.8 \mathrm{kmol}}{124.1 \mathrm{kmol}}=\mathbf{0 . 0 5 4 8} \\
& y_{\mathrm{CO}}=\frac{N_{\mathrm{CO}}}{N_{\text {prod }}}=\frac{1.2 \mathrm{kmol}}{124.1 \mathrm{kmol}}=\mathbf{0 . 0 0 9 7} \\
& y_{\mathrm{H} 2 \mathrm{O}}=\frac{N_{\mathrm{H} 2 \mathrm{O}}}{N_{\text {prod }}}=\frac{9 \mathrm{kmol}}{124.1 \mathrm{kmol}}=\mathbf{0 . 0 7 2 5} \\
& y_{\mathrm{O} 2}=\frac{N_{\mathrm{O} 2}}{N_{\text {prod }}}=\frac{13.1 \mathrm{kmol}}{124.1 \mathrm{kmol}}=\mathbf{0 . 1 0 5 6} \\
& y_{\mathrm{N} 2}=\frac{N_{\mathrm{N} 2}}{N_{\text {prod }}}=\frac{94 \mathrm{kmol}}{124.1 \mathrm{kmol}}=\mathbf{0 . 7 5 7 5}
\end{aligned}
$$

The dew-point temperature of a gas-vapor mixture is the saturation temperature of the water vapor in the product gases corresponding to its partial pressure. That is,

$$
P_{v}=\left(\frac{N_{v}}{N_{\text {prod }}}\right) P_{\text {prod }}=\left(\frac{9 \mathrm{kmol}}{124.1 \mathrm{kmol}}\right)(101.325 \mathrm{kPa})=7.348 \mathrm{kPa}
$$

Thus,

$$
T_{\mathrm{dp}}=T_{\text {sat } @ 7.348 \mathrm{kPa}}=39.9^{\circ} \mathrm{C} \quad \text { (Table A-5 or EES) }
$$

## Enthalpy of Formation and Enthalpy of Combustion

15-41C For combustion processes the enthalpy of reaction is referred to as the enthalpy of combustion, which represents the amount of heat released during a steady-flow combustion process.

15-42C Enthalpy of formation is the enthalpy of a substance due to its chemical composition. The enthalpy of formation is related to elements or compounds whereas the enthalpy of combustion is related to a particular fuel.

15-43C The heating value is called the higher heating value when the $\mathrm{H}_{2} \mathrm{O}$ in the products is in the liquid form, and it is called the lower heating value when the $\mathrm{H}_{2} \mathrm{O}$ in the products is in the vapor form. The heating value of a fuel is equal to the absolute value of the enthalpy of combustion of that fuel.

15-44C If the combustion of a fuel results in a single compound, the enthalpy of formation of that compound is identical to the enthalpy of combustion of that fuel.

15-45C Yes.

15-46C No. The enthalpy of formation of $\mathrm{N}_{2}$ is simply assigned a value of zero at the standard reference state for convenience.

15-47C 1 kmol of $\mathrm{H}_{2}$. This is evident from the observation that when chemical bonds of $\mathrm{H}_{2}$ are destroyed to form $\mathrm{H}_{2} \mathrm{O}$ a large amount of energy is released.

15-48 The enthalpy of combustion of methane at a $25^{\circ} \mathrm{C}$ and 1 atm is to be determined using the data from Table A-26 and to be compared to the value listed in Table A-27.

Assumptions The water in the products is in the liquid phase.
Analysis The stoichiometric equation for this reaction is

$$
\mathrm{CH}_{4}+2\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow \mathrm{CO}_{2}+2 \mathrm{H}_{2} \mathrm{O}(\ell)+7.52 \mathrm{~N}_{2}
$$

Both the reactants and the products are at the standard reference state of $25^{\circ} \mathrm{C}$ and 1 atm . Also, $\mathrm{N}_{2}$ and $\mathrm{O}_{2}$ are stable elements, and thus their enthalpy of formation is zero. Then the enthalpy of combustion of $\mathrm{CH}_{4}$ becomes

$$
h_{C}=H_{P}-H_{R}=\sum N_{P} \bar{h}_{f, P}^{\circ}-\sum N_{R} \bar{h}_{f, R}^{\circ}=\left(N \bar{h}_{f}^{\circ}\right)_{\mathrm{CO}_{2}}+\left(N \bar{h}_{f}^{\circ}\right)_{\mathrm{H}_{2} \mathrm{O}}-\left(N \bar{h}_{f}^{\circ}\right)_{\mathrm{CH}_{4}}
$$

Using $\bar{h}_{f}^{\circ}$ values from Table A-26,

$$
\left.\begin{array}{rl}
h_{C}= & (1 \mathrm{kmol})(-393,520 \mathrm{~kJ} / \mathrm{kmol})+(2 \mathrm{kmol})(-285,830 \mathrm{~kJ} / \mathrm{kmol}) \\
& -(1 \mathrm{kmol})(-74,850 \mathrm{~kJ} / \mathrm{kmol}) \\
= & -\mathbf{8 9 0}, \mathbf{3 3 0} \mathbf{~ k J}(\text { per kmol CH }
\end{array}\right)
$$

The listed value in Table A-27 is $-890,868 \mathrm{~kJ} / \mathrm{kmol}$, which is almost identical to the calculated value. Since the water in the products is assumed to be in the liquid phase, this $h_{c}$ value corresponds to the higher heating value of $\mathrm{CH}_{4}$.

15-49 EES Problem 15-48 is reconsidered. The effect of temperature on the enthalpy of combustion is to be studied.

Analysis The problem is solved using EES, and the solution is given below.

Fuel\$ = 'Methane (CH4)'
T_comb =25 [C]
T_fuel = T_comb +273 "[K]"
T_air1 = T_comb +273 "[K]"
T_prod =T_comb +273 "[K]"
h_bar_comb_TableA27 = -890360 [kJ/kmol]

15-50 The enthalpy of combustion of gaseous ethane at a $25^{\circ} \mathrm{C}$ and 1 atm is to be determined using the data from Table A-26 and to be compared to the value listed in Table A-27.

Assumptions The water in the products is in the liquid phase.
Analysis The stoichiometric equation for this reaction is

$$
\mathrm{C}_{2} \mathrm{H}_{6}+3.5\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow 2 \mathrm{CO}_{2}+3 \mathrm{H}_{2} \mathrm{O}(\ell)+13.16 \mathrm{~N}_{2}
$$

Both the reactants and the products are at the standard reference state of $25^{\circ} \mathrm{C}$ and 1 atm . Also, $\mathrm{N}_{2}$ and $\mathrm{O}_{2}$ are stable elements, and thus their enthalpy of formation is zero. Then the enthalpy of combustion of $\mathrm{C}_{2} \mathrm{H}_{6}$ becomes

$$
h_{C}=H_{P}-H_{R}=\sum N_{P} \bar{h}_{f, P}^{\circ}-\sum N_{R} \bar{h}_{f, R}^{\circ}=\left(N \bar{h}_{f}^{\circ}\right)_{\mathrm{CO}_{2}}+\left(N \bar{h}_{f}^{\circ}\right)_{\mathrm{H}_{2} \mathrm{O}}-\left(N \bar{h}_{f}^{\circ}\right)_{\mathrm{C}_{2} \mathrm{H}_{6}}
$$

Using $\bar{h}_{f}^{\circ}$ values from Table A-26,

$$
\begin{aligned}
h_{C}= & (2 \mathrm{kmol})(-393,520 \mathrm{~kJ} / \mathrm{kmol})+(3 \mathrm{kmol})(-285,830 \mathrm{~kJ} / \mathrm{kmol}) \\
& -(1 \mathrm{kmol})(-84,680 \mathrm{~kJ} / \mathrm{kmol}) \\
= & -\mathbf{1 , 5 5 9 , 8 5 0} \mathbf{~ k J}\left(\text { per } \mathrm{kmolC}_{2} \mathrm{H}_{6}\right)
\end{aligned}
$$

The listed value in Table A-27 is $-1,560,633 \mathrm{~kJ} / \mathrm{kmol}$, which is almost identical to the calculated value. Since the water in the products is assumed to be in the liquid phase, this $h_{c}$ value corresponds to the higher heating value of $\mathrm{C}_{2} \mathrm{H}_{6}$.

15-51 The enthalpy of combustion of liquid octane at a $25^{\circ} \mathrm{C}$ and 1 atm is to be determined using the data from Table A-26 and to be compared to the value listed in Table A-27.

Assumptions The water in the products is in the liquid phase.
Analysis The stoichiometric equation for this reaction is

$$
\mathrm{C}_{8} \mathrm{H}_{18}+12.5\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow 8 \mathrm{CO}_{2}+9 \mathrm{H}_{2} \mathrm{O}(\ell)+47 \mathrm{~N}_{2}
$$

Both the reactants and the products are at the standard reference state of $25^{\circ} \mathrm{C}$ and 1 atm . Also, $\mathrm{N}_{2}$ and $\mathrm{O}_{2}$ are stable elements, and thus their enthalpy of formation is zero. Then the enthalpy of combustion of $\mathrm{C}_{8} \mathrm{H}_{18}$ becomes

$$
h_{C}=H_{P}-H_{R}=\sum N_{P} \bar{h}_{f, P}^{\circ}-\sum N_{R} \bar{h}_{f, R}^{\circ}=\left(N \bar{h}_{f}^{\circ}\right)_{\mathrm{CO}_{2}}+\left(N \bar{h}_{f}^{\circ}\right)_{\mathrm{H}_{2} \mathrm{O}}-\left(N \bar{h}_{f}^{\circ}\right)_{\mathrm{C}_{8} \mathrm{H}_{18}}
$$

Using $\bar{h}_{f}^{\circ}$ values from Table A-26,

$$
\begin{aligned}
h_{C}= & (8 \mathrm{kmol})(-393,520 \mathrm{~kJ} / \mathrm{kmol})+(9 \mathrm{kmol})(-285,830 \mathrm{~kJ} / \mathrm{kmol}) \\
& -(1 \mathrm{kmol})(-249,950 \mathrm{~kJ} / \mathrm{kmol}) \\
= & -\mathbf{5 , 4 7 0 , 6 8 0} \mathbf{~ k J}
\end{aligned}
$$

The listed value in Table A-27 is $-5,470,523 \mathrm{~kJ} / \mathrm{kmol}$, which is almost identical to the calculated value. Since the water in the products is assumed to be in the liquid phase, this $h_{c}$ value corresponds to the higher heating value of $\mathrm{C}_{8} \mathrm{H}_{18}$.

15-52 Ethane is burned with stoichiometric amount of air. The heat transfer is to be determined if both the reactants and products are at $25^{\circ} \mathrm{C}$.

Assumptions The water in the products is in the vapor phase.
Analysis The stoichiometric equation for this reaction is

$$
\mathrm{C}_{2} \mathrm{H}_{6}+3.5\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow 2 \mathrm{CO}_{2}+3 \mathrm{H}_{2} \mathrm{O}+13.16 \mathrm{~N}_{2}
$$

Since both the reactants and the products are at the standard reference state of $25^{\circ} \mathrm{C}$ and 1 atm , the heat transfer for this process is equal to enthalpy of combustion. Note that $\mathrm{N}_{2}$ and
 $\mathrm{O}_{2}$ are stable elements, and thus their enthalpy of formation is zero. Then,

$$
Q=h_{C}=H_{P}-H_{R}=\sum N_{P} \bar{h}_{f, P}^{\circ}-\sum N_{R} \bar{h}_{f, R}^{\circ}=\left(N \bar{h}_{f}^{\circ}\right)_{\mathrm{CO} 2}+\left(N \bar{h}_{f}^{\circ}\right)_{\mathrm{H} 2 \mathrm{O}}-\left(N \bar{h}_{f}^{\circ}\right)_{\mathrm{C} 2 \mathrm{H} 6}
$$

Using $\bar{h}_{f}^{\circ}$ values from Table A-26,

$$
\begin{aligned}
Q & =h_{C}=(2 \mathrm{kmol})(-393,520 \mathrm{~kJ} / \mathrm{kmol})+(3 \mathrm{kmol})(-241,820 \mathrm{~kJ} / \mathrm{kmol})-(1 \mathrm{kmol})(-84,680 \mathrm{~kJ} / \mathrm{kmol}) \\
& =-\mathbf{1}, 427,820 \mathrm{~kJ} / \mathrm{kmol} \mathbf{C} 2 \mathrm{H} 6
\end{aligned}
$$

15-53 Ethane is burned with stoichiometric amount of air at 1 atm and $25^{\circ} \mathrm{C}$. The minimum pressure of the products which will assure that the water in the products will be in vapor form is to be determined.
Assumptions The water in the products is in the vapor phase.
Analysis The stoichiometric equation for this reaction is

$$
\mathrm{C}_{2} \mathrm{H}_{6}+3.5\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow 2 \mathrm{CO}_{2}+3 \mathrm{H}_{2} \mathrm{O}+13.16 \mathrm{~N}_{2}
$$

At the minimum pressure, the product mixture will be saturated with water vapor and

$$
P_{v}=P_{\text {sat@25 }}{ }^{\circ} \mathrm{C}=3.1698 \mathrm{kPa}
$$

The mole fraction of water in the products is

$$
y_{v}=\frac{N_{\mathrm{H} 2 \mathrm{O}}}{N_{\text {prod }}}=\frac{3 \mathrm{kmol}}{(2+3+13.16) \mathrm{kmol}}=0.1652
$$

The minimum pressure of the products is then

$$
P_{\min }=\frac{P_{v}}{y_{v}}=\frac{3.1698 \mathrm{kPa}}{0.1652}=19.2 \mathrm{kPa}
$$

15-54 The higher and lower heating values of coal from Utah are to be determined.
Assumptions 1 Combustion is complete. 2 The combustion products contain $\mathrm{CO}_{2}, \mathrm{CO}, \mathrm{H}_{2} \mathrm{O}, \mathrm{SO}_{2}$, and $\mathrm{N}_{2} .3$ Combustion gases are ideal gases.
Properties The molar masses of $\mathrm{C}, \mathrm{H}_{2}, \mathrm{O}_{2}, \mathrm{~N}_{2}, \mathrm{~S}$, and air are $12,2,32,28,32$, and $29 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).
Analysis The mass fractions of the constituent of the coal when the ash is substituted are

$$
\begin{aligned}
& \mathrm{mf}_{\mathrm{C}}=\frac{m_{\mathrm{C}}}{m_{\text {total }}}=\frac{61.40 \mathrm{~kg}}{(100-5.00) \mathrm{kg}}=\frac{61.40 \mathrm{~kg}}{95.00 \mathrm{~kg}}=0.6463 \\
& \mathrm{mf}_{\mathrm{H} 2}=\frac{m_{\mathrm{H} 2}}{m_{\text {total }}}=\frac{5.79 \mathrm{~kg}}{95.00 \mathrm{~kg}}=0.06095 \\
& \mathrm{mf}_{\mathrm{O} 2}=\frac{m_{\mathrm{O} 2}}{m_{\text {total }}}=\frac{25.31 \mathrm{~kg}}{95.00 \mathrm{~kg}}=0.2664 \\
& \mathrm{mf}_{\mathrm{N} 2}=\frac{m_{\mathrm{N} 2}}{m_{\text {total }}}=\frac{1.09 \mathrm{~kg}}{95.00 \mathrm{~kg}}=0.01147 \\
& \mathrm{mf}_{\mathrm{S}}=\frac{m_{\mathrm{S}}}{m_{\text {total }}}=\frac{1.41 \mathrm{~kg}}{95.00 \mathrm{~kg}}=0.01484
\end{aligned}
$$

We now consider 100 kg of this mixture. Then the mole numbers of each component are

$$
\begin{aligned}
N_{\mathrm{C}} & =\frac{m_{\mathrm{C}}}{M_{\mathrm{C}}}=\frac{64.63 \mathrm{~kg}}{12 \mathrm{~kg} / \mathrm{kmol}}=5.386 \mathrm{kmol} \\
N_{\mathrm{H} 2} & =\frac{m_{\mathrm{H} 2}}{M_{\mathrm{H} 2}}=\frac{6.095 \mathrm{~kg}}{2 \mathrm{~kg} / \mathrm{kmol}}=3.048 \mathrm{kmol} \\
N_{\mathrm{O} 2} & =\frac{m_{\mathrm{O} 2}}{M_{\mathrm{O} 2}}=\frac{26.64 \mathrm{~kg}}{32 \mathrm{~kg} / \mathrm{kmol}}=0.8325 \mathrm{kmol} \\
N_{\mathrm{N} 2} & =\frac{m_{\mathrm{N} 2}}{M_{\mathrm{N} 2}}=\frac{1.147 \mathrm{~kg}}{28 \mathrm{~kg} / \mathrm{kmol}}=0.04096 \mathrm{kmol} \\
N_{\mathrm{S}} & =\frac{m_{\mathrm{S}}}{M_{\mathrm{S}}}=\frac{1.484 \mathrm{~kg}}{32 \mathrm{~kg} / \mathrm{kmol}}=0.04638 \mathrm{kmol}
\end{aligned}
$$

The mole number of the mixture and the mole fractions are

$$
\begin{aligned}
& N_{m}=5.386+3.048+0.8325+0.04096+0.04638=9.354 \mathrm{kmol} \\
& y_{\mathrm{C}}=\frac{N_{\mathrm{C}}}{N_{m}}=\frac{5.386 \mathrm{kmol}}{9.354 \mathrm{kmol}}=0.5758 \\
& y_{\mathrm{H} 2}=\frac{N_{\mathrm{H} 2}}{N_{m}}=\frac{3.048 \mathrm{kmol}}{9.354 \mathrm{kmol}}=0.3258 \\
& y_{\mathrm{O} 2}=\frac{N_{\mathrm{O} 2}}{N_{m}}=\frac{0.8325 \mathrm{kmol}}{9.354 \mathrm{kmol}}=0.0890 \\
& y_{\mathrm{N} 2}=\frac{N_{\mathrm{N} 2}}{N_{m}}=\frac{0.04096 \mathrm{kmol}}{9.354 \mathrm{kmol}}=0.00438 \\
& y_{\mathrm{S}}=\frac{N_{\mathrm{S}}}{N_{m}}=\frac{0.04638 \mathrm{kmol}}{9.354 \mathrm{kmol}}=0.00496
\end{aligned}
$$

Then, the combustion equation in this case may be written as

$$
\begin{aligned}
& 0.5758 \mathrm{C}+0.3258 \mathrm{H}_{2}+0.0890 \mathrm{O}_{2}+0.00438 \mathrm{~N}_{2}+0.00496 \mathrm{~S}+a_{\mathrm{th}}\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \\
& \longrightarrow 0.5758 \mathrm{CO}_{2}+0.3258 \mathrm{H}_{2} \mathrm{O}+0.00496 \mathrm{SO}_{2}+k \mathrm{~N}_{2}
\end{aligned}
$$

According to the species balances,

$$
\begin{array}{ll}
\mathrm{O}_{2} \text { balance }: & 0.0890+a_{\mathrm{th}}=0.5758+0.5 \times 0.3258+0.00496 \longrightarrow a_{\mathrm{th}}=0.6547 \\
\mathrm{~N}_{2} \text { balance }: & k=0.00438+3.76 \times 0.6547=2.466
\end{array}
$$

Substituting,

$$
\begin{aligned}
& 0.5758 \mathrm{C}+0.3258 \mathrm{H}_{2}+0.0890 \mathrm{O}_{2}+0.00438 \mathrm{~N}_{2}+0.00496 \mathrm{~S}+0.6547\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \\
& \longrightarrow 0.5758 \mathrm{CO}_{2}+0.3258 \mathrm{H}_{2} \mathrm{O}+0.00496 \mathrm{SO}_{2}+2.466 \mathrm{~N}_{2}
\end{aligned}
$$

Both the reactants and the products are taken to be at the standard reference state of $25^{\circ} \mathrm{C}$ and 1 atm for the calculation of heating values. The heat transfer for this process is equal to enthalpy of combustion. Note that $\mathrm{C}, \mathrm{S}, \mathrm{H}_{2}, \mathrm{~N}_{2}$ and $\mathrm{O}_{2}$ are stable elements, and thus their enthalpy of formation is zero. Then,

$$
q=h_{C}=H_{P}-H_{R}=\sum N_{P} \bar{h}_{f, P}^{\circ}-\sum N_{R} \bar{h}_{f, R}^{\circ}=\left(N \bar{h}_{f}^{\circ}\right)_{\mathrm{CO} 2}+\left(N \bar{h}_{f}^{\circ}\right)_{\mathrm{H} 2 \mathrm{O}}+\left(N \bar{h}_{f}^{\circ}\right)_{\mathrm{SO} 2}
$$

For the HHV, the water in the products is taken to be liquid. Then,

$$
\begin{aligned}
h_{C}= & (0.5758 \mathrm{kmol})(-393,520 \mathrm{~kJ} / \mathrm{kmol})+(0.3258 \mathrm{kmol})(-285,830 \mathrm{~kJ} / \mathrm{kmol}) \\
& +(0.00496 \mathrm{kmol})(-297,100 \mathrm{~kJ} / \mathrm{kmol}) \\
= & -321,200 \mathrm{~kJ} / \mathrm{kmol} \text { coal }
\end{aligned}
$$

The apparent molecular weight of the coal is

$$
\begin{aligned}
M_{m} & =\frac{m_{m}}{N_{m}}=\frac{(0.5758 \times 12+0.3258 \times 2+0.0890 \times 32+0.00438 \times 28+0.00496 \times 32) \mathrm{kg}}{(0.5758+0.3258+0.0890+0.00438+0.00496) \mathrm{kmol}} \\
& =\frac{10.69 \mathrm{~kg}}{1.000 \mathrm{kmol}}=10.69 \mathrm{~kg} / \mathrm{kmol} \text { coal }
\end{aligned}
$$

The HHV of the coal is then

$$
\mathrm{HHV}=\frac{-h_{C}}{M_{m}}=\frac{321,200 \mathrm{~kJ} / \mathrm{kmol} \mathrm{coal}}{10.69 \mathrm{~kg} / \mathrm{kmol} \text { coal }}=\mathbf{3 0 , 0 0 0} \mathbf{~ k J} / \mathbf{k g} \text { coal }
$$

For the LHV, the water in the products is taken to be vapor. Then,

$$
\begin{aligned}
h_{C}= & (0.5758 \mathrm{kmol})(-393,520 \mathrm{~kJ} / \mathrm{kmol})+(0.3258 \mathrm{kmol})(-241,820 \mathrm{~kJ} / \mathrm{kmol}) \\
& +(0.00496 \mathrm{kmol})(-297,100 \mathrm{~kJ} / \mathrm{kmol}) \\
= & -306,850 \mathrm{~kJ} / \mathrm{kmol} \text { coal }
\end{aligned}
$$

The LHV of the coal is then

$$
\mathrm{LHV}=\frac{-h_{C}}{M_{m}}=\frac{306,850 \mathrm{~kJ} / \mathrm{kmol} \text { coal }}{10.69 \mathrm{~kg} / \mathrm{kmol} \text { coal }}=\mathbf{2 8 , 7 0 0} \mathbf{~ k J} / \mathbf{k g} \text { coal }
$$

## First Law Analysis of Reacting Systems

15-55C In this case $\Delta U+W_{b}=\Delta H$, and the conservation of energy relation reduces to the form of the steady-flow energy relation.

15-56C The heat transfer will be the same for all cases. The excess oxygen and nitrogen enters and leaves the combustion chamber at the same state, and thus has no effect on the energy balance.

15-57C For case (b), which contains the maximum amount of nonreacting gases. This is because part of the chemical energy released in the combustion chamber is absorbed and transported out by the nonreacting gases.

15-58 Propane is burned with an air-fuel ratio of 18 . The heat transfer per kilogram of fuel burned when the temperature of the products is such that liquid water just begins to form in the products is to be determined.

Assumptions 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 Combustion is complete. 5 The reactants are at $25^{\circ} \mathrm{C}$ and 1 atm .6 The fuel is in vapor phase.
Properties The molar masses of propane and air are $44 \mathrm{~kg} / \mathrm{kmol}$ and $29 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).
Analysis The mass of air per kmol of fuel is

$$
\begin{aligned}
m_{\text {air }} & =(\mathrm{AF}) m_{\text {fuel }} \\
& =(18 \mathrm{~kg} \text { air } / \mathrm{kg} \text { fuel })(1 \times 44 \mathrm{~kg} / \mathrm{kmol} \text { fuel }) \\
& =792 \mathrm{~kg} \text { air } / \mathrm{kmol} \text { fuel }
\end{aligned}
$$

The mole number of air per kmol of fuel is then

$$
N_{\text {air }}=\frac{m_{\text {air }}}{M_{\text {air }}}=\frac{792 \mathrm{~kg} \text { air } / \mathrm{kmol} \text { fuel }}{29 \mathrm{~kg} \text { air } / \mathrm{kmol} \text { air }}=27.31 \mathrm{kmol} \text { air } / \mathrm{kmol} \text { fuel }
$$

The combustion equation can be written as

$$
\mathrm{C}_{3} \mathrm{H}_{8}+(27.31 / 4.76)\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 3 \mathrm{CO}_{2}+4 \mathrm{H}_{2} \mathrm{O}+x \mathrm{O}_{2}+(27.31 / 4.76) \times 3.76 \mathrm{~N}_{2}
$$

The coefficient for CO is obtained from $\mathrm{O}_{2}$ balance:

$$
(27.31 / 4.76)=3+2+x \longrightarrow x=0.7374
$$

Substituting,

$$
\mathrm{C}_{3} \mathrm{H}_{8}+5.7374\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 3 \mathrm{CO}_{2}+4 \mathrm{H}_{2} \mathrm{O}+0.7374 \mathrm{O}_{2}+21.57 \mathrm{~N}_{2}
$$

The mole fraction of water in the products is

$$
y_{v}=\frac{N_{\mathrm{H} 2 \mathrm{O}}}{N_{\text {prod }}}=\frac{4 \mathrm{kmol}}{(3+4+0.7374+21.57) \mathrm{kmol}}=\frac{4 \mathrm{kmol}}{29.31 \mathrm{kmol}}=0.1365
$$

The partial pressure of water vapor at 1 atm total pressure is

$$
P_{v}=y_{v} P=(0.1365)(101.325 \mathrm{kPa})=13.83 \mathrm{kPa}
$$

When this mixture is at the dew-point temperature, the water vapor pressure is the same as the saturation pressure. Then,

$$
T_{\mathrm{dp}}=T_{\mathrm{sat} @ 13.83 \mathrm{kPa}}=52.3^{\circ} \mathrm{C} \cong 325 \mathrm{~K}
$$

The heat transfer for this combustion process is determined from the energy balance $E_{\text {in }}-E_{\text {out }}=\Delta E_{\text {system }}$ applied on the combustion chamber with $W=0$. It reduces to

$$
-Q_{\text {out }}=\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{P}-\sum N_{R}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{R}
$$

Assuming the air and the combustion products to be ideal gases, we have $h=h(T)$. From the tables,

|  | $\bar{h}_{f}^{\circ}$ | $\bar{h}_{298 \mathrm{~K}}$ | $\bar{h}_{325 \mathrm{~K}}$ |
| :--- | :--- | :--- | :--- |
| Substance | $\mathrm{kJ} / \mathrm{kmol}$ | $\mathrm{kJ} / \mathrm{kmol}$ | $\mathrm{kJ} / \mathrm{kmol}$ |
| $\mathrm{C}_{3} \mathrm{H}_{8}$ | $-103,850$ | --- | --- |
| $\mathrm{O}_{2}$ | 0 | 8682 | 9473 |
| $\mathrm{~N}_{2}$ | 0 | 8669 | 9452 |
| $\mathrm{H}_{2} \mathrm{O}(g)$ | $-241,820$ | 9904 | 10,808 |
| $\mathrm{CO}_{2}$ | $-393,520$ | 9364 | 10,378 |

Substituting,

$$
\begin{aligned}
-\bar{Q}_{\text {out }} & =(3)(-393,520+10,378-9364)+(4)(-241,820+10,808-9904)+(0.7374)(0+9473-8682) \\
& +(21.57)(0+9452-8669)-(1)(-103,850)-0 \\
& =-2,019,860 \mathrm{~kJ} / \mathrm{kmol} \mathrm{C}_{3} \mathrm{H}_{8}
\end{aligned}
$$

or

$$
\bar{Q}_{\text {out }}=2,019,860 \mathrm{~kJ} / \mathrm{kmol} \mathrm{C} 3 \mathrm{H}_{8}
$$

Then the heat transfer per kg of fuel is

$$
Q_{\text {out }}=\frac{\bar{Q}_{\text {out }}}{M_{\text {fuel }}}=\frac{2,019,860 \mathrm{~kJ} / \mathrm{kmol} \text { fuel }}{44 \mathrm{~kg} / \mathrm{kmol}}=45,900 \mathrm{~kJ} / \mathrm{kg} \mathrm{C}_{3} \mathrm{H}_{8}
$$

15-59 n-Octane is burned with 100 percent excess air. The heat transfer per kilogram of fuel burned for a product temperature of $257^{\circ} \mathrm{C}$ is to be determined.

Assumptions 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 Combustion is complete. 5 The fuel is in vapor phase.
Properties The molar masses of propane and air are $44 \mathrm{~kg} / \mathrm{kmol}$ and $29 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).
Analysis The combustion reaction for stoichiometric air is

$$
\mathrm{C}_{8} \mathrm{H}_{18}+12.5\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow 8 \mathrm{CO}_{2}+9 \mathrm{H}_{2} \mathrm{O}+(12.5 \times 3.76) \mathrm{N}_{2}
$$

The combustion equation with $100 \%$ excess air is

$$
\mathrm{C}_{8} \mathrm{H}_{18}+25\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow 8 \mathrm{CO}_{2}+9 \mathrm{H}_{2} \mathrm{O}+12.5 \mathrm{O}_{2}+94 \mathrm{~N}_{2}
$$

The heat transfer for this combustion process is determined from the energy balance $E_{\text {in }}-E_{\text {out }}=\Delta E_{\text {system }}$ applied on the combustion chamber with $W=0$. It reduces to

$$
-Q_{\mathrm{out}}=\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{P}-\sum N_{R}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{R}
$$

Assuming the air and the combustion products to be ideal gases, we have $h=h(T)$. From the tables,

|  | $\bar{h}_{f}^{\circ}$ | $\bar{h}_{298 \mathrm{~K}}$ | $\bar{h}_{530 \mathrm{~K}}$ |
| :--- | :--- | :--- | :--- |
| Substance | $\mathrm{kJ} / \mathrm{kmol}$ | $\mathrm{kJ} / \mathrm{kmol}$ | $\mathrm{kJ} / \mathrm{kmol}$ |
| $\mathrm{C}_{8} \mathrm{H}_{18}(g)$ | $-208,450$ | --- | --- |
| $\mathrm{O}_{2}$ | 0 | 8682 | 15,708 |
| $\mathrm{~N}_{2}$ | 0 | 8669 | 15,469 |
| $\mathrm{H}_{2} \mathrm{O}(g)$ | $-241,820$ | 9904 | 17,889 |
| $\mathrm{CO}_{2}$ | $-393,520$ | 9364 | 19,029 |

Substituting,

$$
\begin{aligned}
-\bar{Q}_{\text {out }} & =(8)(-393,520+19,029-9364)+(9)(-241,820+17,889-9904)+(12.5)(0+15,708-8682) \\
& +(94)(0+15,469-8669)-(1)(-208,450)-0-0 \\
& =-4,239,880 \mathrm{~kJ} / \mathrm{kmol} \mathrm{C}
\end{aligned} \mathrm{H}_{18} \mathrm{H}_{18}
$$

or

$$
\bar{Q}_{\text {out }}=4,239,880 \mathrm{~kJ} / \mathrm{kmol} \mathrm{C} 8 \mathrm{H}_{18}
$$

Then the heat transfer per kg of fuel is

$$
Q_{\text {out }}=\frac{\bar{Q}_{\text {out }}}{M_{\text {fuel }}}=\frac{4,239,880 \mathrm{~kJ} / \mathrm{kmol} \text { fuel }}{114 \mathrm{~kg} / \mathrm{kmol}}=\mathbf{3 7 , 2 0 0 ~ k J} / \mathrm{kg} \mathrm{C}_{\mathbf{8}} \mathbf{H}_{\mathbf{1 8}}
$$

15-60 A certain coal is burned steadily with $40 \%$ excess air. The heat transfer for a given product temperature is to be determined.
Assumptions 1 Combustion is complete. 2 The combustion products contain $\mathrm{CO}_{2}, \mathrm{CO}, \mathrm{H}_{2} \mathrm{O}, \mathrm{SO}_{2}$, and $\mathrm{N}_{2} .3$ Combustion gases are ideal gases.
Properties The molar masses of $\mathrm{C}, \mathrm{H}_{2}, \mathrm{~N}_{2}, \mathrm{O}_{2}$, S , and air are $12,2,28,32,32$, and $29 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).
Analysis The mass fractions of the constituent of the coal when the ash is substituted are

$$
\begin{aligned}
& \mathrm{mf}_{\mathrm{C}}=\frac{m_{\mathrm{C}}}{m_{\text {total }}}=\frac{39.25 \mathrm{~kg}}{(100-11.20) \mathrm{kg}}=\frac{39.25 \mathrm{~kg}}{88.80 \mathrm{~kg}}=0.4420 \\
& \mathrm{mf}_{\mathrm{H} 2}=\frac{m_{\mathrm{H} 2}}{m_{\text {total }}}=\frac{6.93 \mathrm{~kg}}{88.80 \mathrm{~kg}}=0.07804 \\
& \mathrm{mf}_{\mathrm{O} 2}=\frac{m_{\mathrm{O} 2}}{m_{\text {total }}}=\frac{41.11 \mathrm{~kg}}{88.80 \mathrm{~kg}}=0.4630 \\
& \mathrm{mf}_{\mathrm{N} 2}=\frac{m_{\mathrm{N} 2}}{m_{\text {total }}}=\frac{0.72 \mathrm{~kg}}{88.80 \mathrm{~kg}}=0.00811 \\
& \mathrm{mf}_{\mathrm{S}}=\frac{m_{\mathrm{S}}}{m_{\text {total }}}=\frac{0.79 \mathrm{~kg}}{88.80 \mathrm{~kg}}=0.00890
\end{aligned}
$$

We now consider 100 kg of this mixture. Then the mole numbers of each component are

$$
\begin{aligned}
& N_{\mathrm{C}}=\frac{m_{\mathrm{C}}}{M_{\mathrm{C}}}=\frac{44.20 \mathrm{~kg}}{12 \mathrm{~kg} / \mathrm{kmol}}=3.683 \mathrm{kmol} \\
& N_{\mathrm{H} 2}=\frac{m_{\mathrm{H} 2}}{M_{\mathrm{H} 2}}=\frac{7.804 \mathrm{~kg}}{2 \mathrm{~kg} / \mathrm{kmol}}=3.902 \mathrm{kmol} \\
& N_{\mathrm{O} 2}=\frac{m_{\mathrm{O} 2}}{M_{\mathrm{O} 2}}=\frac{46.30 \mathrm{~kg}}{32 \mathrm{~kg} / \mathrm{kmol}}=1.447 \mathrm{kmol} \\
& N_{\mathrm{N} 2}=\frac{m_{\mathrm{N} 2}}{M_{\mathrm{N} 2}}=\frac{0.811 \mathrm{~kg}}{28 \mathrm{~kg} / \mathrm{kmol}}=0.0290 \mathrm{kmol} \\
& N_{\mathrm{S}}=\frac{m_{\mathrm{S}}}{M_{\mathrm{S}}}=\frac{0.890 \mathrm{~kg}}{32 \mathrm{~kg} / \mathrm{kmol}}=0.0278 \mathrm{kmol}
\end{aligned}
$$

The mole number of the mixture and the mole fractions are

$$
\begin{aligned}
& N_{m}=3.683+3.902+1.447+0.0290+0.0278=9.089 \mathrm{kmol} \\
& y_{\mathrm{C}}=\frac{N_{\mathrm{C}}}{N_{m}}=\frac{3.683 \mathrm{kmol}}{9.089 \mathrm{kmol}}=0.4052 \\
& y_{\mathrm{H} 2}=\frac{N_{\mathrm{H} 2}}{N_{m}}=\frac{3.902 \mathrm{kmol}}{9.089 \mathrm{kmol}}=0.4293 \\
& y_{\mathrm{O} 2}=\frac{N_{\mathrm{O} 2}}{N_{m}}=\frac{1.447 \mathrm{kmol}}{9.089 \mathrm{kmol}}=0.1592 \\
& y_{\mathrm{N} 2}=\frac{N_{\mathrm{N} 2}}{N_{m}}=\frac{0.0290 \mathrm{kmol}}{9.089 \mathrm{kmol}}=0.00319 \\
& y_{\mathrm{S}}=\frac{N_{\mathrm{S}}}{N_{m}}=\frac{0.0278 \mathrm{kmol}}{9.089 \mathrm{kmol}}=0.00306
\end{aligned}
$$

Then, the combustion equation in this case may be written as

$$
\begin{aligned}
0.4052 \mathrm{C}+0.4293 \mathrm{H}_{2}+ & 0.1592 \mathrm{O}_{2}+0.00319 \mathrm{~N}_{2}+0.00306 \mathrm{~S}+1.4 a_{\mathrm{th}}\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \\
& \\
& 0.4052 \mathrm{CO}_{2}+0.4293 \mathrm{H}_{2} \mathrm{O}+0.4 a_{\mathrm{th}} \mathrm{O}_{2}+0.00306 \mathrm{SO}_{2}+1.4 a_{\mathrm{th}} \times 3.76 \mathrm{~N}_{2}
\end{aligned}
$$

According to the $\mathrm{O}_{2}$ mass balance,

$$
0.1592+1.4 a_{\mathrm{th}}=0.4052+0.5 \times 0.4293+0.4 a_{\mathrm{th}}+0.00306 \longrightarrow a_{\mathrm{th}}=0.4637
$$

Substituting,

$$
\begin{aligned}
& 0.4052 \mathrm{C}+0.4293 \mathrm{H}_{2}+0.1592 \mathrm{O}_{2}+0.00319 \mathrm{~N}_{2}+0.00306 \mathrm{~S}+0.6492\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \\
& \longrightarrow 0.4052 \mathrm{CO}_{2}+0.4293 \mathrm{H}_{2} \mathrm{O}+0.1855 \mathrm{O}_{2}+0.00306 \mathrm{SO}_{2}+2.441 \mathrm{~N}_{2}
\end{aligned}
$$

The heat transfer for this combustion process is determined from the energy balance $E_{\text {in }}-E_{\text {out }}=\Delta E_{\text {system }}$ applied on the combustion chamber with $W=0$. It reduces to

$$
-Q_{\mathrm{out}}=\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{P}-\sum N_{R}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{R}
$$

Assuming the air and the combustion products to be ideal gases, we have $h=h(T)$. From the tables,

|  | $\bar{h}_{f}^{\circ}$ | $\bar{h}_{298 \mathrm{~K}}$ | $\bar{h}_{400 \mathrm{~K}}$ |
| :--- | :--- | :--- | :--- |
| Substance | $\mathrm{kJ} / \mathrm{kmol}$ | $\mathrm{kJ} / \mathrm{kmol}$ | $\mathrm{kJ} / \mathrm{kmol}$ |
| $\mathrm{O}_{2}$ | 0 | 8682 | 11,711 |
| $\mathrm{~N}_{2}$ | 0 | 8669 | 11,640 |
| $\mathrm{H}_{2} \mathrm{O}(g)$ | $-241,820$ | 9904 | 13,356 |
| $\mathrm{CO}_{2}$ | $-393,520$ | 9364 | 13,372 |
| $\mathrm{SO}_{2}$ | $-297,100$ | - | - |

The enthalpy change of sulfur dioxide between the standard temperature and the product temperature using constant specific heat assumption is

$$
\Delta \bar{h}_{\mathrm{SO} 2}=c_{p} \Delta T=(41.7 \mathrm{~kJ} / \mathrm{kmol} \cdot \mathrm{~K})(127-25) \mathrm{K}=4253 \mathrm{~kJ} / \mathrm{kmol}
$$

Substituting into the energy balance relation,

$$
\begin{aligned}
-\bar{Q}_{\text {out }} & =(0.4052)(-393,520+13,372-9364)+(0.4293)(-241,820+13,356-9904) \\
& +(0.1855)(0+11,711-8682)+(2.441)(0+11,640-8669)+(0.00306)(-297,100+4253)-0 \\
& =-253,244 \mathrm{~kJ} / \mathrm{kmol} \mathrm{C}_{8} \mathrm{H}_{18} \\
\text { or } \quad \bar{Q}_{\text {out }}= & 253,244 \mathrm{~kJ} / \mathrm{kmol} \mathrm{C}
\end{aligned} 8 \mathrm{H}_{18} 8
$$

Then the heat transfer per kg of fuel is

$$
\begin{aligned}
Q_{\text {out }} & =\frac{\bar{Q}_{\text {out }}}{M_{\text {fuel }}}=\frac{253,244 \mathrm{~kJ} / \mathrm{kmol} \text { fuel }}{(0.4052 \times 12+0.4293 \times 2+0.1592 \times 32+0.00319 \times 28+0.00306 \times 32) \mathrm{kg} / \mathrm{kmol}} \\
& =\frac{253,244 \mathrm{~kJ} / \mathrm{kmol} \text { fuel }}{11.00 \mathrm{~kg} / \mathrm{kmol}}=\mathbf{2 3 , 0 2 0} \mathbf{~ k J} / \mathbf{k g} \text { coal }
\end{aligned}
$$

15-61 Methane is burned completely during a steady-flow combustion process. The heat transfer from the combustion chamber is to be determined for two cases.

Assumptions 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 Combustion is complete.
Analysis The fuel is burned completely with the stoichiometric amount of air, and thus the products will contain only $\mathrm{H}_{2} \mathrm{O}, \mathrm{CO}_{2}$ and $\mathrm{N}_{2}$, but no free $\mathrm{O}_{2}$. Considering 1 kmol of fuel, the theoretical combustion equation can be written as

$$
\mathrm{CH}_{4}+a_{\mathrm{th}}\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow \mathrm{CO}_{2}+2 \mathrm{H}_{2} \mathrm{O}+3.76 a_{\mathrm{th}} \mathrm{~N}_{2}
$$

where $a_{\mathrm{th}}$ is determined from the $\mathrm{O}_{2}$ balance,

$$
a_{\mathrm{th}}=1+1=2
$$

Substituting,

$$
\mathrm{CH}_{4}+2\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow \mathrm{CO}_{2}+2 \mathrm{H}_{2} \mathrm{O}+5.64 \mathrm{~N}_{2}
$$

The heat transfer for this combustion process is determined from the energy balance $E_{\text {in }}-E_{\text {out }}=\Delta E_{\text {system }}$ applied on the combustion chamber with $W=0$. It reduces to

$$
-Q_{\mathrm{out}}=\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{P}-\sum N_{R}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{R}=\sum N_{P} \bar{h}_{f, P}^{\circ}-\sum N_{R} \bar{h}_{f, R}^{\circ}
$$

since both the reactants and the products are at $25^{\circ} \mathrm{C}$ and both the air and the combustion gases can be treated as ideal gases. From the tables,

| Substance | $\bar{h}_{f}^{\circ}$ |
| :--- | :--- |
| $\mathrm{CH}_{4}$ | $-74,850$ |
| $\mathrm{O}_{2}$ | 0 |
| $\mathrm{~N}_{2}$ | 0 |
| $\mathrm{H}_{2} \mathrm{O}(\ell)$ | $-285,830$ |
| $\mathrm{CO}_{2}$ | $-393,520$ |

Thus,

$$
-Q_{\text {out }}=(1)(-393,520)+(2)(-285,830)+0-(1)(-74,850)-0-0=-890,330 \mathrm{~kJ} / \mathrm{kmol} \mathrm{CH}_{4}
$$

or

$$
Q_{\text {out }}=890,330 \mathbf{k J} / \mathbf{k m o l} \mathbf{C H}_{4}
$$

If combustion is achieved with $100 \%$ excess air, the answer would still be the same since it would enter and leave at $25^{\circ} \mathrm{C}$, and absorb no energy.

15-62 Liquid propane is burned with 150 percent excess air during a steady-flow combustion process. The mass flow rate of air and the rate of heat transfer from the combustion chamber are to be determined.
Assumptions 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 Combustion is complete.
Properties The molar masses of propane and air are $44 \mathrm{~kg} / \mathrm{kmol}$ and $29 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A1).

Analysis The fuel is burned completely with excess air, and thus the products will contain only $\mathrm{CO}_{2}, \mathrm{H}_{2} \mathrm{O}$, $\mathrm{N}_{2}$, and some free $\mathrm{O}_{2}$. Considering 1 kmol of $\mathrm{C}_{3} \mathrm{H}_{8}$, the combustion equation can be written as

$$
\mathrm{C}_{3} \mathrm{H}_{8}(\ell)+2.5 a_{\mathrm{th}}\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 3 \mathrm{CO}_{2}+4 \mathrm{H}_{2} \mathrm{O}+1.5 a_{\mathrm{th}} \mathrm{O}_{2}+(2.5)\left(3.76 a_{\mathrm{th}}\right) \mathrm{N}_{2}
$$

where $a_{\mathrm{th}}$ is the stoichiometric coefficient and is determined from the $\mathrm{O}_{2}$ balance,

$$
2.5 a_{\mathrm{th}}=3+2+1.5 a_{\mathrm{th}} \quad \longrightarrow \quad a_{\mathrm{th}}=5
$$

Thus,

$$
\mathrm{C}_{3} \mathrm{H}_{8}(\ell)+12.5\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 3 \mathrm{CO}_{2}+4 \mathrm{H}_{2} \mathrm{O}+7.5 \mathrm{O}_{2}+47 \mathrm{~N}_{2}
$$

(a) The air-fuel ratio for this combustion process is

$$
\mathrm{AF}=\frac{m_{\text {air }}}{m_{\text {fuel }}}=\frac{(12.5 \times 4.76 \mathrm{kmol})(29 \mathrm{~kg} / \mathrm{kmol})}{(3 \mathrm{kmol})(12 \mathrm{~kg} / \mathrm{kmol})+(4 \mathrm{kmol})(2 \mathrm{~kg} / \mathrm{kmol})}=39.22 \mathrm{~kg} \text { air } / \mathrm{kg} \text { fuel }
$$

Thus, $\quad \dot{m}_{\text {air }}=(\mathrm{AF})\left(\dot{m}_{\text {fuel }}\right)=(39.22 \mathrm{~kg}$ air $/ \mathrm{kg}$ fuel $)(1.2 \mathrm{~kg} \mathrm{fuel} / \mathrm{min})=\mathbf{4 7 . 1} \mathbf{~ k g ~ a i r} / \mathbf{m i n}$
(b) The heat transfer for this combustion process is determined from the energy balance $E_{\text {in }}-E_{\text {out }}=\Delta E_{\text {system }}$ applied on the combustion chamber with $W=0$. It reduces to

$$
-Q_{\mathrm{out}}=\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{P}-\sum N_{R}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{R}
$$

Assuming the air and the combustion products to be ideal gases, we have $h=h(T)$. From the tables,

| Substance | $\overline{\mathbf{h}}_{\mathbf{f}}^{\circ}$ <br> $\mathbf{k J} / \mathbf{k m o l}$ | $\overline{\mathbf{h}}_{\mathbf{2 8 5} \mathbf{K}}$ <br> $\mathbf{k J} / \mathbf{k m o l}$ | $\overline{\mathbf{h}}_{\mathbf{2 9 8} \mathbf{K}}$ <br> $\mathbf{k J} / \mathbf{k m o l}$ | $\overline{\mathbf{h}}_{\mathbf{1 2 0 0} \mathbf{K}}$ <br> $\mathbf{k J / k m o l}$ |
| :--- | :--- | :--- | :--- | :--- |
| $\mathrm{C}_{3} \mathrm{H}_{8}(\ell)$ | $-118,910$ | --- | --- | --- |
| $\mathrm{O}_{2}$ | 0 | 8296.5 | 8682 | 38,447 |
| $\mathrm{~N}_{2}$ | 0 | 8286.5 | 8669 | 36,777 |
| $\mathrm{H}_{2} \mathrm{O}(g)$ | $-241,820$ | -- | 9904 | 44,380 |
| $\mathrm{CO}_{2}$ | $-393,520$ | -- | 9364 | 53,848 |

The $\bar{h}_{f}^{\circ}$ of liquid propane is obtained by adding $\bar{h}_{f g}$ of propane at $25^{\circ} \mathrm{C}$ to $\bar{h}_{f}^{\circ}$ of gas propane.
Substituting,

$$
\begin{aligned}
&-Q_{\text {out }}=(3)(-393,520+53,848-9364)+(4)(-241,820+44,380-9904)+(7.5)(0+38,447-8682) \\
&+(47)(0+36,777-8669)-(1)\left(-118,910+h_{298}-h_{298}\right)-(12.5)(0+8296.5-8682) \\
&-(47)(0+8286.5-8669) \\
&=-190,464 \mathrm{~kJ} / \mathrm{kmol} \mathrm{C}_{3} \mathrm{H}_{8} \\
& \text { or } \quad Q_{\text {out }}= \\
& 190,464 \mathrm{~kJ} / \mathrm{kmol} \mathrm{C}_{3} \mathrm{H}_{8}
\end{aligned}
$$

Then the rate of heat transfer for a mass flow rate of $1.2 \mathrm{~kg} / \mathrm{min}$ for the propane becomes

$$
\dot{Q}_{\text {out }}=\dot{N} Q_{\text {out }}=\left(\frac{\dot{m}}{N}\right) Q_{\text {out }}=\left(\frac{1.2 \mathrm{~kg} / \mathrm{min}}{44 \mathrm{~kg} / \mathrm{kmol}}\right)(190,464 \mathrm{~kJ} / \mathrm{kmol})=5194 \mathbf{k J} / \mathrm{min}
$$

15-63E Liquid octane is burned with 180 percent theoretical air during a steady-flow combustion process. The AF ratio and the heat transfer from the combustion chamber are to be determined.
Assumptions 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 Combustion is complete.

Properties The molar masses of $\mathrm{C}_{3} \mathrm{H}_{18}$ and air are $54 \mathrm{~kg} / \mathrm{kmol}$ and $29 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).
Analysis The fuel is burned completely with the excess air, and thus the products will contain only $\mathrm{CO}_{2}$, $\mathrm{H}_{2} \mathrm{O}, \mathrm{N}_{2}$, and some free $\mathrm{O}_{2}$. Considering 1 kmol of $\mathrm{C}_{8} \mathrm{H}_{18}$, the combustion equation can be written as

$$
\mathrm{C}_{8} \mathrm{H}_{18}(\ell)+1.8 a_{\mathrm{th}}\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 8 \mathrm{CO}_{2}+9 \mathrm{H}_{2} \mathrm{O}+0.8 a_{\mathrm{th}} \mathrm{O}_{2}+(1.8)\left(3.76 a_{\mathrm{th}}\right) \mathrm{N}_{2}
$$

where $a_{\mathrm{th}}$ is the stoichiometric coefficient and is determined from the $\mathrm{O}_{2}$ balance,

$$
1.8 a_{\mathrm{th}}=8+4.5+0.8 a_{\mathrm{th}} \quad \longrightarrow \quad a_{\mathrm{th}}=12.5
$$

Thus,

$\mathrm{C}_{8} \mathrm{H}_{18}(\ell)+22.5\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 8 \mathrm{CO}_{2}+9 \mathrm{H}_{2} \mathrm{O}+10 \mathrm{O}_{2}+84.6 \mathrm{~N}_{2}$
(a) $\quad \mathrm{AF}=\frac{m_{\text {air }}}{m_{\text {fuel }}}=\frac{(22.5 \times 4.76 \mathrm{lbmol})(29 \mathrm{lbm} / \mathrm{lbmol})}{(8 \mathrm{lbmol})(12 \mathrm{lbm} / \mathrm{lbmol})+(9 \mathrm{lbmol})(2 \mathrm{lbm} / \mathrm{lbmol})}=27.2$ lbmair/lbmfuel
(b) The heat transfer for this combustion process is determined from the energy balance $E_{\text {in }}-E_{\text {out }}=\Delta E_{\text {system }}$ applied on the combustion chamber with $W=0$. It reduces to

$$
-Q_{\text {out }}=\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{P}-\sum N_{R}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{R}=\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{P}-\sum N_{R} \bar{h}_{f, R}^{\circ}
$$

since all of the reactants are at $77^{\circ} \mathrm{F}$. Assuming the air and the combustion products to be ideal gases, we have $h=h(T)$. From the tables,

|  | $\overline{\mathbf{h}}_{\mathbf{f}}^{\circ}$ | $\overline{\mathbf{h}}_{537 \mathbf{R}}$ | $\overline{\mathbf{h}}_{2500 \mathbf{R}}$ |
| :--- | :--- | :--- | :--- |
| Substance | Btu/lbmol | Btu/lbmol | Btu/lbmol |
| $\mathrm{C}_{8} \mathrm{H}_{18}(\ell)$ | $-107,530$ | --- | --- |
| $\mathrm{O}_{2}$ | 0 | 3725.1 | 19,443 |
| $\mathrm{~N}_{2}$ | 0 | 3729.5 | 18,590 |
| $\mathrm{CO}_{2}$ | $-169,300$ | 4027.5 | 27,801 |
| $\mathrm{H}_{2} \mathrm{O}(g)$ | $-104,040$ | 4258.0 | 22,735 |

Thus,

$$
\begin{aligned}
&-Q_{\text {out }}=(8)(-169,300+27,801-4027.5)+(9)(-104,040+22,735-4258)+(10)(0+19,443-3725.1) \\
&+(84.6)(0+18,590-3729.5)-(1)(-107,530)-0-0 \\

$$

15-64 Benzene gas is burned with 95 percent theoretical air during a steady-flow combustion process. The mole fraction of the CO in the products and the heat transfer from the combustion chamber are to be determined.
Assumptions 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible.
Analysis (a) The fuel is burned with insufficient amount of air, and thus the products will contain some CO as well as $\mathrm{CO}_{2}, \mathrm{H}_{2} \mathrm{O}$, and $\mathrm{N}_{2}$. The theoretical combustion equation of $\mathrm{C}_{6} \mathrm{H}_{6}$ is

$$
\mathrm{C}_{6} \mathrm{H}_{6}+a_{\mathrm{th}}\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 6 \mathrm{CO}_{2}+3 \mathrm{H}_{2} \mathrm{O}+3.76 a_{\mathrm{th}} \mathrm{~N}_{2}
$$

where $a_{\mathrm{th}}$ is the stoichiometric coefficient and is determined from the $\mathrm{O}_{2}$ balance,

$$
a_{\mathrm{th}}=6+1.5=7.5
$$

Then the actual combustion equation can be written as

$$
\mathrm{C}_{6} \mathrm{H}_{6}+0.95 \times 7.5\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow x \mathrm{CO}_{2}+(6-x) \mathrm{CO}+3 \mathrm{H}_{2} \mathrm{O}+26.79 \mathrm{~N}_{2}
$$

$\mathrm{O}_{2}$ balance: $\quad 0.95 \times 7.5=x+(6-x) / 2+1.5 \longrightarrow x=5.25$
Thus, $\quad \mathrm{C}_{6} \mathrm{H}_{6}+7.125\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 5.25 \mathrm{CO}_{2}+0.75 \mathrm{CO}+3 \mathrm{H}_{2} \mathrm{O}+26.79 \mathrm{~N}_{2}$
The mole fraction of CO in the products is

$$
y_{\mathrm{CO}}=\frac{N_{\mathrm{CO}}}{N_{\text {total }}}=\frac{0.75}{5.25+0.75+3+26.79}=0.021 \text { or } 2.1 \%
$$

(b) The heat transfer for this combustion process is determined from the energy balance $E_{\text {in }}-E_{\text {out }}=\Delta E_{\text {system }}$ applied on the combustion chamber with $W=0$. It reduces to

$$
-Q_{\mathrm{out}}=\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{P}-\sum N_{R}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{R}=\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{P}-\sum N_{R} \bar{h}_{f, R}^{\circ}
$$

since all of the reactants are at $25^{\circ} \mathrm{C}$. Assuming the air and the combustion products to be ideal gases, we have $h=h(T)$. From the tables,

| Substance | $\overline{\mathbf{h}}_{\mathbf{f}}^{\circ}$ <br> $\mathbf{k J} / \mathbf{k m o l}$ | $\overline{\mathbf{h}}_{\mathbf{2 9 8} \mathbf{K}}$ <br> $\mathbf{k J} / \mathbf{k m o l}$ | $\overline{\mathbf{h}}_{\mathbf{1 0 0 0} \mathbf{K}}$ <br> $\mathbf{k J} / \mathbf{k m o l}$ |
| :--- | :--- | :--- | :--- |
| $\mathrm{C}_{6} \mathrm{H}_{6}(g)$ | 82,930 | --- | --- |
| $\mathrm{O}_{2}$ | 0 | 8682 | 31,389 |
| $\mathrm{~N}_{2}$ | 0 | 8669 | 30,129 |
| $\mathrm{H}_{2} \mathrm{O}(g)$ | $-241,820$ | 9904 | 35,882 |
| CO | $-110,530$ | 8669 | 30,355 |
| $\mathrm{CO}_{2}$ | $-393,520$ | 9364 | 42,769 |

Thus,

$$
\begin{aligned}
-Q_{\text {out }}= & (5.25)(-393,520+42,769-9364)+(0.75)(-110,530+30,355-8669) \\
& +(3)(-241,820+35,882-9904)+(26.79)(0+30,129-8669)-(1)(82,930)-0-0 \\
= & -2,112,779 \mathrm{~kJ} / \mathrm{kmol} \mathrm{C}_{6} \mathrm{H}_{6}
\end{aligned}
$$

or

$$
\dot{Q}_{\text {out }}=2,112,800 \mathrm{~kJ} / \mathrm{kmol} \mathrm{C}_{6} \mathrm{H}_{6}
$$

15-65E Diesel fuel is burned with 20 percent excess air during a steady-flow combustion process. The required mass flow rate of the diesel fuel for a specified heat transfer rate is to be determined.
Assumptions 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 Combustion is complete.

Analysis The fuel is burned completely with the excess air, and thus the products will contain only $\mathrm{CO}_{2}, \mathrm{H}_{2} \mathrm{O}, \mathrm{N}_{2}$, and some free $\mathrm{O}_{2}$. Considering 1 kmol of $\mathrm{C}_{12} \mathrm{H}_{26}$, the combustion equation can be written as

$$
\mathrm{C}_{12} \mathrm{H}_{26}+1.2 a_{\mathrm{th}}\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 12 \mathrm{CO}_{2}+13 \mathrm{H}_{2} \mathrm{O}+0.2 a_{\mathrm{th}} \mathrm{O}_{2}+(1.2)\left(3.76 a_{\mathrm{th}}\right) \mathrm{N}_{2}
$$

where $a_{\mathrm{th}}$ is the stoichiometric coefficient and is determined from the $\mathrm{O}_{2}$ balance,

$$
1.2 a_{\mathrm{th}}=12+6.5+0.2 a_{\mathrm{th}} \quad \longrightarrow \quad a_{\mathrm{th}}=18.5
$$

Substituting,

$$
\mathrm{C}_{12} \mathrm{H}_{26}+22.2\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 12 \mathrm{CO}_{2}+13 \mathrm{H}_{2} \mathrm{O}+3.7 \mathrm{O}_{2}+83.47 \mathrm{~N}_{2}
$$

The heat transfer for this combustion process is determined from the energy balance $E_{\text {in }}-E_{\text {out }}=\Delta E_{\text {system }}$ applied on the combustion chamber with $W=0$. It reduces to

$$
-Q_{\mathrm{out}}=\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{P}-\sum N_{R}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{R}=\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{P}-\sum N_{R} \bar{h}_{f, R}^{\circ}
$$

since all of the reactants are at $77^{\circ} \mathrm{F}$. Assuming the air and the combustion products to be ideal gases, we have $h=h(T)$. From the tables,

|  | $\overline{\mathbf{h}}_{\mathbf{f}}^{\circ}$ | $\overline{\mathbf{h}}_{\mathbf{5 3 7} \mathbf{R}}$ | $\overline{\mathbf{h}}_{\mathbf{8 0 0} \mathbf{R}}$ |
| :--- | :--- | :--- | :--- |
| Substance | Btu/lbmol | Btu/lbmol | Btu/lbmol |
| $\mathrm{C}_{12} \mathrm{H}_{26}$ | $-125,190$ | --- | --- |
| $\mathrm{O}_{2}$ | 0 | 3725.1 | 5602.0 |
| $\mathrm{~N}_{2}$ | 0 | 3729.5 | 5564.4 |
| $\mathrm{H}_{2} \mathrm{O}(g)$ | $-104,040$ | 4258.0 | 6396.9 |
| $\mathrm{CO}_{2}$ | $-169,300$ | 4027.5 | 6552.9 |

Thus,

$$
\begin{aligned}
-Q_{\text {out }}= & (12)(-169,300+6552.9-4027.5)+(13)(-104,040+6396.9-4258) \\
& +(3.7)(0+5602.0-3725.1)+(83.47)(0+5564.4-3729.5)-(1)(-125,190)-0-0 \\
= & -3,040,716 \mathrm{Btu} / \mathrm{lbmol} \mathrm{C} \\
12 & \mathrm{H}_{26}
\end{aligned}
$$

or

$$
Q_{\text {out }}=3,040,716 \text { Btu/lbmol C } 12 \mathrm{H}_{26}
$$

Then the required mass flow rate of fuel for a heat transfer rate of $1800 \mathrm{Btu} / \mathrm{s}$ becomes

$$
\dot{m}=\dot{N} M=\left(\frac{\dot{Q}}{Q}\right) M=\left(\frac{1800 \mathrm{Btu} / \mathrm{s}}{3,040,716 \mathrm{Btu} / \mathrm{lbmol}}\right)(170 \mathrm{lbm} / \mathrm{lbmol})=\mathbf{0 . 1 0 0 6} \mathbf{~ l b m} / \mathrm{s}
$$

15-66 [Also solved by EES on enclosed CD] Octane gas is burned with 30 percent excess air during a steady-flow combustion process. The heat transfer per unit mass of octane is to be determined.
Assumptions 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. $\mathbf{3}$ Kinetic and potential energies are negligible. 4 Combustion is complete.
Properties The molar mass of $\mathrm{C}_{8} \mathrm{H}_{18}$ is $114 \mathrm{~kg} / \mathrm{kmol}$ (Table A-1).
Analysis The fuel is burned completely with the excess air, and thus the products will contain only $\mathrm{CO}_{2}$, $\mathrm{H}_{2} \mathrm{O}, \mathrm{N}_{2}$, and some free $\mathrm{O}_{2}$. The moisture in the air does not react with anything; it simply shows up as additional $\mathrm{H}_{2} \mathrm{O}$ in the products. Therefore, for simplicity, we will balance the combustion equation using dry air, and then add the moisture to both sides of the equation. Considering 1 kmol of $\mathrm{C}_{8} \mathrm{H}_{18}$, the combustion equation can be written as

$$
\mathrm{C}_{8} \mathrm{H}_{18}(\mathrm{~g})+1.3 a_{\mathrm{th}}\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 8 \mathrm{CO}_{2}+9 \mathrm{H}_{2} \mathrm{O}+0.3 a_{\mathrm{th}} \mathrm{O}_{2}+(1.3)\left(3.76 a_{\mathrm{th}}\right) \mathrm{N}_{2}
$$

where $a_{\mathrm{th}}$ is the stoichiometric coefficient for air. It is determined from

$$
\mathrm{O}_{2} \text { balance: } 1.3 a_{\mathrm{th}}=8+4.5+0.3 a_{\mathrm{th}} \longrightarrow a_{\mathrm{th}}=12.5
$$

Thus,

$$
\mathrm{C}_{8} \mathrm{H}_{18}(\mathrm{~g})+16.25\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 8 \mathrm{CO}_{2}+9 \mathrm{H}_{2} \mathrm{O}+3.75 \mathrm{O}_{2}+61.1 \mathrm{~N}_{2}
$$

Therefore, $16.25 \times 4.76=77.35 \mathrm{kmol}$ of dry air will be used per kmol of the fuel. The partial pressure of the water vapor present in the incoming air is

$$
P_{v, \text { in }}=\phi_{\text {air }} P_{\text {sat } @ 25^{\circ} \mathrm{C}}=(0.60)(3.1698 \mathrm{kPa})=1.902 \mathrm{kPa}
$$

Assuming ideal gas behavior, the number of moles of the moisture that accompanies 77.35 kmol of incoming dry air is determined to be

$$
N_{v, \text { in }}=\left(\frac{P_{v, \text { in }}}{P_{\text {total }}}\right) N_{\text {total }}=\left(\frac{1.902 \mathrm{kPa}}{101.325 \mathrm{kPa}}\right)\left(77.35+N_{v, \text { in }}\right) \longrightarrow N_{v, \text { in }}=1.48 \mathrm{kmol}
$$

The balanced combustion equation is obtained by adding 1.48 kmol of $\mathrm{H}_{2} \mathrm{O}$ to both sides of the equation,

$$
\mathrm{C}_{8} \mathrm{H}_{18}(\mathrm{~g})+16.25\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right)+1.48 \mathrm{H}_{2} \mathrm{O} \longrightarrow 8 \mathrm{CO}_{2}+10.48 \mathrm{H}_{2} \mathrm{O}+3.75 \mathrm{O}_{2}+61.1 \mathrm{~N}_{2}
$$

The heat transfer for this combustion process is determined from the energy balance $E_{\text {in }}-E_{\text {out }}=\Delta E_{\text {system }}$ applied on the combustion chamber with $W=0$. It reduces to

$$
-Q_{\text {out }}=\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{P}-\sum N_{R}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{R}=\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{P}-\sum N_{R} \bar{h}_{f, R}^{\circ}
$$

since all of the reactants are at $25^{\circ} \mathrm{C}$. Assuming the air and the combustion products to be ideal gases, we have $h=h(T)$. From the tables,

| Substance | $\overline{\mathbf{h}}_{\mathbf{f}}^{\circ}$ <br> $\mathbf{k J} / \mathbf{k m o l}$ | $\overline{\mathbf{h}}_{\mathbf{2 9 8} \mathbf{K}}$ <br> $\mathbf{k J J} / \mathbf{k m o l}$ | $\overline{\mathbf{h}}_{\mathbf{6 0 0} \mathbf{K}}$ <br> $\mathbf{k J} / \mathbf{k m o l}$ |
| :--- | :--- | :--- | :--- |
| $\mathrm{C}_{8} \mathrm{H}_{18}(g)$ | $-208, \mathbf{4 5 0}$ | --- | --- |
| $\mathrm{O}_{2}$ | 0 | 8682 | 17,929 |
| $\mathrm{~N}_{2}$ | 0 | 8669 | 17,563 |
| $\mathrm{H}_{2} \mathrm{O}(g)$ | $-241,820$ | 9904 | 20,402 |
| $\mathrm{CO}_{2}$ | $-393,520$ | 9364 | 22,280 |

Substituting,

$$
\begin{aligned}
-Q_{\text {out }}= & (8)(-393,520+22,280-9364)+(10.48)(-241,820+20,402-9904) \\
& +(3.75)(0+17,929-8682)+(61.1)(0+17,563-8669) \\
& -(1)(-208,450)-(1.48)(-241,820)-0-0 \\
= & -4,324,643 \mathrm{~kJ} / \mathrm{kmol} \mathrm{C}_{8} \mathrm{H}_{18}
\end{aligned}
$$

Thus $4,324,643 \mathrm{~kJ}$ of heat is transferred from the combustion chamber for each $\mathrm{kmol}(114 \mathrm{~kg})$ of $\mathrm{C}_{8} \mathrm{H}_{18}$. Then the heat transfer per kg of $\mathrm{C}_{8} \mathrm{H}_{18}$ becomes

$$
q=\frac{Q_{\mathrm{out}}}{M}=\frac{4,324,643 \mathrm{~kJ}}{114 \mathrm{~kg}}=37,935 \mathrm{~kJ} / \mathbf{k g} \mathbf{C}_{\mathbf{8}} \mathbf{H}_{18}
$$

15-67 EES Problem 15-66 is reconsidered. The effect of the amount of excess air on the heat transfer for the combustion process is to be investigated.
Analysis The problem is solved using EES, and the solution is given below.

15-68 Ethane gas is burned with stoichiometric amount of air during a steady-flow combustion process. The rate of heat transfer from the combustion chamber is to be determined.
Assumptions 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. $\mathbf{3}$ Kinetic and potential energies are negligible. 4 Combustion is complete.
Properties The molar mass of $\mathrm{C}_{2} \mathrm{H}_{6}$ is $30 \mathrm{~kg} / \mathrm{kmol}$ (Table A-1).
Analysis The theoretical combustion equation of $\mathrm{C}_{2} \mathrm{H}_{6}$ is

$$
\mathrm{C}_{2} \mathrm{H}_{6}+a_{\mathrm{th}}\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 2 \mathrm{CO}_{2}+3 \mathrm{H}_{2} \mathrm{O}+3.76 a_{\mathrm{th}} \mathrm{~N}_{2}
$$

where $a_{\mathrm{th}}$ is the stoichiometric coefficient and is determined from the $\mathrm{O}_{2}$ balance,

$$
a_{\mathrm{th}}=2+1.5=3.5
$$

Then the actual combustion equation can be written as

$$
\mathrm{C}_{2} \mathrm{H}_{6}+3.5\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 1.9 \mathrm{CO}_{2}+0.1 \mathrm{CO}+3 \mathrm{H}_{2} \mathrm{O}+0.05 \mathrm{O}_{2}+13.16 \mathrm{~N}_{2}
$$

The heat transfer for this combustion process is determined from the energy balance $E_{\text {in }}-E_{\text {out }}=\Delta E_{\text {system }}$ applied on the combustion chamber with $W=0$. It reduces to

$$
-Q_{\mathrm{out}}=\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{P}-\sum N_{R}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{R}
$$

Assuming the air and the combustion products to be ideal gases, we have $h=h(T)$. From the tables,

|  | $\overline{\mathbf{h}}_{\mathbf{f}}^{\circ}$ | $\overline{\mathbf{h}}_{\mathbf{5 0 0} \mathbf{K}}$ | $\overline{\mathbf{h}}_{\mathbf{2 9 8} \mathbf{K}}$ | $\overline{\mathbf{h}}_{\mathbf{8 0 0} \mathbf{K}}$ |
| :--- | :--- | :--- | :--- | :--- |
| Substance | $\mathbf{k J} / \mathbf{k m o l}$ | $\mathbf{k J} / \mathbf{k m o l}$ | $\mathbf{k J} / \mathbf{k m o l}$ | $\mathbf{k J} / \mathbf{k m o l}$ |
| $\mathrm{C}_{2} \mathrm{H}_{6}(g)$ | $-84,680$ | --- | --- | --- |
| $\mathrm{O}_{2}$ | 0 | 14,770 | 8682 | 24,523 |
| $\mathrm{~N}_{2}$ | 0 | 14,581 | 8669 | 23,714 |
| $\mathrm{H}_{2} \mathrm{O}(g)$ | $-241,820$ | -- | 9904 | 27,896 |
| CO | $-110,530$ | --- | 8669 | 23,844 |
| $\mathrm{CO}_{2}$ | $-393,520$ | --- | 9364 | 32,179 |

Thus,

$$
\begin{aligned}
-Q_{\text {out }}= & (1.9)(-393,520+32,179-9364)+(0.1)(-110,530+23,844-8669) \\
& +(3)(-241,820+27,896-9904)+(0.05)(0+24,523-8682)+(13.16)(0+23,714-8669) \\
& -(1)\left(-84,680+h_{298}-h_{298}\right)-(3.5)(0+14,770-8682)-(13.16)(0+14,581-8669) \\
= & -1,201,005 \mathrm{~kJ} / \mathrm{kmol} \mathrm{C}_{2} \mathrm{H}_{6} \\
Q_{\text {out }}= & 1,201,005 \mathrm{~kJ} / \mathrm{kmol} \mathrm{C}_{2} \mathrm{H}_{6}
\end{aligned}
$$

or
Then the rate of heat transfer for a mass flow rate of $3 \mathrm{~kg} / \mathrm{h}$ for the ethane becomes

$$
\dot{Q}_{\mathrm{out}}=\dot{N} Q_{\mathrm{out}}=\left(\frac{\dot{m}}{M}\right) Q_{\mathrm{out}}=\left(\frac{5 \mathrm{~kg} / \mathrm{h}}{30 \mathrm{~kg} / \mathrm{kmol}}\right)(1,201,005 \mathrm{~kJ} / \mathrm{kmol})=\mathbf{2 0 0 , 1 7 0} \mathbf{k J} / \mathbf{h}
$$

15-69 [Also solved by EES on enclosed CD] A mixture of methane and oxygen contained in a tank is burned at constant volume. The final pressure in the tank and the heat transfer during this process are to be determined.
Assumptions 1 Air and combustion gases are ideal gases. 2 Combustion is complete.
Properties The molar masses of $\mathrm{CH}_{4}$ and $\mathrm{O}_{2}$ are $16 \mathrm{~kg} / \mathrm{kmol}$ and $32 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).
Analysis (a) The combustion is assumed to be complete, and thus all the carbon in the methane burns to $\mathrm{CO}_{2}$ and all of the hydrogen to $\mathrm{H}_{2} \mathrm{O}$. The number of moles of $\mathrm{CH}_{4}$ and $\mathrm{O}_{2}$ in the tank are

$$
\begin{aligned}
& N_{\mathrm{CH}_{4}}=\frac{m_{\mathrm{CH}_{4}}}{M_{\mathrm{CH}_{4}}}=\frac{0.12 \mathrm{~kg}}{16 \mathrm{~kg} / \mathrm{kmol}}=7.5 \times 10^{-3} \mathrm{kmol}=7.5 \mathrm{~mol} \\
& N_{\mathrm{O}_{2}}=\frac{m_{\mathrm{O}_{2}}}{M_{\mathrm{O}_{2}}}=\frac{0.6 \mathrm{~kg}}{32 \mathrm{~kg} / \mathrm{kmol}}=18.75 \times 10^{-3} \mathrm{kmol}=18.75 \mathrm{~mol}
\end{aligned}
$$

Then the combustion equation can be written as

$$
7.5 \mathrm{CH}_{4}+18.75 \mathrm{O}_{2} \longrightarrow 7.5 \mathrm{CO}_{2}+15 \mathrm{H}_{2} \mathrm{O}+3.75 \mathrm{O}_{2}
$$

At 1200 K, water exists in the gas phase. Assuming both the reactants and the products to be ideal gases, the final pressure in the tank is determined to be

$$
\left.\begin{array}{l}
P_{R} \boldsymbol{V}=N_{R} R_{u} T_{R} \\
P_{P} \boldsymbol{V}=N_{P} R_{u} T_{P}
\end{array}\right\} P_{P}=P_{R}\left(\frac{N_{P}}{N_{R}}\right)\left(\frac{T_{P}}{T_{R}}\right)
$$

Substituting,

$$
P_{P}=(200 \mathrm{kPa})\left(\frac{26.25 \mathrm{~mol}}{26.25 \mathrm{~mol}}\right)\left(\frac{1200 \mathrm{~K}}{298 \mathrm{~K}}\right)=\mathbf{8 0 5} \mathbf{~ k P a}
$$

which is relatively low. Therefore, the ideal gas assumption utilized earlier is appropriate.
(b) The heat transfer for this constant volume combustion process is determined from the energy balance $E_{\text {in }}-E_{\text {out }}=\Delta E_{\text {system }}$ applied on the combustion chamber with $W=0$. It reduces to

$$
-Q_{\text {out }}=\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}-P \bar{v}\right)_{P}-\sum N_{R}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}-P \bar{v}\right)_{R}
$$

Since both the reactants and products are assumed to be ideal gases, all the internal energy and enthalpies depend on temperature only, and the $P \overline{\boldsymbol{v}}$ terms in this equation can be replaced by $R_{u} T$. It yields

$$
-Q_{\text {out }}=\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}_{1200 \mathrm{~K}}-\bar{h}_{298 \mathrm{~K}}-R_{u} T\right)_{P}-\sum N_{R}\left(\bar{h}_{f}^{\circ}-R_{u} T\right)_{R}
$$

since the reactants are at the standard reference temperature of $25^{\circ} \mathrm{C}$. From the tables,

| Substance | $\overline{\mathbf{h}}_{\mathbf{f}}^{\circ}$ <br> $\mathbf{k J} / \mathbf{k m o l}$ | $\overline{\mathbf{h}}_{\mathbf{2 9 8} \mathbf{K}}$ <br> $\mathbf{k J} / \mathbf{k m o l}$ | $\overline{\mathbf{h}}_{\mathbf{1 2 0 0} \mathbf{K}}$ <br> $\mathbf{k J} / \mathbf{k m o l}$ |
| :--- | :--- | :--- | :--- |
| $\mathrm{CH}_{4}$ | $-74,850$ | --- | --- |
| $\mathrm{O}_{2}$ | 0 | 8682 | 38,447 |
| $\mathrm{H}_{2} \mathrm{O}(g)$ | $-241,820$ | 9904 | 44,380 |
| $\mathrm{CO}_{2}$ | $-393,520$ | 9364 | 53,848 |

Thus,

$$
\begin{aligned}
-Q_{\text {out }}= & (7.5)(-393,520+53,848-9364-8.314 \times 1200) \\
& +(15)(-241,820+44,380-9904-8.314 \times 1200) \\
& +(3.75)(0+38,447-8682-8.314 \times 1200) \\
& -(7.5)(-74,850-8.314 \times 298)-(18.75)(-8.314 \times 298) \\
= & -5,251,791 \mathrm{~J}=-5252 \mathrm{~kJ}
\end{aligned}
$$

Thus $Q_{\text {out }}=5252 \mathbf{k J}$ of heat is transferred from the combustion chamber as 120 g of $\mathrm{CH}_{4}$ burned in this combustion chamber.

15-70 EES Problem 15-69 is reconsidered. The effect of the final temperature on the final pressure and the heat transfer for the combustion process is to be investigated.
Analysis The problem is solved using EES, and the solution is given below.

15-71 Propane is burned with $50 \%$ excess air. The heat transfer per kmol of fuel is to be determined for given reactants and products temperatures.
Assumptions 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 Combustion is complete. 5 The reactants are at $17{ }^{\circ} \mathrm{C}$ and 1 atm .6 The fuel is in vapor phase.
Properties The molar masses of propane and air are $44 \mathrm{~kg} / \mathrm{kmol}$ and $29 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).
Analysis The combustion equation can be written as

$$
\mathrm{C}_{3} \mathrm{H}_{8}+1.5 a_{\mathrm{th}}\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 3 \mathrm{CO}_{2}+4 \mathrm{H}_{2} \mathrm{O}+0.5 a_{\mathrm{th}} \mathrm{O}_{2}+1.5 a_{\mathrm{th}} \times 3.76 \mathrm{~N}_{2}
$$

The stoichiometric coefficient is obtained from $\mathrm{O}_{2}$ balance:

$$
1.5 a_{\mathrm{th}}=3+2+0.5 a_{\mathrm{th}} \longrightarrow a_{\mathrm{th}}=5
$$

Substituting,

$$
\mathrm{C}_{3} \mathrm{H}_{8}+7.5\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 3 \mathrm{CO}_{2}+4 \mathrm{H}_{2} \mathrm{O}+2.5 \mathrm{O}_{2}+28.2 \mathrm{~N}_{2}
$$

The heat transfer for this combustion process is determined from the energy balance $E_{\text {in }}-E_{\text {out }}=\Delta E_{\text {system }}$ applied on the combustion chamber with $W=0$. It reduces to

$$
-Q_{\mathrm{out}}=\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{P}-\sum N_{R}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{R}
$$

Assuming the air and the combustion products to be ideal gases, we have $h=h(T)$. From the tables,

|  | $\bar{h}_{f}^{\circ}$ | $\bar{h}_{290 \mathrm{~K}}$ | $\bar{h}_{298 \mathrm{~K}}$ | $\bar{h}_{370 \mathrm{~K}}$ |
| :--- | :--- | :--- | :--- | :--- |
| Substance | $\mathrm{kJ} / \mathrm{kmol}$ | $\mathrm{kJ} / \mathrm{kmol}$ | $\mathrm{kJ} / \mathrm{kmol}$ | $\mathrm{kJ} / \mathrm{kmol}$ |
| $\mathrm{C}_{3} \mathrm{H}_{8}$ | $-103,850$ | --- | --- | --- |
| $\mathrm{O}_{2}$ | 0 | 8443 | 8682 | 10,809 |
| $\mathrm{~N}_{2}$ | 0 | 8432 | 8669 | 10,763 |
| $\mathrm{H}_{2} \mathrm{O}(g)$ | $-241,820$ | - | 9904 | 12,331 |
| $\mathrm{CO}_{2}$ | $-393,520$ | - | 9364 | 12,148 |

Substituting,

$$
\begin{aligned}
-Q_{\text {out }} & =(3)(-393,520+12,148-9364)+(4)(-241,820+12,331-9904)+(2.5)(0+10,809-8682) \\
& +(28.2)(0+10,763-8669)-(1)(-103,850)-(7.5)(0+8443-8682)-(28.2)(0+8432-8669) \\
& =-1,953,000 \mathrm{~kJ} / \mathrm{kmol} \mathrm{C}_{3} \mathrm{H}_{8}
\end{aligned}
$$

or $\quad Q_{\text {out }}=1,953,000 \mathrm{~kJ} / \mathrm{kmol} \mathrm{C} \mathbf{3}_{3} \mathrm{H}_{8}$
Discussion We neglected the enthalpy difference of propane between the standard temperature $25^{\circ} \mathrm{C}$ and the given temperature $17^{\circ} \mathrm{C}$ since the data is not available. It may be shown that the contribution of this would be small.

15-72E Methane is burned with stoichiometric amount of air in a rigid container. The heat rejected from the container is to be determined.

Assumptions 1 Air and combustion gases are ideal gases. 2 Combustion is complete.
Properties The molar masses of $\mathrm{CH}_{4}$ and air are $16 \mathrm{lbm} / \mathrm{lbmol}$ and $29 \mathrm{lbm} / \mathrm{lbmol}$, respectively (Table A1E).
Analysis The combustion equation for 1 lbmol of fuel is

$$
\mathrm{CH}_{4}+2\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow \mathrm{CO}_{2}+2 \mathrm{H}_{2} \mathrm{O}+7.52 \mathrm{~N}_{2}
$$

The heat transfer for this constant volume combustion process is determined from the energy balance $E_{\text {in }}-E_{\text {out }}=\Delta E_{\text {system }}$ applied on the combustion chamber with $W=0$. It reduces to

$$
-Q_{\mathrm{out}}=\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}-P \overline{\boldsymbol{v}}\right)_{P}-\sum N_{R}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}-P \overline{\boldsymbol{v}}\right)_{R}
$$

Since both the reactants and products are assumed to be ideal gases, all the internal energy and enthalpies depend on temperature only, and the $P \bar{v}$ terms in this equation can be replaced by $R_{u} T$. It yields

$$
-Q_{\mathrm{out}}=\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}_{1300 \mathrm{R}}-\bar{h}_{537 \mathrm{R}}-R_{u} T\right)_{P}-\sum N_{R}\left(\bar{h}_{f}^{\circ}-R_{u} T\right)_{R}
$$

since the reactants are at the standard reference temperature of $77^{\circ} \mathrm{F}$. From the tables,

|  | $\overline{\mathbf{h}}_{\mathbf{f}}^{\circ}$ | $\overline{\mathbf{h}}_{537 \mathrm{R}}$ | $\overline{\mathbf{h}}_{1300 \mathrm{R}}$ |
| :--- | :--- | :--- | :--- |
| Substance | Btu/lbmol | Btu/lbmol | Btu/lbmol |
| $\mathrm{CH}_{4}$ | $-32,210$ | --- | --- |
| $\mathrm{O}_{2}$ | 0 | 3725.1 | 9412.9 |
| $\mathrm{~N}_{2}$ | 0 | 3729.5 | 9153.9 |
| $\mathrm{H}_{2} \mathrm{O}(g)$ | $-104,040$ | 4258.0 | $10,714.5$ |
| $\mathrm{CO}_{2}$ | $-169,300$ | 4027.5 | $12,136.9$ |

Thus,

$$
\begin{aligned}
-Q_{\text {out }}= & (1)(-169,300+12,136.9-4027.5-1.9858 \times 1300) \\
& +(2)(-104,040+10,714.5-4258.0-1.9858 \times 1300) \\
& +(7.52)(0+9153.9-3729.5-1.9858 \times 1300) \\
& -(1)(-32,210-1.9858 \times 537)-(2)(-1.9858 \times 537)-(7.52)(-1.9858 \times 537) \\
= & -299,300 \mathrm{Btu}^{(\mathrm{lbmol} \mathrm{CH}} 4
\end{aligned}
$$

Thus

$$
Q_{\text {out }}=299,300 \mathrm{Btu}^{2} \mathrm{Ibmol} \mathrm{CH} 4
$$

15-73 Wheat straw that is being considered as an alternative fuel is tested in a bomb calorimeter. The heating value of this straw is to be determined and compared to the higher heating value of propane.
Assumptions 1 Combustion is complete.
Analysis The heat released by the combustion is

$$
Q=m c_{v} \Delta T=(100 \mathrm{~kJ} / \mathrm{K})(1.8 \mathrm{~K})=180 \mathrm{~kJ}
$$

The heating value is then

$$
\mathrm{HV}=\frac{Q}{m}=\frac{180 \mathrm{~kJ}}{0.010 \mathrm{~kg}}=\mathbf{1 8}, \mathbf{0 0 0} \mathbf{~ k J} / \mathbf{k g}
$$

From Table A-27, the higher heating value of propane is

$$
\mathrm{HHV}=\mathbf{5 0 , 3 3 0} \mathbf{k J} / \mathbf{k g}
$$

15-74 A mixture of benzene gas and 30 percent excess air contained in a constant-volume tank is ignited. The heat transfer from the combustion chamber is to be determined.

Assumptions 1 Both the reactants and products are ideal gases. 2 Combustion is complete.
Analysis The theoretical combustion equation of $\mathrm{C}_{6} \mathrm{H}_{6}$ with stoichiometric amount of air is

$$
\mathrm{C}_{6} \mathrm{H}_{6}(\mathrm{~g})+a_{\mathrm{th}}\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 6 \mathrm{CO}_{2}+3 \mathrm{H}_{2} \mathrm{O}+3.76 a_{\mathrm{th}} \mathrm{~N}_{2}
$$

where $a_{\mathrm{th}}$ is the stoichiometric coefficient and is determined from the $\mathrm{O}_{2}$ balance,

$$
a_{\mathrm{th}}=6+1.5=7.5
$$

Then the actual combustion equation with $30 \%$ excess air becomes

$$
\mathrm{C}_{6} \mathrm{H}_{6}(\mathrm{~g})+9.75\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 5.52 \mathrm{CO}_{2}+0.48 \mathrm{CO}+3 \mathrm{H}_{2} \mathrm{O}+2.49 \mathrm{O}_{2}+36.66 \mathrm{~N}_{2}
$$

The heat transfer for this constant volume combustion process is determined from the energy balance $E_{\text {in }}-E_{\text {out }}=\Delta E_{\text {system }}$ applied on the combustion chamber with $W=0$. It reduces to

$$
-Q_{\mathrm{out}}=\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}-P \bar{v}\right)_{P}-\sum N_{R}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}-P \bar{v}\right)_{R}
$$

Since both the reactants and the products behave as ideal gases, all the internal energy and enthalpies depend on temperature only, and the $P \bar{v}$ terms in this equation can be replaced by $R_{u} T$.

It yields

$$
-Q_{\text {out }}=\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}_{1000 \mathrm{~K}}-\bar{h}_{298 \mathrm{~K}}-R_{u} T\right)_{P}-\sum N_{R}\left(\bar{h}_{f}^{\circ}-R_{u} T\right)_{R}
$$

since the reactants are at the standard reference temperature of $25^{\circ} \mathrm{C}$. From the tables,

| Substance | $\overline{\mathbf{h}}_{\mathbf{f}}^{\circ}$ | $\overline{\mathbf{h}}_{\mathbf{2 9 8} \mathbf{K}}$ | $\overline{\mathbf{h}}_{\mathbf{1 0 0 0} \mathbf{K}}$ |
| :--- | :--- | :--- | :--- |
| $\mathbf{k J} / \mathbf{k m o l}$ | $\mathbf{k J} / \mathbf{k m o l}$ | $\mathbf{k J / k m o l}$ |  |
| $\mathrm{C}_{6} \mathrm{H}_{6}(g)$ | 82,930 | --- | --- |
| $\mathrm{O}_{2}$ | 0 | 8682 | 31,389 |
| $\mathrm{~N}_{2}$ | 0 | 8669 | 30,129 |
| $\mathrm{H}_{2} \mathrm{O}(g)$ | $-241,820$ | 9904 | 35,882 |
| CO | $-110,530$ | 8669 | 30,355 |
| $\mathrm{CO}_{2}$ | $-393,520$ | 9364 | 42,769 |

Thus,

$$
\begin{aligned}
-Q_{\text {out }}= & (5.52)(-393,520+42,769-9364-8.314 \times 1000) \\
& +(0.48)(-110,530+30,355-8669-8.314 \times 1000) \\
& +(3)(-241,820+35,882-9904-8.314 \times 1000) \\
& +(2.49)(0+31,389-8682-8.314 \times 1000) \\
& +(36.66)(0+30,129-8669-8.314 \times 1000) \\
& -(1)(82,930-8.314 \times 298)-(9.75)(4.76)(-8.314 \times 298) \\
= & -2,200,433 \mathrm{~kJ}
\end{aligned}
$$

or

$$
Q_{\text {out }}=2,200,433 \mathbf{k J}
$$

15-75E A mixture of benzene gas and 30 percent excess air contained in a constant-volume tank is ignited. The heat transfer from the combustion chamber is to be determined.

Assumptions 1 Both the reactants and products are ideal gases. 2 Combustion is complete.
Analysis The theoretical combustion equation of $\mathrm{C}_{6} \mathrm{H}_{6}$ with stoichiometric amount of air is

$$
\mathrm{C}_{6} \mathrm{H}_{6}(\mathrm{~g})+a_{\mathrm{th}}\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 6 \mathrm{CO}_{2}+3 \mathrm{H}_{2} \mathrm{O}+3.76 a_{\mathrm{th}} \mathrm{~N}_{2}
$$

where $a_{\mathrm{th}}$ is the stoichiometric coefficient and is determined from the $\mathrm{O}_{2}$ balance,

$$
a_{\mathrm{th}}=6+1.5=7.5
$$

Then the actual combustion equation with $30 \%$ excess air becomes

$$
\mathrm{C}_{6} \mathrm{H}_{6}(\mathrm{~g})+9.75\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 5.52 \mathrm{CO}_{2}+0.48 \mathrm{CO}+3 \mathrm{H}_{2} \mathrm{O}+2.49 \mathrm{O}_{2}+36.66 \mathrm{~N}_{2}
$$

The heat transfer for this constant volume combustion process is determined from the energy balance $E_{\text {in }}-E_{\text {out }}=\Delta E_{\text {system }}$ applied on the combustion chamber with $\mathrm{W}=0$. It reduces to

$$
-Q_{\text {out }}=\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}-P \bar{v}\right)_{P}-\sum N_{R}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}-P \bar{v}\right)_{R}
$$

Since both the reactants and the products behave as ideal gases, all the internal energy and enthalpies depend on temperature only, and the $P \bar{V}$ terms in this equation can be replaced by $R_{u} T$.

It yields

$$
-Q_{\mathrm{out}}=\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}_{1800 \mathrm{R}}-\bar{h}_{537 \mathrm{R}}-R_{u} T\right)_{P}-\sum N_{R}\left(\bar{h}_{f}^{\circ}-R_{u} T\right)_{R}
$$

since the reactants are at the standard reference temperature of $77^{\circ} \mathrm{F}$. From the tables,

| Substance | $\overline{\mathbf{h}}_{\mathbf{f}}^{\circ}$ | $\overline{\mathbf{h}}_{\mathbf{5 3 7} \mathbf{R}}$ | $\overline{\mathbf{h}}_{\mathbf{1 8 0 0} \mathbf{R}}$ |
| :--- | :--- | :--- | :--- |
|  | Btu/lbmol | Btu/lbmol | Btu/lbmol |
| $\mathrm{C}_{6} \mathrm{H}_{6}(g)$ | 35,6860 | --- | --- |
| $\mathrm{O}_{2}$ | 0 | 3725.1 | $13,485.8$ |
| $\mathrm{~N}_{2}$ | 0 | 3729.5 | $12,956.3$ |
| $\mathrm{H}_{2} \mathrm{O}(g)$ | $-104,040$ | 4258.0 | $15,433.0$ |
| CO | $-47,540$ | 3725.1 | $13,053.2$ |
| $\mathrm{CO}_{2}$ | $-169,300$ | 4027.5 | $18,391.5$ |

Thus,

$$
\begin{aligned}
-Q_{\text {out }}= & (5.52)(-169,300+18,391.5-4027.5-1.986 \times 1800) \\
& +(0.48)(-47,540+13,053.2-3725.1-1.986 \times 1800) \\
& +(3)(-104,040+15,433.0-4258.0-1.986 \times 1800) \\
& +(2.49)(0+13,485.8-3725.1-1.986 \times 1800) \\
& +(36.66)(0+12,956.3-3729.5-1.986 \times 1800) \\
& -(1)(35,680-1.986 \times 537)-(9.75)(4.76)(-1.986 \times 537) \\
= & -946,870 \text { Btu }
\end{aligned}
$$

or

$$
Q_{\text {out }}=946,870 \mathrm{Btu}
$$

15-76 A high efficiency gas furnace burns gaseous propane $\mathrm{C}_{3} \mathrm{H}_{8}$ with 140 percent theoretical air. The volume flow rate of water condensed from the product gases is to be determined.

Assumptions 1 Combustion is complete. 2 The combustion products contain $\mathrm{CO}_{2}, \mathrm{H}_{2} \mathrm{O}, \mathrm{O}_{2}$, and $\mathrm{N}_{2}$ only.
Properties The molar masses of $\mathrm{C}, \mathrm{H}_{2}, \mathrm{O}_{2}$ and air are $12 \mathrm{~kg} / \mathrm{kmol}, 2 \mathrm{~kg} / \mathrm{kmol}, 32 \mathrm{~kg} / \mathrm{kmol}$, and $29 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).
Analysis The reaction equation for 40\% excess air (140\% theoretical air) is

$$
\mathrm{C}_{3} \mathrm{H}_{8}+1.4 a_{\mathrm{th}}\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow B \mathrm{CO}_{2}+D \mathrm{H}_{2} \mathrm{O}+E \mathrm{O}_{2}+F \mathrm{~N}_{2}
$$

where $a_{\mathrm{th}}$ is the stoichiometric coefficient for air. We have automatically accounted for the $40 \%$ excess air by using the factor $1.4 a_{\mathrm{th}}$ instead of $a_{t h}$ for air. The coefficient $a_{\mathrm{th}}$ and other coefficients are to be determined from the mass balances

| Carbon balance: | $B=3$ |
| :--- | :--- |
| Hydrogen balance: | $2 D=8 \longrightarrow D=4$ |
| Oxygen balance: | $2 \times 1.4 a_{\mathrm{th}}=2 B+D+2 E$ |
|  | $0.4 a_{\mathrm{th}}=E$ |
| Nitrogen balance: | $1.4 a_{\mathrm{th}} \times 3.76=F$ |

Nitrogen balance: $\quad 1.4 a_{\text {th }} \times 3.76=F$
Solving the above equations, we find the coefficients ( $E=2, F=$ 26.32, and $a_{\mathrm{th}}=5$ ) and write the balanced reaction equation as

$$
\mathrm{C}_{3} \mathrm{H}_{8}+7\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow 3 \mathrm{CO}_{2}+4 \mathrm{H}_{2} \mathrm{O}+2 \mathrm{O}_{2}+26.32 \mathrm{~N}_{2}
$$

The partial pressure of water in the saturated product mixture at the dew point is

$$
P_{v, \text { prod }}=P_{\text {sat } @ 40^{\circ} \mathrm{C}}=7.3851 \mathrm{kPa}
$$

The vapor mole fraction is

$$
y_{v}=\frac{P_{v, \text { prod }}}{P_{\text {prod }}}=\frac{7.3851 \mathrm{kPa}}{100 \mathrm{kPa}}=0.07385
$$

The kmoles of water condensed is determined from

$$
y_{v}=\frac{N_{\text {water }}}{N_{\text {total, product }}} \longrightarrow 0.07385=\frac{4-N_{\mathrm{w}}}{3+4-N_{\mathrm{w}}+2+26.32} \longrightarrow N_{\mathrm{w}}=1.503 \mathrm{kmol}
$$

The steady-flow energy balance is expressed as

$$
\dot{N}_{\text {fuel }} H_{R}=\dot{Q}_{\text {fuel }}+\dot{N}_{\text {fuel }} H_{P}
$$

where

$$
\begin{aligned}
\dot{Q}_{\text {fuel }} & =\frac{\dot{Q}_{\text {out }}}{\eta_{\text {furnace }}}=\frac{31,650 \mathrm{~kJ} / \mathrm{h}}{0.96}=32,969 \mathrm{~kJ} / \mathrm{h} \\
H_{R} & =\bar{h}_{f \text { fuel } @ 25^{\circ} \mathrm{C}}^{o}+7 \bar{h}_{\mathrm{O} 2 @ 25^{\circ} \mathrm{C}}+26.32 \bar{h}_{\mathrm{N} 2 @ 25^{\circ} \mathrm{C}} \\
& =(-103,847 \mathrm{~kJ} / \mathrm{kmol})+7(0)+26.32(0)=-103,847 \mathrm{~kJ} / \mathrm{kmol}
\end{aligned}
$$ educators for course preparation. If you are a student using this Manual, you are using it without permission.

$$
\begin{aligned}
H_{P} & =3 \bar{h}_{\mathrm{CO} 2 @ 25^{\circ} \mathrm{C}}+4 \bar{h}_{\mathrm{H} 2 \mathrm{O} @ 25^{\circ} \mathrm{C}}+2 \bar{h}_{\mathrm{O} 2 @ 25^{\circ} \mathrm{C}}+26.32 \bar{h}_{\mathrm{N} 2 @ 25^{\circ} \mathrm{C}}+N_{\mathrm{w}}\left(\bar{h}_{f}^{o}{ }_{\mathrm{H} 2 \mathrm{O}(\mathrm{liq})}\right) \\
& =3(-393,520 \mathrm{~kJ} / \mathrm{kmol})+4(-241,820 \mathrm{~kJ} / \mathrm{kmol})+2(0)+26.32(0)+1.503(-285,830 \mathrm{~kJ} / \mathrm{kmol}) \\
& =-2.577 \times 10^{6} \mathrm{~kJ} / \mathrm{kmol}
\end{aligned}
$$

Substituting into the energy balance equation,

$$
\begin{aligned}
\dot{N}_{\text {fuel }} H_{R} & =\dot{Q}_{\text {fuel }}+\dot{N}_{\text {fuel }} H_{P} \\
\dot{N}_{\text {fuel }}(-103,847 \mathrm{~kJ} / \mathrm{kmol}) & =32,969 \mathrm{~kJ} / \mathrm{h}+\dot{N}_{\text {fuel }}\left(-2.577 \times 10^{6} \mathrm{~kJ} / \mathrm{kmol}\right) \\
\dot{N}_{\text {fuel }} & =0.01333 \mathrm{kmol} / \mathrm{h}
\end{aligned}
$$

The molar and mass flow rates of the liquid water are

$$
\begin{aligned}
& \dot{N}_{\mathrm{w}}=N_{\mathrm{w}} \dot{N}_{\text {fuel }}=(1.503 \mathrm{kmol} / \mathrm{kmol} \text { fuel })(0.01333 \mathrm{kmol} \text { fuel } / \mathrm{h})=0.02003 \mathrm{kmol} / \mathrm{h} \\
& \dot{m}_{\mathrm{w}}=\dot{N}_{\mathrm{w}} M_{\mathrm{w}}=(0.02003 \mathrm{kmol} / \mathrm{h})(18 \mathrm{~kg} / \mathrm{kmol})=0.3608 \mathrm{~kg} / \mathrm{h}
\end{aligned}
$$

The volume flow rate of liquid water is

$$
\dot{\boldsymbol{V}}_{\mathrm{w}}=\left(\boldsymbol{v}_{f @ 25^{\circ} \mathrm{C}}\right) \dot{m}_{\mathrm{w}}=\left(0.001003 \mathrm{~m}^{3} / \mathrm{kg}\right)(0.3608 \mathrm{~kg} / \mathrm{h})=0.0003619 \mathrm{~m}^{3} / \mathrm{h}=8.7 \text { L/day }
$$

## Adiabatic Flame Temperature

15-77C For the case of stoichiometric amount of pure oxygen since we have the same amount of chemical energy released but a smaller amount of mass to absorb it.

15-78C Under the conditions of complete combustion with stoichiometric amount of air.

15-79 [Also solved by EES on enclosed CD] Hydrogen is burned with 20 percent excess air during a steadyflow combustion process. The exit temperature of product gases is to be determined.
Assumptions 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 There are no work interactions. 5 The combustion chamber is adiabatic.
Analysis Adiabatic flame temperature is the temperature at which the products leave the combustion chamber under adiabatic conditions ( $Q=0$ ) with no work interactions ( $W=0$ ). Under steady-flow conditions the energy balance $E_{\text {in }}-E_{\text {out }}=\Delta E_{\text {system }}$ applied on the combustion chamber reduces to

$$
\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{P}=\sum N_{R}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{R}
$$

The combustion equation of $\mathrm{H}_{2}$ with $20 \%$ excess air is
$\mathrm{H}_{2}+0.6\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow \mathrm{H}_{2} \mathrm{O}+0.1 \mathrm{O}_{2}+2.256 \mathrm{~N}_{2}$
From the tables,

| Substance | $\overline{\mathbf{h}}_{\mathbf{f}}^{\circ}$ <br> $\mathbf{k J / k m o l}$ | $\overline{\mathbf{h}}_{280 \text { K }}$ <br> $\mathbf{k J / k m o l}$ | $\overline{\mathbf{h}}_{298} \mathbf{K}$ <br> $\mathbf{k J / k m o l}$ |
| :--- | :--- | :--- | :--- |
| $\mathrm{H}_{2}$ | 0 | 7945 | 8468 |
| $\mathrm{O}_{2}$ | 0 | 8150 | 8682 |
| $\mathrm{~N}_{2}$ | 0 | 8141 | 8669 |
| $\mathrm{H}_{2} \mathrm{O}(g)$ | $-241,820$ | 9296 | 9904 |

Thus,

$$
\begin{aligned}
& (1)\left(-241,820+\bar{h}_{\mathrm{H}_{2} \mathrm{O}}-9904\right)+(0.1)\left(0+\bar{h}_{\mathrm{O}_{2}}-8682\right)+(2.256)\left(0+\bar{h}_{\mathrm{N}_{2}}-8669\right) \\
& =(1)(0+7945-8468)+(0.6)(0+8150-8682)+(2.256)(0+8141-8669)
\end{aligned}
$$

It yields

$$
\bar{h}_{\mathrm{H}_{2} \mathrm{O}}+0.1 \bar{h}_{\mathrm{O}_{2}}+2.256 \bar{h}_{\mathrm{N}_{2}}=270,116 \mathrm{~kJ}
$$

The adiabatic flame temperature is obtained from a trial and error solution. A first guess is obtained by dividing the right-hand side of the equation by the total number of moles, which yields 270,116/(1+0.1 + $2.256)=80,488 \mathrm{~kJ} / \mathrm{kmol}$. This enthalpy value corresponds to about 2400 K for $\mathrm{N}_{2}$. Noting that the majority of the moles are $\mathrm{N}_{2}, T_{P}$ will be close to 2400 K , but somewhat under it because of the higher specific heat of $\mathrm{H}_{2} \mathrm{O}$.
At $2300 \mathrm{~K}: \quad \bar{h}_{\mathrm{H}_{2} \mathrm{O}}+0.1 \overline{\mathrm{O}}_{\mathrm{O}_{2}}+2.256 \bar{h}_{\mathrm{N}_{2}}=(1)(98,199)+(0.1)(79,316)+(2.256)(75,676)$ $=276,856 \mathrm{~kJ}$ (Higher than 270,116 kJ)

At $2250 \mathrm{~K}: \quad \bar{h}_{\mathrm{H}_{2} \mathrm{O}}+0.1 \bar{h}_{\mathrm{O}_{2}}+2.256 \bar{h}_{\mathrm{N}_{2}}=(1)(95,562)+(0.1)(77,397)+(2.256)(73,856)$ $=269,921 \mathrm{~kJ}$ (Lower than 270,116 kJ)

By interpolation, $\quad T_{P}=\mathbf{2 2 5 1 . 4} \mathrm{K}$

15-80 EES Problem 15-79 is reconsidered. This problem is to be modified to include the fuels butane, ethane, methane, and propane as well as H 2 ; to include the effects of inlet air and fuel temperatures; and the percent theoretical air supplied.
Analysis The problem is solved using EES, and the solution is given below.

Adiabatic Combustion of fuel CnHm entering at T_fuel with Stoichiometric Air at T_air:
Reaction: $\mathrm{CxHy}+(\mathrm{y} / 4+\mathrm{x})($ Theo_air/100) $(\mathrm{O} 2+3.76 \mathrm{~N} 2)$
<--> xCO2 + (y/2) H2O + 3.76 (y/4 + x) (Theo_air/100) N2 + (y/4 + x) (Theo_air/100-1) O2
T_prod is the adiabatic combustion temperature, assuming no dissociation.
Theo_air is the \% theoretical air. " "The initial guess value of T_prod = 450K ."

Product temperature vs \% theoretical air for hydrogen

PROPRIETARY MATERIAL. © 2008 The McGraw-Hill Companies, Inc. Limited distribution permitted only to teachers and educators for course preparation. If you are a student using this Manual, you are using it without permission.

15-81E Hydrogen is burned with 20 percent excess air during a steady-flow combustion process. The exit temperature of product gases is to be determined.
Assumptions 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 There are no work interactions. 5 The combustion chamber is adiabatic.

Analysis Adiabatic flame temperature is the temperature at which the products leave the combustion chamber under adiabatic conditions $(Q=0)$ with no work interactions $(W=0)$. Under steady-flow conditions the energy balance $E_{\text {in }}-E_{\text {out }}=\Delta E_{\text {system }}$ applied on the combustion chamber reduces to

$$
\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{P}=\sum N_{R}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{R}
$$

The combustion equation of $\mathrm{H}_{2}$ with $20 \%$ excess air is

$$
\mathrm{H}_{2}+0.6\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow \mathrm{H}_{2} \mathrm{O}+0.1 \mathrm{O}_{2}+2.256 \mathrm{~N}_{2}
$$

From the tables,

|  | $\overline{\mathbf{h}}_{\mathbf{f}}^{\circ}$ | $\overline{\mathbf{h}}_{\mathbf{5 0 0} \mathbf{R}}$ | $\overline{\mathbf{h}}_{\mathbf{5 3 7} \mathbf{R}}$ |
| :--- | :--- | :--- | :--- |
| Substance | Btu/lbmol | Btu/lbmol | Btu/lbmol |
| $\mathrm{H}_{2}$ | 0 | 3386.1 | 3640.3 |
| $\mathrm{O}_{2}$ | 0 | 3466.2 | 3725.1 |
| $\mathrm{~N}_{2}$ | 0 | 3472.2 | 3729.5 |
| $\mathrm{H}_{2} \mathrm{O}(g)$ | $-104,040$ | 3962.0 | 4258.0 |

Thus,

$$
\begin{aligned}
& (1)\left(-104,040+\bar{h}_{\mathrm{H}_{2} \mathrm{O}}-4258\right)+(0.1)\left(0+\bar{h}_{\mathrm{O}_{2}}-3725.1\right)+(2.256)\left(0+\bar{h}_{\mathrm{N}_{2}}-3729.5\right) \\
& \quad=(1)(0+3386.1-3640.3)+(0.6)(0+3466.2-3725.1)+(2.256)(0+3472.2-3729.5)
\end{aligned}
$$

It yields

$$
\bar{h}_{\mathrm{H}_{2} \mathrm{O}}+0.1 \bar{h}_{\mathrm{O}_{2}}+2.256 \bar{h}_{\mathrm{N}_{2}}=116,094 \mathrm{Btu}
$$

The adiabatic flame temperature is obtained from a trial and error solution. A first guess is obtained by dividing the right-hand side of the equation by the total number of moles, which yields $116,094 /(1+0.1+$ $2.256)=34,593 \mathrm{Btu} / \mathrm{lbmol}$. This enthalpy value corresponds to about 4400 R for $\mathrm{N}_{2}$. Noting that the majority of the moles are $\mathrm{N}_{2}, T_{P}$ will be close to 4400 R , but somewhat under it because of the higher specific heat of $\mathrm{H}_{2} \mathrm{O}$.

At 4020 R: $\quad \bar{h}_{\mathrm{H}_{2} \mathrm{O}}+0.1 \bar{h}_{\mathrm{O}_{2}}+2.256 \bar{h}_{\mathrm{N}_{2}}=(1)(40,740)+(0.1)(32,989)+(2.256)(31,503)$
$=115,110$ Btu (Lower than 116, 094 Btu)
At $4100 \mathrm{R}: \quad \bar{h}_{\mathrm{H}_{2} \mathrm{O}}+0.1 \bar{h}_{\mathrm{O}_{2}}+2.256 \bar{h}_{\mathrm{N}_{2}}=(1)(41,745)+(0.1)(33,722)+(2.256)(32,198)$ $=117,756$ Btu (Higher than 116,094 Btu)

By interpolation, $\quad T_{P}=4054 \mathrm{R}$

15-82 Methane is burned with 30 percent excess air. The adiabatic flame temperature is to be determined.
Assumptions 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 There are no work interactions. 5 The combustion chamber is adiabatic.

Analysis Under steady-flow conditions the energy balance $E_{\text {in }}-E_{\text {out }}=\Delta E_{\text {system }}$ applied on the combustion chamber with $Q=W=0$ reduces to

$$
\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{P}=\sum N_{R}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{R} \longrightarrow \sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{P}=\sum N_{R} \bar{h}_{f, R}^{\circ}
$$

since all the reactants are at the standard reference temperature of $25^{\circ} \mathrm{C}$. Then,

$$
\mathrm{CH}_{4}+1.3 \times a_{\mathrm{th}}\left(\mathrm{O}_{2}+3.76 N_{2}\right) \longrightarrow \mathrm{CO}_{2}+2 \mathrm{H}_{2} \mathrm{O}+0.3 \mathrm{O}_{2}+1.3 \times a_{\mathrm{th}} \times 3.76 \mathrm{~N}_{2}
$$

where $a_{\mathrm{th}}$ is the stoichiometric coefficient and is determined from the $\mathrm{O}_{2}$ balance,

$$
1.3 a_{\mathrm{th}}=1+1+0.3 a_{\mathrm{th}} \longrightarrow a_{\mathrm{th}}=2
$$

Thus, $\mathrm{CH}_{4}+2.6\left(\mathrm{O}_{2}+3.76 N_{2}\right) \longrightarrow \mathrm{CO}_{2}+2 \mathrm{H}_{2} \mathrm{O}+0.3 \mathrm{O}_{2}+9.776 \mathrm{~N}_{2}$
From the tables,

| Substance | $\overline{\mathbf{h}}_{\mathbf{f}}^{\circ}$ <br> kJ/kmol | $\overline{\mathbf{h}}_{298 \mathrm{~K}}$ <br> kJ/kmol | $\xrightarrow[25^{\circ} \mathrm{C}]{\mathrm{CH}_{4}}$ | Combustion | $\xrightarrow{\text { Products }}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{H}_{4}(\mathrm{~g})$ | -74,850 | --- | Air |  | $T_{P}$ |
| $\mathrm{O}_{2}$ | 0 | 8682 | 30\% excess air $25^{\circ} \mathrm{C}$ |  |  |
| $\mathrm{N}_{2}$ | 0 | 8669 |  |  |  |
| $\mathrm{H}_{2} \mathrm{O}(\mathrm{g})$ | -241,820 | 9904 |  |  |  |
| $\mathrm{CO}_{2}$ | -393,520 | 9364 |  |  |  |

Thus,

$$
\begin{aligned}
& (1)\left(-393,520+\bar{h}_{\mathrm{CO} 2}-9364\right)+(2)\left(-241,820+\bar{h}_{\mathrm{H} 2 \mathrm{O}}-9904\right)+(0.3)\left(0+\bar{h}_{\mathrm{O} 2}-8682\right) \\
& +(9.776)\left(0+\bar{h}_{\mathrm{N} 2}-8669\right)=(1)(-74,850)+0+0 \\
& \bar{h}_{\mathrm{CO} 2}+2 \bar{h}_{\mathrm{H} 2 \mathrm{O}}+0.3 \bar{h}_{\mathrm{O} 2}+9.776 \bar{h}_{\mathrm{N} 2}=918,835 \mathrm{~kJ}
\end{aligned}
$$

It yields
The adiabatic flame temperature is obtained from a trial and error solution. A first guess is obtained by dividing the right-hand side of the equation by the total number of moles, which yields $918,835 /(1+2+0.3$ $+9.776)=70,269 \mathrm{~kJ} / \mathrm{kmol}$. This enthalpy value corresponds to about 2150 K for $\mathrm{N}_{2}$. Noting that the majority of the moles are $\mathrm{N}_{2}, T_{P}$ will be close to 2150 K , but somewhat under it because of the higher specific heat of $\mathrm{H}_{2} \mathrm{O}$.

At 2000 K:

$$
\begin{aligned}
\bar{h}_{\mathrm{CO} 2}+2 \bar{h}_{\mathrm{H} 2 \mathrm{O}}+0.3 \bar{h}_{\mathrm{O} 2}+9.776 \bar{h}_{\mathrm{N} 2} & =100,804+2 \times 82,593+0.3 \times 67,881+9.776 \times 64,810 \\
& =919,936 \mathrm{~kJ} \text { (Higher than } 918,835 \mathrm{~kJ})
\end{aligned}
$$

At 1980 K:

$$
\begin{aligned}
\bar{h}_{\mathrm{CO} 2}+2 \bar{h}_{\mathrm{H} 2 \mathrm{O}}+0.3 \bar{h}_{\mathrm{O} 2}+9.776 \bar{h}_{\mathrm{N} 2} & =99,606+2 \times 81,573+0.3 \times 67,127+9.776 \times 64,090 \\
& =909,434 \mathrm{~kJ}(\text { Lower than } 918,835 \mathrm{~kJ})
\end{aligned}
$$

By interpolation, $\quad T_{P}=1998 \mathrm{~K}=1725^{\circ} \mathrm{C}$

15-83 Octane is burned with 40 percent excess air adiabatically during a steady-flow combustion process. The exit temperature of product gases is to be determined.
Assumptions 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 There are no work interactions. 5 The combustion chamber is adiabatic.
Analysis Under steady-flow conditions the energy balance $E_{\text {in }}-E_{\text {out }}=\Delta E_{\text {system }}$ applied on the
combustion chamber with $Q=W=0$ reduces to

$$
\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{P}=\sum N_{R}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{R}
$$

since all the reactants are at the standard reference temperature of $25^{\circ} \mathrm{C}$. Then,

$$
\mathrm{C}_{8} \mathrm{H}_{18}(\mathrm{l})+1.4 a_{\mathrm{th}}\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 8 \mathrm{CO}_{2}+9 \mathrm{H}_{2} \mathrm{O}+0.4 a_{\mathrm{th}} \mathrm{O}_{2}+(1.4)(3.76) a_{\mathrm{th}} \mathrm{~N}_{2}
$$

where $a_{\mathrm{th}}$ is the stoichiometric coefficient and is determined from the $\mathrm{O}_{2}$ balance,

$$
1.4 a_{\mathrm{th}}=8+4.5+0.4 a_{\mathrm{th}} \longrightarrow a_{\mathrm{th}}=12.5
$$

Thus, $\mathrm{C}_{8} \mathrm{H}_{18}(\mathrm{~g})+17.5\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 8 \mathrm{CO}_{2}+9 \mathrm{H}_{2} \mathrm{O}+5 \mathrm{O}_{2}+65.8 \mathrm{~N}_{2}$
From the tables,

| Substance | $\overline{\mathbf{h}}_{\mathbf{f}}^{\circ}$ <br> $\mathbf{k J} / \mathbf{k m o l}$ | $\overline{\mathbf{h}}_{\mathbf{2 9 8 k}}$ <br> $\mathbf{k J} / \mathbf{k m o l}$ | $\overline{\mathbf{h}}_{580 \mathbf{K}}$ <br> $\mathbf{k J} / \mathbf{k m o l}$ |
| :--- | :--- | :--- | :--- |
| $\mathrm{C}_{8} \mathrm{H}_{18}(l)$ | $-249,950$ | --- | --- |
| $\mathrm{O}_{2}$ | 0 | 8682 | 17,290 |
| $\mathrm{~N}_{2}$ | 0 | 8669 | 16,962 |
| $\mathrm{H}_{2} \mathrm{O}(g)$ | $-241,820$ | 9904 | --- |
| $\mathrm{CO}_{2}$ | $-393,520$ | 9364 | --- |

Thus,

$$
\begin{aligned}
& (8)\left(-393,520+\bar{h}_{\mathrm{CO} 2}-9364\right)+(9)\left(-241,820+\bar{h}_{\mathrm{H} 2 \mathrm{O}}-9904\right)+(5)\left(0+\bar{h}_{\mathrm{O} 2}-8682\right) \\
& +(65.8)\left(0+\bar{h}_{\mathrm{N} 2}-8669\right)=(1)(-249,950)+(17.5)(0+17,290-8682)+(65.8)(16,962-8669)
\end{aligned}
$$

It yields $\quad 8 \bar{h}_{\mathrm{CO} 2}+9 \bar{h}_{\mathrm{H} 2 \mathrm{O}}+5 \bar{h}_{\mathrm{O} 2}+65.8 \bar{h}_{\mathrm{N} 2}=6,548,788 \mathrm{~kJ}$
The adiabatic flame temperature is obtained from a trial and error solution. A first guess is obtained by dividing the right-hand side of the equation by the total number of moles, which yields $6,548,788 /(8+9+5$ $+65.8)=74,588 \mathrm{~kJ} / \mathrm{kmol}$. This enthalpy value corresponds to about 2250 K for $\mathrm{N}_{2}$. Noting that the majority of the moles are $\mathrm{N}_{2}, T_{P}$ will be close to 2250 K , but somewhat under it because of the higher specific heat of $\mathrm{H}_{2} \mathrm{O}$.
At 2100 K:

$$
\begin{aligned}
8 \bar{h}_{\mathrm{CO} 2}+9 \bar{h}_{\mathrm{H} 2 \mathrm{O}}+5 \bar{h}_{\mathrm{O} 2}+65.8 \bar{h}_{\mathrm{N} 2} & =(8)(106,864)+(9)(87,735)+(5)(71,668)+(65.8)(68,417) \\
& =6,504,706 \mathrm{~kJ}(\text { Lower than } 6,548,788 \mathrm{~kJ})
\end{aligned}
$$

At 2150 K :

$$
\begin{aligned}
8 \bar{h}_{\mathrm{CO} 2}+9 \bar{h}_{\mathrm{H} 2 \mathrm{O}}+5 \bar{h}_{\mathrm{O} 2}+65.8 \bar{h}_{\mathrm{N} 2} & =(8)(109,898)+(9)(90,330)+(5)(73,573)+(65.8)(70,226) \\
& =6,680,890 \mathrm{~kJ} \text { (Higher than } 6,548,788 \mathrm{~kJ})
\end{aligned}
$$

By interpolation, $\quad T_{P}=\mathbf{2 1 1 3} \mathrm{K}=1840^{\circ} \mathrm{C}$

15-84 A certain coal is burned with 50 percent excess air adiabatically during a steady-flow combustion process. The temperature of product gases is to be determined.
Assumptions 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 There are no work interactions. 5 The combustion chamber is adiabatic.
Properties The molar masses of $\mathrm{C}, \mathrm{H}_{2}, \mathrm{~N}_{2}, \mathrm{O}_{2}, \mathrm{~S}$, and air are $12,2,28,32,32$, and $29 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).
Analysis The mass fractions of the constituent of the coal when the ash is substituted are

$$
\begin{aligned}
\mathrm{mf}_{\mathrm{C}} & =\frac{m_{\mathrm{C}}}{m_{\text {total }}}=\frac{79.61 \mathrm{~kg}}{(100-8.62) \mathrm{kg}}=\frac{79.61 \mathrm{~kg}}{91.38 \mathrm{~kg}}=0.8712 \\
\mathrm{mf}_{\mathrm{H} 2} & =\frac{m_{\mathrm{H} 2}}{m_{\text {total }}}=\frac{4.66 \mathrm{~kg}}{91.38 \mathrm{~kg}}=0.05100 \\
\mathrm{mf}_{\mathrm{O} 2} & =\frac{m_{\mathrm{O} 2}}{m_{\text {total }}}=\frac{4.76 \mathrm{~kg}}{91.38 \mathrm{~kg}}=0.05209 \\
\mathrm{mf}_{\mathrm{N} 2} & =\frac{m_{\mathrm{N} 2}}{m_{\text {total }}}=\frac{1.83 \mathrm{~kg}}{91.38 \mathrm{~kg}}=0.02003 \\
\mathrm{mf}_{\mathrm{S}} & =\frac{m_{\mathrm{S}}}{m_{\text {total }}}=\frac{0.52 \mathrm{~kg}}{91.38 \mathrm{~kg}}=0.00569
\end{aligned}
$$

79.61\% C
4.66\% $\mathrm{H}_{2}$
4.76\% O
$1.83 \% \mathrm{~N}_{2}$
0.52\% S
8.62\% ash
(by mass)

We now consider 100 kg of this mixture. Then the mole numbers of each component are

$$
\begin{aligned}
N_{\mathrm{C}} & =\frac{m_{\mathrm{C}}}{M_{\mathrm{C}}}=\frac{87.12 \mathrm{~kg}}{12 \mathrm{~kg} / \mathrm{kmol}}=7.26 \mathrm{kmol} \\
N_{\mathrm{H} 2} & =\frac{m_{\mathrm{H} 2}}{M_{\mathrm{H} 2}}=\frac{5.10 \mathrm{~kg}}{2 \mathrm{~kg} / \mathrm{kmol}}=2.55 \mathrm{kmol} \\
N_{\mathrm{O} 2} & =\frac{m_{\mathrm{O} 2}}{M_{\mathrm{O} 2}}=\frac{5.209 \mathrm{~kg}}{32 \mathrm{~kg} / \mathrm{kmol}}=0.1628 \mathrm{kmol} \\
N_{\mathrm{N} 2} & =\frac{m_{\mathrm{N} 2}}{M_{\mathrm{N} 2}}=\frac{2.003 \mathrm{~kg}}{28 \mathrm{~kg} / \mathrm{kmol}}=0.07154 \mathrm{kmol} \\
N_{\mathrm{S}} & =\frac{m_{\mathrm{S}}}{M_{\mathrm{S}}}=\frac{0.569 \mathrm{~kg}}{32 \mathrm{~kg} / \mathrm{kmol}}=0.01778 \mathrm{kmol}
\end{aligned}
$$

The mole number of the mixture and the mole fractions are

$$
\begin{aligned}
N_{m} & =7.26+2.55+0.1628+0.07154+0.01778=10.062 \mathrm{kmol} \\
y_{\mathrm{C}} & =\frac{N_{\mathrm{C}}}{N_{m}}=\frac{7.26 \mathrm{kmol}}{10.06 \mathrm{kmol}}=0.7215 \\
y_{\mathrm{H} 2} & =\frac{N_{\mathrm{H} 2}}{N_{m}}=\frac{2.55 \mathrm{kmol}}{10.06 \mathrm{kmol}}=0.2535 \\
y_{\mathrm{O} 2} & =\frac{N_{\mathrm{O} 2}}{N_{m}}=\frac{0.1628 \mathrm{kmol}}{10.06 \mathrm{kmol}}=0.01618 \\
y_{\mathrm{N} 2} & =\frac{N_{\mathrm{N} 2}}{N_{m}}=\frac{0.07154 \mathrm{kmol}}{10.06 \mathrm{kmol}}=0.00711 \\
y_{\mathrm{S}} & =\frac{N_{\mathrm{S}}}{N_{m}}=\frac{0.01778 \mathrm{kmol}}{10.06 \mathrm{kmol}}=0.00177
\end{aligned}
$$

Then, the combustion equation in this case may be written as

$$
\begin{aligned}
0.7215 \mathrm{C}+0.2535 \mathrm{H}_{2}+0.01618 \mathrm{O}_{2}+ & 0.00711 \mathrm{~N}_{2}+0.00177 \mathrm{~S}+1.5 a_{\mathrm{th}}\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \\
& \longrightarrow \mathrm{CO}_{2}+y \mathrm{H}_{2} \mathrm{O}+\mathrm{zSO}_{2}+k \mathrm{~N}_{2}+0.5 a_{t h} \mathrm{O}_{2}
\end{aligned}
$$

According to the species balances,
C balance: $x=0.7215$
$\mathrm{H}_{2}$ balance: $y=0.2535$
S balance: $z=0.00177$
$\mathrm{O}_{2}$ balance:
$0.01618+1.5 a_{\mathrm{th}}=x+0.5 y+z+0.5 a_{\mathrm{th}}$
$1.5 a_{\mathrm{th}}-0.5 a_{\mathrm{th}}=0.7215+0.5(0.2535)+0.00177-0.01617 \longrightarrow a_{\mathrm{th}}=0.8339$
$\mathrm{N}_{2}$ balance: $0.00711+1.5 \times 3.76 a_{\mathrm{th}}=k \longrightarrow k=0.00711+1.5 \times 3.76 \times 0.8339=4.710$
Substituting,

$$
\begin{aligned}
0.7215 \mathrm{C}+0.2535 \mathrm{H}_{2} & +0.01617 \mathrm{O}_{2}+0.00711 \mathrm{~N}_{2}+0.00177 \mathrm{~S}+1.2509\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \\
& \longrightarrow 0.7215 \mathrm{CO}_{2}+0.2535 \mathrm{H}_{2} \mathrm{O}+0.0018 \mathrm{SO}_{2}+4.71 \mathrm{~N}_{2}+0.4170 \mathrm{O}_{2}
\end{aligned}
$$

Under steady-flow conditions the energy balance $E_{\text {in }}-E_{\text {out }}=\Delta E_{\text {system }}$ applied on the combustion chamber with $Q=W=0$ reduces to

$$
\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{P}=\sum N_{R}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{R} \longrightarrow \sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{P}=\sum N_{R} \bar{h}_{f, R}^{\circ}
$$

From the tables,

| Substance | $\overline{\mathbf{h}}_{\mathbf{f}}^{\circ}$ <br> $\mathbf{k J} / \mathbf{k m o l}$ | $\overline{\mathbf{h}}_{298 \mathbf{K}}$ <br> $\mathbf{k J} / \mathbf{k m o l}$ | $\overline{\mathbf{h}}_{400 \mathbf{K}}$ <br> $\mathbf{k J} / \mathbf{k m o l}$ |
| :--- | :--- | :--- | :--- |
| $\mathrm{O}_{2}$ | 0 | 8682 | 11,711 |
| $\mathrm{~N}_{2}$ | 0 | 8669 | 11,640 |
| $\mathrm{H}_{2} \mathrm{O}(g)$ | $-241,820$ | 9904 | --- |
| $\mathrm{CO}_{2}$ | $-393,520$ | 9364 | --- |

Thus,

$$
\begin{aligned}
& (0.7215)\left(-393,520+\bar{h}_{\mathrm{CO} 2}-9364\right)+(0.2535)\left(-241,820+\bar{h}_{\mathrm{H} 2 \mathrm{O}}-9904\right)+(0.4170)\left(0+\bar{h}_{\mathrm{O} 2}-8682\right) \\
& +(4.71)\left(0+\bar{h}_{\mathrm{N} 2}-8669\right)=(1.2509)(0+11,711-8682)+(4.703)(11,640-8669)
\end{aligned}
$$

It yields $\quad 0.7215 \bar{h}_{\mathrm{CO} 2}+0.2535 \bar{h}_{\mathrm{H} 2 \mathrm{O}}+0.4170 \bar{h}_{\mathrm{O} 2}+4.71 \bar{h}_{\mathrm{N} 2}=416,706 \mathrm{~kJ}$
The product temperature is obtained from a trial and error solution. A first guess is obtained by dividing the right-hand side of the equation by the total number of moles, which yields
$416,706 /(0.7215+0.2535+0.4170+4.71)=68,290 \mathrm{~kJ} / \mathrm{kmol}$. This enthalpy value corresponds to about 2100 K for $\mathrm{N}_{2}$. Noting that the majority of the moles are $\mathrm{N}_{2}, T_{P}$ will be close to 2100 K , but somewhat under it because of the higher specific heat of $\mathrm{H}_{2} \mathrm{O}$.
At 2000 K:

$$
\begin{aligned}
0.7215 \bar{h}_{\mathrm{CO} 2}+0.2535 \bar{h}_{\mathrm{H} 2 \mathrm{O}}+0.4170 \bar{h}_{\mathrm{O} 2}+4.71 \bar{h}_{\mathrm{N} 2} & =(0.7215)(100,804)+(0.2535)(82,593) \\
& +(0.4170)(67,881)+(4.71)(64,810) \\
& =427,229 \mathrm{~kJ} \quad(\text { Higher than } 416,706 \mathrm{~kJ})
\end{aligned}
$$

At 1980 K:

$$
\begin{aligned}
0.7215 \bar{h}_{\mathrm{CO} 2}+0.2535 \bar{h}_{\mathrm{H} 2 \mathrm{O}}+0.4170 \bar{h}_{\mathrm{O} 2}+4.71 \bar{h}_{\mathrm{N} 2} & =(0.7215)(99,606)+(0.2535)(81,573) \\
& +(0.4170)(67,127)+(4.71)(64,090) \\
& =422,400 \mathrm{~kJ} \quad(\text { Higher than } 416,706 \mathrm{~kJ})
\end{aligned}
$$

By extrapolation, $\quad T_{P}=1956 \mathrm{~K}=1683^{\circ} \mathrm{C}$

15-85 A certain coal is burned with 50 percent excess air adiabatically during a steady-flow combustion process. The combustion gases are expanded in an isentropic turbine. The work produced by this turbine is to be determined.
Assumptions 1 Steady operating conditions exist. 2 Combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 The effect of sulfur in the energy and entropy balances is negligible.

Properties The molar masses of $\mathrm{C}, \mathrm{O}_{2}, \mathrm{H}_{2}, \mathrm{~S}$, and air are $12,32,2,32$, and $29 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).
Analysis The balanced combustion equation from the previous problem is

$$
\begin{aligned}
0.7215 \mathrm{C}+0.2535 \mathrm{H}_{2} & +0.01617 \mathrm{O}_{2}+0.00711 \mathrm{~N}_{2}+0.00177 \mathrm{~S}+1.2509\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \\
& \longrightarrow 0.7215 \mathrm{CO}_{2}+0.2535 \mathrm{H}_{2} \mathrm{O}+0.0018 \mathrm{SO}_{2}+4.71 \mathrm{~N}_{2}+0.4170 \mathrm{O}_{2}
\end{aligned}
$$

The change of the entropy of this mixture during the expansion is given by

$$
\Delta \bar{s}=\sum y\left(\bar{s}_{2}^{\mathrm{o}}-\bar{s}_{1}^{\mathrm{o}}-R \ln \frac{P_{2}}{P_{1}}\right)
$$

Since there is no entropy change during an isentropic process, this equation becomes

$$
\sum y\left(\bar{s}_{2}^{\mathrm{o}}-\bar{s}_{1}^{\mathrm{o}}\right)=R_{u} \ln \frac{P_{2}}{P_{1}} \sum y=(8.314 \mathrm{~kJ} / \mathrm{kmol} \cdot \mathrm{~K}) \ln \frac{140 \mathrm{kPa}}{1380 \mathrm{kPa}}(6.1038 \mathrm{kmol})=-116.1 \mathrm{~kJ} / \mathrm{K}
$$

Here, the total moles of the products are 6.1038 kmol . The exit temperature of the combustion gases may be determined by a trial-error method. The inlet temperature is $1956 \mathrm{~K}(\cong 1960 \mathrm{~K})$ from the previous problem. Guessing the exit temperature to be 1000 K gives (Tables A-18 through A-23)

$$
\begin{aligned}
\sum y\left(\bar{s}_{2}^{\mathrm{o}}-\bar{s}_{1}^{\mathrm{o}}\right) & =(0.7215)(269.215-307.992)+(0.2535)(232.597-263.542) \\
& +(4.71)(228.057-251.242)+(0.417)(243.471-267.891) \\
& =-155.2 \mathrm{~kJ} / \mathrm{K}
\end{aligned}
$$

For the exit temperature of 1200 K ,

$$
\begin{aligned}
\sum y\left(\bar{s}_{2}^{\mathrm{o}}-\bar{s}_{1}^{\mathrm{o}}\right)= & (0.7215)(297.307-307.992)+(0.2535)(240.333-263.542) \\
& +(4.71)(234.115-251.242)+(0.417)(249.906-267.891) \\
& =-101.8 \mathrm{~kJ} / \mathrm{K}
\end{aligned}
$$

By interpolation, $T_{2}=1146 \mathrm{~K}$
The work produced during the isentropic expansion of combustion gases from 1956 K to 1146 K is (Tables A-18 through A-23)

$$
\begin{aligned}
\bar{w}_{\text {out }} & =\sum y\left(\bar{h}_{1}-\bar{h}_{2}\right)=(0.7215)(98,160-50,819)+(0.2535)(80,352-42,037) \\
& +(4.71)(63,236-34,961)+(0.417)(66,223-36,527) \\
& =189,428 \mathrm{~kJ} / \mathrm{kmol} \text { fuel }
\end{aligned}
$$

The molar mass of the product gases is

$$
M_{m}=\frac{m_{m}}{N_{m}}=\frac{(0.7215 \times 44+0.2535 \times 18+0.0018 \times 64+4.71 \times 28+0.4170 \times 32) \mathrm{kg}}{(0.7215+0.2535+0.0018+4.71+0.417) \mathrm{kmol}}=29.76 \mathrm{~kg} / \mathrm{kmol}
$$

The work produced per kg of the fuel is then

$$
w_{\text {out }}=\frac{\bar{w}_{\text {out }}}{M_{m}}=\frac{189,428 \mathrm{~kJ} / \mathrm{kmol} \text { fuel }}{29.76 \mathrm{~kg} / \mathrm{kmol}}=\mathbf{6 3 6 5} \mathbf{~ k J} / \mathbf{k g} \text { fuel }
$$

15-86 Ethyl alcohol is burned with 200 percent excess air adiabatically in a constant volume container. The final pressure and temperature of product gases are to be determined.
Assumptions 1 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 There are no work interactions. 5 The combustion chamber is adiabatic.

Analysis The combustion equation is

$$
\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}+3 a_{\mathrm{th}}\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow 2 \mathrm{CO}_{2}+3 \mathrm{H}_{2} \mathrm{O}+3 a_{\mathrm{th}} \times 3.76 \mathrm{~N}_{2}+2 a_{\mathrm{th}} \mathrm{O}_{2}
$$

where $a_{\mathrm{th}}$ is the stoichiometric coefficient and is determined from the $\mathrm{O}_{2}$ balance,

$$
0.5+3 a_{\mathrm{th}}=2+1.5+2 a_{\mathrm{th}} \longrightarrow a_{\mathrm{th}}=3
$$

Substituting,

$$
\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}+9\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow 2 \mathrm{CO}_{2}+3 \mathrm{H}_{2} \mathrm{O}+33.84 \mathrm{~N}_{2}+6 \mathrm{O}_{2} \text { For this constant-volume }
$$ process, the energy balance $E_{\text {in }}-E_{\text {out }}=\Delta E_{\text {system }}$ applied on the combustion chamber with $Q=W=0$ reduces to

$$
\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}-P \bar{v}\right)_{P}=\sum N_{R}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}-P \bar{v}\right)_{R}
$$

Since both the reactants and products are assumed to be ideal gases, all the internal energy and enthalpies depend on temperature only, and the $P \bar{v}$ terms in this equation can be replaced by $R_{u} T$. It yields

$$
\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}-R_{u} T\right)_{P}=\sum N_{R}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}-R_{u} T\right)_{R}
$$

From the tables,

| Substance | $\overline{\mathbf{h}}^{\circ}$ | $\overline{\mathbf{h}}_{298 \mathrm{~K}}$ | $\begin{aligned} & \text { Air }+\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH} \\ & 25^{\circ} \mathrm{C}, 100 \mathrm{kPa} \end{aligned}$ |
| :---: | :---: | :---: | :---: |
|  | kJ/kmol | kJ/kmol |  |
| $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(\mathrm{g})$ | -235,310 | --- |  |
| $\mathrm{O}_{2}$ | 0 | 8682 | $T_{p}$ |
| $\mathrm{N}_{2}$ | 0 | 8669 |  |
| $\mathrm{H}_{2} \mathrm{O}(\mathrm{g})$ | -241,820 | 9904 |  |
| $\mathrm{CO}_{2}$ | -393,520 | 9364 |  |

Thus,

$$
\begin{aligned}
& (2)\left(-393,520+\bar{h}_{\mathrm{CO} 2}-9364-8.314 \times T_{p}\right)+(3)\left(-241,820+\bar{h}_{\mathrm{H} 2 \mathrm{O}}-9904-8.314 \times T_{p}\right) \\
& +(6)\left(0+\bar{h}_{\mathrm{O} 2}-8682-8.314 \times T_{p}\right)+(33.84)\left(0+\bar{h}_{\mathrm{N} 2}-8669-8.314 \times T_{p}\right) \\
& =(1)(-235,310-8.314 \times 298)+(9)(0-8.314 \times 298)+(33.84)(-8.314 \times 298)
\end{aligned}
$$

It yields

$$
2 \bar{h}_{\mathrm{CO} 2}+3 \bar{h}_{\mathrm{H} 2 \mathrm{O}}+6 \bar{h}_{\mathrm{O} 2}+33.84 \bar{h}_{\mathrm{N} 2}-372.8 T_{p}=-343,927+1,906,391=1,562,464 \mathrm{~kJ}
$$

The adiabatic flame temperature is obtained from a trial and error solution. A first guess may be obtained by assuming all the products are nitrogen and using nitrogen enthalpy in the above equation. That is,

$$
44.84 \bar{h}_{\mathrm{N} 2}-372.8 T_{p}=1,562,464 \mathrm{~kJ}
$$

An investigation of Table A-18 shows that this equation is satisfied at a temperature close to 1600 K but it will be somewhat under it because of the higher specific heat of $\mathrm{H}_{2} \mathrm{O}$.

At 1500 K :

$$
(2)(71,078)+(3)(57,999)+(6)(49,292)+(33.84)(47,073)-(372.8)(1500)=1,645,655
$$

(Higher than 1,562,464 kJ)
At 1400 K:

$$
(2)(65,271)+(3)(53,351)+(6)(45,648)+(33.84)(43,605)-(372.8)(1400)=1,518,156
$$

(Lower than 1,562,464 kJ)
By interpolation,

$$
T_{P}=1435 \mathrm{~K}
$$

The volume of reactants when 1 kmol of fuel is burned is

$$
\left.\boldsymbol{V}=\boldsymbol{V}_{\text {fuel }}+\boldsymbol{V}_{\text {air }}=\left(N_{\text {fuel }}+N_{\text {air }}\right) \frac{R_{u} T}{P}=(1+42.84) \mathrm{kmol}\right) \frac{(8.314 \mathrm{~kJ} / \mathrm{kmol} \cdot \mathrm{~K})(298 \mathrm{~K})}{100 \mathrm{kPa}}=1086 \mathrm{~m}^{3}
$$

The final pressure is then

$$
P=N_{\text {prod }} \frac{R_{u} T}{V}=(44.84 \mathrm{kmol}) \frac{(8.314 \mathrm{~kJ} / \mathrm{kmol} \cdot \mathrm{~K})(1435 \mathrm{~K})}{1086 \mathrm{~m}^{3}}=493 \mathrm{kPa}
$$

15-87 A mixture of hydrogen and the stoichiometric amount of air contained in a constant-volume tank is ignited. The final temperature in the tank is to be determined.
Assumptions 1 The tank is adiabatic. 2 Both the reactants and products are ideal gases. 3 There are no work interactions. 4 Combustion is complete.
Analysis The combustion equation of $\mathrm{H}_{2}$ with stoichiometric amount of air is

$$
\mathrm{H}_{2}+0.5\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow \mathrm{H}_{2} \mathrm{O}+1.88 \mathrm{~N}_{2}
$$

The final temperature in the tank is determined from the energy balance relation $E_{\text {in }}-E_{\text {out }}=\Delta E_{\text {system }}$ for reacting closed systems under adiabatic conditions ( $Q=0$ ) with no work interactions ( $W=0$ ),

$$
\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}-P \overline{\boldsymbol{v}}\right)_{P}=\sum N_{R}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}-P \overline{\boldsymbol{v}}\right)_{R}
$$

Since both the reactants and the products behave as ideal gases, all the internal energy and enthalpies depend on temperature only, and the $P \overline{\boldsymbol{v}}$ terms in this equation can be replaced by $R_{u} T$.

It yields

$$
\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}_{T_{P}}-\bar{h}_{298 \mathrm{~K}}-R_{u} T\right)_{P}=\sum N_{R}\left(\bar{h}_{f}^{\circ} R_{u} T\right)_{R}
$$

since the reactants are at the standard reference temperature of $25^{\circ} \mathrm{C}$. From the tables,

|  | $\overline{\mathbf{h}}_{\mathbf{f}}^{\circ}$ | $\overline{\mathbf{h}}_{\mathbf{2 9 8} \mathbf{K}}$ |
| :--- | :--- | :--- |
| Substance | $\mathbf{k J} / \mathbf{k m o l}$ | $\mathbf{k J} / \mathbf{k m o l}$ |
| $\mathrm{H}_{2}$ | 0 | 8468 |
| $\mathrm{O}_{2}$ | 0 | 8682 |
| $\mathrm{~N}_{2}$ | 0 | 8669 |
| $\mathrm{H}_{2} \mathrm{O}(g)$ | $-241,820$ | 9904 |

Thus,

$$
\begin{aligned}
(1)\left(-241,820+\bar{h}_{\mathrm{H}_{2} \mathrm{O}}-9904-8.314 \times T_{P}\right)+(1.88)\left(0+\bar{h}_{\mathrm{N}_{2}}-8669-8.314 \times T_{P}\right) \\
=(1)(0-8.314 \times 298)+(0.5)(0-8.314 \times 298)+(1.88)(0-8.314 \times 298)
\end{aligned}
$$

It yields $\quad \bar{h}_{\mathrm{H}_{2} \mathrm{O}}+1.88 \bar{h}_{\mathrm{N}_{2}}-23.94 \times T_{P}=259,648 \mathrm{~kJ}$
The temperature of the product gases is obtained from a trial and error solution,
At $3050 \mathrm{~K}: \quad \bar{h}_{\mathrm{H}_{2} \mathrm{O}}+1.88 \bar{h}_{\mathrm{N}_{2}}-23.94 \times T_{P}=(1)(139,051)+(1.88)(103,260)-(23.94)(3050)$

$$
=260,163 \mathrm{~kJ} \text { (Higher than 259,648 kJ) }
$$

At $3000 \mathrm{~K}: \quad \bar{h}_{\mathrm{H}_{2} \mathrm{O}}+1.88 \bar{h}_{\mathrm{N}_{2}}-23.94 \times T_{P}=(1)(136,264)+(1.88)(101,407)-(23.94)(3000)$ $=255,089 \mathrm{~kJ}$ (Lower than 259,648 kJ)

By interpolation, $\quad T_{P}=3045 \mathrm{~K}$ educators for course preparation. If you are a student using this Manual, you are using it without permission.

## Entropy Change and Second Law Analysis of Reacting Systems

15-88C Assuming the system exchanges heat with the surroundings at $T_{0}$, the increase-in-entropy principle can be expressed as

$$
S_{\mathrm{gen}}=\sum N_{P} \bar{s}_{P}-\sum N_{R} \bar{s}_{R}+\frac{Q_{\mathrm{out}}}{T_{0}}
$$

15-89C By subtracting $R \ln \left(P / P_{0}\right)$ from the tabulated value at 1 atm. Here $P$ is the actual pressure of the substance and $P_{0}$ is the atmospheric pressure.

15-90C It represents the reversible work associated with the formation of that compound.

15-91 Hydrogen is burned steadily with oxygen. The reversible work and exergy destruction (or irreversibility) are to be determined.
Assumptions 1 Combustion is complete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible.
Analysis The combustion equation is

$$
\mathrm{H}_{2}+0.5 \mathrm{O}_{2} \longrightarrow \mathrm{H}_{2} \mathrm{O}
$$

The $\mathrm{H}_{2}$, the $\mathrm{O}_{2}$, and the $\mathrm{H}_{2} \mathrm{O}$ are at $25^{\circ} \mathrm{C}$ and 1 atm, which is the standard reference state and also the state of the surroundings. Therefore, the reversible work in this case is simply the difference between the Gibbs function of formation of the reactants and that of the products,

$$
\begin{aligned}
W_{\text {rev }} & =\sum N_{R} \bar{g}_{f, R}^{\circ}-\sum N_{P} \bar{g}_{f, P}^{\circ}=N_{\mathrm{H}_{2}} \bar{g}_{f, \mathrm{H}_{2}}^{\circ}{ }^{\stackrel{ }{ } 0}+N_{\mathrm{O}_{2}} \bar{g}_{f, \mathrm{O}_{2}}^{\circ}{ }^{\stackrel{ }{ } 0}-N_{\mathrm{H}_{2} \mathrm{O}} \bar{g}_{f, \mathrm{H}_{2} \mathrm{O}}^{\circ}=-N_{\mathrm{H}_{2} \mathrm{O}} \bar{g}_{f, \mathrm{H}_{2} \mathrm{O}}^{\circ} \\
& \left.=-(1 \mathrm{kmol})(-237,180 \mathrm{~kJ} / \mathrm{kmol})=\mathbf{2 3 7 , 1 8 0} \mathbf{~ k J} \text { (per kmol of } \mathrm{H}_{2}\right)
\end{aligned}
$$

since the $g_{f}^{\circ}$ of stable elements at $25^{\circ} \mathrm{C}$ and 1 atm is zero. Therefore, $237,180 \mathrm{~kJ}$ of work could be done as 1 kmol of $\mathrm{H}_{2}$ is burned with 0.5 kmol of $\mathrm{O}_{2}$ at $25^{\circ} \mathrm{C}$ and 1 atm in an environment at the same state. The reversible work in this case represents the exergy of the reactants since the product (the $\mathrm{H}_{2} \mathrm{O}$ ) is at the state of the surroundings.

This process involves no actual work. Therefore, the reversible work and exergy destruction are identical,

$$
X_{\text {destruction }}=237,180 \mathbf{k J} \quad\left(\text { per kmol of } \mathrm{H}_{2}\right)
$$

We could also determine the reversible work without involving the Gibbs function,

$$
\begin{aligned}
W_{\text {rev }} & =\sum N_{R}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}-T_{0} \bar{s}\right)_{R}-\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}-T_{0} \bar{s}\right)_{P} \\
& =\sum N_{R}\left(\bar{h}_{f}^{\circ}-T_{0} \bar{s}\right)_{R}-\sum N_{P}\left(\bar{h}_{f}^{\circ}-T_{0} \bar{s}\right)_{P} \\
& =N_{\mathrm{H}_{2}}\left(\bar{h}_{f}^{\circ}-T_{0} \bar{s}^{\circ}\right)_{\mathrm{H}_{2}}+N_{\mathrm{O}_{2}}\left(\bar{h}_{f}^{\circ}-T_{0} \bar{s}^{\circ}\right)_{\mathrm{O}_{2}}-N_{\mathrm{H}_{2} \mathrm{O}}\left(\bar{h}_{f}^{\circ}-T_{0} \bar{s}^{\circ}\right)_{\mathrm{H}_{2} \mathrm{O}}
\end{aligned}
$$

Substituting,

$$
W_{\text {rev }}=(1)(0-298 \times 130.58)+(0.5)(0-298 \times 205.03)-(1)(-285,830-298 \times 69.92)=237,204 \mathrm{~kJ}
$$

which is almost identical to the result obtained before.

15-92 Ethylene gas is burned steadily with 20 percent excess air. The temperature of products, the entropy generation, and the exergy destruction (or irreversibility) are to be determined.
Assumptions 1 Combustion is complete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible.
Analysis (a) The fuel is burned completely with the excess air, and thus the products will contain only $\mathrm{CO}_{2}$, $\mathrm{H}_{2} \mathrm{O}, \mathrm{N}_{2}$, and some free $\mathrm{O}_{2}$. Considering 1 kmol of $\mathrm{C}_{2} \mathrm{H}_{4}$, the combustion equation can be written as

$$
\mathrm{C}_{2} \mathrm{H}_{4}(\mathrm{~g})+1.2 a_{\mathrm{th}}\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 2 \mathrm{CO}_{2}+2 \mathrm{H}_{2} \mathrm{O}+0.2 a_{\mathrm{th}} \mathrm{O}_{2}+(1.2)(3.76) a_{\mathrm{th}} \mathrm{~N}_{2}
$$

where $a_{\mathrm{th}}$ is the stoichiometric coefficient and is determined from the $\mathrm{O}_{2}$ balance,

$$
1.2 a_{\mathrm{th}}=2+1+0.2 a_{\mathrm{th}} \quad \longrightarrow \quad a_{\mathrm{th}}=3
$$

Thus,

$$
\mathrm{C}_{2} \mathrm{H}_{4}(\mathrm{~g})+3.6\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 2 \mathrm{CO}_{2}+2 \mathrm{H}_{2} \mathrm{O}+0.6 \mathrm{O}_{2}+13.54 \mathrm{~N}_{2}
$$

Under steady-flow conditions, the exit temperature of the product gases can be determined from the steadyflow energy equation, which reduces to

$$
\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{P}=\sum N_{R} \bar{h}_{f, R}^{\circ}=\left(N \bar{h}_{f}^{\circ}\right)_{\mathrm{C}_{2} \mathrm{H}_{4}}
$$

since all the reactants are at the standard reference state, and for $\mathrm{O}_{2}$ and $\mathrm{N}_{2}$. From the tables,

Substituting,

$$
\begin{aligned}
& (2)\left(-393,520+\bar{h}_{\mathrm{CO}_{2}}-9364\right)+(2)\left(-241,820+\bar{h}_{\mathrm{H}_{2} \mathrm{O}}-9904\right) \\
& +(0.6)\left(0+\bar{h}_{\mathrm{O}_{2}}-8682\right)+(13.54)\left(0+\bar{h}_{\mathrm{N}_{2}}-8669\right)=(1)(52,280)
\end{aligned}
$$

or, $\quad 2 \bar{h}_{\mathrm{CO}_{2}}+2 \bar{h}_{\mathrm{H}_{2} \mathrm{O}}+0.6 \bar{h}_{\mathrm{O}_{2}}+13.54 \bar{h}_{\mathrm{N}_{2}}=1,484,083 \mathrm{~kJ}$
By trial and error,

$$
T_{P}=2269.6 \mathrm{~K}
$$

(b) The entropy generation during this adiabatic process is determined from

$$
S_{\mathrm{gen}}=S_{P}-S_{R}=\sum N_{P} \bar{s}_{P}-\sum N_{R} \bar{s}_{R}
$$

The $\mathrm{C}_{2} \mathrm{H}_{4}$ is at $25^{\circ} \mathrm{C}$ and 1 atm , and thus its absolute entropy is $219.83 \mathrm{~kJ} / \mathrm{kmol} \cdot \mathrm{K}$ (Table A-26). The entropy values listed in the ideal gas tables are for 1 atm pressure. Both the air and the product gases are at a total pressure of 1 atm , but the entropies are to be calculated at the partial pressure of the components which is equal to $P_{i}=y_{\mathrm{i}} P_{\text {total }}$, where $y_{\mathrm{i}}$ is the mole fraction of component $i$. Also, educators for course preparation. If you are a student using this Manual, you are using it without permission.

$$
S_{i}=N_{i} \bar{s}_{i}\left(T, P_{i}\right)=N_{i}\left(\bar{s}_{i}^{\circ}\left(T, P_{0}\right)-R_{u} \ln \left(y_{i} P_{m}\right)\right)
$$

The entropy calculations can be presented in tabular form as

|  | $\mathbf{N}_{\mathbf{i}}$ | $\mathbf{y}_{\mathbf{i}}$ | $\overline{\mathbf{s}}_{\mathbf{i}}^{\circ}(\mathbf{T}, \mathbf{1 a t m})$ | $\mathbf{R}_{\mathbf{u}} \ln \left(\mathbf{y}_{\mathbf{i}} \mathbf{P}_{\mathbf{m}}\right)$ | $\mathbf{N}_{\mathbf{i}} \overline{\mathbf{S}}_{\mathbf{i}}$ |
| :--- | :--- | :--- | :--- | :--- | :---: |
| $\mathrm{C}_{2} \mathrm{H}_{4}$ | 1 | 1.00 | 219.83 | --- | 219.83 |
| $\mathrm{O}_{2}$ | 3.6 | 0.21 | 205.14 | -12.98 | 784.87 |
| $\mathrm{~N}_{2}$ | 13.54 | 0.79 | 191.61 | -1.96 | 2620.94 |
|  |  |  |  |  | $S_{R}=3625.64 \mathrm{~kJ} / \mathrm{K}$ |
| $\mathrm{CO}_{2}$ | 2 | 0.1103 | 316.881 | -18.329 | 670.42 |
| $\mathrm{H}_{2} \mathrm{O}$ | 2 | 0.1103 | 271.134 | -18.329 | 578.93 |
| $\mathrm{O}_{2}$ | 0.6 | 0.0331 | 273.467 | -28.336 | 181.08 |
| $\mathrm{~N}_{2}$ | 13.54 | 0.7464 | 256.541 | -2.432 | 3506.49 |

Thus,

$$
S_{\mathrm{gen}}=S_{P}-S_{R}=4936.92-3625.64=\mathbf{1 3 1 1 . 2 8} \mathbf{~ k J} / \mathbf{k m o l} \cdot \mathbf{K}
$$

and
(c) $\quad X_{\text {destroyed }}=T_{0} S_{\text {gen }}=(298 \mathrm{~K})\left(1311.28 \mathrm{~kJ} / \mathrm{kmol} \cdot \mathrm{K} \mathrm{C}_{2} \mathrm{H}_{4}\right)=\mathbf{3 9 0 , 7 6 0} \mathbf{~ k J}\left(\right.$ per $\left.\mathrm{kmol}_{2} \mathrm{H}_{4}\right)$

15-93 Liquid octane is burned steadily with 50 percent excess air. The heat transfer rate from the combustion chamber, the entropy generation rate, and the reversible work and exergy destruction rate are to be determined.

Assumptions 1 Combustion is complete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible.
Analysis (a) The fuel is burned completely with the excess air, and thus the products will contain only $\mathrm{CO}_{2}, \mathrm{H}_{2} \mathrm{O}, \mathrm{N}_{2}$, and some free $\mathrm{O}_{2}$. Considering $1 \mathrm{kmol}_{8} \mathrm{H}_{18}$, the combustion equation can be written as

$$
\mathrm{C}_{8} \mathrm{H}_{18}(\ell)+1.5 a_{\mathrm{th}}\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 8 \mathrm{CO}_{2}+9 \mathrm{H}_{2} \mathrm{O}+0.5 a_{\mathrm{th}} \mathrm{O}_{2}+(1.5)(3.76) a_{\mathrm{th}} \mathrm{~N}_{2}
$$

where $a_{\mathrm{th}}$ is the stoichiometric coefficient and is determined from the $\mathrm{O}_{2}$ balance,

$$
1.5 a_{\mathrm{th}}=8+4.5+0.5 a_{\mathrm{th}} \quad \longrightarrow \quad a_{\mathrm{th}}=12.5
$$

Thus,

$$
\mathrm{C}_{8} \mathrm{H}_{18}(\ell)+18.75\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 8 \mathrm{CO}_{2}+9 \mathrm{H}_{2} \mathrm{O}+6.25 \mathrm{O}_{2}+70.5 \mathrm{~N}_{2}
$$

Under steady-flow conditions the energy balance $E_{\text {in }}-E_{\text {out }}=\Delta E_{\text {system }}$ applied on the combustion chamber with $W=0$ reduces to

$$
-Q_{\text {out }}=\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{P}-\sum N_{R}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{R}=\sum N_{P} \bar{h}_{f, P}^{\circ}-\sum N_{R} \bar{h}_{f, R}^{\circ}
$$

since all of the reactants are at $25^{\circ} \mathrm{C}$. Assuming the air and the combustion products to be ideal gases, we have $h=h(T)$. From the tables,

| Substance | $\overline{\mathbf{h}}_{\mathbf{f}}^{\circ}$ <br> $\mathbf{k J} / \mathbf{k m o l}$ |
| :--- | :--- |
| $\mathrm{C}_{8} \mathrm{H}_{18}(\ell)$ | $-249,950$ |
| $\mathrm{O}_{2}$ | 0 |
| $\mathrm{~N}_{2}$ | 0 |
| $\mathrm{H}_{2} \mathrm{O}(l)$ | $-285,830$ |
| $\mathrm{CO}_{2}$ | $-393,520$ |

Substituting,

$$
-Q_{\text {out }}=(8)(-393,520)+(9)(-285,830)+0+0-(1)(-249,950)-0-0=-5,470,680 \mathrm{~kJ} / \mathrm{kmol} \text { of } \mathrm{C}_{8} \mathrm{H}_{18}
$$

or

$$
Q_{\text {out }}=5,470,680 \mathrm{~kJ} / \mathrm{kmol} \text { of } \mathrm{C}_{8} \mathrm{H}_{18}
$$

The $\mathrm{C}_{8} \mathrm{H}_{18}$ is burned at a rate of $0.25 \mathrm{~kg} / \mathrm{min}$ or

Thus,

$$
\dot{N}=\frac{\dot{m}}{M}=\frac{0.25 \mathrm{~kg} / \mathrm{min}}{[(8)(12)+(18)(1)] \mathrm{kg} / \mathrm{kmol}}=2.193 \times 10^{-3} \mathrm{kmol} / \mathrm{min}
$$

$$
\dot{Q}_{\text {out }}=\dot{N} Q_{\text {out }}=\left(2.193 \times 10^{-3} \mathrm{kmol} / \mathrm{min}\right)(5,470,680 \mathrm{~kJ} / \mathrm{kmol})=\mathbf{1 1 , 9 9 7} \mathbf{~ k J} / \mathbf{m i n}
$$

The heat transfer for this process is also equivalent to the enthalpy of combustion of liquid $\mathrm{C}_{8} \mathrm{H}_{18}$, which could easily be de determined from Table A-27 to be $\bar{h}_{C}=5,470,740 \mathrm{~kJ} / \mathrm{kmol} \mathrm{C}_{8} \mathrm{H}_{18}$.
(b) The entropy generation during this process is determined from

$$
S_{\mathrm{gen}}=S_{P}-S_{R}+\frac{Q_{\mathrm{out}}}{T_{\text {surr }}} \longrightarrow S_{\mathrm{gen}}=\sum N_{P} \bar{S}_{P}-\sum N_{R} \bar{S}_{R}+\frac{Q_{\mathrm{out}}}{T_{\text {surr }}}
$$

The $\mathrm{C}_{8} \mathrm{H}_{18}$ is at $25^{\circ} \mathrm{C}$ and 1 atm , and thus its absolute entropy is $\overline{\mathrm{s}}_{\mathrm{C}_{8} \mathrm{H}_{18}}=360.79 \mathrm{~kJ} / \mathrm{kmol} . \mathrm{K}$ (Table A-26). The entropy values listed in the ideal gas tables are for 1 atm pressure. Both the air and the product gases are at a total pressure of 1 atm , but the entropies are to be calculated at the partial pressure of the components which is equal to $P_{i}=y_{\mathrm{i}} P_{\text {totala }}$, where $y_{\mathrm{i}}$ is the mole fraction of component $i$. Also,

$$
S_{i}=N_{i} \bar{s}_{i}\left(T, P_{i}\right)=N_{i}\left(\bar{s}_{i}^{\circ}\left(T, P_{0}\right)-R_{u} \ln \left(\mathrm{y}_{i} P_{m}\right)\right)
$$

The entropy calculations can be presented in tabular form as

|  | $\mathbf{N}_{\mathbf{i}}$ | $\mathbf{y}_{\mathbf{i}}$ | $\overline{\mathbf{s}}_{\mathbf{i}}^{\circ}(\mathbf{T}, \mathbf{1 a t m})$ | $\mathbf{R}_{\mathbf{u}} \mathbf{l n}\left(\mathbf{y}_{\mathbf{i}} \mathbf{P}_{\mathbf{m}}\right)$ | $\mathbf{N}_{\mathbf{i}} \overline{\mathbf{s}}_{\mathbf{i}}$ |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathrm{C}_{8} \mathrm{H}_{18}$ | 1 | 1.00 | 360.79 | -- | 360.79 |
| $\mathrm{O}_{2}$ | 18.75 | 0.21 | 205.14 | -12.98 | 4089.75 |
| $\mathrm{~N}_{2}$ | 70.50 | 0.79 | 191.61 | -1.96 | 13646.69 |
|  |  |  |  | $S_{R}=18,097.23 \mathrm{~kJ} / \mathrm{K}$ |  |
| $\mathrm{CO}_{2}$ | 8 | 0.0944 | 213.80 | -19.62 | 1867.3 |
| $\mathrm{H}_{2} \mathrm{O}(\ell)$ | 9 | --- | 69.92 | --- | 629.3 |
| $\mathrm{O}_{2}$ | 6.25 | 0.0737 | 205.04 | -21.68 | 1417.6 |
| $\mathrm{~N}_{2}$ | 70.50 | 0.8319 | 191.61 | -1.53 | $13,616.3$ |
|  |  |  |  |  | $S_{P}=17,531 \mathrm{~kJ} / \mathrm{K}$ |

Thus,

$$
S_{\text {gen }}=S_{P}-S_{R}+\frac{Q_{\text {surr }}}{T_{\text {surr }}}=17,531-18,097+\frac{5,470,523 \mathrm{~kJ}}{298 \mathrm{~K}}=17,798 \mathrm{~kJ} / \mathrm{kmol} \cdot \mathrm{~K}
$$

and

$$
\dot{S}_{\mathrm{gen}}=\dot{N} S_{\mathrm{gen}}=\left(2.193 \times 10^{-3} \mathrm{kmol} / \mathrm{min}\right)(17,798 \mathrm{~kJ} / \mathrm{kmol} \cdot \mathrm{~K})=39.03 \mathbf{~ k J} / \mathbf{m i n} \cdot \mathbf{K}
$$

(c) The exergy destruction rate associated with this process is determined from

$$
\dot{X}_{\text {destroyed }}=T_{0} \dot{S}_{\text {gen }}=(298 \mathrm{~K})(39.03 \mathrm{~kJ} / \mathrm{min} \cdot \mathrm{~K})=11,632 \mathrm{~kJ} / \mathrm{min}=193.9 \mathbf{k W}
$$

15-94E Benzene gas is burned steadily with 95 percent theoretical air. The heat transfer rate from the combustion chamber and the exergy destruction are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Air and the combustion gases are ideal gases. 3 Changes in kinetic and potential energies are negligible.
Analysis (a) The fuel is burned with insufficient amount of air, and thus the products will contain some CO as well as $\mathrm{CO}_{2}, \mathrm{H}_{2} \mathrm{O}$, and $\mathrm{N}_{2}$. The theoretical combustion equation of $\mathrm{C}_{6} \mathrm{H}_{6}$ is

$$
\mathrm{C}_{6} \mathrm{H}_{6}+a_{\mathrm{th}}\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 6 \mathrm{CO}_{2}+3 \mathrm{H}_{2} \mathrm{O}+3.76 a_{\mathrm{th}} \mathrm{~N}_{2}
$$

where $a_{\mathrm{th}}$ is the stoichiometric coefficient and is determined from the $\mathrm{O}_{2}$ balance,

$$
a_{\mathrm{th}}=6+1.5=7.5
$$

Then the actual combustion equation can be written as

$$
\mathrm{C}_{6} \mathrm{H}_{6}+(0.95)(7.5)\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow x \mathrm{CO}_{2}+(6-x) \mathrm{CO}+3 \mathrm{H}_{2} \mathrm{O}+26.79 \mathrm{~N}_{2}
$$

The value of $x$ is determined from an $\mathrm{O}_{2}$ balance,

$$
(0.95)(7.5)=x+(6-x) / 2+1.5 \longrightarrow x=5.25
$$

Thus,

$$
\mathrm{C}_{6} \mathrm{H}_{6}+7.125\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 5.25 \mathrm{CO}_{2}+0.75 \mathrm{CO}+3 \mathrm{H}_{2} \mathrm{O}+26.79 \mathrm{~N}_{2}
$$

Under steady-flow conditions the energy balance $E_{\text {in }}-E_{\text {out }}=\Delta E_{\text {system }}$ applied on the combustion chamber with $W=0$ reduces to

$$
-Q_{\mathrm{out}}=\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{P}-\sum N_{R}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{R}=\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{P}-\sum N_{R} \bar{h}_{f, R}^{\circ}
$$

since all of the reactants are at $77^{\circ} \mathrm{F}$. Assuming the air and the combustion products to be ideal gases, we have $h=h(T)$.
From the tables,

|  | $\overline{\mathbf{h}}_{\mathbf{f}}^{\circ}$ | $\overline{\mathbf{h}}_{537 \mathbf{R}}$ | $\overline{\mathbf{h}}_{\mathbf{1 5 0 0} \mathbf{R}}$ |
| :--- | :--- | :--- | :--- |
| Substance | Btu/lbmol | Btu/lbmol | Btu/lbmol |
| $\mathrm{C}_{6} \mathrm{H}_{6}(g)$ | 35,680 | --- | --- |
| $\mathrm{O}_{2}$ | 0 | 3725.1 | $11,017.1$ |
| $\mathrm{~N}_{2}$ | 0 | 3729.5 | $10,648.0$ |
| $\mathrm{H}_{2} \mathrm{O}(g)$ | $-104,040$ | 4258.0 | $12,551.4$ |
| CO | $-47,540$ | 3725.1 | $10,711.1$ |
| $\mathrm{CO}_{2}$ | $-169,300$ | 4027.5 | $14,576.0$ |

Thus,

$$
\begin{aligned}
-Q_{\text {out }} & =(5.25)(-169,300+14,576-4027.5)+(0.75)(-47,540+10,711.1-3725.1) \\
& +(3)(-104,040+12,551.4-4258)+(26.79)(0+10,648-3729.5)-(1)(35,680)-0-0 \\
& =-\mathbf{1 , 0 0 1}, \mathbf{4 3 4} \mathbf{~ B t u} / \mathbf{l b m o l} \text { of } \mathbf{C}_{\mathbf{6}} \mathbf{H}_{\mathbf{6}}
\end{aligned}
$$ educators for course preparation. If you are a student using this Manual, you are using it without permission.

(b) The entropy generation during this process is determined from

$$
S_{\mathrm{gen}}=S_{P}-S_{R}+\frac{Q_{\mathrm{out}}}{T_{\text {surr }}}=\sum N_{P} \bar{s}_{P}-\sum N_{R} \bar{s}_{R}+\frac{Q_{\text {out }}}{T_{\text {surr }}}
$$

The $\mathrm{C}_{6} \mathrm{H}_{6}$ is at $77^{\circ} \mathrm{F}$ and 1 atm , and thus its absolute entropy is $\bar{s}_{\mathrm{C}_{6} \mathrm{H}_{6}}=64.34 \mathrm{Btu} / \mathrm{lbmol} \cdot \mathrm{R}$ (Table A-26E).
The entropy values listed in the ideal gas tables are for 1 atm pressure. Both the air and the product gases are at a total pressure of 1 atm , but the entropies are to be calculated at the partial pressure of the components which is equal to $P_{i}=y_{\mathrm{i}} P_{\text {total }}$, where $y_{\mathrm{i}}$ is the mole fraction of component $i$. Also,

$$
S_{i}=N_{i} \bar{s}_{i}\left(T, P_{i}\right)=N_{i}\left(\bar{s}_{i}^{\circ}\left(T, P_{0}\right)-R_{u} \ln \left(y_{i} P_{m}\right)\right)
$$

The entropy calculations can be presented in tabular form as

|  | $\mathbf{N}_{\mathbf{i}}$ | $\mathbf{y}_{\mathbf{i}}$ | $\overline{\mathbf{s}}_{\mathbf{i}}^{\circ}(\mathbf{T}, \mathbf{1 a t m})$ | $\mathbf{R}_{\mathbf{u}} \mathbf{l n}\left(\mathbf{y}_{\mathbf{i}} \mathbf{P}_{\mathbf{m}}\right)$ | $\mathbf{N}_{\mathbf{i}} \overline{\mathbf{s}}_{\mathbf{i}}$ |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathrm{C}_{6} \mathrm{H}_{6}$ | 1 | 1.00 | 64.34 | --- | 64.34 |
| $\mathrm{O}_{2}$ | 7.125 | 0.21 | 49.00 | -3.10 | 371.21 |
| $\mathrm{~N}_{2}$ | 26.79 | 0.79 | 45.77 | -0.47 | 1238.77 |
|  |  |  |  |  | $S_{R}=1674.32 \mathrm{Btu} / \mathrm{R}$ |
| $\mathrm{CO}_{2}$ | 5.25 | 0.1467 | 61.974 | -3.812 | 345.38 |
| CO | 0.75 | 0.0210 | 54.665 | -7.672 | 46.75 |
| $\mathrm{H}_{2} \mathrm{O}(g)$ | 3 | 0.0838 | 53.808 | -4.924 | 176.20 |
| $\mathrm{~N}_{2}$ | 26.79 | 0.7485 | 53.071 | -0.575 | 1437.18 |
|  |  |  |  |  | $S_{P}=2005.51 \mathrm{Btu} / \mathrm{R}$ |

Thus,

$$
S_{\text {gen }}=S_{P}-S_{R}+\frac{Q_{\text {out }}}{T_{\text {surr }}}=2005.51-1674.32+\frac{+1,001,434}{537}=2196.1 \mathrm{Btu} / \mathrm{R}
$$

Then the exergy destroyed is determined from

$$
X_{\text {destroyed }}=T_{0} S_{\text {gen }}=(537 \mathrm{R})(2196.1 \mathrm{Btu} / \mathrm{lbmol} \cdot \mathrm{R})=\mathbf{1 , 1 7 9 , 3 0 6} \mathbf{B t u} / \mathbf{R}\left(\text { per lbmol C } 6_{6} \mathrm{H}_{6}\right)
$$

15-95 [Also solved by EES on enclosed CD] Liquid propane is burned steadily with 150 percent excess air. The mass flow rate of air, the heat transfer rate from the combustion chamber, and the rate of entropy generation are to be determined.
Assumptions 1 Combustion is complete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible.
Properties The molar masses of $\mathrm{C}_{3} \mathrm{H}_{8}$ and air are $44 \mathrm{~kg} / \mathrm{kmol}$ and $29 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).
Analysis (a) The fuel is burned completely with the excess air, and thus the products will contain only $\mathrm{CO}_{2}$, $\mathrm{H}_{2} \mathrm{O}, \mathrm{N}_{2}$, and some free $\mathrm{O}_{2}$. Considering 1 kmol of $\mathrm{C}_{3} \mathrm{H}_{8}$, the combustion equation can be written as

$$
\mathrm{C}_{3} \mathrm{H}_{8}(\ell)+2.5 a_{\mathrm{th}}\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 3 \mathrm{CO}_{2}+4 \mathrm{H}_{2} \mathrm{O}+1.5 a_{\mathrm{th}} \mathrm{O}_{2}+(2.5)(3.76) a_{\mathrm{th}} \mathrm{~N}_{2}
$$

where $a_{\mathrm{th}}$ is the stoichiometric coefficient and is determined from the $\mathrm{O}_{2}$ balance,

$$
2.5 a_{\mathrm{th}}=3+2+1.5 a_{\mathrm{th}} \quad \longrightarrow \quad a_{\mathrm{th}}=5
$$

Substituting,

$$
\mathrm{C}_{3} \mathrm{H}_{8}(\ell)+12.5\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 3 \mathrm{CO}_{2}+4 \mathrm{H}_{2} \mathrm{O}+7.5 \mathrm{O}_{2}+47 \mathrm{~N}_{2}
$$

The air-fuel ratio for this combustion process is

$$
\mathrm{AF}=\frac{m_{\mathrm{air}}}{m_{\text {fuel }}}=\frac{(12.5 \times 4.76 \mathrm{kmol})(29 \mathrm{~kg} / \mathrm{kmol})}{(3 \mathrm{kmol})(12 \mathrm{~kg} / \mathrm{kmol})+(4 \mathrm{kmol})(2 \mathrm{~kg} / \mathrm{kmol})}=39.2 \mathrm{~kg} \text { air } / \mathrm{kg} \text { fuel }
$$

Thus,

$$
\dot{m}_{\text {air }}=(\mathrm{AF})\left(\dot{m}_{\text {fuel }}\right)=(39.2 \mathrm{~kg} \text { air } / \mathrm{kg} \text { fuel })(0.4 \mathrm{~kg} \text { fuel } / \mathrm{min})=\mathbf{1 5 . 7} \mathbf{~ k g ~ a i r} / \mathbf{m i n}
$$

(b) Under steady-flow conditions the energy balance $E_{\text {in }}-E_{\text {out }}=\Delta E_{\text {system }}$ applied on the combustion chamber with $W=0$ reduces to

$$
-Q_{\mathrm{out}}=\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{P}-\sum N_{R}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{R}
$$

Assuming the air and the combustion products to be ideal gases, we have $h=h(T)$. From the tables, (The $\bar{h}_{f}^{\circ}$ of liquid propane is obtained by adding the $h_{f g}$ at $25^{\circ} \mathrm{C}$ to $\bar{h}_{f}^{\circ}$ of gaseous propane).

|  | $\overline{\mathbf{h}}_{\mathbf{f}}^{\circ}$ | $\overline{\mathbf{h}}_{\mathbf{2 8 5} \mathbf{K}}$ | $\overline{\mathbf{h}}_{\mathbf{2 9 8} \mathbf{K}}$ | $\overline{\mathbf{h}}_{\mathbf{1 2 0 0} \mathbf{K}}$ |
| :--- | :--- | :--- | :--- | :--- |
| Substance | $\mathbf{k J} / \mathbf{k m o l}$ | $\mathbf{k J} / \mathbf{k m o l}$ | $\mathbf{k J} / \mathbf{k m o l}$ | $\mathbf{k J} / \mathbf{k m o l}$ |
| $\mathrm{C}_{3} \mathrm{H}_{8}(\ell)$ | $-118,910$ | --- | --- | --- |
| $\mathrm{O}_{2}$ | 0 | 8296.5 | 8682 | 38,447 |
| $\mathrm{~N}_{2}$ | 0 | 8286.5 | 8669 | 36,777 |
| $\mathrm{H}_{2} \mathrm{O}(g)$ | $-241,820$ | -- | 9904 | 44,380 |
| $\mathrm{CO}_{2}$ | $-393,520$ | --- | 9364 | 53,848 |

Thus,

$$
\begin{aligned}
-Q_{\text {out }} & =(3)(-393,520+53,848-9364)+(4)(-241,820+44,380-9904) \\
& +(7.5)(0+38,447-8682)+(47)(0+36,777-8669)-(1)\left(-118,910+h_{298}-h_{298}\right) \\
& -(12.5)(0+8296.5-8682)-(47)(0+8286.5-8669) \\
& =-190,464 \mathrm{~kJ} / \mathrm{kmol} \text { of } \mathrm{C}_{3} \mathrm{H}_{8}
\end{aligned}
$$

Thus $190,464 \mathrm{~kJ}$ of heat is transferred from the combustion chamber for each $\mathrm{kmol}(44 \mathrm{~kg})$ of propane. This corresponds to $190,464 / 44=4328.7 \mathrm{~kJ}$ of heat transfer per kg of propane. Then the rate of heat transfer for a mass flow rate of $0.4 \mathrm{~kg} / \mathrm{min}$ for the propane becomes

$$
\dot{Q}_{\text {out }}=\dot{m} q_{\text {out }}=(0.4 \mathrm{~kg} / \mathrm{min})(4328.7 \mathrm{~kJ} / \mathrm{kg})=\mathbf{1 7 3 2} \mathbf{~ k J} / \mathbf{m i n}
$$

(c) The entropy generation during this process is determined from

$$
S_{\mathrm{gen}}=S_{P}-S_{R}+\frac{Q_{\text {out }}}{T_{\text {surr }}}=\sum N_{P} \bar{s}_{P}-\sum N_{R} \bar{s}_{R}+\frac{Q_{\text {out }}}{T_{\text {surr }}}
$$

The $\mathrm{C}_{3} \mathrm{H}_{8}$ is at $25^{\circ} \mathrm{C}$ and 1 atm , and thus its absolute entropy for the gas phase is $\bar{s}_{\mathrm{C}_{3} \mathrm{H}_{8}}=269.91 \mathrm{~kJ} / \mathrm{kmol} \cdot \mathrm{K}$
(Table A-26). Then the entropy of $\mathrm{C}_{3} \mathrm{H}_{8}(\ell)$ is obtained from

$$
s_{\mathrm{C}_{3} \mathrm{H}_{8}}(\ell) \cong s_{\mathrm{C}_{3} \mathrm{H}_{8}}(\mathrm{~g})-s_{f g}=s_{\mathrm{C}_{3} \mathrm{H}_{8}}(\mathrm{~g})-\frac{\bar{h}_{f g}}{T}=269.91-\frac{15,060}{298.15}=219.4 \mathrm{~kJ} / \mathrm{kmol} \cdot \mathrm{~K}
$$

The entropy values listed in the ideal gas tables are for 1 atm pressure. Both the air and the product gases are at a total pressure of 1 atm , but the entropies are to be calculated at the partial pressure of the components which is equal to $P_{\mathrm{i}}=y_{\mathrm{i}} P_{\text {total }}$, where $y_{\mathrm{i}}$ is the mole fraction of component $i$. Then,

$$
S_{i}=N_{i} \bar{s}_{i}\left(T, P_{i}\right)=N_{i}\left(\bar{s}_{i}^{\circ}\left(T, P_{0}\right)-R_{u} \ln \left(y_{i} P_{m}\right)\right)
$$

The entropy calculations can be presented in tabular form as

|  | $\mathbf{N}_{\mathbf{i}}$ | $\mathbf{y}_{\mathbf{i}}$ | $\overline{\mathbf{s}}_{\mathbf{i}}^{\circ}(\mathbf{T}, \mathbf{1 a t m})$ | $\mathbf{R}_{\mathbf{u}} \ln \left(\mathbf{y}_{\mathbf{i}} \mathbf{P}_{\mathbf{m}}\right)$ | $\mathbf{N}_{\mathbf{i}} \overline{\mathbf{i}}_{\mathbf{i}}$ |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathrm{C}_{3} \mathrm{H}_{8}$ | 1 | --- | 219.40 | -- | 219.40 |
| $\mathrm{O}_{2}$ | 12.5 | 0.21 | 203.70 | -12.98 | 2708.50 |
| $\mathrm{~N}_{2}$ | 47 | 0.79 | 190.18 | -1.96 | 9030.58 |
|  |  |  |  |  | $S_{R}=11,958.48 \mathrm{~kJ} / \mathrm{K}$ |
| $\mathrm{CO}_{2}$ | 3 | 0.0488 | 279.307 | -25.112 | 913.26 |
| $\mathrm{H}_{2} \mathrm{O}(g)$ | 4 | 0.0650 | 240.333 | -22.720 | 1052.21 |
| $\mathrm{O}_{2}$ | 7.5 | 0.1220 | 249.906 | -17.494 | 2005.50 |
| $\mathrm{~N}_{2}$ | 47 | 0.7642 | 234.115 | -2.236 | 11108.50 |
|  |  |  |  |  | $S_{P}=15,079.47 \mathrm{~kJ} / \mathrm{K}$ |

Thus,

$$
S_{\mathrm{gen}}=S_{P}-S_{R}+\frac{Q_{\text {out }}}{T_{\text {surr }}}=15,079.47-11,958.48+\frac{190,464}{298}=3760.1 \mathrm{~kJ} / \mathrm{K}\left(\text { per kmol C }{ }_{3} \mathrm{H}_{8}\right)
$$

Then the rate of entropy generation becomes

$$
\dot{S}_{\text {gen }}=(\dot{N})\left(S_{\text {gen }}\right)=\left(\frac{0.4}{44} \mathrm{kmol} / \mathrm{min}\right)(3760.1 \mathrm{~kJ} / \mathrm{kmol} \cdot \mathrm{~K})=34.2 \mathbf{k J} / \mathbf{m i n} \cdot \mathbf{K}
$$

15-96 EES Problem 15-95 is reconsidered. The effect of the surroundings temperature on the rate of exergy destruction is to be studied.
Analysis The problem is solved using EES, and the solution is given below.

15-97 Liquid octane is burned steadily with 200 percent excess air in a automobile engine. The maximum amount of work that can be produced by this engine is to be determined.
Assumptions 1 Combustion is complete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible.
Analysis The fuel is burned completely with the excess air, and thus the products will contain only $\mathrm{CO}_{2}$, $\mathrm{H}_{2} \mathrm{O}, \mathrm{N}_{2}$, and some free $\mathrm{O}_{2}$. Considering $1 \mathrm{kmol} \mathrm{C}_{8} \mathrm{H}_{18}$, the combustion equation can be written as
$\mathrm{C}_{8} \mathrm{H}_{18}(\ell)+3 a_{\mathrm{th}}\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 8 \mathrm{CO}_{2}+9 \mathrm{H}_{2} \mathrm{O}+2 a_{\mathrm{th}} \mathrm{O}_{2}+(3)(3.76) a_{\mathrm{th}} \mathrm{N}_{2}$
where $a_{\mathrm{th}}$ is the stoichiometric coefficient and is determined from the $\mathrm{O}_{2}$ balance,

$$
3 a_{\mathrm{th}}=8+4.5+2 a_{\mathrm{th}} \longrightarrow a_{\mathrm{th}}=12.5
$$

Thus,

$\mathrm{C}_{8} \mathrm{H}_{18}(\ell)+37.5\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 8 \mathrm{CO}_{2}+9 \mathrm{H}_{2} \mathrm{O}+25 \mathrm{O}_{2}+141 \mathrm{~N}_{2}$
Under steady-flow conditions the energy balance $E_{\text {in }}-E_{\text {out }}=\Delta E_{\text {system }}$ applied on the combustion chamber with $W=0$ reduces to

$$
-Q_{\text {out }}=\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{P}-\sum N_{R}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{R}
$$

Assuming the air and the combustion products to be ideal gases, we have $h=h(T)$. From the tables,

|  | $\overline{\mathbf{h}}_{\mathbf{f}}^{\circ}$ | $\overline{\mathbf{h}}_{\mathbf{2 9 8 k}}$ | $\overline{\mathbf{h}}_{350 \mathbf{K}}$ |
| :--- | :--- | :--- | :--- |
| Substance | $\mathbf{k J} / \mathbf{k m o l}$ | $\mathbf{k J} / \mathbf{k m o l}$ | $\mathbf{k J} / \mathbf{k m o l}$ |
| $\mathrm{C}_{8} \mathrm{H}_{18}(\ell)$ | $-249,950$ | --- | --- |
| $\mathrm{O}_{2}$ | 0 | 8682 | 10,213 |
| $\mathrm{~N}_{2}$ | 0 | 8669 | 10,180 |
| $\mathrm{H}_{2} \mathrm{O}(g)$ | $-241,820$ | 9904 | 11,652 |
| $\mathrm{CO}_{2}$ | $-393,520$ | 9364 | 11,351 |

Thus,

$$
\begin{aligned}
-Q_{\text {out }} & =(8)(-393,520+11,351-9364)+(9)(-241,820+11,652-9904) \\
& +(25)(0+10,213-8682)+(141)(0+10,180-8669)-(1)(-249,950) \\
& =-4,791,636 \mathrm{~kJ} / \mathrm{kmol} \text { of } \mathrm{C}_{8} \mathrm{H}_{18}
\end{aligned}
$$

The entropy generation during this process is determined from

$$
S_{\text {gen }}=S_{P}-S_{R}+\frac{Q_{\text {out }}}{T_{\text {surr }}}=\sum N_{P} \bar{S}_{P}-\sum N_{R} \bar{S}_{R}+\frac{Q_{\text {out }}}{T_{\text {surr }}}
$$

The entropy values listed in the ideal gas tables are for 1 atm pressure. Both the air and the product gases are at a total pressure of 1 atm , but the entropies are to be calculated at the partial pressure of the components which is equal to $P_{\mathrm{i}}=y_{\mathrm{i}} P_{\text {total }}$, where $y_{\mathrm{i}}$ is the mole fraction of component $i$. Then,

$$
S_{i}=N_{i} \bar{s}_{i}\left(T, P_{i}\right)=N_{i}\left(\bar{s}_{i}^{\circ}\left(T, P_{0}\right)-R_{u} \ln \left(y_{i} P_{m}\right)\right)
$$

The entropy calculations can be presented in tabular form as

|  | $\mathbf{N}_{\mathbf{i}}$ | $\mathbf{y}_{\mathbf{i}}$ | $\overline{\mathbf{s}}_{\mathbf{i}}^{\circ}(\mathbf{T}, \mathbf{1 a t m})$ | $\mathbf{R}_{\mathbf{u}} \mathbf{l n}\left(\mathbf{y}_{\mathbf{i}} \mathbf{P}_{\mathbf{m}}\right)$ | $\mathbf{N}_{\mathbf{i}} \overline{\mathbf{s}}_{\mathbf{i}}$ |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathrm{C}_{8} \mathrm{H}_{18}$ | 1 | --- | 466.73 | --- | 466.73 |
| $\mathrm{O}_{2}$ | 37.5 | 0.21 | 205.04 | -12.98 | 8175.75 |
| $\mathrm{~N}_{2}$ | 141 | 0.79 | 191.61 | -1.960 | $27,293.37$ |
|  |  |  |  |  | $S_{R}=35,936 \mathrm{~kJ} / \mathrm{K}$ |
| $\mathrm{CO}_{2}$ | 8 | 0.0437 | 219.831 | -26.03 | 1966.89 |
| $\mathrm{H}_{2} \mathrm{O}(g)$ | 9 | 0.0492 | 194.125 | -25.04 | 1972.49 |
| $\mathrm{O}_{2}$ | 25 | 0.1366 | 209.765 | -16.55 | 5657.88 |
| $\mathrm{~N}_{2}$ | 141 | 0.7705 | 196.173 | -2.17 | $27,966.36$ |
|  |  |  |  |  | $S_{P}=37,565 \mathrm{~kJ} / \mathrm{K}$ |

Thus,

$$
S_{\text {gen }}=S_{P}-S_{R}+\frac{Q_{\text {out }}}{T_{\text {surr }}}=37,565-35,936+\frac{4,791,636}{298}=17,708 \mathrm{~kJ} / \mathrm{K}\left(\text { per kmol C }{ }_{8} \mathrm{H}_{18}\right)
$$

The maximum work is equal to the exergy destruction

$$
W_{\max }=X_{\text {dest }}=T_{0} S_{\text {gen }}=(298)(17,708 \mathrm{~kJ} / \mathrm{K})=5,276,984 \mathrm{~kJ} / \mathrm{K}\left(\text { per kmol C }{ }_{8} \mathrm{H}_{18}\right)
$$

Per unit mass basis,

$$
W_{\max }=\frac{5,276,984 \mathrm{~kJ} / \mathrm{K} \cdot \mathrm{kmol}}{114 \mathrm{~kg} / \mathrm{kmol}}=\mathbf{4 6 , 2 9 0} \mathbf{~ k J} / \mathbf{k g} \text { fuel }
$$

15-98 Methane is burned steadily with 200 percent excess air in a automobile engine. The maximum amount of work that can be produced by this engine is to be determined.
Assumptions 1 Combustion is complete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible.
Analysis The fuel is burned completely with the excess air, and thus the products will contain only $\mathrm{CO}_{2}$, $\mathrm{H}_{2} \mathrm{O}, \mathrm{N}_{2}$, and some free $\mathrm{O}_{2}$. Considering $1 \mathrm{kmol} \mathrm{CH}_{4}$, the combustion equation can be written as
$\mathrm{CH}_{4}+3 a_{\mathrm{th}}\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow \mathrm{CO}_{2}+2 \mathrm{H}_{2} \mathrm{O}+2 a_{\mathrm{th}} \mathrm{O}_{2}+(3)(3.76) a_{\mathrm{th}} \mathrm{N}_{2}$
where $a_{\mathrm{th}}$ is the stoichiometric coefficient and is determined from the $\mathrm{O}_{2}$ balance,

$$
3 a_{\mathrm{th}}=1+1+2 a_{\mathrm{th}} \longrightarrow a_{\mathrm{th}}=2
$$

Thus,
$\mathrm{CH}_{4}+6\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow \mathrm{CO}_{2}+2 \mathrm{H}_{2} \mathrm{O}+4 \mathrm{O}_{2}+22.56 \mathrm{~N}_{2}$

Under steady-flow conditions the energy balance $E_{\text {in }}-E_{\text {out }}=\Delta E_{\text {system }}$ applied on the combustion chamber with $W=0$ reduces to

$$
-Q_{\mathrm{out}}=\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{P}-\sum N_{R}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{R}
$$

Assuming the air and the combustion products to be ideal gases, we have $h=h(T)$. From the tables,

|  | $\overline{\mathbf{h}}_{\mathbf{f}}^{\circ}$ | $\overline{\mathbf{h}}_{\mathbf{2 9 8 K}}$ | $\overline{\mathbf{h}}_{350 \mathbf{K}}$ |
| :--- | :--- | :--- | :--- |
| Substance | $\mathbf{k J} / \mathbf{k m o l}$ | $\mathbf{k J} / \mathbf{k m o l}$ | $\mathbf{k J} / \mathbf{k m o l}$ |
| $\mathrm{CH}_{4}$ | $-74,850$ | --- | --- |
| $\mathrm{O}_{2}$ | 0 | 8682 | 10,213 |
| $\mathrm{~N}_{2}$ | 0 | 8669 | 10,180 |
| $\mathrm{H}_{2} \mathrm{O}(g)$ | $-241,820$ | 9904 | 11,652 |
| $\mathrm{CO}_{2}$ | $-393,520$ | 9364 | 11,351 |

Thus,

$$
\begin{aligned}
-Q_{\text {out }} & =(1)(-393,520+11,351-9364)+(2)(-241,820+11,652-9904) \\
& +(4)(0+10,213-8682)+(22.56)(0+10,180-8669)-(1)(-74,850) \\
& =-756,615 \mathrm{~kJ} / \mathrm{kmol} \text { of } \mathrm{CH}_{4}
\end{aligned}
$$

The entropy generation during this process is determined from

$$
S_{\mathrm{gen}}=S_{P}-S_{R}+\frac{Q_{\mathrm{out}}}{T_{\mathrm{surr}}}=\sum N_{P} \bar{S}_{P}-\sum N_{R} \bar{S}_{R}+\frac{Q_{\mathrm{out}}}{T_{\text {surr }}}
$$

The entropy values listed in the ideal gas tables are for 1 atm pressure. Both the air and the product gases are at a total pressure of 1 atm , but the entropies are to be calculated at the partial pressure of the components which is equal to $P_{\mathrm{i}}=y_{\mathrm{i}} P_{\text {total }}$, where $y_{\mathrm{i}}$ is the mole fraction of component $i$. Then,

$$
S_{i}=N_{i} \bar{s}_{i}\left(T, P_{i}\right)=N_{i}\left(\bar{s}_{i}^{\circ}\left(T, P_{0}\right)-R_{u} \ln \left(y_{i} P_{m}\right)\right)
$$

The entropy calculations can be presented in tabular form as

|  | $\mathbf{N}_{\mathbf{i}}$ | $\mathbf{y}_{\mathbf{i}}$ | $\overline{\mathbf{s}}_{\mathbf{i}}^{\circ}(\mathbf{T}, \mathbf{1 a t m})$ | $\mathbf{R}_{\mathbf{u}} \mathbf{l n}\left(\mathbf{y}_{\mathbf{i}} \mathbf{P}_{\mathbf{m}}\right)$ | $\mathbf{N}_{\mathbf{i}} \overline{\mathbf{s}}_{\mathbf{i}}$ |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathrm{CH}_{4}$ | 1 | --- | 186.16 | --- | 186.16 |
| $\mathrm{O}_{2}$ | 6 | 0.21 | 205.04 | -12.98 | 1308.12 |
| $\mathrm{~N}_{2}$ | 22.56 | 0.79 | 191.61 | -1.960 | 4366.94 |
|  |  |  |  |  | $S_{R}=5861.22 \mathrm{~kJ} / \mathrm{K}$ |
| $\mathrm{CO}_{2}$ | 1 | 0.0338 | 219.831 | -28.16 | 247.99 |
| $\mathrm{H}_{2} \mathrm{O}(g)$ | 2 | 0.0677 | 194.125 | -22.39 | 433.03 |
| $\mathrm{O}_{2}$ | 4 | 0.1353 | 209.765 | -16.63 | 905.58 |
| $\mathrm{~N}_{2}$ | 22.56 | 0.7632 | 196.173 | -2.25 | 4476.42 |
|  |  |  |  |  | $S_{P}=6063.02 \mathrm{~kJ} / \mathrm{K}$ |

Thus,

$$
S_{\text {gen }}=S_{P}-S_{R}+\frac{Q_{\text {out }}}{T_{\text {surr }}}=6063.02-5861.22+\frac{756,615}{298}=2741 \mathrm{~kJ} / \mathrm{K}(\text { per kmol CH } 44)
$$

The maximum work is equal to the exergy destruction

$$
W_{\max }=X_{\text {dest }}=T_{0} S_{\mathrm{gen}}=(298)(2741 \mathrm{~kJ} / \mathrm{K})=816,818 \mathrm{~kJ} / \mathrm{K}\left(\text { per } \mathrm{kmol} \mathrm{CH}_{4}\right)
$$

Per unit mass basis,

$$
W_{\max }=\frac{816,818 \mathrm{~kJ} / \mathrm{K} \cdot \mathrm{kmol}}{16 \mathrm{~kg} / \mathrm{kmol}}=\mathbf{5 1 , 0 5 0} \mathbf{~ k J} / \mathrm{kg} \text { fuel }
$$

15-99 Liquid octane is burned steadily with 30 percent excess air. The entropy generation and exergy destruction per unit mass of the fuel are to be determined.
Assumptions 1 Combustion is complete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible.
Properties The molar masses of $\mathrm{C}_{8} \mathrm{H}_{18}$ and air are $114 \mathrm{~kg} / \mathrm{kmol}$ and $29 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).
Analysis The fuel is burned completely with the excess air, and thus the products will contain only $\mathrm{CO}_{2}$, $\mathrm{H}_{2} \mathrm{O}, \mathrm{N}_{2}$, and some free $\mathrm{O}_{2}$. Considering $1 \mathrm{kmol} \mathrm{C}_{8} \mathrm{H}_{18}$, the combustion equation can be written as
$\mathrm{C}_{8} \mathrm{H}_{18}(\ell)+1.3 a_{\mathrm{th}}\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 8 \mathrm{CO}_{2}+9 \mathrm{H}_{2} \mathrm{O}+0.3 a_{\mathrm{th}} \mathrm{O}_{2}+(1.3)(3.76) a_{\mathrm{th}} \mathrm{N}_{2}$
where $a_{\mathrm{th}}$ is the stoichiometric coefficient and is determined from the $\mathrm{O}_{2}$ balance,

$$
1.3 a_{\mathrm{th}}=8+4.5+0.3 a_{\mathrm{th}} \longrightarrow a_{\mathrm{th}}=12.5
$$

Thus,
$\mathrm{C}_{8} \mathrm{H}_{18}(\ell)+16.25\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 8 \mathrm{CO}_{2}+9 \mathrm{H}_{2} \mathrm{O}+3.75 \mathrm{O}_{2}+61.1 \mathrm{~N}_{2}$
(b) Under steady-flow conditions the energy balance $E_{\text {in }}-E_{\text {out }}=\Delta E_{\text {system }}$ applied on the combustion chamber with $W=0$ reduces to

$$
-Q_{\text {out }}=\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{P}-\sum N_{R}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{R}
$$

Assuming the air and the combustion products to be ideal gases, we have $h=h(T)$. From the tables,

| Substance | $\overline{\mathbf{h}}_{\mathbf{f}}^{\circ}$ <br> $\mathbf{k J} / \mathbf{k m o l}$ | $\overline{\mathbf{h}}_{298 \mathrm{~K}}$ <br> $\mathbf{k J} / \mathbf{k m o l}$ | $\overline{\mathbf{h}}_{600 \mathrm{~K}}$ <br> $\mathbf{k J} / \mathbf{k m o l}$ | $\overline{\mathbf{h}}_{1500 \mathrm{~K}}$ <br> $\mathbf{k J} / \mathbf{k m o l}$ |
| :--- | :--- | :--- | :--- | :--- |
| $\mathrm{C}_{8} \mathrm{H}_{18}(\ell)$ | $-249,950$ | --- | --- | --- |
| $\mathrm{O}_{2}$ | 0 | 8682 | 17,929 | 49,292 |
| $\mathrm{~N}_{2}$ | 0 | 8669 | 17,563 | 47,073 |
| $\mathrm{H}_{2} \mathrm{O}(g)$ | $-241,820$ | 9904 | --- | 57,999 |
| $\mathrm{CO}_{2}$ | $-393,520$ | 9364 | --- | 71,078 |

Thus,

$$
\begin{aligned}
-Q_{\text {out }}= & (8)(-393,520+71,078-9364)+(9)(-241,820+57,999-9904) \\
& +(3.75)(0+49,292-8682)+(61.1)(0+47,073-8669)-(1)(-249,950) \\
& -(16.25)(0+17,929-8682)-(61.1)(0+17,563-8669) \\
= & -2,342,938 \mathrm{~kJ} / \mathrm{kmol} \text { of } \mathrm{C}_{8} \mathrm{H}_{18}
\end{aligned}
$$

The entropy generation during this process is determined from

$$
S_{\text {gen }}=S_{P}-S_{R}+\frac{Q_{\text {out }}}{T_{\text {surr }}}=\sum N_{P} \bar{s}_{P}-\sum N_{R} \bar{s}_{R}+\frac{Q_{\text {out }}}{T_{\text {surr }}}
$$

The entropy values listed in the ideal gas tables are for 1 atm pressure. Both the air and the product gases are at a total pressure of $P_{m}=600 \mathrm{kPa}(=600 / 101.325=5.92 \mathrm{~atm})$, but the entropies are to be calculated at
the partial pressure of the components which is equal to $P_{\mathrm{i}}=y_{\mathrm{i}} P_{\text {total }}$, where $y_{\mathrm{i}}$ is the mole fraction of component $i$. Then,

$$
S_{i}=N_{i} \bar{s}_{i}\left(T, P_{i}\right)=N_{i}\left(\bar{s}_{i}^{\circ}\left(T, P_{0}\right)-R_{u} \ln \left(y_{i} P_{m}\right)\right)
$$

The entropy calculations can be presented in tabular form as

|  | $\mathbf{N}_{\mathbf{i}}$ | $\mathbf{y}_{\mathbf{i}}$ | $\overline{\mathbf{s}}_{\mathbf{i}}^{\circ}(\mathbf{T}, \mathbf{1 a t m})$ | $\mathbf{R}_{\mathbf{u}} \ln \left(\mathbf{y}_{\mathbf{i}} \mathbf{P}_{\mathbf{m}}\right)$ | $\mathbf{N}_{\mathbf{i}} \overline{\mathbf{s}}_{\mathbf{i}}$ |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathrm{C}_{8} \mathrm{H}_{18}$ | 1 | --- | 466.73 | 14.79 | 451.94 |
| $\mathrm{O}_{2}$ | 16.25 | 0.21 | 226.35 | 1.81 | 3648.78 |
| $\mathrm{~N}_{2}$ | 61.1 | 0.79 | 212.07 | 12.83 | $12,173.56$ |
|  |  |  |  |  | $S_{R}=16,274.28 \mathrm{~kJ} / \mathrm{K}$ |
| $\mathrm{CO}_{2}$ | 8 | 0.0977 | 292.11 | -4.552 | 2373.30 |
| $\mathrm{H}_{2} \mathrm{O}(g)$ | 9 | 0.1100 | 250.45 | -3.566 | 2286.14 |
| $\mathrm{O}_{2}$ | 3.75 | 0.0458 | 257.97 | -10.85 | 1008.08 |
| $\mathrm{~N}_{2}$ | 61.1 | 0.7465 | 241.77 | 12.35 | $14,017.56$ |
|  |  |  |  |  | $S_{P}=19,685.08 \mathrm{~kJ} / \mathrm{K}$ |

Thus,

$$
S_{\text {gen }}=S_{P}-S_{R}+\frac{Q_{\text {out }}}{T_{\text {surr }}}=19,685.08-16,274.28+\frac{2,342,938}{298}=11,273 \mathrm{~kJ} / \mathrm{K}\left(\text { per kmol C } \mathrm{B}_{8} \mathrm{H}_{18}\right)
$$

The exergy detstuction is

$$
X_{\text {dest }}=T_{0} S_{\text {gen }}=(298)(11,273 \mathrm{~kJ} / \mathrm{K})=3,359,354 \mathrm{~kJ} / \mathrm{K}\left(\text { per kmol C } 88 \mathrm{H}_{18}\right)
$$

The entropy generation and exergy destruction per unit mass of the fuel are

$$
\begin{aligned}
& S_{\text {gen }}=\frac{\bar{S}_{\text {gen }}}{M_{\text {fuel }}}=\frac{11,273 \mathrm{~kJ} / \mathrm{K} \cdot \mathrm{kmol}}{114 \mathrm{~kg} / \mathrm{kmol}}=\mathbf{9 8 . 8 9} \mathbf{~ k J} / \mathrm{K} \cdot \mathbf{k g ~ C}_{3} \mathbf{H}_{\mathbf{8}} \\
& X_{\text {dest }}=\frac{\bar{X}_{\text {dest }}}{M_{\text {fuel }}}=\frac{3,359,954 \mathrm{~kJ} / \mathrm{K} \cdot \mathrm{kmol}}{114 \mathrm{~kg} / \mathrm{kmol}}=\mathbf{2 9 , 4 7 0} \mathbf{~ k J} / \mathbf{k g ~ C}_{3} \mathbf{H}_{\mathbf{8}}
\end{aligned}
$$

## Review Problems

15-100 A sample of a certain fluid is burned in a bomb calorimeter. The heating value of the fuel is to be determined.

Properties The specific heat of water is $4.18 \mathrm{~kJ} / \mathrm{kg} .{ }^{\circ} \mathrm{C}$ (Table A-3).
Analysis We take the water as the system, which is a closed system, for which the energy balance on the system $E_{\text {in }}-E_{\text {out }}=\Delta E_{\text {system }}$ with $W=0$ can be written as

$$
Q_{\mathrm{in}}=\Delta U
$$

or

$$
\begin{aligned}
Q_{\text {in }} & =m c \Delta T \\
& =(2 \mathrm{~kg})\left(4.18 \mathrm{~kJ} / \mathrm{kg} \cdot{ }^{\circ} \mathrm{C}\right)\left(2.5^{\circ} \mathrm{C}\right) \\
& =20.90 \mathrm{~kJ}(\text { per gram of fuel })
\end{aligned}
$$

Therefore, heat transfer per kg of the fuel would be $20,900 \mathrm{~kJ} / \mathrm{kg}$ fuel. Disregarding the slight energy stored in the gases of the combustion chamber, this value corresponds to the heating value of the fuel.

15-101E Hydrogen is burned with 100 percent excess air. The AF ratio and the volume flow rate of air are to be determined.
Assumptions 1 Combustion is complete. 2 Air and the combustion gases are ideal gases.
Properties The molar masses of $\mathrm{H}_{2}$ and air are $2 \mathrm{~kg} / \mathrm{kmol}$ and $29 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).
Analysis (a) The combustion is complete, and thus products will contain only $\mathrm{H}_{2} \mathrm{O}, \mathrm{O}_{2}$ and $\mathrm{N}_{2}$. The moisture in the air does not react with anything; it simply shows up as additional $\mathrm{H}_{2} \mathrm{O}$ in the products. Therefore, for simplicity, we will balance the combustion equation using dry air, and then add the moisture to both sides of the equation. The combustion equation in this case can be written as

$$
\mathrm{H}_{2}+2 a_{\mathrm{th}}\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow \mathrm{H}_{2} \mathrm{O}+a_{\mathrm{th}} \mathrm{O}_{2}+(2)(3.76) a_{\mathrm{th}} \mathrm{~N}_{2}
$$

where $a_{\mathrm{th}}$ is the stoichiometric coefficient for air. It is determined from

O2 balance: $2 a_{\mathrm{th}}=0.5+a_{\mathrm{th}} \quad \longrightarrow \quad a_{\mathrm{th}}=0.5$
Substituting, $\mathrm{H}_{2}+\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow \mathrm{H}_{2} \mathrm{O}+0.5 \mathrm{O}_{2}+3.76 \mathrm{~N}_{2}$
Therefore, 4.76 lbmol of dry air will be used per kmol of the fuel.
 The partial pressure of the water vapor present in the incoming air is

$$
P_{v, \text { in }}=\phi_{\mathrm{air}} P_{\mathrm{sat} @ 90^{\circ} \mathrm{F}}=(0.60)(0.69904 \mathrm{psi})=0.419 \mathrm{psia}
$$

The number of moles of the moisture that accompanies 4.76 lbmol of incoming dry air $\left(\mathrm{N}_{\mathrm{v}, \text { in }}\right)$ is determined to be

$$
N_{v, \text { in }}=\left(\frac{P_{v, \text { in }}}{P_{\text {total }}}\right) N_{\text {total }}=\left(\frac{0.419 \text { psia }}{14.5 \text { psia }}\right)\left(4.76+N_{v, \text { in }}\right) \longrightarrow N_{v, \text { in }}=0.142 \mathrm{lbmol}
$$

The balanced combustion equation is obtained by substituting the coefficients determined earlier and adding 0.142 lbmol of $\mathrm{H}_{2} \mathrm{O}$ to both sides of the equation,

$$
\mathrm{H}_{2}+\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right)+0.142 \mathrm{H}_{2} \mathrm{O} \longrightarrow 1.142 \mathrm{H}_{2} \mathrm{O}+0.5 \mathrm{O}_{2}+3.76 \mathrm{~N}_{2}
$$

The air-fuel ratio is determined by taking the ratio of the mass of the air to the mass of the fuel,

$$
\mathrm{AF}=\frac{m_{\mathrm{air}}}{m_{\text {fuel }}}=\frac{(4.76 \mathrm{lbmol})(29 \mathrm{lbm} / \mathrm{lbmol})+(0.142 \mathrm{lbmol})(18 \mathrm{lbm} / \mathrm{lbmol})}{(1 \mathrm{lbmol})(2 \mathrm{lbm} / \mathrm{lbmol})}=\mathbf{7 0 . 3} \mathbf{~ l b m} \text { air } / \mathbf{l b m f u e l}
$$

(b) The mass flow rate of $\mathrm{H}_{2}$ is given to be $10 \mathrm{lbm} / \mathrm{h}$. Since we need 70.3 lbm air per lbm of $\mathrm{H}_{2}$, the required mass flow rate of air is

$$
\dot{m}_{\mathrm{air}}=(\mathrm{AF})\left(\dot{m}_{\text {fuel }}\right)=(70.3)(25 \mathrm{lbm} / \mathrm{h})=1758 \mathrm{lbm} / \mathrm{h}
$$

The mole fractions of water vapor and the dry air in the incoming air are

$$
y_{\mathrm{H}_{2} \mathrm{O}}=\frac{N_{\mathrm{H}_{2} \mathrm{O}}}{N_{\text {total }}}=\frac{0.142}{4.76+0.142}=0.029 \text { and } y_{\text {dryair }}=1-0.029=0.971
$$

Thus,

$$
\begin{aligned}
M & =(y M)_{\mathrm{H}_{2} \mathrm{O}}+(y M)_{\mathrm{dryair}}=(0.029)(18)+(0.971)(29)=28.7 \mathrm{lbm} / \mathrm{lbmol} \\
\boldsymbol{v} & =\frac{R T}{P}=\frac{\left(10.73 / 28.7 \mathrm{psia} \cdot \mathrm{ft}^{3} / \mathrm{lbm} \cdot \mathrm{R}\right)(550 \mathrm{R})}{14.5 \mathrm{psia}}=14.18 \mathrm{ft}^{3} / \mathrm{lbm} \\
\dot{\boldsymbol{v}} & =\dot{m} \boldsymbol{v}=(1758 \mathrm{lbm} / \mathrm{h})\left(14.18 \mathrm{ft}^{3} / \mathrm{lbm}\right)=\mathbf{2 4 , 9 2 8} \mathbf{~ f t}^{3} / \mathbf{h}
\end{aligned}
$$

15-102 A gaseous fuel with a known composition is burned with dry air, and the volumetric analysis of products gases is determined. The AF ratio, the percent theoretical air used, and the volume flow rate of air are to be determined.
Assumptions 1 Combustion is complete. 2 Air and the combustion gases are ideal gases.
Properties The molar masses of $\mathrm{C}, \mathrm{H}_{2}, \mathrm{~N}_{2}, \mathrm{O}_{2}$, and air are $12,2,28,32$, and $29 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).

Analysis Considering 100 kmol of dry products, the combustion equation can be written as

$$
\begin{aligned}
& x\left(0.80 \mathrm{CH}_{4}+0.15 \mathrm{~N}_{2}+0.05 \mathrm{O}_{2}\right)+a\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \\
& \longrightarrow 3.36 \mathrm{CO}_{2}+0.09 \mathrm{CO}+14.91 \mathrm{O}_{2}+81.64 \mathrm{~N}_{2}+b \mathrm{H}_{2} \mathrm{O}
\end{aligned}
$$

The unknown coefficients $x, a$, and $b$ are determined from mass balances,

$$
\begin{aligned}
& \mathrm{C}: 0.80 x=3.36+0.09 \longrightarrow x=4.31 \\
& \mathrm{H}: 3.2 x=2 b \quad b=6.90 \\
& \mathrm{~N}_{2}: 0.15 x+3.76 a=81.64 \longrightarrow a=21.54
\end{aligned}
$$

$\left[\right.$ Check $\left.\mathrm{O}_{2}: 0.05 x+a=3.36+0.045+14.91+b / 2 \longrightarrow a=21.54\right]$

Thus,

$$
\begin{aligned}
4.31\left(0.80 \mathrm{CH}_{4}+0.15 \mathrm{~N}_{2}+\right. & \left.0.05 \mathrm{O}_{2}\right)+21.54\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \\
& \longrightarrow 3.36 \mathrm{CO}_{2}+0.09 \mathrm{CO}+14.91 \mathrm{O}_{2}+81.64 \mathrm{~N}_{2}+6.9 \mathrm{H}_{2} \mathrm{O}
\end{aligned}
$$

The combustion equation for 1 kmol of fuel is obtained by dividing the above equation by 4.31,

$$
\begin{aligned}
\left(0.80 \mathrm{CH}_{4}+0.15 \mathrm{~N}_{2}+0.05 \mathrm{O}_{2}\right) & +5.0\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \\
\longrightarrow & 0.78 \mathrm{CO}_{2}+0.02 \mathrm{CO}+3.46 \mathrm{O}_{2}+18.95 \mathrm{~N}_{2}+1.6 \mathrm{H}_{2} \mathrm{O}
\end{aligned}
$$

(a) The air-fuel ratio is determined from its definition,

$$
\mathrm{AF}=\frac{m_{\text {air }}}{m_{\text {fuel }}}=\frac{(5.0 \times 4.76 \mathrm{kmol})(29 \mathrm{~kg} / \mathrm{kmol})}{0.8 \times 16+0.15 \times 28+0.05 \times 32}=\mathbf{3 7 . 1} \mathbf{~ k g ~ a i r} / \mathbf{k g} \text { fuel }
$$

(b) To find the percent theoretical air used, we need to know the theoretical amount of air, which is determined from the theoretical combustion equation of the fuel,

$$
\begin{aligned}
& \left(0.80 \mathrm{CH}_{4}+0.15 \mathrm{~N}_{2}+0.05 \mathrm{O}_{2}\right)+a_{\mathrm{th}}\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 0.8 \mathrm{CO}_{2}+1.6 \mathrm{H}_{2} \mathrm{O}+\left(0.15+3.76 a_{\mathrm{th}}\right) \mathrm{N}_{2} \\
& \mathrm{O}_{2}: 0.05+a_{\mathrm{th}}=0.8+0.8 \longrightarrow a_{\mathrm{th}}=1.55
\end{aligned}
$$

Then, Percent theoretical air $=\frac{m_{\text {air,act }}}{m_{\text {air,th }}}=\frac{N_{\text {air,act }}}{N_{\text {air,th }}}=\frac{(5.0)(4.76) \mathrm{kmol}}{(1.55)(4.76) \mathrm{kmol}}=\mathbf{3 2 3 \%}$
(c) The specific volume, mass flow rate, and the volume flow rate of air at the inlet conditions are

$$
\begin{aligned}
\boldsymbol{v} & =\frac{R T}{P}=\frac{\left(0.287 \mathrm{kPa} \cdot \mathrm{~m}^{3} / \mathrm{kg} \cdot \mathrm{~K}\right)(298 \mathrm{~K})}{100 \mathrm{kPa}}=0.855 \mathrm{~m}^{3} / \mathrm{kg} \\
\dot{m}_{\text {air }} & =(\mathrm{AF}) \dot{m}_{\text {fuel }}=(37.1 \mathrm{~kg} \mathrm{air} / \mathrm{kg} \text { fuel })(1.4 \mathrm{~kg} \text { fuel } / \mathrm{min})=51.94 \mathrm{~m}^{3} / \mathrm{min} \\
\dot{\boldsymbol{V}}_{\text {air }} & =(\dot{m} \boldsymbol{v})_{\text {air }}=(51.94 \mathrm{~kg} / \mathrm{min})\left(0.855 \mathrm{~m}^{3} / \mathrm{kg}\right)=\mathbf{4 4 . 4} \mathbf{m}^{3} / \mathbf{m i n}
\end{aligned}
$$

15-103 Propane is burned with stoichiometric amount of oxygen. The mass fractions of each of the products and the mass of water in the products per unit mass of fuel burned are to be determined.
Assumptions 1 Combustion is complete. 2 The combustion products contain $\mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$. 3 Combustion gases are ideal gases.
Properties The molar masses of $\mathrm{C}, \mathrm{H}_{2}, \mathrm{O}_{2}$, and air are $12 \mathrm{~kg} / \mathrm{kmol}, 2 \mathrm{~kg} / \mathrm{kmol}, 32 \mathrm{~kg} / \mathrm{kmol}$, and $29 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).

Analysis The combustion equation in this case is

$$
\mathrm{C}_{3} \mathrm{H}_{8}+5 \mathrm{O}_{2} \longrightarrow 3 \mathrm{CO}_{2}+4 \mathrm{H}_{2} \mathrm{O}
$$

The mass of each product and the total mass are

$$
\begin{aligned}
& m_{\mathrm{CO} 2}=N_{\mathrm{CO} 2} M_{\mathrm{CO} 2}=(3 \mathrm{kmol})(44 \mathrm{~kg} / \mathrm{kmol})=132 \mathrm{~kg} \\
& m_{\mathrm{H} 2 \mathrm{O}}=N_{\mathrm{H} 2 \mathrm{O}} M_{\mathrm{H} 2 \mathrm{O}}=(4 \mathrm{kmol})(18 \mathrm{~kg} / \mathrm{kmol})=72 \mathrm{~kg} \\
& m_{\text {total }}=m_{\mathrm{CO} 2}+m_{\mathrm{H} 2 \mathrm{O}}=132+72=204 \mathrm{~kg}
\end{aligned}
$$

Then the mass fractions are

$$
\begin{aligned}
\mathrm{mf}_{\mathrm{CO} 2} & =\frac{m_{\mathrm{CO} 2}}{m_{\text {total }}}=\frac{132 \mathrm{~kg}}{204 \mathrm{~kg}}=\mathbf{0 . 6 4 7 1} \\
\mathrm{mf}_{\mathrm{H} 2 \mathrm{O}} & =\frac{m_{\mathrm{H} 2 \mathrm{O}}}{m_{\text {total }}}=\frac{72 \mathrm{~kg}}{204 \mathrm{~kg}}=\mathbf{0 . 3 5 2 9}
\end{aligned}
$$

The mass of water in the products per unit mass of fuel burned is determined from

$$
\frac{m_{\mathrm{H} 2 \mathrm{O}}}{m_{\mathrm{C} 3 \mathrm{H} 8}}=\frac{72 \mathrm{~kg}}{44 \mathrm{~kg}}=\mathbf{1 . 6 4} \mathrm{kg} \mathrm{H}_{2} \mathrm{O} / \mathrm{kg} \mathrm{C}_{3} \mathrm{H}_{\mathbf{8}}
$$

15-104 A coal from Utah is burned with $20 \%$ excess air. The mass of water in the products per unit mass of coal burned and the dew-point temperature of the water vapor in the products are to be determined.
Assumptions 1 Combustion is complete. 2 The combustion products contain $\mathrm{CO}_{2}, \mathrm{CO}, \mathrm{H}_{2} \mathrm{O}, \mathrm{SO}_{2}, \mathrm{O}_{2}$, and $\mathrm{N}_{2} .3$ Combustion gases are ideal gases.
Properties The molar masses of $\mathrm{C}, \mathrm{O}_{2}, \mathrm{H}_{2}, \mathrm{~S}$, and $\mathrm{N}_{2}$ are 12, 32, 2, 32, and $28 \mathrm{lbm} / \mathrm{lbmol}$, respectively (Table A-1E).

Analysis The mass fractions of the constituent of the coal when the ash is substituted are

$$
\begin{aligned}
& \mathrm{mf}_{\mathrm{C}}=\frac{m_{\mathrm{C}}}{m_{\text {total }}}=\frac{61.40 \mathrm{lbm}}{(100-5.00) \mathrm{lbm}}=\frac{61.40 \mathrm{lbm}}{95.00 \mathrm{lbm}}=0.6463 \\
& \mathrm{mf}_{\mathrm{H} 2}=\frac{m_{\mathrm{H} 2}}{m_{\text {total }}}=\frac{5.79 \mathrm{lbm}}{95.00 \mathrm{lbm}}=0.06095 \\
& \mathrm{mf}_{\mathrm{O} 2}=\frac{m_{\mathrm{O} 2}}{m_{\text {total }}}=\frac{25.31 \mathrm{lbm}}{95.00 \mathrm{lbm}}=0.2664 \\
& \mathrm{mf}_{\mathrm{N} 2}=\frac{m_{\mathrm{N} 2}}{m_{\text {total }}}=\frac{1.09 \mathrm{lbm}}{95.00 \mathrm{lbm}}=0.01147 \\
& \mathrm{mf}_{\mathrm{S}}=\frac{m_{\mathrm{S}}}{m_{\text {total }}}=\frac{1.41 \mathrm{lbm}}{95.00 \mathrm{lbm}}=0.01484
\end{aligned}
$$

$61.40 \% \mathrm{C}$
$5.79 \% \mathrm{H}_{2}$
$25.31 \% \mathrm{O}_{2}$
$1.09 \% \mathrm{~N}_{2}$
$1.41 \% \mathrm{~S}$
$5.00 \%$ ash
(by mass)

We now consider 100 lbm of this mixture. Then the mole numbers of each component are

$$
\begin{aligned}
N_{\mathrm{C}} & =\frac{m_{\mathrm{C}}}{M_{\mathrm{C}}}=\frac{64.63 \mathrm{lbm}}{12 \mathrm{lbm} / \mathrm{lbmol}}=5.386 \mathrm{lbmol} \\
N_{\mathrm{H} 2} & =\frac{m_{\mathrm{H} 2}}{M_{\mathrm{H} 2}}=\frac{6.095 \mathrm{lbm}}{2 \mathrm{lbm} / \mathrm{lbmol}}=3.048 \mathrm{lbmol} \\
N_{\mathrm{O} 2} & =\frac{m_{\mathrm{O} 2}}{M_{\mathrm{O} 2}}=\frac{26.64 \mathrm{lbm}}{32 \mathrm{lbm} / \mathrm{lbmol}}=0.8325 \mathrm{lbmol} \\
N_{\mathrm{N} 2} & =\frac{m_{\mathrm{N} 2}}{M_{\mathrm{N} 2}}=\frac{1.147 \mathrm{lbm}}{28 \mathrm{lbm} / \mathrm{lbmol}}=0.04096 \mathrm{lbmol} \\
N_{\mathrm{S}} & =\frac{m_{\mathrm{S}}}{M_{\mathrm{S}}}=\frac{1.484 \mathrm{lbm}}{32 \mathrm{lbm} / \mathrm{lbmol}}=0.04638 \mathrm{lbmol}
\end{aligned}
$$

The mole number of the mixture and the mole fractions are

$$
\begin{aligned}
N_{m} & =5.386+3.048+0.8325+0.04096+0.04638=9.354 \mathrm{lbmol} \\
y_{\mathrm{C}} & =\frac{N_{\mathrm{C}}}{N_{m}}=\frac{5.386 \mathrm{lbmol}}{9.354 \mathrm{lbmol}}=0.5758 \\
y_{\mathrm{H} 2} & =\frac{N_{\mathrm{H} 2}}{N_{m}}=\frac{3.048 \mathrm{lbmol}}{9.354 \mathrm{lbmol}}=0.3258 \\
y_{\mathrm{O} 2} & =\frac{N_{\mathrm{O} 2}}{N_{m}}=\frac{0.8325 \mathrm{lbmol}}{9.354 \mathrm{lbmol}}=0.0890 \\
y_{\mathrm{N} 2} & =\frac{N_{\mathrm{N} 2}}{N_{m}}=\frac{0.04096 \mathrm{lbmol}}{9.354 \mathrm{lbmol}}=0.00438 \\
y_{\mathrm{S}} & =\frac{N_{\mathrm{S}}}{N_{m}}=\frac{0.04638 \mathrm{lbmol}}{9.354 \mathrm{lbmol}}=0.00496
\end{aligned}
$$

Then, the combustion equation in this case may be written as educators for course preparation. If you are a student using this Manual, you are using it without permission.

$$
\begin{aligned}
& 0.5758 \mathrm{C}+0.3258 \mathrm{H}_{2}+0.0890 \mathrm{O}_{2}+0.00438 \mathrm{~N}_{2}+0.00496 \mathrm{~S}+1.2 a_{\mathrm{th}}\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \\
& \longrightarrow 0.5758 \mathrm{CO}_{2}+0.3258 \mathrm{H}_{2} \mathrm{O}+0.00496 \mathrm{SO}_{2}+0.2 a_{\mathrm{th}} \mathrm{O}_{2}+1.2 a_{\mathrm{th}} \times 3.76 \mathrm{kN}
\end{aligned}
$$

According to the oxygen balance,

$$
\mathrm{O}_{2} \text { balance: } 0.0890+1.2 a_{\mathrm{th}}=0.5758+0.5 \times 0.3258+0.00496+0.2 a_{\mathrm{th}} \longrightarrow a_{\mathrm{th}}=0.6547
$$

Substituting,

$$
\begin{aligned}
& 0.5758 \mathrm{C}+0.3258 \mathrm{H}_{2}+0.0890 \mathrm{O}_{2}+0.00438 \mathrm{~N}_{2}+0.00496 \mathrm{~S}+0.7856\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \\
& 0.5758 \mathrm{CO}_{2}+0.3258 \mathrm{H}_{2} \mathrm{O}+0.00496 \mathrm{SO}_{2}+0.1309 \mathrm{O}_{2}+2.954 \mathrm{~N}_{2}
\end{aligned}
$$

The mass of water in the products per unit mass of fuel burned is determined from

$$
\begin{aligned}
\frac{m_{\mathrm{H} 2 \mathrm{O}}}{m_{\text {coal }}} & =\frac{(0.3258 \times 18) \mathrm{lbm}}{(0.5758 \times 12+0.3258 \times 2+0.0890 \times 32+0.00438 \times 28+0.00496 \times 32) \mathrm{lbm}} \\
& =\frac{5.864 \mathrm{~kg}}{10.69 \mathrm{~kg}}=\mathbf{0 . 5 4 8 6} \mathbf{~ l b m ~ \mathbf { H } _ { 2 }} \mathbf{O} \text { Olbm coal }
\end{aligned}
$$

The dew-point temperature of a gas-vapor mixture is the saturation temperature of the water vapor in the product gases corresponding to its partial pressure. That is,

$$
P_{v}=\left(\frac{N_{v}}{N_{\text {prod }}}\right) P_{\text {prod }}=\left(\frac{0.3258 \mathrm{lbmol}}{(0.5758+0.3258+0.00496+0.1309+2.954) \mathrm{lbmol}}\right)(14.696 \mathrm{psia})=1.20 \mathrm{psia}
$$

Thus,

$$
T_{\mathrm{dp}}=T_{\text {sat } @ 1.20 \text { psia }}=\mathbf{1 0 8}^{\circ} \mathbf{F} \quad \text { (from EES) }
$$

15-105 Octane is burned steadily with 60 percent excess air. The dew-point temperature of the water vapor in the products is to be determined.

Assumptions 1 Combustion is complete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases.
Properties The molar masses of $\mathrm{C}_{8} \mathrm{H}_{18}$ and air are $114 \mathrm{~kg} / \mathrm{kmol}$ and $29 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A1).

Analysis The fuel is burned completely with the excess air, and thus the products will contain only $\mathrm{CO}_{2}$, $\mathrm{H}_{2} \mathrm{O}, \mathrm{N}_{2}$, and some free $\mathrm{O}_{2}$. Considering 1 kmol

$\mathrm{C}_{8} \mathrm{H}_{18}$, the combustion equation can be written as

$$
\mathrm{C}_{8} \mathrm{H}_{18}+1.6 a_{\mathrm{th}}\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 8 \mathrm{CO}_{2}+9 \mathrm{H}_{2} \mathrm{O}+0.6 a_{\mathrm{th}} \mathrm{O}_{2}+(1.6)(3.76) a_{\mathrm{th}} \mathrm{~N}_{2}
$$

where $a_{\mathrm{th}}$ is the stoichiometric coefficient and is determined from the $\mathrm{O}_{2}$ balance,

$$
1.6 a_{\mathrm{th}}=8+4.5+0.6 a_{\mathrm{th}} \longrightarrow a_{\mathrm{th}}=12.5
$$

Thus,

$$
\mathrm{C}_{8} \mathrm{H}_{18}+20\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 8 \mathrm{CO}_{2}+9 \mathrm{H}_{2} \mathrm{O}+7.5 \mathrm{O}_{2}+75.2 \mathrm{~N}_{2}
$$

The dew-point temperature of a gas-vapor mixture is the saturation temperature of the water vapor in the product gases corresponding to its partial pressure. That is,

$$
P_{v}=\left(\frac{N_{v}}{N_{\text {prod }}}\right) P_{\text {prod }}=\left(\frac{9 \mathrm{kmol}}{(8+9+7.5+75.2) \mathrm{kmol}}\right)(101.325 \mathrm{kPa})=9.147 \mathrm{kPa}
$$

Thus,

$$
T_{\mathrm{dp}}=T_{\text {sat } @ 9.147 \mathrm{kPa}}=44.1^{\circ} \mathrm{C} \quad \text { (from EES) }
$$

15-106 Methane is burned steadily with 50 percent excess air. The dew-point temperature of the water vapor in the products is to be determined.
Assumptions 1 Combustion is complete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases.
Properties The molar masses of $\mathrm{CH}_{4}$ and air are $16 \mathrm{~kg} / \mathrm{kmol}$ and $29 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).
Analysis The fuel is burned completely with the excess air, and thus the products will contain only $\mathrm{CO}_{2}$, $\mathrm{H}_{2} \mathrm{O}, \mathrm{N}_{2}$, and some free $\mathrm{O}_{2}$. Considering $1 \mathrm{kmol} \mathrm{CH}_{4}$, the combustion equation can be written as

$$
\mathrm{CH}_{4}+1.5 a_{\mathrm{th}}\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow \mathrm{CO}_{2}+2 \mathrm{H}_{2} \mathrm{O}+0.5 a_{\mathrm{th}} \mathrm{O}_{2}+(1.5)(3.76) a_{\mathrm{th}} \mathrm{~N}_{2}
$$

where $a_{\mathrm{th}}$ is the stoichiometric coefficient and is determined from the $\mathrm{O}_{2}$ balance,

$$
1.5 a_{\mathrm{th}}=1+1+0.5 a_{\mathrm{th}} \longrightarrow a_{\mathrm{th}}=2
$$

Thus,
$\mathrm{CH}_{4}+3\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow \mathrm{CO}_{2}+2 \mathrm{H}_{2} \mathrm{O}+\mathrm{O}_{2}+11.28 \mathrm{~N}_{2}$

The dew-point temperature of a gas-vapor mixture is the saturation temperature of the water vapor in the product gases corresponding to its partial pressure. That is,

$$
P_{v}=\left(\frac{N_{v}}{N_{\text {prod }}}\right) P_{\text {prod }}=\left(\frac{2 \mathrm{kmol}}{(1+2+1+11.28) \mathrm{kmol}}\right)(101.325 \mathrm{kPa})=13.26 \mathrm{kPa}
$$

Thus,

$$
T_{\mathrm{dp}}=T_{\text {sat@13.26 kPa }}=51.4^{\circ} \mathbf{C} \quad(\text { from EES })
$$

15-107 The higher and lower heating values of gaseous methane are to be determined and compared to the listed values.

Assumptions 1 Combustion is complete. 2 The combustion products contain $\mathrm{CO}_{2}, \mathrm{H}_{2} \mathrm{O}$, and $\mathrm{N}_{2} .3$ Combustion gases are ideal gases.
Properties The molar masses of $\mathrm{C}, \mathrm{O}_{2}, \mathrm{H}_{2}$, and air are 12, 32, 2, and $29 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).

Analysis The combustion reaction with stoichiometric air is

$$
\mathrm{CH}_{4}+2\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow \mathrm{CO}_{2}+2 \mathrm{H}_{2} \mathrm{O}+7.52 \mathrm{~N}_{2}
$$

Both the reactants and the products are taken to be at the standard reference state of $25^{\circ} \mathrm{C}$ and 1 atm for the calculation of heating values. The heat transfer for this process is equal to enthalpy of combustion. Note that $\mathrm{N}_{2}$ and $\mathrm{O}_{2}$ are stable elements, and thus their enthalpy of formation is zero. Then,

$$
q=h_{C}=H_{P}-H_{R}=\sum N_{P} \bar{h}_{f, P}^{\circ}-\sum N_{R} \bar{h}_{f, R}^{\circ}=\left(N \bar{h}_{f}^{\circ}\right)_{\mathrm{CO} 2}+\left(N \bar{h}_{f}^{\circ}\right)_{\mathrm{H} 2 \mathrm{O}}-\left(N \bar{h}_{f}^{\circ}\right)_{\mathrm{CH} 4}
$$

For the HHV, the water in the products is taken to be liquid. Then,

$$
\begin{aligned}
h_{C} & =(1 \mathrm{kmol})(-393,520 \mathrm{~kJ} / \mathrm{kmol})+(2 \mathrm{kmol})(-285,830 \mathrm{~kJ} / \mathrm{kmol})-(1 \mathrm{kmol})(-74,850 \mathrm{~kJ} / \mathrm{kmol}) \\
& =-890,330 \mathrm{~kJ} / \mathrm{kmol} \text { methane }
\end{aligned}
$$

The HHV of the methane is

$$
\mathrm{HHV}=\frac{-h_{C}}{M_{m}}=\frac{890,330 \mathrm{~kJ} / \mathrm{kmol} \mathrm{CH}_{4}}{16.043 \mathrm{~kg} / \mathrm{kmol} \mathrm{CH}_{4}}=\mathbf{5 5 , 5 0 0} \mathbf{~ k J} / \mathrm{kg} \mathrm{CH}_{4}
$$

The listed value from Table A-27 is $\mathbf{5 5 , 5 3 0} \mathbf{~ k J} \mathbf{k g}$. For the LHV, the water in the products is taken to be vapor. Then,

$$
\begin{aligned}
h_{C} & =(1 \mathrm{kmol})(-393,520 \mathrm{~kJ} / \mathrm{kmol})+(2 \mathrm{kmol})(-241,820 \mathrm{~kJ} / \mathrm{kmol})-(1 \mathrm{kmol})(-74,850 \mathrm{~kJ} / \mathrm{kmol}) \\
& =-802,310 \mathrm{~kJ} / \mathrm{kmol} \text { methane }
\end{aligned}
$$

The LHV of the coal is then

$$
\mathrm{LHV}=\frac{-h_{C}}{M_{m}}=\frac{-802,310 \mathrm{~kJ} / \mathrm{kmol} \mathrm{CH}_{4}}{16.043 \mathrm{~kg} / \mathrm{kmol} \mathrm{CH}_{4}}=\mathbf{5 0 , 0 1 0} \mathbf{~ k J} / \mathbf{k g ~ C H}_{4}
$$

The listed value from Table A-27 is $\mathbf{5 0 , 0 5 0} \mathbf{~ k J} / \mathbf{k g}$. The calculated and listed values are practically identical.

15-108 An expression for the HHV of a gaseous alkane $\mathrm{C}_{\mathrm{n}} \mathrm{H}_{2 \mathrm{n}+2}$ in terms of n is to be developed.
Assumptions 1 Combustion is complete. 2 The combustion products contain $\mathrm{CO}_{2}, \mathrm{H}_{2} \mathrm{O}$, and $\mathrm{N}_{2} .3$ Combustion gases are ideal gases.
Analysis The complete reaction balance for 1 kmol of fuel is

$$
\mathrm{C}_{n} \mathrm{H}_{2 n+2}+\frac{3 n+1}{2}\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow n \mathrm{CO}_{2}+(n+1) \mathrm{H}_{2} \mathrm{O}+\frac{3 n+1}{2}(3.76) \mathrm{N}_{2}
$$

Both the reactants and the products are taken to be at the standard reference state of $25^{\circ} \mathrm{C}$ and 1 atm for the calculation of heating values. The heat transfer for this process is equal to enthalpy of combustion. Note that $\mathrm{N}_{2}$ and $\mathrm{O}_{2}$ are stable elements, and thus their enthalpy of formation is zero. Then,

$$
q=h_{C}=H_{P}-H_{R}=\sum N_{P} \bar{h}_{f, P}^{\circ}-\sum N_{R} \bar{h}_{f, R}^{\circ}=\left(N \bar{h}_{f}^{\circ}\right)_{\mathrm{CO} 2}+\left(N \bar{h}_{f}^{\circ}\right)_{\mathrm{H} 2 \mathrm{O}}-\left(N \bar{h}_{f}^{\circ}\right)_{\mathrm{fuel}}
$$

For the HHV, the water in the products is taken to be liquid. Then,

$$
h_{C}=n(-393,520)+(n+1)(-285,830)-\left(\bar{h}_{f}^{\circ}\right)_{\text {fuel }}
$$

The HHV of the fuel is

$$
\text { HHV }=\frac{-h_{C}}{M_{\text {fuel }}}=\frac{n(-393,520)+(n+1)(-285,830)-\left(\bar{h}_{f}^{\circ}\right)_{\text {fuel }}}{M_{\text {fuel }}}
$$

For the LHV, the water in the products is taken to be vapor. Then,

$$
\mathrm{LHV}=\frac{n(-393,520)+(n+1)(-241,820)-\left(\bar{h}_{f}^{\circ}\right)_{\text {fuel }}}{M_{\text {fuel }}}
$$

15-109 A coal from Colorado is burned with 10 percent excess air during a steady-flow combustion process. The fraction of the water in the combustion products that is liquid and the fraction that is vapor are to be determined.
Assumptions 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 There are no work interactions. 5 The combustion chamber is adiabatic.
Properties The molar masses of $\mathrm{C}, \mathrm{H}_{2}, \mathrm{~N}_{2}, \mathrm{O}_{2}, \mathrm{~S}$, and air are $12,2,28,32,32$, and $29 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).

Analysis The mass fractions of the constituent of the coal when the ash is substituted are

$$
\begin{aligned}
& \mathrm{mf}_{\mathrm{C}}=\frac{m_{\mathrm{C}}}{m_{\text {total }}}=\frac{79.61 \mathrm{~kg}}{(100-8.62) \mathrm{kg}}=\frac{79.61 \mathrm{~kg}}{91.38 \mathrm{~kg}}=0.8712 \\
& \mathrm{mf}_{\mathrm{H} 2}=\frac{m_{\mathrm{H} 2}}{m_{\text {total }}}=\frac{4.66 \mathrm{~kg}}{91.38 \mathrm{~kg}}=0.05100 \\
& \mathrm{mf}_{\mathrm{O} 2}=\frac{m_{\mathrm{O} 2}}{m_{\text {total }}}=\frac{4.76 \mathrm{~kg}}{91.38 \mathrm{~kg}}=0.05209 \\
& \mathrm{mf}_{\mathrm{N} 2}=\frac{m_{\mathrm{N} 2}}{m_{\text {total }}}=\frac{1.83 \mathrm{~kg}}{91.38 \mathrm{~kg}}=0.02003 \\
& \mathrm{mf}_{\mathrm{S}}=\frac{m_{\mathrm{S}}}{m_{\text {total }}}=\frac{0.52 \mathrm{~kg}}{91.38 \mathrm{~kg}}=0.00569
\end{aligned}
$$

$79.61 \%$ C
4.66\% $\mathrm{H}_{2}$
4.76\% $\mathrm{O}_{2}$
$1.83 \% \mathrm{~N}_{2}$
0.52\% S
8.62\% ash
(by mass)

We now consider 100 kg of this mixture. Then the mole numbers of each component are

$$
\begin{aligned}
& N_{\mathrm{C}}=\frac{m_{\mathrm{C}}}{M_{\mathrm{C}}}=\frac{87.12 \mathrm{~kg}}{12 \mathrm{~kg} / \mathrm{kmol}}=7.26 \mathrm{kmol} \\
& N_{\mathrm{H} 2}=\frac{m_{\mathrm{H} 2}}{M_{\mathrm{H} 2}}=\frac{5.10 \mathrm{~kg}}{2 \mathrm{~kg} / \mathrm{kmol}}=2.55 \mathrm{kmol} \\
& N_{\mathrm{O} 2}=\frac{m_{\mathrm{O} 2}}{M_{\mathrm{O} 2}}=\frac{5.209 \mathrm{~kg}}{32 \mathrm{~kg} / \mathrm{kmol}}=0.1628 \mathrm{kmol} \\
& N_{\mathrm{N} 2}=\frac{m_{\mathrm{N} 2}}{M_{\mathrm{N} 2}}=\frac{2.003 \mathrm{~kg}}{28 \mathrm{~kg} / \mathrm{kmol}}=0.07154 \mathrm{kmol} \\
& N_{\mathrm{S}}=\frac{m_{\mathrm{S}}}{M_{\mathrm{S}}}=\frac{0.569 \mathrm{~kg}}{32 \mathrm{~kg} / \mathrm{kmol}}=0.01778 \mathrm{kmol}
\end{aligned}
$$

The mole number of the mixture and the mole fractions are

$$
\begin{aligned}
N_{m} & =7.26+2.55+0.1628+0.07154+0.01778=10.062 \mathrm{kmol} \\
y_{\mathrm{C}} & =\frac{N_{\mathrm{C}}}{N_{m}}=\frac{7.26 \mathrm{kmol}}{10.06 \mathrm{kmol}}=0.7215 \\
y_{\mathrm{H} 2} & =\frac{N_{\mathrm{H} 2}}{N_{m}}=\frac{2.55 \mathrm{kmol}}{10.06 \mathrm{kmol}}=0.2535 \\
y_{\mathrm{O} 2} & =\frac{N_{\mathrm{O} 2}}{N_{m}}=\frac{0.1628 \mathrm{kmol}}{10.06 \mathrm{kmol}}=0.01618 \\
y_{\mathrm{N} 2} & =\frac{N_{\mathrm{N} 2}}{N_{m}}=\frac{0.07154 \mathrm{kmol}}{10.06 \mathrm{kmol}}=0.00711 \\
y_{\mathrm{S}} & =\frac{N_{\mathrm{S}}}{N_{m}}=\frac{0.01778 \mathrm{kmol}}{10.06 \mathrm{kmol}}=0.00177
\end{aligned}
$$

Then, the combustion equation in this case may be written as

$$
\begin{aligned}
0.7215 \mathrm{C}+0.2535 \mathrm{H}_{2}+ & 0.01618 \mathrm{O}_{2}+0.00711 \mathrm{~N}_{2}+0.00177 \mathrm{~S}+1.1 a_{\mathrm{th}}\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \\
& \longrightarrow 0.7215 \mathrm{CO}_{2}+0.2535 \mathrm{H}_{2} \mathrm{O}+0.00177 \mathrm{SO}_{2}+1.1 a_{\mathrm{th}} \times 3.76 \mathrm{~N}_{2}+0.1 a_{t h} \mathrm{O}_{2}
\end{aligned}
$$

According to the oxygen balance,

$$
\mathrm{O}_{2} \text { balance : } 0.01618+1.1 a_{\mathrm{th}}=0.7215+(0.5)(0.2535)+(0.00177)+0.1 a_{\mathrm{th}} \longrightarrow a_{\mathrm{th}}=0.8339
$$

Substituting,

$$
\begin{aligned}
0.7215 \mathrm{C}+0.2535 \mathrm{H}_{2} & +0.01617 \mathrm{O}_{2}+0.00711 \mathrm{~N}_{2}+0.00177 \mathrm{~S}+0.9173\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \\
& \longrightarrow 0.7215 \mathrm{CO}_{2}+0.2535 \mathrm{H}_{2} \mathrm{O}+0.0018 \mathrm{SO}_{2}+3.449 \mathrm{~N}_{2}+0.0834 \mathrm{O}_{2}
\end{aligned}
$$

If the mixture leaves the boiler saturated with water, the partial pressure of water in the product mixture would be

$$
P_{v}=P_{\text {sat } @ 50^{\circ} \mathrm{C}}=12.352 \mathrm{kPa}
$$

and the water mole fraction would be

$$
y_{v}=\frac{P_{v}}{P}=\frac{12.352 \mathrm{kPa}}{101.325 \mathrm{kPa}}=0.1219
$$

The actual mole fraction of water in the products is

$$
y_{v}=\frac{N_{\mathrm{H} 2 \mathrm{O}}}{N_{\text {prod }}}=\frac{0.2535 \mathrm{kmol}}{(0.7215+0.2535+0.0018+3.449+0.0834) \mathrm{kmol}}=0.0562
$$

Since the actual mole fraction of the water is less than that when the mixture is saturated, the mixture never becomes saturated and hence, no condensate is formed. All of the water in the mixture is then in the vapor form at this temperature.

15-110 Butane is burned with stoichiometric amount of air. The fraction of the water in the products that is liquid is to be determined.
Assumptions 1 Combustion is complete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases.
Analysis The fuel is burned completely with the air, and thus the products will contain only $\mathrm{CO}_{2}, \mathrm{H}_{2} \mathrm{O}$, and $\mathrm{N}_{2}$. Considering $1 \mathrm{kmol} \mathrm{C}_{4} \mathrm{H}_{10}$, the combustion equation can be written as

$$
\mathrm{C}_{4} \mathrm{H}_{10}+6.5\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 4 \mathrm{CO}_{2}+5 \mathrm{H}_{2} \mathrm{O}+24.44 \mathrm{~N}_{2}
$$

The mole fraction of water in the products is

$$
y_{v}=\frac{N_{\mathrm{H} 2 \mathrm{O}}}{N_{\text {prod }}}=\frac{5 \mathrm{kmol}}{(4+5+24.44) \mathrm{kmol}}=0.1495
$$

The saturation pressure for the water vapor is

$$
P_{v}=P_{\text {sat } @ 40^{\circ} \mathrm{C}}=7.3851 \mathrm{kPa}
$$

When the combustion gases are saturated, the mole fraction of the water vapor will be

$$
y_{g}=\frac{P_{v}}{P}=\frac{7.3851 \mathrm{kPa}}{101.325 \mathrm{kPa}}=0.0729
$$

The mole fraction of the liquid water is then

$$
y_{f}=y_{v}-y_{g}=0.1495-0.0729=0.0766
$$

Thus, the fraction of liquid water in the combustion products is

$$
f_{\text {liquid }}=\frac{y_{f}}{y_{g}}=\frac{0.0766}{0.1495}=\mathbf{0 . 5 1 2}
$$

15-111 CO gas is burned with air during a steady-flow combustion process. The rate of heat transfer from the combustion chamber is to be determined.
Assumptions 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 There are no work interactions. 5 Combustion is complete.
Properties The molar masses of CO and air are $28 \mathrm{~kg} / \mathrm{kmol}$ and $29 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).
Analysis We first need to calculate the amount of air used per kmol of CO before we can write the combustion equation,

$$
\begin{aligned}
& \boldsymbol{v}_{\mathrm{CO}}=\frac{R T}{P}=\frac{\left(0.2968 \mathrm{kPa} \cdot \mathrm{~m}^{3} / \mathrm{kg} \cdot \mathrm{~K}\right)(310 \mathrm{~K})}{(110 \mathrm{kPa})}=0.836 \mathrm{~m}^{3} / \mathrm{kg} \\
& \dot{m}_{\mathrm{CO}}=\frac{\dot{\boldsymbol{v}}_{\mathrm{CO}}}{\boldsymbol{v}_{\mathrm{CO}}}=\frac{0.4 \mathrm{~m}^{3} / \mathrm{min}}{0.836 \mathrm{~m}^{3} / \mathrm{kg}}=0.478 \mathrm{~kg} / \mathrm{min}
\end{aligned}
$$

Then the molar air-fuel ratio becomes

$$
\overline{\mathrm{AF}}=\frac{N_{\mathrm{air}}}{N_{\text {fuel }}}=\frac{\dot{m}_{\text {air }} / M_{\text {air }}}{\dot{m}_{\text {fuel }} / M_{\text {fuel }}}=\frac{(1.5 \mathrm{~kg} / \mathrm{min}) /(29 \mathrm{~kg} / \mathrm{kmol})}{(0.478 \mathrm{~kg} / \mathrm{min}) /(28 \mathrm{~kg} / \mathrm{kmol})}=3.03 \mathrm{kmol} \text { air } / \mathrm{kmol} \text { fuel }
$$

Thus the number of moles of $\mathrm{O}_{2}$ used per mole of CO is $3.03 / 4.76=0.637$. Then the combustion equation in this case can be written as

$$
\mathrm{CO}+0.637\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow \mathrm{CO}_{2}+0.137 \mathrm{O}_{2}+2.40 \mathrm{~N}_{2}
$$

Under steady-flow conditions the energy balance $E_{\text {in }}-E_{\text {out }}=\Delta E_{\text {system }}$ applied on the combustion chamber with $W=0$ reduces to

$$
-Q_{\mathrm{out}}=\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{P}-\sum N_{R}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{R}
$$

Assuming the air and the combustion products to be ideal gases, we have $h=h(T)$. From the tables,

|  | $\overline{\mathbf{h}}_{\mathbf{f}}^{\circ}$ | $\overline{\mathbf{h}}_{\mathbf{2 9 8} \mathbf{K}}$ | $\overline{\mathbf{h}}_{\mathbf{3 1 0} \mathbf{K}}$ | $\overline{\mathbf{h}}_{\mathbf{9 0 0} \mathbf{K}}$ |
| :--- | :--- | :--- | :--- | :--- |
| Substance | $\mathbf{k J} / \mathbf{k m o l}$ | $\mathbf{k J} / \mathbf{k m o l}$ | $\mathbf{k J} / \mathbf{k m o l}$ | $\mathbf{k J} / \mathbf{k m o l}$ |
| CO | $-110,530$ | 8669 | 9014 | 27,066 |
| $\mathrm{O}_{2}$ | 0 | 8682 | --- | 27,928 |
| $\mathrm{~N}_{2}$ | 0 | 8669 | --- | 26,890 |
| $\mathrm{CO}_{2}$ | $-393,520$ | 9364 | --- | 37,405 |

Thus,

$$
\begin{aligned}
-Q_{\text {out }}= & (1)(-393,520+37,405-9364)+(0.137)(0+27,928-8682) \\
& +(2.4)(0+26,890-8669)-(1)(-110,530+9014-8669)-0-0 \\
= & -208,927 \mathrm{~kJ} / \mathrm{kmol} \text { of CO }
\end{aligned}
$$

Then the rate of heat transfer for a mass flow rate of $0.956 \mathrm{~kg} / \mathrm{min}$ for CO becomes

$$
\dot{Q}_{\text {out }}=\dot{N} Q_{\text {out }}=\left(\frac{\dot{m}}{N}\right) Q_{\text {out }}=\left(\frac{0.478 \mathrm{~kg} / \mathrm{min}}{28 \mathrm{~kg} / \mathrm{kmol}}\right)(208,927 \mathrm{~kJ} / \mathrm{kmol})=3567 \mathrm{~kJ} / \mathrm{min}
$$

15-112 Methane gas is burned steadily with dry air. The volumetric analysis of the products is given. The percentage of theoretical air used and the heat transfer from the combustion chamber are to be determined.
Assumptions 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 There are no work interactions.
Analysis (a) Considering 100 kmol of dry products, the combustion equation can be written as

$$
x \mathrm{CH}_{4}+a\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow 5.20 \mathrm{CO}_{2}+0.33 \mathrm{CO}+11.24 \mathrm{O}_{2}+83.23 \mathrm{~N}_{2}+b \mathrm{H}_{2} \mathrm{O}
$$

The unknown coefficients $x, a$, and $b$ are determined from mass balances,

$$
\begin{array}{ll}
\mathrm{N}_{2}: 3.76 a=83.23 & \longrightarrow a=22.14 \\
\mathrm{C}: x=5.20+0.33 & \longrightarrow x=5.53 \\
\mathrm{H}: 4 x=2 b \quad \longrightarrow b=11.06
\end{array}
$$

(Check $\mathrm{O}_{2}: a=5.20+0.165+11.24+b / 2 \longrightarrow 22.14=22.14$ )

Thus, $\quad 5.53 \mathrm{CH}_{4}+22.14\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow 5.20 \mathrm{CO}_{2}+0.33 \mathrm{CO}+11.24 \mathrm{O}_{2}+83.23 \mathrm{~N}_{2}+11.06 \mathrm{H}_{2} \mathrm{O}$
The combustion equation for 1 kmol of fuel is obtained by dividing the above equation by 5.53

$$
\mathrm{CH}_{4}+4\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow 0.94 \mathrm{CO}_{2}+0.06 \mathrm{CO}+2.03 \mathrm{O}_{2}+15.05 \mathrm{~N}_{2}+2 \mathrm{H}_{2} \mathrm{O}
$$

To find the percent theoretical air used, we need to know the theoretical amount of air, which is determined from the theoretical combustion equation of the fuel,

$$
\begin{aligned}
& \mathrm{CH}_{4}+a_{\mathrm{th}}\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow \mathrm{CO}_{2}+2 \mathrm{H}_{2} \mathrm{O}+3.76 a_{\mathrm{th}} \mathrm{~N}_{2} \\
& \mathrm{O}_{2}:
\end{aligned} \quad a_{\mathrm{th}}=1+1 \longrightarrow a_{\mathrm{th}}=2.0
$$

Then, $\quad$ Percent theoretical air $=\frac{m_{\text {air,act }}}{m_{\text {air,th }}}=\frac{N_{\text {air,act }}}{N_{\text {air,th }}}=\frac{(4.0)(4.76) \mathrm{kmol}}{(2.0)(4.76) \mathrm{kmol}}=\mathbf{2 0 0 \%}$
(b) Under steady-flow conditions, energy balance applied on the combustion chamber reduces to

$$
-Q_{\mathrm{out}}=\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{P}-\sum N_{R}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{R}
$$

Assuming the air and the combustion products to be ideal gases, we have $h=h(T)$. From the tables,

| Substance | $\overline{\mathbf{h}}_{\mathbf{f}}^{\circ}$ <br> $\mathbf{k J} / \mathbf{k m o l}$ | $\overline{\mathbf{h}}_{\mathbf{2 9 0} \mathbf{K}}$ <br> $\mathbf{k J} / \mathbf{k m o l}$ | $\overline{\mathbf{h}}_{\mathbf{2 9 8} \mathbf{K}}$ <br> $\mathbf{k J} / \mathbf{k m o l}$ | $\overline{\mathbf{h}}_{\mathbf{7 0 0} \mathbf{K}}$ <br> $\mathbf{k J} / \mathbf{k m o l}$ |
| :--- | :--- | :--- | :--- | :--- |
| $\mathrm{CH}_{4}(g)$ | $-74,850$ | --- | --- | --- |
| $\mathrm{O}_{2}$ | 0 | 8443 | 8682 | 21,184 |
| $\mathrm{~N}_{2}$ | 0 | 8432 | 8669 | 20,604 |
| $\mathrm{H}_{2} \mathrm{O}(g)$ | $-241,820$ | --- | 9904 | 24,088 |
| CO | $-110,530$ | --- | 8669 | 20,690 |
| $\mathrm{CO}_{2}$ | $-393,520$ | --- | 9364 | 27,125 |

Thus,

$$
\begin{aligned}
-Q_{\text {out }}= & (0.94)(-393,520+27,125-9364)+(0.06)(-110,530+20,690-8669) \\
& +(2)(-241,820+24,088-9904)+(2.03)(0+21,184-8682)+(15.04)(0+20,604-8669) \\
& -(1)\left(-74,850+h_{298}-h_{298}\right)-(4)(0+8443-8682)-(15.04)(0+8432-8669) \\
= & -530,022 \mathrm{~kJ} / \mathrm{kmolCH}_{4} \\
\text { or } \quad Q_{\text {out }}= & \mathbf{5 3 0 , 0 2 2} \mathbf{~ k J} / \mathbf{k m o l ~ C H}_{4}
\end{aligned}
$$

15-113 Propane gas is burned with air during a steady-flow combustion process. The adiabatic flame temperature is to be determined for different cases.
Assumptions 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 There are no work interactions. 5 The combustion chamber is adiabatic.

Analysis Adiabatic flame temperature is the temperature at which the products leave the combustion chamber under adiabatic conditions $(Q=0)$ with no work interactions $(W=0)$. Under steady-flow conditions the energy balance $E_{\text {in }}-E_{\text {out }}=\Delta E_{\text {system }}$ applied on the combustion chamber reduces to

$$
\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{P}=\sum N_{R}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{R} \longrightarrow \sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}_{T}-\bar{h}^{\circ}\right)_{P}=\left(N \bar{h}_{f}^{\circ}\right)_{\mathrm{C}_{3} \mathrm{H}_{8}}
$$

since all the reactants are at the standard reference temperature of $25^{\circ} \mathrm{C}$, and $\bar{h}_{f}^{\circ}=0$ for $\mathrm{O}_{2}$ and $\mathrm{N}_{2}$.
(a) The theoretical combustion equation of $\mathrm{C}_{3} \mathrm{H}_{8}$ with stoichiometric amount of air is

$$
\mathrm{C}_{3} \mathrm{H}_{8}(g)+5\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 3 \mathrm{CO}_{2}+4 \mathrm{H}_{2} \mathrm{O}+18.8 \mathrm{~N}_{2}
$$

From the tables,

| Substance | $\overline{\mathbf{h}}_{\mathbf{f}}^{\circ}$ | $\overline{\mathbf{h}}_{\mathbf{2 9 8} \mathbf{K}}$ |
| :--- | :--- | :--- |
| $\mathbf{k J} / \mathbf{k m o l}$ | $\mathbf{k J} / \mathbf{k m o l}$ |  |
| $\mathrm{C}_{3} \mathrm{H}_{8}(g)$ | $-103,850$ | --- |
| $\mathrm{O}_{2}$ | 0 | 8682 |
| $\mathrm{~N}_{2}$ | 0 | 8669 |
| $\mathrm{H}_{2} \mathrm{O}(g)$ | $-241,820$ | 9904 |
| CO | $-110,530$ | 8669 |
| $\mathrm{CO}_{2}$ | $-393,520$ | 9364 |

Thus,

$$
(3)\left(-393,520+\bar{h}_{\mathrm{CO}_{2}}-9364\right)+(4)\left(-241,820+\bar{h}_{\mathrm{H}_{2} \mathrm{O}}-9904\right)+(18.8)\left(0+\bar{h}_{\mathrm{N}_{2}}-8669\right)=(1)(-103,850)
$$

It yields

$$
3 \bar{h}_{\mathrm{CO}_{2}}+4 \bar{h}_{\mathrm{H}_{2} \mathrm{O}}+18.8 \bar{h}_{\mathrm{N}_{2}}=2,274,675 \mathrm{~kJ}
$$

The adiabatic flame temperature is obtained from a trial and error solution. A first guess is obtained by dividing the right-hand side of the equation by the total number of moles, which yields 2,274,675 / (3+4+ $18.8)=88,165 \mathrm{~kJ} / \mathrm{kmol}$. This enthalpy value corresponds to about 2650 K for $\mathrm{N}_{2}$. Noting that the majority of the moles are $\mathrm{N}_{2}, T_{P}$ will be close to 2650 K , but somewhat under it because of the higher specific heats of $\mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$.

At $2400 \mathrm{~K}: \quad 3 \bar{h}_{\mathrm{CO}_{2}}+4 \bar{h}_{\mathrm{H}_{2} \mathrm{O}}+18.8 \bar{h}_{\mathrm{N}_{2}}=(3)(125,152)+(4)(103,508)+(18.8)(79,320)$ $=2,280,704 \mathrm{~kJ}$ (Higher than 2,274,675 kJ)

At $2350 \mathrm{~K}: \quad 3 \bar{h}_{\mathrm{CO}_{2}}+4 \bar{h}_{\mathrm{H}_{2} \mathrm{O}}+18.8 \bar{h}_{\mathrm{N}_{2}}=(3)(122,091)+(4)(100,846)+(18.8)(77,496)$

$$
=2,226,582 \mathrm{~kJ}(\text { Lower than } 2,274,675 \mathrm{~kJ})
$$

By interpolation, $\quad T_{P}=2394 \mathrm{~K}$
(b) The balanced combustion equation for complete combustion with $300 \%$ theoretical air is

$$
\mathrm{C}_{3} \mathrm{H}_{8}(\mathrm{~g})+15\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 3 \mathrm{CO}_{2}+4 \mathrm{H}_{2} \mathrm{O}+10 \mathrm{O}_{2}+56.4 \mathrm{~N}_{2}
$$

Substituting known numerical values,

$$
\begin{aligned}
&(3)(-393,520\left.+\bar{h}_{\mathrm{CO}_{2}}-9364\right)+(4)\left(-241,820+\bar{h}_{\mathrm{H}_{2} \mathrm{O}}-9904\right) \\
&+(10)\left(0+\bar{h}_{\mathrm{O}_{2}}-8682\right)+(56.4)\left(0+\bar{h}_{\mathrm{N}_{2}}-8669\right)=(1)(-103,850)
\end{aligned}
$$

which yields

$$
3 \bar{h}_{\mathrm{CO}_{2}}+4 \bar{h}_{\mathrm{H}_{2} \mathrm{O}}+10 \bar{h}_{\mathrm{O}_{2}}+56.4 \bar{h}_{\mathrm{N}_{2}}=2,687,450 \mathrm{~kJ}
$$

The adiabatic flame temperature is obtained from a trial and error solution. A first guess is obtained by dividing the right-hand side of the equation by the total number of moles, which yields 2,687,449 / (3+4+ $10+56.4)=36,614 \mathrm{~kJ} / \mathrm{kmol}$. This enthalpy value corresponds to about 1200 K for $\mathrm{N}_{2}$. Noting that the majority of the moles are $\mathrm{N}_{2}, T_{P}$ will be close to 1200 K , but somewhat under it because of the higher specific heats of $\mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$.

At 1160 K:

$$
\begin{aligned}
3 \bar{h}_{\mathrm{CO}_{2}}+4 \bar{h}_{\mathrm{H}_{2} \mathrm{O}}+10 \bar{h}_{\mathrm{O}_{2}}+56.4 \bar{h}_{\mathrm{N}_{2}} & =(3)(51,602)+(4)(42,642)+(10)(37,023)+(56.4)(35,430) \\
& =2,693,856 \mathrm{~kJ}(\text { Higher than } 2,687,450 \mathrm{~kJ})
\end{aligned}
$$

At 1140 K :

$$
\begin{aligned}
3 \bar{h}_{\mathrm{CO}_{2}}+4 \bar{h}_{\mathrm{H}_{2} \mathrm{O}}+10 \bar{h}_{\mathrm{O}_{2}}+56.4 \bar{h}_{\mathrm{N}_{2}} & =(3)(50,484)+(4)(41,780)+(10)(36,314)+(56.4)(34,760) \\
& =2,642,176 \mathrm{~kJ}(\text { Lower than } 2,687,450 \mathrm{~kJ})
\end{aligned}
$$

By interpolation, $\quad T_{P}=1158 \mathrm{~K}$
(c) The balanced combustion equation for incomplete combustion with $95 \%$ theoretical air is

$$
\mathrm{C}_{3} \mathrm{H}_{8}(g)+4.75\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 2.5 \mathrm{CO}_{2}+0.5 \mathrm{CO}+4 \mathrm{H}_{2} \mathrm{O}+17.86 \mathrm{~N}_{2}
$$

Substituting known numerical values,

$$
\begin{aligned}
& (2.5)\left(-393,520+\bar{h}_{\mathrm{CO}_{2}}-9364\right)+(0.5)\left(-110,530+\bar{h}_{\mathrm{CO}}-8669\right) \\
& \quad+(4)\left(-241,820+\bar{h}_{\mathrm{H}_{2} \mathrm{O}}-9904\right)+(17.86)\left(0+\bar{h}_{\mathrm{N}_{2}}-8669\right)=(1)(-103,850)
\end{aligned}
$$

which yields

$$
2.5 \bar{h}_{\mathrm{CO}_{2}}+0.5 \bar{h}_{\mathrm{CO}}+4 \bar{h}_{\mathrm{H}_{2} \mathrm{O}}+17.86 \bar{h}_{\mathrm{N}_{2}}=2,124,684 \mathrm{~kJ}
$$

The adiabatic flame temperature is obtained from a trial and error solution. A first guess is obtained by dividing the right-hand side of the equation by the total number of moles, which yields 2,124,684 / (2.5 + 4 $+0.5+17.86)=85,466 \mathrm{~kJ} / \mathrm{kmol}$. This enthalpy value corresponds to about 2550 K for $\mathrm{N}_{2}$. Noting that the majority of the moles are $\mathrm{N}_{2}, T_{P}$ will be close to 2550 K , but somewhat under it because of the higher specific heats of $\mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$.

At 2350 K:

$$
\begin{aligned}
2.5 \bar{h}_{\mathrm{CO}_{2}}+0.5 \bar{h}_{\mathrm{CO}}+4 \bar{h}_{\mathrm{H}_{2} \mathrm{O}}+17.86 \bar{h}_{\mathrm{N}_{2}} & =(2.5)(122,091)+(0.5)(78,178)+(4)(100,846)+(17.86)(77,496) \\
& =2,131,779 \mathrm{~kJ} \text { (Higher than } 2,124,684 \mathrm{~kJ})
\end{aligned}
$$

At 2300 K:

$$
\begin{aligned}
2.5 \bar{h}_{\mathrm{CO}_{2}}+0.5 \bar{h}_{\mathrm{CO}}+4 \bar{h}_{\mathrm{H}_{2} \mathrm{O}}+17.86 \bar{h}_{\mathrm{N}_{2}} & =(2.5)(119,035)+(0.5)(76,345)+(4)(98,199)+(17.86)(75,676) \\
& =2,080,129 \mathrm{~kJ}(\text { Lower than } 2,124,684 \mathrm{~kJ})
\end{aligned}
$$

By interpolation, $\quad T_{P}=2343 \mathrm{~K}$

15-114 The highest possible temperatures that can be obtained when liquid gasoline is burned steadily with air and with pure oxygen are to be determined.
Assumptions 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 There are no work interactions. 5 The combustion chamber is adiabatic.
Analysis The highest possible temperature that can be achieved during a combustion process is the temperature which occurs when a fuel is burned completely with stoichiometric amount of air in an adiabatic combustion chamber. It is determined from

$$
\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{P}=\sum N_{R}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{R} \longrightarrow \sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}_{T}-\bar{h}^{\circ}\right)_{P}=\left(N \bar{h}_{f}^{\circ}\right)_{\mathrm{C}_{8} \mathrm{H}_{18}}
$$

since all the reactants are at the standard reference temperature of $25^{\circ} \mathrm{C}$, and for $\mathrm{O}_{2}$ and $\mathrm{N}_{2}$. The theoretical combustion equation of $\mathrm{C}_{8} \mathrm{H}_{18}$ air is

$$
\mathrm{C}_{8} \mathrm{H}_{18}+12.5\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 8 \mathrm{CO}_{2}+9 \mathrm{H}_{2} \mathrm{O}+47 \mathrm{~N}_{2}
$$

From the tables,

| Substance | $\overline{\mathbf{h}}_{\mathbf{f}}^{\circ}$ <br> kJ/kmol | $\overline{\mathbf{h}}_{298 \mathrm{~K}}$ <br> kJ/kmol | $\xrightarrow[5^{\circ}{ }^{\circ}]{\mathrm{C}_{8} \mathrm{H}_{18}}$ |  | Products |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{C}_{8} \mathrm{H}_{18}(\ell)$ | -249,950 | --- |  | Combustion <br> chamber | $\xrightarrow{\text { Prod }}$ |
| $\mathrm{O}_{2}$ | 0 | 8682 | Air |  | $T_{P, \text { max }}$ |
| $\mathrm{N}_{2}$ | 0 | 8669 |  |  |  |
| $\mathrm{H}_{2} \mathrm{O}(\mathrm{g})$ | -241,820 | 9904 |  |  |  |

Thus,

$$
(8)\left(-393,520+\bar{h}_{\mathrm{CO}_{2}}-9364\right)+(9)\left(-241,820+\bar{h}_{\mathrm{H}_{2} \mathrm{O}}-9904\right)+(47)\left(0+\bar{h}_{\mathrm{N}_{2}}-8669\right)=(1)(-249,950)
$$

It yields $\quad 8 \bar{h}_{\mathrm{CO}_{2}}+9 \bar{h}_{\mathrm{H}_{2} \mathrm{O}}+47 \overline{\mathrm{~h}}_{\mathrm{N}_{2}}=5,646,081 \mathrm{~kJ}$
The adiabatic flame temperature is obtained from a trial and error solution. A first guess is obtained by dividing the right-hand side of the equation by the total number of moles, which yields 5,646,081/(8+9+ $47)=88,220 \mathrm{~kJ} / \mathrm{kmol}$. This enthalpy value corresponds to about 2650 K for $\mathrm{N}_{2}$. Noting that the majority of the moles are $\mathrm{N}_{2}, T_{P}$ will be close to 2650 K , but somewhat under it because of the higher specific heat of $\mathrm{H}_{2} \mathrm{O}$.
At $2400 \mathrm{~K}: \quad 8 \bar{h}_{\mathrm{CO}_{2}}+9 \bar{h}_{\mathrm{H}_{2} \mathrm{O}}+47 \bar{h}_{\mathrm{N}_{2}}=(8)(125,152)+(9)(103,508)+(47)(79,320)$

$$
=5,660,828 \mathrm{~kJ}(\text { Higher than } 5,646,081 \mathrm{~kJ})
$$

At $2350 \mathrm{~K}: \quad 8 \bar{h}_{\mathrm{CO}_{2}}+9 \bar{h}_{\mathrm{H}_{2} \mathrm{O}}+47 \bar{h}_{\mathrm{N}_{2}}=(8)(122,091)+(9)(100,846)+(47)(77,496)$

$$
=5,526,654 \mathrm{~kJ}(\text { Lower than } 5,646,081 \mathrm{~kJ})
$$

By interpolation, $\quad T_{P}=2395 \mathrm{~K}$
If the fuel is burned with stoichiometric amount of pure $\mathrm{O}_{2}$, the combustion equation would be

$$
\mathrm{C}_{8} \mathrm{H}_{18}+12.5 \mathrm{O}_{2} \longrightarrow 8 \mathrm{CO}_{2}+9 \mathrm{H}_{2} \mathrm{O}
$$

Thus,

$$
(8)\left(-393,520+\bar{h}_{\mathrm{CO}_{2}}-9364\right)+(9)\left(-241,820+\bar{h}_{\mathrm{H}_{2} \mathrm{O}}-9904\right)=(1)(-249,950)
$$

It yields

$$
8 \bar{h}_{\mathrm{CO}_{2}}+9 \bar{h}_{\mathrm{H}_{2} \mathrm{O}}=5,238,638 \mathrm{~kJ}
$$

The adiabatic flame temperature is obtained from a trial and error solution. A first guess is obtained by dividing the right-hand side of the equation by the total number of moles, which yields $5,238,638 /(8+9)=$ $308,155 \mathrm{~kJ} / \mathrm{kmol}$. This enthalpy value is higher than the highest enthalpy value listed for $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{CO}_{2}$. Thus an estimate of the adiabatic flame temperature can be obtained by extrapolation.
At $3200 \mathrm{~K}: \quad 8 \bar{h}_{\mathrm{CO}_{2}}+9 \bar{h}_{\mathrm{H}_{2} \mathrm{O}}=(8)(174,695)+(9)(147,457)=2,724,673 \mathrm{~kJ}$
At $3250 \mathrm{~K}: \quad 8 \bar{h}_{\mathrm{CO}_{2}}+9 \bar{h}_{\mathrm{H}_{2} \mathrm{O}}=(8)(177,822)+(9)(150,272)=2,775,024 \mathrm{~kJ}$
By extrapolation, we get $T_{P}=\mathbf{3 5 9 7} \mathbf{K}$. However, the solution of this problem using EES gives $\mathbf{5 6 4 5} \mathbf{K}$. The large difference between these two values is due to extrapolation.

15-115 Methyl alcohol vapor is burned with the stoichiometric amount of air in a combustion chamber. The maximum pressure that can occur in the combustion chamber if the combustion takes place at constant volume and the maximum volume of the combustion chamber if the combustion occurs at constant pressure are to be determined.
Assumptions 1 Combustion is complete. 2 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible.

Analysis (a) The combustion equation of $\mathrm{CH}_{3} \mathrm{OH}(\mathrm{g})$ with stoichiometric amount of air is

$$
\mathrm{CH}_{3} \mathrm{OH}+a_{\mathrm{th}}\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow \mathrm{CO}_{2}+2 \mathrm{H}_{2} \mathrm{O}+3.76 a_{\mathrm{th}} \mathrm{~N}_{2}
$$

where $a_{\mathrm{th}}$ is the stoichiometric coefficient and is determined from the $\mathrm{O}_{2}$ balance,

$$
1+2 a_{\mathrm{th}}=2+2 \quad \longrightarrow \quad a_{\mathrm{th}}=1.5
$$

Thus,

$$
\mathrm{CH}_{3} \mathrm{OH}+1.5\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow \mathrm{CO}_{2}+2 \mathrm{H}_{2} \mathrm{O}+5.64 \mathrm{~N}_{2}
$$

The final temperature in the tank is determined from the energy balance relation $E_{\text {in }}-E_{\text {out }}=\Delta E_{\text {system }}$ for reacting closed systems under adiabatic conditions $(Q=0)$ with no work interactions ( $W=0$ ),

$$
0=\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}-P \bar{v}\right)_{P}-\sum N_{R}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}-P \overline{\boldsymbol{v}}\right)_{R}
$$

Assuming both the reactants and the products to behave as ideal gases, all the internal energy and enthalpies depend on temperature only, and the $P \bar{v}$ terms in this equation can be replaced by $R_{u} T$. It yields

$$
\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}_{T_{P}}-\bar{h}_{298 K}-R_{u} T\right)_{P}=\sum N_{R}\left(\bar{h}_{f}^{\circ}-R_{u} T\right)_{R}
$$

since the reactants are at the standard reference temperature of $25^{\circ} \mathrm{C}$. From the tables,

|  | $\overline{\mathbf{h}}_{\mathbf{f}}^{\circ}$ | $\overline{\mathbf{h}}_{\mathbf{2 9 8} \mathbf{K}}$ |
| :--- | :--- | :--- |
| Substance | $\mathbf{k J} / \mathbf{k m o l}$ | $\mathbf{k J} / \mathbf{k m o l}$ |
| $\mathrm{CH}_{3} \mathrm{OH}$ | $-200,670$ | --- |
| $\mathrm{O}_{2}$ | 0 | 8682 |
| $\mathrm{~N}_{2}$ | 0 | 8669 |
| $\mathrm{H}_{2} \mathrm{O}(g)$ | $-241,820$ | 9904 |
| $\mathrm{CO}_{2}$ | $-393,520$ | 9364 |

Thus,

$$
\begin{aligned}
& (1)\left(-393,520+\bar{h}_{\mathrm{CO}_{2}}-9364-8.314 \times T_{P}\right)+(2)\left(-241,820+\bar{h}_{\mathrm{H}_{2} \mathrm{O}}-9904-8.314 \times T_{P}\right) \\
& +(5.64)\left(0+\bar{h}_{\mathrm{N}_{2}}-8669-8.314 \times T_{P}\right)=(1)(-200,670-8.314 \times 298)+(1.5)(0-8.314 \times 298) \\
& +(5.64)(0-8.314 \times 298)
\end{aligned}
$$

It yields

$$
\bar{h}_{\mathrm{CO}_{2}}+2 \bar{h}_{\mathrm{H}_{2} \mathrm{O}}+5.64 \bar{h}_{\mathrm{N}_{2}}-71.833 \times T_{P}=734,388 \mathrm{~kJ}
$$

The temperature of the product gases is obtained from a trial and error solution,
At 2850 K:

$$
\begin{aligned}
\bar{h}_{\mathrm{CO}_{2}}+2 \bar{h}_{\mathrm{H}_{2} \mathrm{O}}+5.64 \bar{h}_{\mathrm{N}_{2}}-71.833 \times T_{P} & =(1)(152,908)+(2)(127,952)+(5.64)(95,859)-(71.833)(2850) \\
& =744,733 \mathrm{~kJ} \text { (Higher than } 734,388 \mathrm{~kJ})
\end{aligned}
$$

At 2800 K:

$$
\begin{aligned}
\bar{h}_{\mathrm{CO}_{2}}+2 \bar{h}_{\mathrm{H}_{2} \mathrm{O}}+5.64 \bar{h}_{\mathrm{N}_{2}}-71.833 \times T_{P} & =(1)(149,808)+(2)(125,198)+(5.64)(94,014)-(71.833)(2800) \\
& =729,311 \mathrm{~kJ}(\text { Lower than } 734,388 \mathrm{~kJ})
\end{aligned}
$$

By interpolation $\quad T_{P}=2816 \mathrm{~K}$
Since both the reactants and the products behave as ideal gases, the final (maximum) pressure that can occur in the combustion chamber is determined to be

$$
\frac{P_{1} \boldsymbol{V}}{P_{2} V}=\frac{N_{1} R_{u} T_{1}}{N_{2} R_{u} T_{2}} \longrightarrow P_{2}=\frac{N_{2} T_{2}}{N_{1} T_{1}} P_{1}=\frac{(8.64 \mathrm{kmol})(2816 \mathrm{~K})}{(8.14 \mathrm{kmol})(298 \mathrm{~K})}(98 \mathrm{kPa})=\mathbf{9 8 3} \mathbf{~ k P a}
$$

(b) The combustion equation of $\mathrm{CH}_{3} \mathrm{OH}(\mathrm{g})$ remains the same in the case of constant pressure. Further, the boundary work in this case can be combined with the $u$ terms so that the first law relation can be expressed in terms of enthalpies just like the steady-flow process,

$$
Q=\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{P}-\sum N_{R}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{R}
$$

Since both the reactants and the products behave as ideal gases, we have $h=h(T)$. Also noting that $Q=0$ for an adiabatic combustion process, the 1st law relation reduces to

$$
\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}_{T_{P}}-\bar{h}_{298 \mathrm{~K}}\right)_{P}=\sum N_{R}\left(\bar{h}_{f}^{\circ}\right)_{R}
$$

since the reactants are at the standard reference temperature of $25^{\circ} \mathrm{C}$. Then using data from the mini table above, we get

$$
\begin{aligned}
(1)\left(-393,520+\bar{h}_{\mathrm{CO}_{2}}-9364\right)+(2)\left(-241,820+\bar{h}_{\mathrm{H}_{2} \mathrm{O}}-9904\right) & +(5.64)\left(0+\bar{h}_{\mathrm{N}_{2}}-8669\right) \\
& =(1)(-200,670)+(1.5)(0)+(5.64)(0)
\end{aligned}
$$

It yields

$$
\bar{h}_{\mathrm{CO}_{2}}+2 \bar{h}_{\mathrm{H}_{2} \mathrm{O}}+5.64 \bar{h}_{\mathrm{N}_{2}}=754,555 \mathrm{~kJ}
$$

The temperature of the product gases is obtained from a trial and error solution,
At $2350 \mathrm{~K}: \quad \bar{h}_{\mathrm{CO}_{2}}+2 \bar{h}_{\mathrm{H}_{2} \mathrm{O}}+5.64 \bar{h}_{\mathrm{N}_{2}}=(1)(122,091)+(2)(100,846)+(5.64)(77,496)$

$$
=760,860 \mathrm{~kJ}(\text { Higher than } 754,555 \mathrm{~kJ})
$$

At $2300 \mathrm{~K}: \quad \bar{h}_{\mathrm{CO}_{2}}+2 \bar{h}_{\mathrm{H}_{2} \mathrm{O}}+5.64 \bar{h}_{\mathrm{N}_{2}}=(1)(119,035)+(2)(98,199)+(5.64)(75,676)$ $=742,246 \mathrm{~kJ}$ (Lower than 754,555 kJ)

By interpolation, $\quad T_{P}=2333 \mathrm{~K}$
Treating both the reactants and the products as ideal gases, the final (maximum) volume that the combustion chamber can have is determined to be

$$
\frac{P \boldsymbol{V}_{1}}{P \boldsymbol{V}_{2}}=\frac{N_{1} R_{u} T_{1}}{N_{2} R_{u} T_{2}} \longrightarrow \boldsymbol{V}_{2}=\frac{N_{2} T_{2}}{N_{1} T_{1}} \boldsymbol{V}_{1}=\frac{(8.64 \mathrm{kmol})(2333 \mathrm{~K})}{(8.14 \mathrm{kmol})(298 \mathrm{~K})}(0.8 \mathrm{~L})=6.65 \mathrm{~L}
$$

15-116 Problem 15-115 is reconsidered. The effect of the initial volume of the combustion chamber on the maximum pressure of the chamber for constant volume combustion or the maximum volume of the chamber for constant pressure combustion is to be investigated.

Analysis The problem is solved using EES, and the solution is given below.

Constant pressure combustion of CH 3 OH

Constant volume combustion of CH 3 OH

15-117 Methane is burned with the stoichiometric amount of air in a combustion chamber. The maximum pressure that can occur in the combustion chamber if the combustion takes place at constant volume and the maximum volume of the combustion chamber if the combustion occurs at constant pressure are to be determined.

Assumptions 1 Combustion is complete. 2 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible.

Analysis (a) The combustion equation of $\mathrm{CH}_{4}(\mathrm{~g})$ with stoichiometric amount of air is

$$
\mathrm{CH}_{4}+a_{\mathrm{th}}\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow \mathrm{CO}_{2}+2 \mathrm{H}_{2} \mathrm{O}+3.76 a_{\mathrm{th}} \mathrm{~N}_{2}
$$

where $a_{\mathrm{th}}$ is the stoichiometric coefficient and is determined from the $\mathrm{O}_{2}$ balance,

$$
a_{\mathrm{th}}=1+1 \quad \longrightarrow \quad a_{\mathrm{th}}=2
$$

Thus,

$$
\mathrm{CH}_{4}+2\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow \mathrm{CO}_{2}+2 \mathrm{H}_{2} \mathrm{O}+7.52 \mathrm{~N}_{2}
$$

The final temperature in the tank is determined from the energy balance relation $E_{\text {in }}-E_{\text {out }}=\Delta E_{\text {system }}$ for reacting closed systems under adiabatic conditions $(Q=0)$ with no work interactions ( $W=0$ ),

$$
0=\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}-P \overline{\boldsymbol{v}}\right)_{P}-\sum N_{R}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}-P \overline{\boldsymbol{v}}\right)_{R}
$$

Since both the reactants and the products behave as ideal gases, all the internal energy and enthalpies depend on temperature only, and the $P \bar{v}$ terms in this equation can be replaced by $R_{u} T$. It yields

$$
\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}_{T_{P}}-\bar{h}_{298 \mathrm{~K}}-R_{u} T\right)_{P}=\sum N_{R}\left(\bar{h}_{f}^{\circ}-R_{u} T\right)_{R}
$$

since the reactants are at the standard reference temperature of $25^{\circ} \mathrm{C}$. From the tables,

|  | $\overline{\mathbf{h}}_{\mathbf{f}}^{\circ}$ | $\overline{\mathbf{h}}_{298 \text { K }}$ |
| :--- | :--- | :--- |
| Substance | $\mathbf{k J} / \mathbf{k m o l}$ | $\mathbf{k J} / \mathbf{k m o l}$ |
| $\mathrm{CH}_{4}$ | $-74,850$ | --- |
| $\mathrm{O}_{2}$ | 0 | 8682 |
| $\mathrm{~N}_{2}$ | 0 | 8669 |
| $\mathrm{H}_{2} \mathrm{O}(g)$ | $-241,820$ | 9904 |
| $\mathrm{CO}_{2}$ | $-393,520$ | 9364 |

Thus,

$$
\begin{aligned}
& (1)\left(-393,520+\bar{h}_{\mathrm{CO}_{2}}-9364-8.314 \times T_{P}\right)+(2)\left(-241,820+\bar{h}_{\mathrm{H}_{2} \mathrm{O}}-9904-8.314 \times T_{P}\right) \\
& +(7.52)\left(0+\bar{h}_{\mathrm{N}_{2}}-8669-8.314 \times T_{P}\right)=(1)(-74,850-8.314 \times 298)+(2)(0-8.314 \times 298) \\
& +(7.52)(0-8.314 \times 298)
\end{aligned}
$$

It yields

$$
\bar{h}_{\mathrm{CO}_{2}}+2 \bar{h}_{\mathrm{H}_{2} \mathrm{O}}+7.52 \bar{h}_{\mathrm{N}_{2}}-87.463 \times T_{P}=870,609 \mathrm{~kJ}
$$

The temperature of the product gases is obtained from a trial and error solution,
At 2850 K:

$$
\begin{aligned}
\bar{h}_{\mathrm{CO}_{2}}+2 \bar{h}_{\mathrm{H}_{2} \mathrm{O}}+7.52 \bar{h}_{\mathrm{N}_{2}}-87.463 \times T_{P} & =(1)(152,908)+(2)(127,952)+(7.52)(95,859)-(87.463)(2850) \\
& =880,402 \mathrm{~kJ}(\text { Higher than } 870,609 \mathrm{~kJ})
\end{aligned}
$$

At 2800 K:

$$
\begin{aligned}
\bar{h}_{\mathrm{CO}_{2}}+2 \bar{h}_{\mathrm{H}_{2} \mathrm{O}}+7.52 \bar{h}_{\mathrm{N}_{2}}-87.463 \times T_{P} & =(1)(149,808)+(2)(125,198)+(7.52)(94,014)-(87.463)(2800) \\
& =862,293 \mathrm{~kJ}(\text { Lower than } 870,609 \mathrm{~kJ})
\end{aligned}
$$

By interpolation, $\quad T_{P}=2823 \mathrm{~K}$
Treating both the reactants and the products as ideal gases, the final (maximum) pressure that can occur in the combustion chamber is determined to be

$$
\frac{P_{1} \boldsymbol{V}}{P_{2} \boldsymbol{V}}=\frac{N_{1} R_{u} T_{1}}{N_{2} R_{u} T_{2}} \longrightarrow P_{2}=\frac{N_{2} T_{2}}{N_{1} T_{1}} P_{1}=\frac{(10.52 \mathrm{kmol})(2823 \mathrm{~K})}{(10.52 \mathrm{kmol})(298 \mathrm{~K})}(98 \mathrm{kPa})=\mathbf{9 2 8} \mathbf{~ k P a}
$$

(b) The combustion equation of $\mathrm{CH}_{4}(\mathrm{~g})$ remains the same in the case of constant pressure. Further, the boundary work in this case can be combined with the $u$ terms so that the first law relation can be expressed in terms of enthalpies just like the steady-flow process,

$$
Q=\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{P}-\sum N_{R}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{R}
$$

Again since both the reactants and the products behave as ideal gases, we have $h=h(T)$. Also noting that $Q$ $=0$ for an adiabatic combustion process, the energy balance relation reduces to

$$
\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}_{T_{P}}-\bar{h}_{298 \mathrm{~K}}\right)_{P}=\sum N_{R}\left(\bar{h}_{f}^{\circ}\right)_{R}
$$

since the reactants are at the standard reference temperature of $25^{\circ} \mathrm{C}$. Then using data from the mini table above, we get

$$
\begin{aligned}
(1)\left(-393,520+\bar{h}_{\mathrm{CO}_{2}}-9364\right)+(2)\left(-241,820+\bar{h}_{\mathrm{H}_{2} \mathrm{O}}-9904\right) & +(7.52)\left(0+\bar{h}_{\mathrm{N}_{2}}-8669\right) \\
& =(1)(-74,850)+(2)(0)+(7.52)(0)
\end{aligned}
$$

It yields

$$
\bar{h}_{\mathrm{CO}_{2}}+2 \bar{h}_{\mathrm{H}_{2} \mathrm{O}}+7.52 \bar{h}_{\mathrm{N}_{2}}=896,673 \mathrm{~kJ}
$$

The temperature of the product gases is obtained from a trial and error solution,
At $2350 \mathrm{~K}: \quad \bar{h}_{\mathrm{CO}_{2}}+2 \bar{h}_{\mathrm{H}_{2} \mathrm{O}}+7.52 \bar{h}_{\mathrm{N}_{2}}=(1)(122,091)+(2)(100,846)+(7.52)(77,496)$ $=906,553 \mathrm{~kJ}$ (Higher than 896,673 kJ)

At $2300 \mathrm{~K}: \quad \bar{h}_{\mathrm{CO}_{2}}+2 \bar{h}_{\mathrm{H}_{2} \mathrm{O}}+7.52 \bar{h}_{\mathrm{N}_{2}}=(1)(119,035)+(2)(98,199)+(7.52)(75,676)$ $=884,517 \mathrm{~kJ}$ (Lower than 896,673 kJ)

By interpolation, $\quad T_{P}=2328 \mathrm{~K}$
Treating both the reactants and the products as ideal gases, the final (maximum) volume that the combustion chamber can have is determined to be

$$
\frac{P V_{1}}{P \boldsymbol{V}_{2}}=\frac{N_{1} R_{u} T_{1}}{N_{2} R_{u} T_{2}} \longrightarrow \boldsymbol{V}_{2}=\frac{N_{2} T_{2}}{N_{1} T_{1}} \boldsymbol{V}_{1}=\frac{(10.52 \mathrm{kmol})(2328 \mathrm{~K})}{(10.52 \mathrm{kmol})(298 \mathrm{~K})}(0.8 \mathrm{~L})=6.25 \mathbf{L}
$$

15-118 A mixture of $40 \%$ by volume methane, CH4, and $60 \%$ by volume propane, C3H8, is burned completely with theoretical air. The amount of water formed during combustion process that will be condensed is to be determined.
Assumptions 1 Combustion is complete. 2 The combustion products contain $\mathrm{CO}_{2}, \mathrm{H}_{2} \mathrm{O}$, and $\mathrm{N}_{2}$ only.

Analysis The combustion equation in this case can be written as

$$
0.4 \mathrm{CH}_{4}+0.6 \mathrm{C}_{3} \mathrm{H}_{8}+a_{\mathrm{th}}\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow B \mathrm{CO}_{2}+D \mathrm{H}_{2} \mathrm{O}+F \mathrm{~N}_{2}
$$

where $a_{\mathrm{th}}$ is the stoichiometric coefficient for air. The coefficient $a_{\mathrm{th}}$ and other coefficients are to be determined from the mass balances

Carbon balance:

$$
B=0.4+3 \times 0.6=2.2
$$

Hydrogen balance: $\quad 2 D=4 \times 0.4+8 \times 0.6=2 D \longrightarrow D=3.2$
Oxygen balance: $\quad 2 a_{\mathrm{th}}=2 B+D \longrightarrow 2 a_{\mathrm{th}}=2(2.2)+3.2 \longrightarrow a_{\mathrm{th}}=3.8$
Nitrogen balance: $\quad 3.76 a_{\mathrm{th}}=F \longrightarrow 3.76(3.8)=F \longrightarrow F=14.29$
Then, we write the balanced reaction equation as

$$
0.4 \mathrm{CH}_{4}+0.6 \mathrm{C}_{3} \mathrm{H}_{8}+3.8\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow 2.2 \mathrm{CO}_{2}+3.2 \mathrm{H}_{2} \mathrm{O}+14.29 \mathrm{~N}_{2}
$$

The vapor mole fraction in the products is

$$
y_{v}=\frac{3.2}{2.2+3.2+14.29}=0.1625
$$

The partial pressure of water in the products is

$$
P_{\mathrm{v}, \text { prod }}=y_{v} P_{\text {prod }}=(0.1625)(100 \mathrm{kPa})=16.25 \mathrm{kPa}
$$

The dew point temperature of the products is

$$
T_{\mathrm{dp}}=T_{\text {sat@ } 16.25 \mathrm{kPa}}=55.64^{\circ} \mathrm{C}
$$

The partial pressure of the water vapor remaining in the products at the product temperature is

$$
P_{\mathrm{v}}=P_{\text {sat @ } 39^{\circ} \mathrm{C}}=7.0 \mathrm{kPa}
$$

The kmol of water vapor in the products at the product temperature is

$$
\begin{aligned}
P_{v} & =\frac{N_{v}}{N_{\text {total, product }}} P_{\text {prod }} \\
7.0 \mathrm{kPa} & =\frac{N_{v}}{2.2+N_{v}+14.29} \\
N_{v} & =1.241 \mathrm{kmol}
\end{aligned}
$$

The kmol of water condensed is

$N_{w}=3.2-1.241=1.96 \mathbf{k m o l}$ water/kmol fuel educators for course preparation. If you are a student using this Manual, you are using it without permission.

15-119 Methane is burned steadily with 50 percent excess air in a steam boiler. The amount of steam generated per unit of fuel mass burned, the change in the exergy of the combustion streams, the change in the exergy of the steam stream, and the lost work potential are to be determined.
Assumptions 1 Combustion is complete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible.

Properties The molar masses of $\mathrm{CH}_{4}$ and air are $16 \mathrm{~kg} / \mathrm{kmol}$ and $29 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).
Analysis (a) The fuel is burned completely with the excess air, and thus the products will contain only $\mathrm{CO}_{2}, \mathrm{H}_{2} \mathrm{O}, \mathrm{N}_{2}$, and some free $\mathrm{O}_{2}$. Considering $1 \mathrm{kmol} \mathrm{CH}_{4}$, the combustion equation can be written as

$$
\mathrm{CH}_{4}+3\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow \mathrm{CO}_{2}+2 \mathrm{H}_{2} \mathrm{O}+\mathrm{O}_{2}+11.28 \mathrm{~N}_{2}
$$

Under steady-flow conditions the energy balance $E_{\text {in }}-E_{\text {out }}=\Delta E_{\text {system }}$ applied on the combustion chamber with $W=0$ reduces to

$$
-Q_{\mathrm{out}}=\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{P}-\sum N_{R}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{R}
$$

Assuming the air and the combustion products to be ideal gases, we have $h=h(T)$. From the tables,

|  | $\overline{\mathbf{h}}_{\mathbf{f}}^{\circ}$ | $\overline{\mathbf{h}}_{\mathbf{2 9 8 K}}$ | $\overline{\mathbf{h}}_{500 \mathrm{~K}}$ |
| :--- | :--- | :--- | :--- |
| Substance | $\mathbf{k J} / \mathbf{k m o l}$ | $\mathbf{k J} / \mathbf{k m o l}$ | $\mathbf{k J} / \mathbf{k m o l}$ |
| $\mathrm{CH}_{4}$ | $-74,850$ | --- | --- |
| $\mathrm{O}_{2}$ | 0 | 8682 | 14,770 |
| $\mathrm{~N}_{2}$ | 0 | 8669 | 14,581 |
| $\mathrm{H}_{2} \mathrm{O}(g)$ | $-241,820$ | 9904 | 16,828 |
| $\mathrm{CO}_{2}$ | $-393,520$ | 9364 | 17,678 |

Thus,

$$
\begin{aligned}
-Q_{\text {out }} & =(1)(-393,520+17,678-9364)+(2)(-241,820+16,828-9904) \\
& +(1)(0+14,770-8682)+(11.28)(0+14,581-8669)-(1)(-74,850) \\
& =-707,373 \mathrm{~kJ} / \mathrm{kmol} \text { of fuel }
\end{aligned}
$$

The heat loss per unit mass of the fuel is

$$
Q_{\text {out }}=\frac{707,373 \mathrm{~kJ} / \mathrm{kmol} \text { of fuel }}{16 \mathrm{~kg} / \mathrm{kmol} \text { of fuel }}=44,211 \mathrm{~kJ} / \mathrm{kg} \text { fuel }
$$

The amount of steam generated per unit mass of fuel burned is determined from an energy balance to be (Enthalpies of steam are from tables A-4 and A-6)

$$
\frac{m_{s}}{m_{f}}=\frac{Q_{\text {out }}}{\Delta h_{s}}=\frac{44,211 \mathrm{~kJ} / \mathrm{kg} \text { fuel }}{(3214.5-852.26) \mathrm{kJ} / \mathrm{kg} \text { steam }}=\mathbf{1 8 . 7 2} \mathbf{~ k g} \text { steam } / \mathbf{k g} \text { fuel }
$$

(b) The entropy generation during this process is determined from

$$
S_{\mathrm{gen}}=S_{P}-S_{R}+\frac{Q_{\mathrm{out}}}{T_{\mathrm{surr}}}=\sum N_{P} \bar{s}_{P}-\sum N_{R} \bar{s}_{R}+\frac{Q_{\mathrm{out}}}{T_{\mathrm{surr}}}
$$

The entropy values listed in the ideal gas tables are for 1 atm pressure. Both the air and the product gases are at a total pressure of 1 atm , but the entropies are to be calculated at the partial pressure of the components which is equal to $P_{\mathrm{i}}=y_{\mathrm{i}} P_{\text {total }}$, where $y_{\mathrm{i}}$ is the mole fraction of component $i$. Then,

$$
S_{i}=N_{i} \bar{s}_{i}\left(T, P_{i}\right)=N_{i}\left(\bar{s}_{i}^{\circ}\left(T, P_{0}\right)-R_{u} \ln \left(y_{i} P_{m}\right)\right)
$$

The entropy calculations can be presented in tabular form as

|  | $\mathbf{N}_{\mathbf{i}}$ | $\mathbf{y}_{\mathbf{i}}$ | $\overline{\mathbf{s}}_{\mathbf{i}}^{\circ}(\mathbf{T , 1 a t m})$ | $\mathbf{R}_{\mathbf{u}} \ln \left(\mathbf{y}_{\mathbf{i}} \mathbf{P}_{\mathbf{m}}\right)$ | $\mathbf{N}_{\mathbf{i}} \overline{\mathbf{s}}_{\mathbf{i}}$ |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathrm{CH}_{4}$ | 1 | --- | 186.16 | 0 | 186.16 |
| $\mathrm{O}_{2}$ | 3 | 0.21 | 205.04 | -12.98 | 654.06 |
| $\mathrm{~N}_{2}$ | 11.28 | 0.79 | 191.61 | -1.960 | 2183.47 |
|  |  |  |  |  | $S_{R}=3023.69 \mathrm{~kJ} / \mathrm{K}$ |
| $\mathrm{CO}_{2}$ | 1 | 0.0654 | 234.814 | -22.67 | 257.48 |
| $\mathrm{H}_{2} \mathrm{O}(g)$ | 2 | 0.1309 | 206.413 | -16.91 | 446.65 |
| $\mathrm{O}_{2}$ | 1 | 0.0654 | 220.589 | -22.67 | 243.26 |
| $\mathrm{~N}_{2}$ | 11.28 | 0.7382 | 206.630 | -2.524 | 2359.26 |
|  |  |  |  |  | $S_{P}=3306.65 \mathrm{~kJ} / \mathrm{K}$ |

Thus,

$$
S_{\text {gen }}=S_{P}-S_{R}+\frac{Q_{\text {out }}}{T_{\text {surr }}}=3306.65-3023.69+\frac{707,373}{298}=2657 \mathrm{~kJ} / \mathrm{K}(\text { per kmol fuel })
$$

The exergy change of the combustion streams is equal to the exergy destruction since there is no actual work output. That is,

$$
\Delta X_{\text {gases }}=-X_{\text {dest }}=-T_{0} S_{\text {gen }}=-(298 \mathrm{~K})(2657 \mathrm{~kJ} / \mathrm{K})=-791,786 \mathrm{~kJ} / \mathrm{kmol} \text { fuel }
$$

Per unit mass basis,

$$
\Delta X_{\text {gases }}=\frac{-791,786 \mathrm{~kJ} / \mathrm{kmol} \text { fuel }}{16 \mathrm{~kg} / \mathrm{kmol}}=-49,490 \mathrm{~kJ} / \mathrm{kg} \text { fuel }
$$

Note that the exergy change is negative since the exergy of combustion gases decreases.
(c) The exergy change of the steam stream is

$$
\Delta X_{\text {steam }}=\Delta h-T_{0} \Delta s=(3214.5-852.26)-(298)(6.7714-2.3305)=1039 \mathbf{k J} / \mathbf{k g} \text { steam }
$$

(d) The lost work potential is the negative of the net exergy change of both streams:

$$
\begin{aligned}
X_{\text {dest }} & =-\left(\frac{m_{s}}{m_{f}} \Delta X_{\text {steam }}+\Delta X_{\text {gases }}\right) \\
& =-[(18.72 \mathrm{~kg} \text { steam } / \mathrm{kg} \text { fuel })(1039 \mathrm{~kJ} / \mathrm{kg} \text { steam })+(-49,490 \mathrm{~kJ} / \mathrm{kg} \text { fuel })] \\
& =\mathbf{3 0 , 0 4 0} \mathbf{~ k J} / \mathbf{k g} \text { fuel }
\end{aligned}
$$

15-120 A coal from Utah is burned steadily with 50 percent excess air in a steam boiler. The amount of steam generated per unit of fuel mass burned, the change in the exergy of the combustion streams, the change in the exergy of the steam stream, and the lost work potential are to be determined.
Assumptions 1 Combustion is complete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible. 5 The effect of sulfur on the energy and entropy balances is negligible.
Properties The molar masses of $\mathrm{C}, \mathrm{H}_{2}, \mathrm{~N}_{2}, \mathrm{O}_{2}, \mathrm{~S}$, and air are $12,2,28,32,32$, and $29 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).
Analysis (a) The mass fractions of the constituent of the coal when the ash is substituted are

$$
\begin{aligned}
& \mathrm{mf}_{\mathrm{C}}=\frac{m_{\mathrm{C}}}{m_{\text {total }}}=\frac{61.40 \mathrm{~kg}}{(100-5.00) \mathrm{kg}}=\frac{61.40 \mathrm{~kg}}{95.00 \mathrm{~kg}}=0.6463 \\
& \mathrm{mf}_{\mathrm{H} 2}=\frac{m_{\mathrm{H} 2}}{m_{\text {total }}}=\frac{5.79 \mathrm{~kg}}{95.00 \mathrm{~kg}}=0.06095 \\
& \mathrm{mf}_{\mathrm{O} 2}=\frac{m_{\mathrm{O} 2}}{m_{\text {total }}}=\frac{25.31 \mathrm{~kg}}{95.00 \mathrm{~kg}}=0.2664 \\
& \mathrm{mf}_{\mathrm{N} 2}=\frac{m_{\mathrm{N} 2}}{m_{\text {total }}}=\frac{1.09 \mathrm{~kg}}{95.00 \mathrm{~kg}}=0.01147 \\
& \mathrm{mf}_{\mathrm{S}}=\frac{m_{\mathrm{S}}}{m_{\text {total }}}=\frac{1.41 \mathrm{~kg}}{95.00 \mathrm{~kg}}=0.01484
\end{aligned}
$$

$$
\begin{gathered}
61.40 \% \mathrm{C} \\
5.79 \% \mathrm{H}_{2} \\
25.31 \% \mathrm{O}_{2} \\
1.09 \% \mathrm{~N}_{2} \\
1.41 \% \mathrm{~S} \\
5.00 \% \text { ash } \\
\text { (by mass) }
\end{gathered}
$$

We now consider 100 kg of this mixture. Then the mole numbers of each component are

$$
\begin{aligned}
N_{\mathrm{C}} & =\frac{m_{\mathrm{C}}}{M_{\mathrm{C}}}=\frac{64.63 \mathrm{~kg}}{12 \mathrm{~kg} / \mathrm{kmol}}=5.386 \mathrm{kmol} \\
N_{\mathrm{H} 2} & =\frac{m_{\mathrm{H} 2}}{M_{\mathrm{H} 2}}=\frac{6.095 \mathrm{~kg}}{2 \mathrm{~kg} / \mathrm{kmol}}=3.048 \mathrm{kmol} \\
N_{\mathrm{O} 2} & =\frac{m_{\mathrm{O} 2}}{M_{\mathrm{O} 2}}=\frac{26.64 \mathrm{~kg}}{32 \mathrm{~kg} / \mathrm{kmol}}=0.8325 \mathrm{kmol} \\
N_{\mathrm{N} 2} & =\frac{m_{\mathrm{N} 2}}{M_{\mathrm{N} 2}}=\frac{1.147 \mathrm{~kg}}{28 \mathrm{~kg} / \mathrm{kmol}}=0.04096 \mathrm{kmol} \\
N_{\mathrm{S}} & =\frac{m_{\mathrm{S}}}{M_{\mathrm{S}}}=\frac{1.484 \mathrm{~kg}}{32 \mathrm{~kg} / \mathrm{kmol}}=0.04638 \mathrm{kmol}
\end{aligned}
$$

$25^{\circ} \mathrm{C}$

The mole number of the mixture and the mole fractions are

$$
\begin{aligned}
& N_{m}=5.386+3.048+0.8325+0.04096+0.04638=9.354 \mathrm{kmol} \\
& y_{\mathrm{C}}=\frac{N_{\mathrm{C}}}{N_{m}}=\frac{5.386 \mathrm{kmol}}{9.354 \mathrm{kmol}}=0.5758 \\
& y_{\mathrm{H} 2}=\frac{N_{\mathrm{H} 2}}{N_{m}}=\frac{3.048 \mathrm{kmol}}{9.354 \mathrm{kmol}}=0.3258 \\
& y_{\mathrm{O} 2}=\frac{N_{\mathrm{O} 2}}{N_{m}}=\frac{0.8325 \mathrm{kmol}}{9.354 \mathrm{kmol}}=0.0890 \\
& y_{\mathrm{N} 2}=\frac{N_{\mathrm{N} 2}}{N_{m}}=\frac{0.04096 \mathrm{kmol}}{9.354 \mathrm{kmol}}=0.00438 \\
& y_{\mathrm{S}}=\frac{N_{\mathrm{S}}}{N_{m}}=\frac{0.04638 \mathrm{kmol}}{9.354 \mathrm{kmol}}=0.00496
\end{aligned}
$$ educators for course preparation. If you are a student using this Manual, you are using it without permission.

Then, the combustion equation in this case may be written as

$$
\begin{aligned}
& 0.5758 \mathrm{C}+0.3258 \mathrm{H}_{2}+0.0890 \mathrm{O}_{2}+0.00438 \mathrm{~N}_{2}+0.00496 \mathrm{~S}+1.5 a_{\mathrm{th}}\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \\
& \longrightarrow 0.5758 \mathrm{CO}_{2}+0.3258 \mathrm{H}_{2} \mathrm{O}+0.00496 \mathrm{SO}_{2}+0.5 a_{\mathrm{th}} \mathrm{O}_{2}+1.5 a_{\mathrm{th}} \times 3.76 \mathrm{~N}_{2}
\end{aligned}
$$

According to the oxygen balance,

$$
\mathrm{O}_{2} \text { balance: } 0.0890+1.5 a_{\mathrm{th}}=0.5758+0.5 \times 0.3258+0.00496+0.5 a_{\mathrm{th}} \longrightarrow a_{\mathrm{th}}=0.6547
$$

Substituting,

$$
\begin{aligned}
0.5758 \mathrm{C}+0.3258 \mathrm{H}_{2}+ & 0.0890 \mathrm{O}_{2}+0.00438 \mathrm{~N}_{2}+0.00496 \mathrm{~S}+0.9821\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \\
& \longrightarrow 0.5758 \mathrm{CO}_{2}+0.3258 \mathrm{H}_{2} \mathrm{O}+0.00496 \mathrm{SO}_{2}+0.3274 \mathrm{O}_{2}+3.693 \mathrm{~N}_{2}
\end{aligned}
$$

The apparent molecular weight of the coal is

$$
\begin{aligned}
M_{m} & =\frac{m_{m}}{N_{m}}=\frac{(0.5758 \times 12+0.3258 \times 2+0.0890 \times 32+0.00438 \times 28+0.00496 \times 32) \mathrm{kg}}{(0.5758+0.3258+0.0890+0.00438+0.0496) \mathrm{kmol}} \\
& =\frac{10.69 \mathrm{~kg}}{1.045 \mathrm{kmol}}=10.23 \mathrm{~kg} / \mathrm{kmol} \text { coal }
\end{aligned}
$$

Under steady-flow conditions the energy balance $E_{\text {in }}-E_{\text {out }}=\Delta E_{\text {system }}$ applied on the combustion chamber with $W=0$ reduces to

$$
-Q_{\mathrm{out}}=\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{P}-\sum N_{R}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{R}
$$

Assuming the air and the combustion products to be ideal gases, we have $h=h(T)$. From the tables,

|  | $\overline{\mathbf{h}}_{\mathbf{f}}^{\circ}$ | $\overline{\mathbf{h}}_{\mathbf{2 9 8 K}}$ | $\overline{\mathbf{h}}_{500 \mathbf{K}}$ |
| :--- | :--- | :--- | :--- |
| Substance | $\mathbf{k J} / \mathbf{k m o l}$ | $\mathbf{k J} / \mathbf{k m o l}$ | $\mathbf{k J} / \mathbf{k m o l}$ |
| $\mathrm{O}_{2}$ | 0 | 8682 | 14,770 |
| $\mathrm{~N}_{2}$ | 0 | 8669 | 14,581 |
| $\mathrm{H}_{2} \mathrm{O}(g)$ | $-241,820$ | 9904 | 16,828 |
| $\mathrm{CO}_{2}$ | $-393,520$ | 9364 | 17,678 |

Thus,

$$
\begin{aligned}
-Q_{\text {out }} & =(0.5758)(-393,520+17,678-9364)+(0.3258)(-241,820+16,828-9904) \\
& +(0.3274)(0+14,770-8682)+(3.693)(0+14,581-8669)-0 \\
& =-274,505 \mathrm{~kJ} / \mathrm{kmol} \text { of fuel }
\end{aligned}
$$

The heat loss per unit mass of the fuel is

$$
Q_{\text {out }}=\frac{274,505 \mathrm{~kJ} / \mathrm{kmol} \text { of fuel }}{10.23 \mathrm{~kg} / \mathrm{kmol} \text { of fuel }}=26,833 \mathrm{~kJ} / \mathrm{kg} \text { fuel }
$$

The amount of steam generated per unit mass of fuel burned is determined from an energy balance to be (Enthalpies of steam are from tables A-4 and A-6)

$$
\frac{m_{s}}{m_{f}}=\frac{Q_{\text {out }}}{\Delta h_{s}}=\frac{26,833 \mathrm{~kJ} / \mathrm{kg} \text { fuel }}{(3214.5-852.26) \mathrm{kJ} / \mathrm{kg} \text { steam }}=\mathbf{1 1 . 3 6} \mathbf{~ k g} \text { steam } / \mathrm{kg} \text { fuel }
$$

(b) The entropy generation during this process is determined from

$$
S_{\mathrm{gen}}=S_{P}-S_{R}+\frac{Q_{\mathrm{out}}}{T_{\text {surr }}}=\sum N_{P} \bar{s}_{P}-\sum N_{R} \bar{s}_{R}+\frac{Q_{\text {out }}}{T_{\text {surr }}}
$$

The entropy values listed in the ideal gas tables are for 1 atm pressure. Both the air and the product gases are at a total pressure of 1 atm , but the entropies are to be calculated at the partial pressure of the components which is equal to $P_{\mathrm{i}}=y_{\mathrm{i}} P_{\text {total }}$, where $y_{\mathrm{i}}$ is the mole fraction of component $i$. Then,

$$
S_{i}=N_{i} \bar{s}_{i}\left(T, P_{i}\right)=N_{i}\left(\bar{s}_{i}^{\circ}\left(T, P_{0}\right)-R_{u} \ln \left(y_{i} P_{m}\right)\right)
$$

The entropy calculations can be presented in tabular form as

|  | $\mathbf{N}_{\mathbf{i}}$ | $\mathbf{y}_{\mathbf{i}}$ | $\overline{\mathbf{s}}_{\mathbf{i}}^{\circ}(\mathbf{T}, \mathbf{1} \mathbf{a t m})$ | $\mathbf{R}_{\mathbf{u}} \mathbf{l n}\left(\mathbf{y}_{\mathbf{i}} \mathbf{P}_{\mathbf{m}}\right)$ | $\mathbf{N}_{\mathbf{i}} \overline{\mathbf{s}}_{\mathbf{i}}$ |
| :--- | :--- | :--- | :--- | :--- | :--- |
| C | 0.5758 | 0.5758 | 5.74 | -4.589 | 5.95 |
| $\mathrm{H}_{2}$ | 0.3258 | 0.3258 | 130.68 | -9.324 | 45.61 |
| $\mathrm{O}_{2}$ | 0.0890 | 0.0890 | 205.04 | -20.11 | 20.04 |
| $\mathrm{~N}_{2}$ | 0.00438 | 0.00438 | 191.61 | -45.15 | 1.04 |
| $\mathrm{O}_{2}$ | 0.9821 | 0.21 | 205.04 | -12.98 | 214.12 |
| $\mathrm{~N}_{2}$ | 3.693 | 0.79 | 191.61 | -1.960 | 714.85 |
|  |  |  |  |  | $S_{R}=1001.61 \mathrm{~kJ} / \mathrm{K}$ |
| $\mathrm{CO}_{2}$ | 0.5758 | 0.1170 | 234.814 | -17.84 | 145.48 |
| $\mathrm{H}_{2} \mathrm{O}(g)$ | 0.3258 | 0.0662 | 206.413 | -22.57 | 74.60 |
| $\mathrm{O}_{2}$ | 0.3274 | 0.0665 | 220.589 | -22.54 | 79.60 |
| $\mathrm{~N}_{2}$ | 3.693 | 0.7503 | 206.630 | -2.388 | 771.90 |
|  |  |  |  |  | $S_{P}=1071.58 \mathrm{~kJ} / \mathrm{K}$ |

Thus,

$$
S_{\text {gen }}=S_{P}-S_{R}+\frac{Q_{\text {out }}}{T_{\text {surr }}}=1071.58-1001.61+\frac{274,505}{298}=991.1 \mathrm{~kJ} / \mathrm{K}(\text { per kmol fuel })
$$

The exergy change of the combustion streams is equal to the exergy destruction since there is no actual work output. That is,

$$
\Delta X_{\text {gases }}=-X_{\text {dest }}=-T_{0} S_{\text {gen }}=-(298 \mathrm{~K})(991.1 \mathrm{~kJ} / \mathrm{K})=-295,348 \mathrm{~kJ} / \mathrm{kmol} \text { fuel }
$$

Per unit mass basis,

$$
\Delta X_{\text {gases }}=\frac{-295,348 \mathrm{~kJ} / \mathrm{K}}{10.23 \mathrm{~kg} / \mathrm{kmol}}=-\mathbf{2 8 , 8 7 0} \mathbf{~ k J} / \mathbf{k g} \text { fuel }
$$

Note that the exergy change is negative since the exergy of combustion gases decreases.
(c) The exergy change of the steam stream is

$$
\Delta X_{\text {steam }}=\Delta h-T_{0} \Delta s=(3214.5-852.26)-(298)(6.7714-2.3305)=\mathbf{1 0 3 9} \mathbf{~ k J} / \mathbf{k g} \text { steam }
$$

(d) The lost work potential is the negative of the net exergy change of both streams:

$$
\begin{aligned}
X_{\text {dest }} & =-\left(\frac{m_{s}}{m_{f}} \Delta X_{\text {steam }}+\Delta X_{\text {gases }}\right) \\
& =-[(11.36 \mathrm{~kg} \text { steam } / \mathrm{kg} \text { fuel })(1039 \mathrm{~kJ} / \mathrm{kg} \text { steam })+(-28,870 \mathrm{~kJ} / \mathrm{kg} \text { fuel })] \\
& =\mathbf{1 7 , 0 7 0} \mathbf{~ k J} / \mathbf{k g} \text { fuel }
\end{aligned}
$$

15-121 Octane is burned with stoichiometric amount of air. The maximum work that can be produced is to be determined.

Assumptions 1 Combustion is complete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible.

Analysis The combustion equation is
$\mathrm{C}_{8} \mathrm{H}_{18}+12.5\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 8 \mathrm{CO}_{2}+9 \mathrm{H}_{2} \mathrm{O}+47 \mathrm{~N}_{2}$
The reactants and products are at $25^{\circ} \mathrm{C}$ and 1 atm , which is the standard reference state and also the state of the surroundings. Therefore, the reversible work in this case is simply the difference between the Gibbs function of formation of the reactants and that of the products,

$$
\begin{aligned}
W_{\text {rev }} & =\sum N_{R} \bar{g}_{f, R}^{\circ}-\sum N_{P} \bar{g}_{f, P}^{\circ} \\
& =(1)(16,530)-(8)(-394,360)-(9)(-228,590) \\
& =5,228,720 \mathrm{~kJ} \quad \text { (per kmol of fuel) }
\end{aligned}
$$

since the $g_{f}^{\circ}$ of stable elements at $25^{\circ} \mathrm{C}$ and 1 atm is zero. Per unit mass basis,

$$
W_{\text {rev }}=\frac{5,228,720 \mathrm{~kJ} / \mathrm{kmol}}{114 \mathrm{~kg} / \mathrm{kmol}}=45,870 \mathrm{~kJ} / \mathrm{kg} \text { fuel }
$$

15-122 Octane is burned with $100 \%$ excess air. The maximum work that can be produced is to be determined.

Assumptions 1 Combustion is complete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible.
Analysis The combustion equation is

$$
\mathrm{C}_{8} \mathrm{H}_{18}+25\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 8 \mathrm{CO}_{2}+9 \mathrm{H}_{2} \mathrm{O}+12.5 \mathrm{O}_{2}+94 \mathrm{~N}_{2}
$$

The reactants and products are at $25^{\circ} \mathrm{C}$ and 1 atm , which is the standard reference state and also the state of the surroundings. Therefore, the reversible work in this case is simply the difference between the Gibbs function of formation of the reactants and that of the products,

$$
\begin{aligned}
W_{\text {rev }} & =\sum N_{R} \bar{g}_{f, R}^{\circ}-\sum N_{P} \bar{g}_{f, P}^{\circ} \\
& =(1)(16,530)-(8)(-394,360)-(9)(-228,590) \\
& =5,228,720 \mathrm{~kJ} \quad(\text { per kmol of fuel })
\end{aligned}
$$

since the $g_{f}^{\circ}$ of stable elements at $25^{\circ} \mathrm{C}$ and 1 atm is zero. Per unit mass basis,

$$
W_{\text {rev }}=\frac{5,228,720 \mathrm{~kJ} / \mathrm{kmol}}{114 \mathrm{~kg} / \mathrm{kmol}}=45,870 \mathrm{~kJ} / \mathrm{kg} \text { fuel }
$$

15-123E Methane is burned with 100 percent excess air. The combustion is incomplete. The maximum work that can be produced is to be determined.
Assumptions 1 Combustion is incomplete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible.
Analysis The combustion equation is

$$
\mathrm{CH}_{4}+4\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 0.90 \mathrm{CO}_{2}+0.10 \mathrm{CO}+2 \mathrm{H}_{2} \mathrm{O}+x \mathrm{O}_{2}+15.04 \mathrm{~N}_{2}
$$

The coefficient for $\mathrm{O}_{2}$ is determined from its mass balance as

$$
4=0.9+(0.5)(0.10)+1+x \longrightarrow x=2.05
$$

Substituting,

$$
\mathrm{CH}_{4}+4\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 0.90 \mathrm{CO}_{2}+0.10 \mathrm{CO}+2 \mathrm{H}_{2} \mathrm{O}+2.05 \mathrm{O}_{2}+15.04 \mathrm{~N}_{2}
$$

The reactants and products are at $77^{\circ} \mathrm{F}$ and 1 atm, which is the standard reference state and also the state of the surroundings. Therefore, the reversible work in this case is simply the difference between the Gibbs function of formation of the reactants and that of the products,

$$
\begin{aligned}
W_{\text {rev }} & =\sum N_{R} \bar{g}_{f, R}^{\circ}-\sum N_{P} \bar{g}_{f, P}^{\circ} \quad 1 \mathrm{~atm}, 77^{\circ} \mathrm{F} \\
& =(1)(-21,860)-(0.9)(-169,680)-(0.10)(-59,010)-(2)(-98,350) \\
& =333,453 \text { Btu (per lbmol of fuel) }
\end{aligned}
$$

since the $g_{f}^{\circ}$ of stable elements at $77^{\circ} \mathrm{F}$ and 1 atm is zero. Per unit mass basis,

$$
W_{\text {rev }}=\frac{333,453 \mathrm{Btu} / \mathrm{lbmol}}{16 \mathrm{lbm} / \mathrm{lbmol}}=\mathbf{2 0 , 8 4 0} \mathbf{~ B t u / l b m} \text { fuel }
$$

15-124 A gaseous fuel mixture of $30 \%$ propane, $\mathrm{C}_{3} \mathrm{H}_{8}$, and $70 \%$ butane, $\mathrm{C}_{4} \mathrm{H}_{10}$, on a volume basis is burned with an air-fuel ratio of 20 . The moles of nitrogen in the air supplied to the combustion process, the moles of water formed in the combustion process, and the moles of oxygen in the product gases are to be determined.
Assumptions 1 Combustion is complete. 2 The combustion products contain $\mathrm{CO}_{2}, \mathrm{H}_{2} \mathrm{O}$, and $\mathrm{N}_{2}$ only.

Properties The molar masses of $\mathrm{C}, \mathrm{H}_{2}, \mathrm{O}_{2}$ and air are $12 \mathrm{~kg} / \mathrm{kmol}, 2 \mathrm{~kg} / \mathrm{kmol}, 32 \mathrm{~kg} / \mathrm{kmol}$, and $29 \mathrm{~kg} / \mathrm{kmol}$, respectively (Table A-1).

Analysis The theoretical combustion equation in this case can be written as

$$
0.3 \mathrm{C}_{3} \mathrm{H}_{8}+0.7 \mathrm{C}_{4} \mathrm{H}_{10}+a_{\mathrm{th}}\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow B \mathrm{CO}_{2}+D \mathrm{H}_{2} \mathrm{O}+F \mathrm{~N}_{2}
$$

where $a_{\mathrm{th}}$ is the stoichiometric coefficient for air. The coefficient $a_{\mathrm{th}}$ and other coefficients are to be determined from the mass balances

$$
\begin{array}{ll}
\text { Carbon balance: } & B=3 \times 0.3+4 \times 0.7=3.7 \\
\text { Hydrogen balance: } & 2 D=8 \times 0.3+10 \times 0.7=2 D \longrightarrow D=4.7
\end{array}
$$

$$
\text { Oxygen balance: } \quad 2 a_{\mathrm{th}}=2 B+D \longrightarrow 2 a_{\mathrm{th}}=2 \times 3.7+4.7 \longrightarrow a_{\mathrm{th}}=6.05
$$

$$
\text { Nitrogen balance: } \quad 3.76 a_{\mathrm{th}}=F \longrightarrow 3.76 \times 6.05=F \longrightarrow F=22.75
$$

Then, we write the balanced theoretical reaction equation as

$$
0.3 \mathrm{C}_{3} \mathrm{H}_{8}+0.7 \mathrm{C}_{4} \mathrm{H}_{10}+6.05\left[\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right] \longrightarrow 3.7 \mathrm{CO}_{2}+4.7 \mathrm{H}_{2} \mathrm{O}+22.75 \mathrm{~N}_{2}
$$

The air-fuel ratio for the theoretical reaction is determined from

$$
\mathrm{AF}_{\text {th }}=\frac{m_{\text {air }}}{m_{\text {fuel }}}=\frac{(6.05 \times 4.75 \mathrm{kmol})(29 \mathrm{~kg} / \mathrm{kmol})}{(0.3 \times 44+0.7 \times 58) \mathrm{kg}}=15.47 \mathrm{~kg} \mathrm{air} / \mathrm{kg} \text { fuel }
$$

The percent theoretical air is

$$
\text { PercentTH }{ }_{\mathrm{air}}=\frac{\mathrm{AF}_{\text {actual }}}{\mathrm{AF}_{\mathrm{th}}}=\frac{20}{15.47} \times 100=129.3 \%
$$

The moles of nitrogen supplied is

$$
\mathrm{N}_{\mathrm{N} 2}=\frac{\text { PercentTH }_{\mathrm{air}}}{100} \times a_{\mathrm{th}} \times 3.76=\frac{129.3}{100}(6.05)(3.76)=\mathbf{2 9 . 4 1} \mathbf{k m o l} \text { per kmol fuel }
$$

The moles of water formed in the combustion process is

$$
\mathrm{N}_{\mathrm{H} 2 \mathrm{O}}=D=4.7 \text { kmol per kmol fuel }
$$

The moles of oxygen in the product gases is

$$
\mathrm{N}_{\mathrm{O} 2}=\left(\frac{\text { Percent } \mathrm{TH}_{\mathrm{air}}}{100}-1\right) a_{\mathrm{th}}=\left(\frac{129.3}{100}-1\right)(6.05)=\mathbf{1 . 7 7} \mathbf{~ k m o l} \text { per kmol fuel }
$$

15-125 It is to be shown that the work output of the Carnot engine will be maximum when $T_{p}=\sqrt{T_{0} T_{a f}}$. It is also to be shown that the maximum work output of the Carnot engine in this case becomes
$w=C T_{\mathrm{af}}\left(1-\frac{\sqrt{T_{0}}}{\sqrt{T_{\mathrm{af}}}}\right)^{2}$.
Analysis The combustion gases will leave the combustion chamber and enter the heat exchanger at the adiabatic flame temperature $T_{\text {af }}$ since the chamber is adiabatic and the fuel is burned completely. The combustion gases experience no change in their chemical composition as they flow through the heat exchanger. Therefore, we can treat the combustion gases as a gas stream with a constant specific heat $c_{p}$. Noting that the heat exchanger involves no work interactions, the energy balance equation for this singlestream steady-flow device can be written as

$$
\dot{Q}=\dot{m}\left(h_{e}-h_{i}\right)=\dot{m} C\left(T_{p}-T_{\mathrm{af}}\right)
$$

where $\dot{Q}$ is the negative of the heat supplied to the heat engine. That is,

$$
\dot{Q}_{H}=-\dot{Q}=\dot{m} C\left(T_{\mathrm{af}}-T_{p}\right)
$$

Then the work output of the Carnot heat engine can be expressed as

$$
\begin{equation*}
\dot{W}=\dot{Q}_{H}\left(1-\frac{T_{0}}{T_{p}}\right)=\dot{m} C\left(T_{\mathrm{af}}-T_{p}\right)\left(1-\frac{T_{0}}{T_{p}}\right) \tag{1}
\end{equation*}
$$

Taking the partial derivative of $\dot{\mathrm{W}}$ with respect to $T_{p}$ while holding $T_{\text {af }}$ and $T_{0}$ constant gives

$$
\frac{\partial W}{\partial T_{p}}=0 \longrightarrow-\dot{m} C\left(1-\frac{T_{0}}{T_{p}}\right)+\dot{m} C\left(T_{p}-T_{\mathrm{af}}\right) \frac{T_{0}}{T_{p}^{2}}=0
$$

Solving for $T_{p}$ we obtain

$$
T_{p}=\sqrt{T_{0} T_{\mathrm{af}}}
$$

which the temperature at which the work output of the Carnot engine will be a maximum. The maximum work output is determined by substituting the relation above into Eq. (1),

$$
\dot{W}=\dot{m} C\left(T_{\mathrm{af}}-T_{p}\right)\left(1-\frac{T_{0}}{T_{p}}\right)=\dot{m} C\left(T_{\mathrm{af}}-\sqrt{T_{0} T_{\mathrm{af}}}\right)\left(1-\frac{T_{0}}{\sqrt{T_{0} T_{\mathrm{af}}}}\right)
$$

It simplifies to

$$
\dot{W}=\dot{m} C T_{\mathrm{af}}\left(1-\frac{\sqrt{T_{0}}}{\sqrt{T_{\mathrm{af}}}}\right)^{2}
$$

or

$$
w=C T_{\mathrm{af}}\left(1-\frac{\sqrt{T_{0}}}{\sqrt{T_{\mathrm{af}}}}\right)^{2}
$$

which is the desired relation.

15－126 It is to be shown that the work output of the reversible heat engine operating at the specified conditions is $\dot{W}_{\mathrm{rev}}=\dot{m} C T_{0}\left(\frac{T_{\mathrm{af}}}{T_{0}}-1-\ln \frac{T_{\mathrm{af}}}{T_{0}}\right)$ ．It is also to be shown that the effective flame temperature $T_{e}$ of the furnace considered is $T_{e}=\frac{T_{\mathrm{af}}-T_{0}}{\ln \left(T_{\mathrm{af}} / T_{0}\right)}$ ．

Analysis The combustion gases will leave the combustion chamber and enter the heat exchanger at the adiabatic flame temperature $T_{\text {af }}$ since the chamber is adiabatic and the fuel is burned completely．The combustion gases experience no change in their chemical composition as they flow through the heat exchanger．Therefore，we can treat the combustion gases as a gas stream with a constant specific heat $c_{p}$ ． Also，the work output of the reversible heat engine is equal to the reversible work $W_{\text {rev }}$ of the heat exchanger as the combustion gases are cooled from $T_{\text {af }}$ to $T_{0}$ ．That is，

$$
\begin{aligned}
\dot{W}_{\mathrm{rev}} & =\dot{m}\left(h_{i}-h_{e}-T_{0}\left(s_{i}-s_{e}\right)\right) \\
& =\dot{m} C\left(T_{\mathrm{af}}-T_{0}-T_{0}\left(C \ln \frac{T_{\mathrm{af}}}{T_{0}}-R \ln \frac{P_{\mathrm{af}}^{⿶ 凵 ⿱ 乛 ⿰ ㇒ 乛 亅 ㇒ ~_{0}^{0}}}{P_{0}}\right)\right) \\
& =\dot{m} C\left(T_{\mathrm{af}}-T_{0}-T_{0} C \ln \frac{T_{\mathrm{af}}}{T_{0}}\right)
\end{aligned}
$$

$$
\dot{Q}_{H}=\dot{m}\left(h_{i}-h_{e}\right)=\dot{m} C\left(T_{\mathrm{af}}-T_{0}\right)
$$

A Carnot heat engine which receives this much heat at a constant temperature $T_{e}$ will produce work in the amount of

$$
\begin{equation*}
\dot{W}=\dot{Q}_{H} \eta_{\mathrm{th}, \text { Carnot }}=\dot{m} C\left(T_{\mathrm{af}}-T_{0}\right)\left(1-\frac{T_{0}}{T_{e}}\right) \tag{2}
\end{equation*}
$$

Setting equations（1）and（2）equal to each other yields

$$
\begin{aligned}
\dot{m} C T_{0}\left(\frac{T_{\mathrm{af}}}{T_{0}}-1-\ln \frac{T_{\mathrm{af}}}{T_{0}}\right) & =\dot{m} C\left(T_{\mathrm{af}}-T_{0}\right)\left(1-\frac{T_{0}}{T_{e}}\right) \\
T_{\mathrm{af}}-T_{0}-T_{0} \ln \frac{T_{\mathrm{af}}}{T_{0}} & =T_{\mathrm{af}}-T_{\mathrm{af}} \frac{T_{0}}{T_{e}}-T_{0}+T_{0} \frac{T_{0}}{T_{e}}
\end{aligned}
$$

Simplifying and solving for $T_{e}$ ，we obtain

$$
T_{e}=\frac{T_{\mathrm{af}}-T_{0}}{\ln \left(T_{\mathrm{af}} / T_{0}\right)}
$$

which is the desired relation．

15-127 EES The effect of the amount of air on the adiabatic flame temperature of liquid octane $\left(\mathrm{C}_{8} \mathrm{H}_{18}\right)$ is to be investigated.

Analysis The problem is solved using EES, and the solution is given below.

Adiabatic Combustion of fuel CnHm entering at T_fuel with Stoichiometric Air at T_air:
Reaction: $\mathrm{CxHyOz}+(y / 4+x-z / 2)($ Theo_air/100 $)(\mathrm{O} 2+3.76 \mathrm{~N} 2)$

## Fundamentals of Engineering (FE) Exam Problems

15-133 A fuel is burned with 90 percent theoretical air. This is equivalent to
(a) $10 \%$ excess air
(b) $90 \%$ excess air
(d) $90 \%$ deficiency of air
(e) stoichiometric amount of air
(c) $10 \%$ deficiency of air

Answer (c) 10\% deficiency of air
Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
air_th=0.9
"air_th=air_access+1"
air_th=1-air_deficiency
```

15-134 Propane $\mathrm{C}_{3} \mathrm{H}_{8}$ is burned with 150 percent theoretical air. The air-fuel mass ratio for this combustion process is
(a) 5.3
(b) 10.5
(c) 15.7
(d) 23.4
(e) 39.3

Answer (d) 23.4
Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).
n_C=3
n_H=8
m_fuel=n_H*1+n_C*12
a_th=n_C+n_H/4
coeff=1.5 "coeff=1 for theoretical combustion, 1.5 for 50\% excess air"
n_O2=coeff*a_th
n_N2=3.76*n_O2
m_air=n_O2*32+n_N2*28
AF=m_air/m_fuel

15-135 One kmol of methane $\left(\mathrm{CH}_{4}\right)$ is burned with an unknown amount of air during a combustion process. If the combustion is complete and there are 2 kmol of free $\mathrm{O}_{2}$ in the products, the air-fuel mass ratio is
(a) 34.3
(b) 17.2
(c) 19.0
(d) 14.9
(e) 12.1

Answer (a) 34.3
Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).
n_C=1
n_H=4
m_fuel=n_H*1+n_C*12
a_th=n_C+n_H/4
(coeff-1)*a_th=2 "O2 balance: Coeff=1 for theoretical combustion, 1.5 for $50 \%$ excess air"
n_O2=coeff*a_th
n_N2=3.76*n_O2
m_air=n_O2*32+n_N2*28
AF=m_air/m_fuel
"Some Wrong Solutions with Common Mistakes:"
W1_AF=1/AF "Taking the inverse of AF"
W2_AF=n_O2+n_N2 "Finding air-fuel mole ratio"
W3_AF=AF/coeff "Ignoring excess air"

15-136 A fuel is burned steadily in a combustion chamber. The combustion temperature will be the highest except when
(a) the fuel is preheated.
(b) the fuel is burned with a deficiency of air.
(c) the air is dry.
(d) the combustion chamber is well insulated.
(e) the combustion is complete.

Answer (b) the fuel is burned with a deficiency of air.

15-137 An equimolar mixture of carbon dioxide and water vapor at 1 atm and $60^{\circ} \mathrm{C}$ enter a dehumidifying section where the entire water vapor is condensed and removed from the mixture, and the carbon dioxide leaves at 1 atm and $60^{\circ} \mathrm{C}$. The entropy change of carbon dioxide in the dehumidifying section is
(a) $-2.8 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}$
(b) $-0.13 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}$
(c) 0
(d) $0.13 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}$
(e) $2.8 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}$

Answer (b) $-0.13 \mathrm{~kJ} / \mathrm{kg} \cdot \mathrm{K}$
Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

Cp_CO2=0.846
R_CO2=0.1889

15-138 Methane $\left(\mathrm{CH}_{4}\right)$ is burned completely with $80 \%$ excess air during a steady-flow combustion process. If both the reactants and the products are maintained at $25^{\circ} \mathrm{C}$ and 1 atm and the water in the products exists in the liquid form, the heat transfer from the combustion chamber per unit mass of methane is
(a) $890 \mathrm{MJ} / \mathrm{kg}$
(b) $802 \mathrm{MJ} / \mathrm{kg}$
(c) $75 \mathrm{MJ} / \mathrm{kg}$
(d) $56 \mathrm{MJ} / \mathrm{kg}$
(e) $50 \mathrm{MJ} / \mathrm{kg}$

Answer (d) $56 \mathrm{MJ} / \mathrm{kg}$
Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

T= 25 "C"

15-140 Acetylene gas $\left(\mathrm{C}_{2} \mathrm{H}_{2}\right)$ is burned completely during a steady-flow combustion process. The fuel and the air enter the combustion chamber at $25^{\circ} \mathrm{C}$, and the products leave at 1500 K . If the enthalpy of the products relative to the standard reference state is $-404 \mathrm{MJ} / \mathrm{kmol}$ of fuel, the heat transfer from the combustion chamber is
(a) $177 \mathrm{MJ} / \mathrm{kmol}$
(b) $227 \mathrm{MJ} / \mathrm{kmol}$
(c) $404 \mathrm{MJ} / \mathrm{kmol}$
(d) $631 \mathrm{MJ} / \mathrm{kmol}$
(e) $751 \mathrm{MJ} / \mathrm{kmol}$

Answer (d) $631 \mathrm{MJ} / \mathrm{kmol}$
Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

## 15-143 $\cdot$ 15-147 Design and Essay Problems

15-143 A certain industrial process generates a liquid solution of ethanol and water as the waste product. The solution is to be burned using methane. A combustion process is to be developed to accomplish this incineration process with minimum amount of methane.
Analysis The mass flow rate of the liquid ethanol-water solution is given to be $10 \mathrm{~kg} / \mathrm{s}$. Considering that the mass fraction of ethanol in the solution is 0.2 ,

$$
\begin{aligned}
\dot{m}_{\text {ethanol }} & =(0.2)(10 \mathrm{~kg} / \mathrm{s})=2 \mathrm{~kg} / \mathrm{s} \\
\dot{m}_{\text {water }} & =(0.8)(10 \mathrm{~kg} / \mathrm{s})=8 \mathrm{~kg} / \mathrm{s}
\end{aligned}
$$

Noting that the molar masses $M_{\text {ethanol }}=46$ and $M_{\text {water }}=18 \mathrm{~kg} / \mathrm{kmol}$ and that mole numbers $N=m / M$, the mole flow rates become

$$
\begin{gathered}
\dot{N}_{\text {ethanol }}=\frac{\dot{m}_{\text {ethanol }}}{M_{\text {ethanol }}}=\frac{2 \mathrm{~kg} / \mathrm{s}}{46 \mathrm{~kg} / \mathrm{kmol}}=0.04348 \mathrm{kmol} / \mathrm{s} \\
\dot{N}_{\text {water }}=\frac{\dot{m}_{\text {water }}}{M_{\text {water }}}=\frac{8 \mathrm{~kg} / \mathrm{s}}{18 \mathrm{~kg} / \mathrm{kmol}}=0.44444 \mathrm{kmol} / \mathrm{s}
\end{gathered}
$$

Note that

$$
\frac{\dot{N}_{\text {water }}}{\dot{N}_{\text {ethanol }}}=\frac{0.44444}{0.04348}=10.222 \mathrm{kmol} \mathrm{H}_{2} \mathrm{O} / \mathrm{kmol} \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}
$$

That is, 10.222 moles of liquid water is present in the solution for each mole of ethanol.
Assuming complete combustion, the combustion equation of $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(\ell)$ with stoichiometric amount of air is

$$
\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(\ell)+a_{\mathrm{th}}\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 2 \mathrm{CO}_{2}+3 \mathrm{H}_{2} \mathrm{O}+3.76 a_{\mathrm{th}} \mathrm{~N}_{2}
$$

where $a_{\mathrm{th}}$ is the stoichiometric coefficient and is determined from the $\mathrm{O}_{2}$ balance,

$$
1+2 a_{\mathrm{th}}=4+3 \longrightarrow a_{\mathrm{th}}=3
$$

Thus,

$$
\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(\ell)+3\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow 2 \mathrm{CO}_{2}+3 \mathrm{H}_{2} \mathrm{O}+11.28 \mathrm{~N}_{2}
$$

Noting that 10.222 kmol of liquid water accompanies each kmol of ethanol, the actual combustion equation can be written as

$$
\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(\ell)+3\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right)+10.222 \mathrm{H}_{2} \mathrm{O}(\ell) \longrightarrow 2 \mathrm{CO}_{2}+3 \mathrm{H}_{2} \mathrm{O}(\mathrm{~g})+11.28 \mathrm{~N}_{2}+10.222 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

The heat transfer for this combustion process is determined from the steady-flow energy balance equation with $W=0$,

$$
Q=\sum N_{P}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{P}-\sum N_{R}\left(\bar{h}_{f}^{\circ}+\bar{h}-\bar{h}^{\circ}\right)_{R}
$$

Assuming the air and the combustion products to be ideal gases, we have $h=h(T)$. We assume all the reactants to enter the combustion chamber at the standard reference temperature of $25^{\circ} \mathrm{C}$. Furthermore, we assume the products to leave the combustion chamber at 1400 K which is a little over the required temperature of $1100^{\circ} \mathrm{C}$. From the tables,

| Substance | $\overline{\mathbf{h}}_{\mathbf{f}}^{\circ}$ <br> $\mathbf{k J} / \mathbf{k m o l}$ | $\overline{\mathbf{h}}_{\mathbf{2 9 8} \mathbf{K}}$ <br> $\mathbf{k J} / \mathbf{k m o l}$ | $\overline{\mathbf{h}}_{\mathbf{1 4 0 0} \mathbf{K}}$ <br> $\mathbf{k J} / \mathbf{k m o l}$ |
| :--- | :--- | :--- | :--- |
| $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(\ell)$ | $-277,690$ | --- | --- |
| $\mathrm{CH}_{4}$ | $-74,850$ | --- | --- |
| $\mathrm{O}_{2}$ | 0 | 8682 | 45,648 |
| $\mathrm{~N}_{2}$ | 0 | 8669 | 43,605 |
| $\mathrm{H}_{2} \mathrm{O}(g)$ | $-241,820$ | 9904 | 53,351 |
| $\mathrm{H}_{2} \mathrm{O}(\ell)$ | $-285,830$ | --- | --- |
| $\mathrm{CO}_{2}$ | $-393,520$ | 9364 | 65,271 |

Thus,

$$
\begin{aligned}
Q & =(2)(-393,520+65,271-9364)+(3)(-241,820+53,351-9904) \\
& +(11.28)(0+43,605-8669)-(1)(-277,690)-0-0 \\
& +(10.222)(-241,820+53,351-9904)-(10.222)(-285,830) \\
& =295,409 \mathrm{~kJ} / \mathrm{kmol} \text { of } \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}
\end{aligned}
$$

The positive sign indicates that 295,409 kJ of heat must be supplied to the combustion chamber from another source (such as burning methane) to ensure that the combustion products will leave at the desired temperature of 1400 K . Then the rate of heat transfer required for a mole flow rate of 0.04348 kmol $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH} / \mathrm{s} \mathrm{CO}$ becomes

$$
\dot{Q}=\dot{N} Q=(0.04348 \mathrm{kmol} / \mathrm{s})(295,409 \mathrm{~kJ} / \mathrm{kmol})=12,844 \mathrm{~kJ} / \mathrm{s}
$$

Assuming complete combustion, the combustion equation of $\mathrm{CH}_{4}(\mathrm{~g})$ with stoichiometric amount of air is

$$
\mathrm{CH}_{4}+a_{\mathrm{th}}\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow \mathrm{CO}_{2}+2 \mathrm{H}_{2} \mathrm{O}+3.76 a_{\mathrm{th}} \mathrm{~N}_{2}
$$

where $a_{\mathrm{th}}$ is the stoichiometric coefficient and is determined from the $\mathrm{O}_{2}$ balance, Thus,

$$
\begin{aligned}
& a_{\mathrm{th}}=1+1 \longrightarrow a_{\mathrm{th}}=2 \\
& \mathrm{CH}_{4}+2\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \longrightarrow \mathrm{CO}_{2}+2 \mathrm{H}_{2} \mathrm{O}+7.52 \mathrm{~N}_{2}
\end{aligned}
$$

The heat transfer for this combustion process is determined from the steady-flow energy balance $E_{\text {in }}-E_{\text {out }}=\Delta E_{\text {system }}$ equation as shown above under the same assumptions and using the same mini table:

$$
\begin{aligned}
Q & =(1)(-393,520+65,271-9364)+(2)(-241,820+53,351-9904) \\
& +(7.52)(0+43,605-8669)-(1)(-74,850)-0-0 \\
& =-396,790 \mathrm{~kJ} / \mathrm{kmol} \text { of } \mathrm{CH}_{4}
\end{aligned}
$$

That is, $396,790 \mathrm{~kJ}$ of heat is supplied to the combustion chamber for each kmol of methane burned. To supply heat at the required rate of $12,844 \mathrm{~kJ} / \mathrm{s}$, we must burn methane at a rate of

$$
\dot{N}_{\mathrm{CH}_{4}}=\frac{\dot{Q}}{Q}=\frac{12,844 \mathrm{~kJ} / \mathrm{s}}{396,790 \mathrm{~kJ} / \mathrm{kmol}}=0.03237 \mathrm{kmolCH}_{4} / \mathrm{s}
$$

or,

$$
\dot{m}_{\mathrm{CH}_{4}}=M_{\mathrm{CH}_{4}} \dot{N}_{\mathrm{CH}_{4}}=(16 \mathrm{~kg} / \mathrm{kmol})\left(0.03237 \mathrm{kmolCH}_{4} / \mathrm{s}\right)=\mathbf{0 . 5 1 7 9} \mathbf{~ k g} / \mathbf{s}
$$

Therefore, we must supply methane to the combustion chamber at a minimum rate $0.5179 \mathrm{~kg} / \mathrm{s}$ in order to maintain the temperature of the combustion chamber above 1400 K .
